Running Title: mDia2–MIRO1 cross-talk promotes pro-tumorigenic protein secretion by CAFs

Keywords: Cancer-associated fibroblasts; mDia2; MIRO1; mitochondria; squamous carcinogenesis

Conflicts of interests

The authors have declared that no conflict of interest exists.

Abstract: Cancer-associated fibroblasts (CAF) are key regulators of tumorigenesis. Further insights into the tumor promoting mechanisms of action of CAFs could help improved cancer diagnosis and treatment. Here we show that the formin mDia2 regulates the positioning and function of mitochondria in dermal fibroblasts, thereby promoting a pro-tumorigenic CAF phenotype. Mechanistically, mDia2 stabilized the mitochondrial trafficking protein MIRO1. Loss of mDia2 or MIRO1 in fibroblasts or CAFs reduced the presence of mitochondria and ATP levels near the plasma membrane and at CAF-tumor cell contact sites, caused metabolic alterations characteristic of mitochondrial dysfunction, and suppressed the secretion of pro-tumorigenic proteins. In mouse models of squamous carcinogenesis, genetic or pharmacological inhibition of mDia2, MIRO1, or their common upstream regulator activin A inhibited tumor formation. Consistently, co-upregulation of mDia2 and MIRO1 in the stroma of various human cancers negatively correlated with survival. This work unveils a key role of mitochondria in the pro-tumorigenic CAF phenotype and identifies an activin A/mDia2/MIRO1 signaling axis in CAFs with diagnostic and therapeutic potential.

Significance: Inhibition of mDia2/MIRO1-mediated mitochondrial positioning in cancer-associated fibroblasts induces mitochondrial dysfunction and suppresses tumor growth, revealing a promising therapeutic strategy to target tumor-stroma crosstalk.

Introduction

Cancer-associated fibroblasts (CAFs) are major components of the tumor microenvironment (TME), which, together with mutations and epigenetic alterations in the tumor cells, plays a crucial role in determining malignancy. CAFs most often promote tumor growth via paracrine control of cancer cells (1). This involves increased expression of cytokines, growth factors and extracellular matrix (ECM) proteins and possibly alterations in protein secretion pathways. Recent studies identified cytoskeletal abnormalities in CAFs (2), including perturbations of the acto-myosin cytoskeleton, which impact on actin-based protrusions, cell contractility and motility (3,4). A key regulator of the actin cytoskeleton is the formin mDia2 (DIAPH3) (5,6), which is upregulated in CAFs and promotes the CAF phenotype by enhancing the formation of filopodia and cell migration, as well as the expression of CAF marker genes (7,8). In dermal fibroblasts and skin CAFs, mDia2 is a downstream target of the pro-tumorigenic cytokine activin A, a member of the transforming growth factor beta (TGF-β) superfamily that is highly expressed by skin cancer cells and also by cells in the TME (9). Activin A induced the expression of genes that encode pro-fibrotic and pro-tumorigenic proteins in dermal fibroblasts, which in turn stimulate cancer cell proliferation and migration (7,10). The activin A-induced increase in mDia2 levels prevent p53 nuclear accumulation, thereby promoting the expression of CAF marker genes and pro-tumorigenic activities of fibroblasts (7). This paracrine axis is highly relevant to human cancer as overexpression of both activin A and mDia2 correlates with poor prognosis in several malignancies (7).

Here we discovered that mitochondrial positioning and function play a key role in regulating the skin CAF phenotype and cancer progression, and depend on mDia2 and its ability to stabilize the atypical Rho GTPase MIRO1 (RHOT1). Targeting the activin A-mDia2-MIRO1

66 signaling axis and the resulting mitochondrial/metabolic alterations in CAFs is therefore a
67 promising strategy for the treatment of different human cancers.

Materials and Methods

Animals

NOD/SCID (NOD.CB17-Prkdc^{scid}/NCrCrl) mice were housed under specific pathogen-free conditions and received food and water *ad libitum*. Mouse maintenance and all animal experiments were approved by the veterinary authorities of Zurich, Switzerland (Kantonales Veterinäramt Zürich).

Human skin cancer samples and CAFs

Normal human skin and skin cancer samples were obtained anonymously from the Department of Dermatology, University Hospital of Zurich (in the context of the Biobank project), approved by the local and cantonal Research Ethics Committees. Normal skin was from healthy adult volunteers or from the edges of skin tumors (SCCs), which had been diagnosed by experienced pathologists. Written informed consent was obtained from all subjects, and the experiments conformed to the principles set out in the WMA Declaration of Helsinki and the Department of Health and Human Services Belmont Report.

CAFs were directly isolated from skin SCC biopsies alongside their paired normal skin fibroblasts as described previously, with some modifications (11). Briefly, skin samples were digested with trypsin, followed by digestion with collagenase. Cells were cultivated with J2 feeder cells. Fibroblasts/CAFs were separated from SCC cells upon short incubation with trypsin and then cultivated without feeder cells in DMEM, 10% fetal bovine serum (FBS), 1% penicillin/streptomycin (P/S). The CAF phenotype was confirmed by expression of skin CAF markers (12), and fibroblast cultures isolated from SCCs that did not have CAF properties were excluded.

For fibroblast/CAF isolation from mouse ear tumors, we adapted a previously published protocol (13). Briefly, the tumor was minced into small pieces and incubated with 2.5 ml of a collagenase type II solution (500 U/ml; Worthington Biochemical Corporation, Lakewood, NJ) for 1 h at 37°C with manual agitation every 15 min. The cell suspension was poured through a 100 µm cell strainer and the content centrifuged at 1,200 r.p.m. for 5 min. The resulting cell pellet was re-suspended in 8 ml of DMEM/10% FBS/P/S and plated in two 6 cm dishes. Medium was changed the following day, and cells were passaged prior to confluency.

Cell lines

HaCaT keratinocytes and SCC13 cells were obtained from Prof. Petra Boukamp, Leibniz Institute Düsseldorf, Germany. Authentication of the cell lines was performed by the "Deutsche Sammlung von Mikroorganismen und Zellkulturen" (DSMZ) GmbH, Braunschweig, Germany. Absence of mycoplasma was confirmed by PCR using the PCR Mycoplasma Test Kit I/C (PromoKine, Heidelberg, Germany) on a monthly basis.

siRNA-mediated knock-down

Knock-down of MIRO1 and mDia2 in primary human fibroblasts was performed using previously characterized siRNAs (14-16). Cells were transfected with MIRO1, mDia2 or control siRNAs using Lipofectamine™ RNAiMAX Transfection Reagent (Thermo Fisher Scientific, Waltham, MA) according to the manufacturer's instructions and incubated for 24-48 h prior to analysis. To visualize/confirm the knock-down efficiency *in vivo*, the siRNAs were pre-labeled with fluorescein using the Label IT® siRNA Tracker™ (MIR 7216, MIRUS Bio LCC, Madison, WI).

Generation of human fibroblasts with shRNA-mediated knock-down of mDia2

Primary human dermal fibroblasts (HDFs) were infected with lentiviruses pLKO.1-shmDia2 TRCN0000150903, which target mouse *mDia2* and human *DIAPH3.* The construct had been previously characterized for specificity, and results had been confirmed with another shRNA (17,18).

Measurement of ATP and LDH levels

ATP levels were measured using the CellTiter-Glo Assay according to the manufacturer's instructions (Promega, Madison, WI). Briefly, cells were plated in triplicate in opaque 96-well plates. After 24 h incubation, they were incubated for 10 min with CellTiter-Glo reagent, and luminescence was measured using a 96-well plate reader. LDH assays were performed as described previously (19).

Analysis of cytokine concentrations

The concentrations of several cytokines in the supernatant of fibroblasts were measured by LEGENDplex human inflammation panel 1 (#740808, Biolegend) according to the manufacturer's protocol. All samples were analyzed in technical duplicates, and averages of biological replicates were used for statistical analysis. Flow cytometry was performed using a BD LSRFortessa, and data were analyzed using FlowJo v10 (Tristar).

Seahorse XF Cell Mito Stress Test

Fibroblasts were plated in XF96 seahorse plates at 100,000 cells per well in DMEM/ 10% FCS/ PS), and the medium was subsequently switched to Seahorse XF base medium (103335-100, Agilent Technologies, Santa Clara, CA) supplemented with 10 mM glucose or galactose, 1 mM sodium pyruvate and 2 mM glutamine (assay concentration according to the manufacturer of the kit: https://www.agilent.com/cs/library/usermanuals/public/XF_Cell_Mito_Stress_Test_Kit_User_Guide.pdf) and further incubated in a CO_2-free incubator for 1 h. Oligomycin, FCCP (carbonyl cyanide-p-trifluoromethoxyphenylhydrazone) and antimycin A/rotenone were prepared in XF assay medium with final concentrations of 1 μM, 1.5 μM and 1/0.1 μM, respectively, and provided by the Seahorse XF Cell Mito Stress Test Kit (#103015-100; Agilent Technologies). The compounds were serially injected to measure OCR of cells in the XF96 plate.

Transfection of human fibroblasts

Wild-type or mutant Flag-tagged mDia2 cDNAs (17,20) were subcloned into the retroviral pMX vector (Cell Biolabs, San Diego, CA). pGEM-MIRO1 and cyto-Ruby3-iATPSnFR$^{1.0}$ (ATP biosensors (21)) plasmids were purchased from Sino Biological Inc. (Beijing, China, #HG15898-G) or Addgene (Watertown, MA, #102551), respectively. Plasmid vectors and Lipofectamine™ 2000 (#11668030, Invitrogen, Carlsbad, CA) were incubated with Opti-MEM™ I Reduced Serum Medium (#31985062, Thermo Fisher Scientific) at room temperature for 20 min. The mixture was then added to primary human fibroblasts. After 6 h incubation, the medium was replaced by normal culture medium containing 10% FBS. Cells were allowed to recover for 24-48 h prior to analysis.

ER and mitochondrial staining

Fibroblasts were seeded on glass coverslips in 24-well plates with complete medium and incubated at 37º C. They were stained with ER-Tracker™ Blue-White DPX (Thermo Fisher Scientific, E12353), MitoTracker-Green (Thermo Fisher Scientific, M7514), CellROX-Orange (Thermo Fisher Scientific, C10443), MitoSOX-Red (Thermo Fisher Scientific, M36008) or MitoTracker Red CMXRos (Thermo Fisher Scientific, M7512) diluted 1:1000 in complete medium for 45 min at 37º C. Subsequently, cells were washed and fixed with 3.7% formaldehyde in complete medium for 15 min at 37º C. After washing, they were mounted with Mowiol (Sigma-Aldrich, St. Louis, MO). Images were acquired with an Axio Imager.A1 microscope (Carl Zeiss AG, Oberkochen, Germany).

RNA isolation and qRT-PCR

RNA isolation and quantitative qRT-PCR were performed as described (13) using the primers listed in Supplementary Table 1. Values obtained for the first control were set to 1.

Histology, immunostaining, and image analysis

Histological analysis and immunostainings were performed as described (13) using the antibodies listed in Supplementary Table 2. Immunofluorescence images were analyzed in Fiji (22) and normalized to cell number for *in vitro* experiments with at least 9 microscopic fields of view for each condition analyzed. Curvature of ECM fibers *in vivo* was analyzed with the ImageJ quantification tool TWOMBLI (23). Mitochondrial networks were analyzed using MiNA (24). Mitochondrial and ATP distribution were determined by measurement of MitoTracker or ATP biosensor fluorescence intensity relative to the highest intensity value. We calculated the average

for every 10% incremental distance from the perinuclear region to the plasma membrane using ImageJ (Fiji) plot-profile tool. The relative distance is indicated with values from 1 - 10; at least 100-200 intensity profiles were measured. All images were processed in an identical way by adjusting brightfield/contrast and subtracting background signal to identify cell edge/contour using a wide-field microscope.

Proximity ligation assay

Proximity ligation assays (PLA) were performed with mDia2 (sc-293288, Santa Cruz, Santa Cruz, CA), MIRO1 (NBP1-59021, Novus Biologicals, Littleton, CA) and TRAK1 (H00022906-M01A, Thermo Fisher Scientific) antibodies (1:500) and MitoTracker Green as described for fluorescence microscopy, followed by ligation of probes specific for each antibody using a PLA Kit (DUO92101, Sigma-Aldrich). Samples treated without primary antibodies were used as negative controls.

Preparation of protein lysates and Western blot analysis

Preparation of protein lysates and Western blot were performed as previously described (13). Some lysates were collected from cells pre-treated with the proteasome inhibitor epoxomicin (10 μM) (S2619, Selleckchem, Houston, TX), the mDia2 inhibitor SMIFH2 (25 μM) (S4826, Sigma-Aldrich) or recombinant activin A (20 ng/ml) (#120-14, PeproTech, Cranbury, NJ).

Antibodies against INHBA (sc166503, Santa Cruz, Santa Cruz, CA, 1:500 diluted), mDia2 (recognizing both the murine and human proteins; 1:5,000 diluted) (17,18), α-SMA (A2547, Sigma-Aldrich, 1:500 diluted), HSP60 (ab59457, Abcam, Cambridge, UK, 1:500 diluted), FN1 (ab2413, Abcam, 1:500 diluted), COL4A1 (#10710, Progen, Heidelberg, Germany, 1:500

diluted), ELN (ab21610, Abcam, 1:500 diluted), MIRO1 (NBP1-59021, Novus Biologicals, Littleton, CA, 1:500 diluted), POSTN (ab14041, Abcam, 1:500 diluted), calnexin (NB300-518, Novus Biologicals, 1:500 diluted), GM130 (MABT1363, Sigma-Aldrich, 1:500 diluted), GAPDH (5G4, HyTest, Turku, Finland, 1:10,000 diluted), α-tubulin (T5168, Sigma-Aldrich, 1:10,000 diluted), and vinculin (V4505, Sigma-Aldrich, 1:2,000 diluted), were used. Secondary antibodies were anti-rabbit or anti-mouse IgG (W4011 and W4021, Promega, 1:8,000 diluted) conjugated with horseradish peroxidase, and chemiluminescence was determined using the WesternBright ECL Detection System (Advansta, San Jose, CA). Bands were visualized using Fusion Solo 6S (Witec AG, Sursee, Switzerland), and intensity was quantified with ImageJ software (National Institutes of Health, Bethesda, MD). Loading controls of different molecular weight were used depending on the protein that was analyzed in the experiment.

Chromatin immunoprecipitation (ChIP)

HDFs (approx. 5×10^8 cells) at 80–90% confluency, which had been pre-treated with activin A (20 ng/ml) for 6 h, were collected, resuspended in DMEM, and subjected to ChIP as previously described (25). The purified DNA fragments were used for PCR amplification using the primers listed in Supplementary Table 3.

Migration assays

For scratch assays, cells were grown to 100% confluency and treated with 2 μg/ml mitomycin C (Sigma-Aldrich) for 2 h to inhibit cell proliferation. One or several scratches were made into the cell layer using a sterile 200 μl pipette tip. Dead cells and debris were washed off with pre-

warmed PBS. The same area was photographed directly after scratching and at different time points thereafter.

To determine the capacity of the matrix deposited by fibroblasts to stimulate SCC cell migration, SCC13 cells were seeded on culture inserts (#80209, Ibidi, Gräfelfing, Germany) that were placed on top of the matrix that had been deposited by fibroblasts. The insert was then removed for migration assays.

Chemotactic transwell migration was assessed as described (7). Briefly, SCC13 cells were seeded on the insert of the transwell plates in DMEM/1% FBS and let to migrate for 24 h towards CM from fibroblasts.

Isolation of fibroblast secretomes and matrisomes

Cells were plated at 70-90% confluency in DMEM/10% FBS/P/S. On the following day, they were pre-treated with 2 µg/ml mitomycin C and cultured in starvation medium (DMEM/1 % FBS/P/S) with 1 µg/ml doxycycline (DOX) for an additional 3 days. Conditioned media and ECM were prepared as previously described (13). Total secreted protein concentration was determined using the Bradford method (26).

Skin tumorigenesis assays

Tumorigenesis assays in mouse ear skin were performed as described (12). Briefly, 3 µl cell suspension ($2x10^5$ cancer cells in Hanks`s buffer) was injected intradermally into the ear of NOD/SCID mice. For tumor cell/fibroblast co-injection experiments, we injected 10^5 cancer cells and an equal number of fibroblasts. Tumor formation was monitored over 2-5 weeks, followed by sacrifice of the animals and analysis of the isolated tumors.

For MIRO1-Reducer treatment experiments, SCC13 cells and primary human CAFs were co-injected intradermally, and tumor formation was observed during 2 weeks. Tumors were then treated with MIRO1-Reducer (2.5 μM) (#7091, Tocris, Bristol, UK) or vehicle (DMSO) every 3–4 days by direct injection into the tumor. Tumors were harvested three days after the last injection.

Spheroid formation and growth assay

Spheroid assays were performed and reported according to experimental parameters proposed by The MISpheroID Consortium (27). Twenty μl conditioned media from primary human skin fibroblasts (pre-conditioned medium: DMEM/1% FBS/1% P/S) and containing 2,000 SCC13 cells were placed on the lids of 6 cm culture plates using a hanging-drop method (28). To prevent dehydration, 5 ml PBS were added to the bottom. Cells were incubated at 37°C and 5% CO_2. Spheroids were incubated for 3 days and analyzed for increase in spheroid area.

Bioinformatic analysis

Gene expression data for *MIRO1* were acquired from publicly available gene expression profiling data of human cancers (GSE45001, GSE9014, and GSE40595) and analyzed using the GEO2R analysis tool in the GEO database (29) and Gene Expression Profiling Interactive Analysis 2.0 (GEPIA2) (30). Single cell RNA sequencing (scRNA-seq) data from melanomas were investigated through the use of publicly available scRNA datasets (https://singlecell.broadinstitute.org/single_cell). The correlation between *MIRO1* expression and expression of other genes in pan-cancer was investigated using Tumor IMmune Estimation Resource 2 (TIMER2) (http://timer.cistrome.org/) (31). The effect of MIRO1 knock-down in

genome-wide knock-down screens was analyzed using DepMap (DepMap.org). Survival graphs were generated based on the PROGgene gene expression–based survival analysis web application by using median gene expression value as a dividing point, and statistical analysis of patient survival data was done as described (32).

Ex vivo tumor explant cultures

Ear skin tumors were cut into fragments of approximately 0.5 cm^2 and cultured at the air–liquid interface in DMEM/10% FBS supplemented with 5 µg/ml insulin (I5500), 0.1 nM cholera toxin (C8052), 10 ng/ml epidermal growth factor (E4127), 50 IU/ml P/S and 0.4 µg/ml hydrocortisone (#386698) (all from Sigma-Aldrich). After overnight incubation, they were treated with follistatin (50 ng/ml) (#120-13, Peprotech, Rocky Hill, NJ) for 6 h and embedded in paraffin.

Mitochondrial extraction

Mitochondrial extraction was carried out using the Mitochondria Isolation Kit for Cultured Cells (#89874, Thermo Fisher Scientific). In brief, 20,000,000 primary human fibroblasts were trypsinized, suspended in 1 ml of complete DMEM and centrifuged at 850 g for 2 min. The supernatant was discarded, and 800 µl Reagent A (with 1x cOmpleteTM EDTA-free cocktail proteinase inhibitor (Sigma-Aldrich)) was added to the pellet. After vortexing at medium speed for 5 sec, the samples were incubated on ice for 2 min. Ten µl of Reagent B were then added and vortexed for 5 sec. The cells were then incubated on ice for 5 min, vortexing every minute. 800 µl of Reagent C (with 1x cOmpleteTM EDTA-free cocktail proteinase inhibitor) were then added and the cells were inverted several times. Samples were centrifuged at 700 g for 10 min at 4° C. The pellet contained the total cell lysate and was stored at -20°C. The supernatant was collected

and centrifuged again at 3,000 g for 15 min. The resultant supernatant (cytosolic fraction) and the pellet (mitochondrial fraction) were stored at -20°C.

Statistical analysis

Statistical analysis was performed using the PRISM software, version 9 for Mac OS X or Windows (GraphPad Software Inc, San Diego, CA). For comparison of two groups, unpaired Student's t-test was performed; for comparison of more than two groups, one-way or two-way ANOVA and Bonferroni's multiple comparisons test were used. Non-significant (ns) $p>0.05$, *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$.

Data availability

The data generated in this study are available within the article and its Supplementary Data files.

Results

mDia2 promotes protein secretion and ECM deposition by primary human fibroblasts

The key role of mDia2 in fibroblast-CAF reprogramming (7,8) and the pivotal contribution of CAF-derived soluble factors and ECM proteins to cancer progression (33), prompted us to assess the involvement of mDia2 in the production of a pro-tumorigenic matrisome and secretome. Knock-down of mDia2 in primary human dermal fibroblasts (HDF) using shRNA (sh-mDia2) (17) indeed reduced the overall amounts of secreted proteins compared to cells transduced with lentiviruses carrying an empty vector (sh-EV cells) (**Fig. 1A**). The levels of secreted fibronectin 1 (FN1) and collagen IV (COL4), and of activin A (9) (encoded by the *INHBA* gene), which follow the classical ER-Golgi secretion pathway (34), were markedly reduced by mDia2 knock-down, while their intracellular levels were not affected (**Fig. 1B-E**). This suggested that mDia2 regulates protein secretion. Indeed, the ECM deposited by the sh-mDia2 cells was strongly depleted of FN1, COL1 and elastin (ELN), and the conditioned medium (CM) of sh-mDia2 cells contained significantly lower amounts of IFN-α2, IL-1β, and IL-6, compared to control cells (**Fig. 1F, G**). Importantly, it failed to promote anchorage-independent spheroid growth of SCC13 cells (**Fig. 1H**). mDia2 knock-down HDFs also showed less stress fibers, and reduced migratory abilities (**Fig. 1I-K**). These phenotypes, as well as the reduced FN1 secretion, were rescued by re-expression of wild-type mDia2, but not of an actin polymerization-deficient mDia2 mutant (17,35) (**Fig. 1J-L**). Neither wild-type nor mutant mDia2 expression affected the intracellular FN1 levels (**Fig. 1M**).

mDia2 regulates mitochondrial distribution and function in fibroblasts

To unravel how mDia2 regulates protein secretion, we analyzed key components of the secretory pathway. mDia2 knock-down HDFs showed the expected size increase (7,35), but they

neither exhibited obvious morphological abnormalities of the endoplasmic reticulum (ER), the Golgi apparatus, or the microtubule network nor significant differences in the levels of the ER or Golgi markers calnexin and GM130, respectively (Supplementary Fig. S1A-D).

Given that efficient protein secretion requires a high cellular metabolic activity and intact mitochondria (36), and that the actin cytoskeleton contributes to the structural integrity and dynamics of mitochondria (37), we stained mitochondria in mDia2 knock-down HDFs with MitoTracker. mDia2 depleted cells showed perinuclear clustering of mitochondria, whereas mitochondria in control fibroblasts were evenly distributed from perinuclear to peripheral regions (**Fig. 2A**). These results were verified with two published siRNAs (16) and with HDFs from two different donors (Supplementary Fig. S1E-I). There was also a small increase in mitochondrial mean branch length and network branch in sh-mDia2 fibroblasts, indicative of elongated and hyper-fused mitochondria. Furthermore, the localization of mDia2 in primary human foreskin and breast skin fibroblasts was suggestive of an association with the mitochondrial network (Supplementary Fig. S2A, B). Co-staining with MitoTracker supported this association in human fibroblasts, whereas the co-localization of mDia2 and mitochondria was less obvious in different epithelial cell lines (Supplementary Fig. S2C). Western blot analysis of subcellular fractions of HDFs confirmed the known localization of mDia2 in the cytoplasm of fibroblasts (7), but also showed its association with mitochondria. The mitochondria-binding protein MIRO1 and the mitochondrial matrix and housekeeping protein HSP60 served as positive controls (**Fig. 2B**). The partial co-localization of MIRO1 and mDia2 in skin fibroblasts bolsters this conclusion (Supplementary Fig. S2D). Proper mitochondrial distribution in mDia2 knock-down fibroblasts was restored upon re-expression of wild-type

mDia2, but not of the IA mutant (**Fig. 2C, D**). Moreover, wild-type mDia2 partially rescued mitochondrial topology (Supplementary Fig. S2E).

The altered position and topology of mitochondria in the mDia2 knock-down fibroblasts were accompanied by a strong increase in intracellular reactive oxygen species (ROS) and mitochondrial superoxide levels (**Fig. 2E, F**). However, this did not affect cell viability as shown by measurement of lactate dehydrogenase (LDH) in the supernatant (**Fig. 2G**). Total intracellular ATP levels were only mildly affected (**Fig. 2H**). Re-expression of wild-type mDia2, but not of the IA mutant, rescued and even further increased intracellular ATP levels compared to control cells (**Fig. 2H**). Levels of mitochondrial DNA and of HSP60 were only slightly reduced in the mDia2 knock-down cells (**Fig. 2I, J**), suggesting that the increased ROS levels are not a consequence of an increase in the number of mitochondria.

Replacing glucose in the cell culture medium by galactose allows unmasking mitochondrial dysfunctions, particularly defects in oxidative phosphorylation (OXPHOS), because (i) cells rely on OXPHOS for efficient ATP production and (ii) oxidation of galactose to pyruvate via glycolysis does not yield net ATP (38). When cultured in the presence of galactose, the mDia2 knock-down fibroblasts displayed an even more dramatic reduction in the secretion of FN1 and COLI (**Fig. 2K** *vs.* **1F**). This correlated with impairments in the mitochondrial oxygen respiration rate (OCR) and reduced ATP-linked mitochondrial respiration in mDia2 knock-down *vs.* control fibroblasts (**Fig. 2L**). Only a slight reduction in the basal respiration rate was observed in medium with glucose, suggesting partial compensation by glycolysis (Supplementary Fig. S2F). The basal OCR/ECAR (extracellular acidification rate) ratio of mDia2 knock-down fibroblasts was significantly higher compared to control cells, indicating

their relatively higher reliance on mitochondrial OXPHOS (Supplementary Fig. S2G). These results identify mitochondrial dysfunction in mDia2 knock-down fibroblasts.

mDia2 stabilizes the mitochondrial trafficking protein MIRO1

Our results raise the possibility that mDia2 affects proteins involved in mitochondrial trafficking. Among them, Rho-GTPase MIRO1/RHOT1 (39) was an attractive candidate. Indeed, MIRO1 protein, but not mRNA levels were strongly reduced in the mDia2 knock-down fibroblasts (**Fig. 3A, B**). Knock-down of mDia2 in fibroblasts also reduced MIRO1 protein levels in the mitochondrial fraction (**Fig. 3C**). MIRO1 co-localized with mitochondria and clustered in the perinuclear region of sh-mDia2 fibroblasts (**Fig. 3D**).

Re-expression of wild-type, but not IA mDia2, partially restored MIRO1 protein levels in the mDia2 knock-down fibroblasts (**Fig. 3E**). Consistent with the findings that mDia2 increases proteasome activity (20) and that ubiquitinated MIRO1 is targeted for proteasomal degradation (40), the proteasome inhibitor epoxomicin partially rescued MIRO1 protein levels in the mDia2 knock-down fibroblasts and normalized their mitochondrial distribution and topology (**Fig. 3F, G)**. The stabilization of MIRO1 by mDia2 is likely the consequence of their physical interaction as supported by PLA (**Fig. 3H**). PLA combined with MitoTracker staining showed that the mDia2-MIRO1 complex localizes to mitochondria (**Fig. 3I**).

mDia2 and MIRO1 levels in human cancer stroma are predictors of poor prognosis

We next tested if MIRO1 is abnormally expressed and functionally relevant in human cancer tissue. We first made use of the Cancer Dependency Map (Depmap), a genome-wide loss-of-function screening database (41), to determine the effect of MIRO1 knock-down on cancer

features. Dependency score analysis showed that MIRO1 plays an integral role in the proliferation and survival of various cancer cells (Supplementary Fig. S3A). Analysis of data from "The Cancer Genome Atlas" (TCGA) revealed a consistent upregulation of *MIRO1* in the stroma of liver, breast and ovarian cancer in comparison to stroma of healthy tissue (**Fig. 4A**), which was not observed in bulk tumor tissue (Supplementary Fig. S3B). ScRNA-seq showed remarkable co-expression of *DIAPH3* and *MIRO1* in melanoma CAFs (**Fig. 4B**). Strong expression of *MIRO1* positively correlates with that of *mDia2* and *INHBA*, but not of *TGFB1*, in different cancers (**Fig. 4C**). Kaplan–Meier survival analysis showed a strong association of high co-expression of *mDia2* and *MIRO1* with decreased survival of patients with liver or lung cancer (**Fig. 4D**). Notably, numbers of MIRO1-positive cells were much higher in the stroma of epithelial skin cancers than in healthy skin (**Fig. 4E**). Co-staining of SCC sections for MIRO1 and the pan-fibroblast marker PDGFR-α indicated that many of the MIRO1-positive cells are indeed fibroblasts. Co-expression of both proteins was less pronounced in normal skin (Supplementary Fig. S3C). These findings point to a pro-tumorigenic effect of MIRO1 in CAFs of different human cancers, although an additional pro-tumorigenic function of this protein in cancer cells or other cells of the TME cannot be excluded.

To assess the functional relevance of the high MIRO1 levels in CAFs for cutaneous SCC pathogenesis, we used low-passage primary CAFs and matched normal HDFs (NF) from human SCC lesions and non-tumorigenic skin, respectively. The cultured CAFs showed a significantly higher expression of MIRO1, mDia2 and other CAF markers, such as INHBA and FN1, compared to NFs, and they strongly promoted anchorage-independent growth of SCC13 cells in spheroids (**Fig. 4F-H**). The increased expression of mDia2 and MIRO1 in CAFs *vs.* NFs did not further enhance peripheral mitochondrial positioning (**Fig. 4I**). However, using a fluorescent

ATP sensor, we found that ATP was clearly detectable at the cell periphery of CAFs, but not of NFs from two different donors, while strong perinuclear fluorescence was observed in both CAFs and NFs (**Fig. 4J,** Supplementary Fig. S3D). Thus, ATP levels near the plasma membrane, which are required to supply energy for protein secretion (42), are higher in CAFs compared to NFs. Mitochondria were also more fragmented in CAFs, resulting in decreased median branch length (**Fig. 4K**). MIRO1, in complex with TRAK1 and microtubule motor proteins, regulates anterograde mitochondrial movement in mammalian cells, the increase of which promotes cancer cell invasiveness and viability (43). Using PLA, we found a higher MIRO1-TRAK1 interaction in CAFs *vs.* NFs (Supplementary Fig. S3E). These findings strongly suggest that mitochondrial trafficking and function are altered in CAFs, thereby promoting protein secretion. Indeed, deposition of FN1 and COL1 was strongly increased in the same CAFs (**Fig. 4L**). Overexpression of MIRO1 in NFs recapitulated the pro-tumorigenic secretion-dependent effects of CAFs. In particular, isolated CM and decellularized ECM from NFs overexpressing MIRO1 promoted spheroid formation and proliferation of the weakly malignant SCC13 cell line (**Fig. 4M, N**). This is in line with their increased deposition of the pro-tumorigenic ECM proteins FN1 and COLI (**Fig. 4O**). Treatment of MIRO1-overexpressing fibroblasts with FCCP to disrupt the mitochondrial membrane potential and consequent ATP production reduced the deposition of FN1 and COL1 (Supplementary Fig. 3F, G). This further supports the functional link between mitochondrial activity and the secretion of pro-tumorigenic proteins by fibroblasts with high MIRO1 levels. Finally, overexpression of wild-type MIRO1 in mDia2 knock-down fibroblasts rescued their mitochondrial distribution defect (**Fig. 4P, Q**).

MIRO1 is a target of activin A/Smad2/3 signaling in fibroblasts

The co-upregulation of *INHBA*, *mDia2* and *MIRO1* in CAFs raised the question as to whether *MIRO1* expression is also controlled by activin A. Indeed, treatment of HDFs with activin A increased the expression of *MIRO1* (**Fig. 5A**). We identified a conserved SMAD binding element (SBE) within the 2-kb region upstream of the *MIRO1* gene transcription start site (TSS), and activin A promoted binding of SMAD2/3 to this SBE (**Fig. 5B**). *In vivo*, MIRO1 was strongly expressed in the stroma of xenograft tumors that formed upon injection of SCC13 cells overexpressing *INHBA* (7) into the ear skin of immuno-deficient NOD/SCID mice (**Fig. 5C**). *Vice versa*, overexpression of the secreted activin antagonist follistatin in SCC13 cells (7) reduced the expression of MIRO1 in the stroma, and a similar effect was observed when biopsies from tumors generated by wild-type SCC13 cells were treated *ex vivo* with follistatin (**Fig. 5D, E**). Characterization of HDFs with DOX-inducible expression of follistatin (Fb FST) showed that both the mRNA and protein levels of MIRO1 and mDia2 were significantly down-regulated (**Fig. 5F-I**). Furthermore, Fb FST exhibited changes in mitochondrial distribution (**Fig. 5J**), resembling those observed in mDia2-depleted fibroblasts. These abnormalities as well as the reduced efficacy of CM of Fb FST to promote anchorage-independent growth of SCC13 cells in spheroids were rescued by overexpression of MIRO1 in these cells (**Fig. 5K-M).** These results demonstrate that *MIRO1* is a direct and functionally relevant target of activin A.

MIRO1 is required for efficient protein secretion by CAFs

Given the crucial role of mDia2 in the conversion of murine dermal fibroblasts into pro-tumorigenic CAFs (7), we determined if knock-down of MIRO1 had a similar effect as knock-down of mDia2. MIRO1 silencing in patient-derived CAFs (**Fig. 6A, B** and Supplementary Fig. S4A) had no effect on the expression of major skin CAF marker genes. Accordingly, nuclear p53

levels in si-MIRO1 cells were similar to those in control cells (**Fig. 6C**). In addition, MIRO1 silencing did not affect the expression of other small GTPases (*RHOA*, *CDC42*, *RALA* and *RHOT2*) (12,44) (**Fig. 6D**). However, it caused the expected perinuclear mitochondrial clustering, reduced the deposition of COL1 and also enhanced the levels of mitochondrial superoxide (**Fig. 6E-G**). When we cultured si-MIRO1 cells in medium containing high glucose, total cellular ATP levels were not reduced by MIRO1 knock-down (Supplementary Fig. S4B), as previously shown with other cells (45,46). However, the distribution of intracellular ATP was affected, with ATP being reduced at the cell periphery (Supplementary Fig. S4C). When cells were cultured in medium containing galactose instead of glucose, MIRO1 knock-down caused a significant reduction of total cellular ATP levels and an even more dramatic increase in mitochondrial superoxide (Supplementary Fig. S4D, E *vs.* **Fig. 6G**). This correlated with lower proliferation and migration rates of si-MIRO1 CAFs in medium with galactose (Supplementary Fig. S4F, G**)**. Survival of MIRO1 knock-down cells was reduced in medium with galactose, but not in medium with glucose (**Fig. 6H**). Basal and maximal OCR as well as ATP-linked OCR were significantly lower in si-MIRO1 *vs.* control CAFs cultured in the presence of galactose, but not in the presence of glucose (**Fig. 6I**). These results suggest that MIRO1 knock-down cells fail to increase their oxygen consumption capacity via OXPHOS when cultured in galactose medium and further points to their mitochondrial dysfunction.

Overall protein secretion was already reduced in the MIRO1 knock-down CAFs when cultured in glucose medium, and they deposited much less FN1 and COL1 (**Fig. 6J-L)**. However, expression of the CAF markers *INHBA* and *ACTA2* was comparable at the RNA (**Fig. 6D)** and protein levels (**Fig. 6M**). Similar results were obtained using a second siRNA (Supplementary Fig. S4H, I). HDFs with DOX-inducible overexpression of *INHBA* (Fb Act),

493 which acquire a CAF phenotype (7), confirmed these findings. In these cells, the knock-down of
494 MIRO1 significantly reduced the secretion of mature activin A and resulted in the concomitant
495 intracellular accumulation of the INHBA precursor, while INHBA mRNA levels were not
496 affected (Supplementary Fig. S5A-E). Taken together, we observed similar changes in protein
497 secretion and mitochondrial positioning in fibroblasts with either MIRO1 or mDia2 knock-down.
498
499 *mDia2 and MIRO1 position mitochondria at CAF-tumor cell contact sites to support the pro-*
500 *tumorigenic activity of CAFs*
501 We next analyzed co-cultures of SCC13 cells with either sh-EV or sh-mDia2 fibroblasts
502 and found that mitochondria in control fibroblasts were much closer to SCC13 cells (**Fig. 7A, B**).
503 Pharmacological inhibition of formins in SCC patient-derived CAFs by 25 μM SMIFH2, a dose
504 that is optimal for mDia2 inhibition (18), reduced the levels of mDia2 and also those of MIRO1
505 (**Fig. 7C**). This correlated with a reduction in F-actin staining and perinuclear mitochondrial
506 clustering in SMIFH2-treated CAFs (**Fig. 7D**). Importantly, SMIFH2-treated HDFs displayed
507 reduced secretion of FN1 and COL1, but no significant changes in their intracellular levels
508 (Supplementary Fig. S6A, B). These data support the relevance of mDia2-dependent regulation
509 of MIRO1 and mitochondria in NFs and patient-derived CAFs, which may affect cancer cells by
510 regulating protein secretion.
511 To test the relevance of MIRO1 in CAFs for squamous carcinogenesis, we co-cultured
512 SCC13 cells with si-MIRO1 CAFs. These cells exhibited a similar defective mitochondrial
513 distribution as sh-mDia2 fibroblasts (**Fig. 7E**). Consistently, incubation of SCC13 cells with CM
514 collected from si-MIRO1 or control patient CAFs showed that the CM from the si-MIRO1 CAFs
515 was significantly less efficient in promoting migration and anchorage-independent growth of the

tumor cells in chemotactic transwell and spheroid formation assays (**Fig. 7F, G**). When we plated SCC13 cells on the de-cellularized matrix deposited by either control or si-MIRO1 CAFs, the colony-forming and migratory capacities of the cancer cells were significantly lower on matrix deposited by si-MIRO1 CAFs (Supplementary Fig. S7A, B).

In vivo, intradermal co-injection of SCC13 cells (**Fig. 7H)** or of highly malignant A431 carcinoma cells (Supplementary Fig. S7C) and control primary human SCC CAFs into the ear of NOD/SCID mice resulted in rapid and efficient tumor formation. These data clearly demonstrate a pro-tumorigenic effect of MIRO1 in human fibroblasts. The tumors showed invasive growth, which was much less pronounced when si-MIRO CAFs were used (**Fig. 7H**, inset). Reduced expression of MIRO1 in the stroma of the few palpable tumors that developed under these conditions and in fibroblasts isolated from resected tumors was still visible at the assay end point (Supplementary Fig. S7D-G). This correlated with significantly reduced deposition of collagen and increased collagen curvature (**Fig. 7I-J)**, a feature of non-malignant matrix remodeling (47). Tumor cell proliferation was also reduced, while there was no difference in the area covered by blood or lymphatic vessels (Supplementary Fig. S7H, I). Finally, we assessed the therapeutic potential of MIRO1 inhibition *in vivo*. Palpable ear skin xenograft tumors formed by SCC13 cells and primary human CAFs were injected with "MIRO1-Reducer" (48) every 3-4 days over 18 days to induce degradation of MIRO1. Remarkably, this treatment strongly suppressed tumor growth (**Fig. 7K**) and correlated with reduced MIRO1 protein levels in the fibroblasts isolated from the treated tumors (Supplementary Fig. S7J).

Taken together, these results demonstrate that MIRO1 is required for the efficient secretion of proteins from CAFs, which promotes cancer-cell proliferation and malignant SCC growth. Furthermore, they show that mDia2 acts through MIRO1 and mitochondria to control

pro-tumorigenic protein secretion and matrix deposition *in vivo*. Finally, they identify mDia2 and MIRO1 as important stromal targets for cancer therapy.

Discussion

We discovered a key role of mDia2 in the regulation of protein secretion by HDFs and CAFs, which involves stabilization of MIRO1 as well as appropriate positioning of mitochondria and ATP production at the cell periphery. While recent studies have highlighted the importance of cellular metabolism for matrix protein synthesis in fibroblasts (49) and of metabolic reprogramming in the acquisition of a CAF phenotype (50), our work reveals that proper mitochondrial distribution and activity strongly impact on the secretion of pro-tumorigenic proteins by these cells. Knock-down of mDia2 impaired this process and led to intracellular accumulation of otherwise secreted proteins. Our biochemical and microscopy data demonstrate that mDia2 is associated with mitochondria in skin fibroblasts. These findings are consistent with actin assembly being implicated in reorganizing and shuffling mitochondria during mitosis and mitophagy (37,51). Some of the molecular players involved in these actin-based processes are known (52), but neither mDia2's association with mitochondria nor its role in the regulation of mitochondrial distribution and function had been described. Furthermore, we discovered that mDia2 interacts with MIRO1 and that MIRO1 is essential to sustain the pro-tumorigenic activities of skin CAFs by allowing appropriate mitochondrial distribution and metabolic functions. First, we show that not only mDia2, but also MIRO1 is overexpressed in the stroma of various cancers, and that their combined overexpression correlates with reduced survival of patients with liver, lung, or pancreatic cancer. Second, knock-down of either mDia2 or MIRO1 strongly reduced the pro-tumorigenic effects of patient-derived skin cancer CAFs *in vitro* and *in vivo*. The reduction in mDia2 and/or MIRO1 expression was associated with inefficient OXPHOS, reduced ATP levels – in particular at the cell periphery-, and significantly reduced deposition of matrix proteins by CAFs. This is not the result of a transcriptional effect, since

MIRO1 silencing did not alter the expression of several CAF marker genes. Rather, impaired mitochondrial distribution and function in these cells provide a likely explanation for the observed secretory deficiency. This is consistent with the important role of MIRO1 in the release of neurotransmitters and insulin from presynaptic nerve terminals or pancreatic β-cells, respectively (53,54), and the positioning of mitochondria near secretory sites, thereby supplying ATP to support exocytosis (55). The co-expression of mDia2 and MIRO1 is at least in part controlled by activin A-Smad2/3 signaling. Two independent mechanisms allow mDia2 to regulate MIRO1 expression: the first mechanism involves a positive feedback loop whereby high mDia2 levels promote *INHBA*/activin A expression in fibroblasts and its secretion, which in turn increases *mDia2* and *MIRO1* transcription in these cells ((7) and this study). The second relies on the ability of mDia2 to stabilize MIRO1 in fibroblasts, possibly by preventing its proteasomal degradation (this study). The mDia2-MIRO1 interaction may contribute to this effect, since mDia2 binds to ubiquitinated proteins and reduces proteasomal activity (20).

Given that optimal MIRO1 expression is key to the maintenance of a pro-tumorigenic CAF phenotype, follistatin, neutralizing activin antibodies, or soluble activin receptor antagonists (56), which allow concomitant suppression of both mDia2 and MIRO1 activities, could be exploited to prevent the fibroblast-to-CAF reprogramming during tumor progression and may also reduce the pro-tumorigenic activities of already existing CAFs. Suppression of mitochondrial activity, *e.g.*, through cancer drugs that target mitochondrial metabolism in the tumor cells, is a promising approach for cancer treatment (57). Our results strongly suggest that perturbing mitochondrial positioning and function in CAFs may be therapeutically equally important. Therefore, we advocate further exploration of the potential of activin antagonists, the

586 rational design of mDia2-specific formin inhibitors, and the development of next-generation
587 MIRO1 inhibitors for cancer treatment.

605 and analyzed data; M.D.F isolated the human CAFs; M.K provided reagents and expertise for
606 LEGENDPlex and Seahorse analyses; M.I. contributed to the design of the mDia2 and MIRO1
607 experiments and provided mDia2 expertise and reagents. M.C. wrote and S.W., M.I. edited the

608 manuscript, S.W. acquired the funding. All co-authors made important comments on the

609 manuscript.

Figure legends

Fig. 1. mDia2 promotes protein secretion from HDFs

A Quantification of total proteins secreted by sh-EV and -mDia2 HDFs. *n*=3.

B Representative Western blots of conditioned media (CM) of sh-EV and -mDia2 fibroblasts for fibronectin 1 (FN1), collagen (COL)4A1, and INHBA under reducing conditions. Ponceau S staining of the membrane served as loading control.

C, D Representative immunofluorescence images of sh-EV and sh-mDia2 fibroblasts stained for INHBA, FN1, and ELN (C), and quantification of intracellular fluorescence intensity (D). *n*=3.

E Western blot for FN1, COL4, elastin (ELN) and vinculin (VIN, loading control) using total lysates of sh-EV or -mDia2 fibroblasts. *n*=3.

F Representative FN1, COL1A1 and ELN immunofluorescence images and quantification of the stained area in de-cellularized matrix from sh-EV and sh-mDia2 fibroblasts cultured in glucose-containing medium. *n*=3.

G Interferon (IFN)-α2, interleukin (IL)-1β, and IL-6 concentrations (ng/ml) in supernatants from sh-EV and -mDia2 fibroblasts. *n*=3.

H Quantification of SCC13 tumor spheroid area in hanging drop including CM from sh-mDia2 and sh-EV fibroblasts and representative images (left). The area of the spheroid formed in one control sample was set to 1. *n*=10-11.

I Western blots of total lysate from sh-EV or -mDia2 fibroblasts transfected with expression vectors encoding wild-type mDia2 (WT), an actin-polymerization-deficient mDia2 mutant (IA) or empty vector (pMX) for mDia2 and GAPDH.

J, K Percentage of total cells with actin stress fibers (J) and scratch closure (K) of sh-EV and sh-mDia2 fibroblasts transfected with expression vectors encoding WT or IA mDia2 or pMX. *n*=3 (J) and 6 (K).

L, M sh-EV or -mDia2 fibroblasts were transfected with expression vectors encoding WT or IA mDia2 or pMX. Quantification of FN1 immunofluorescence staining of de-cellularized ECM (L), and representative Western blot of total cell lysate and data quantification (M). *n*=3.

Graphs show mean ± SEM. ns $p>0.05$, *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$ (one way ANOVA with Bonferroni post-hoc test (D, E, J, K-M), or unpaired Student's t-test (A, F-H)). Scale bars: 50 μm (C), 100 μm (F).

Fig. 2. mDia2 regulates mitochondrial function in HDFs

A Representative images of sh-EV and sh-mDia2 HDFs stained with MitoTracker (green), rhodamine-coupled phalloidin (red) and Hoechst (blue). Graph shows fluorescence intensity of MitoTracker relative to the highest intensity value. The relative distance is indicated with values from 1 to 10 (see example on the top). *n*=10.

B Representative Western blots for mDia2, MIRO1 and HSP60 using cytoplasmic (Ct) and mitochondrial (Mt) fractions, and total lysate (TL) of HDFs.

C, D sh-mDia2 fibroblasts were transfected with pMX-WT or pMX-IA expression vectors or pMX, and stained with MitoTracker (C). sh-EV fibroblasts were used for comparison. Bar graph shows fluorescence intensity distribution of MitoTracker relative to the highest intensity value from the perinuclear region to the plasma membrane (D) as described in (A). *n*=6.

E-G Representative images of sh-EV and sh-mDia2 HDFs stained with CellROX (E) or MitoSOX (F) (red), counterstained with Hoechst (blue). Bar graphs show quantification of staining intensity. Cells were analyzed for LDH release (G). *n*=3-4.

H Relative intracellular ATP levels in sh-EV or sh-mDia2 HDFs transfected with pMX-WT, pMX-IA or pMX. *n*=3.

I Relative levels of mtDNA in sh-EV and sh-mDia2 HDFs determined by qPCR. *n*=3.

J Western blot of total lysate of sh-EV or -mDia2 fibroblasts for HSP60 and GAPDH, and quantification of the HSP60/GAPDH ratio. *n*=3.

K Quantification of FN1- and COL I-stained area in de-cellularized matrix from sh-EV and -mDia2 fibroblasts cultured in galactose-containing medium. *n*=3.

L Quantification of data from Seahorse analysis from sh-EV and sh-mDia2 HDFs cultured in galactose-containing medium. *n*=6.

Graphs show mean ± SEM. ns $p>0.05$, *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$ (one-way ANOVA with Bonferroni post-hoc test (H), two-way ANOVA with Bonferroni post-hoc test (A, D), or unpaired Student's t-test (E-G, I-L)). Scale bars: 25 μm (A, C), 100 μm (E, F).

Fig. 3. mDia2 binds and stabilizes MIRO1 in primary human fibroblasts

A Representative Western blot of total lysate of sh-EV or -mDia2 fibroblasts for mDia2, MIRO1, GAPDH, and α-tubulin.

B qRT–PCR analysis for *MIRO1* using RNA from sh-EV and sh-mDia2 HDFs. *n*=3.

C Representative Western blot of mitochondrial fractions from sh-EV and sh-mDia2 fibroblasts probed for mDia2, MIRO1 and HSP60, and quantification of mitochondrial mDia2/HSP60 or MIRO1/HSP60 ratios. *n*=3.

D Representative images of sh-EV and sh-mDia2 HDFs immunostained for MIRO1 (red), counterstained with MitoTracker (green) and Hoechst (blue). Dotted lines outline the cell border.

E Western blot of total lysate from sh-EV or -mDia2 fibroblasts transfected with pMX-WT, pMX-IA or pMX-control for MIRO1 and GAPDH, and quantification of the MIRO1/GAPDH ratio. *n*=3.

F Representative Western blots for MIRO1 and vinculin using total lysates of sh-EV and sh-mDia2 fibroblasts treated for 2 h with epoxomicin (Epox) (10 μM), and quantification of the MIRO1/VINCULIN ratio. *n*=3 biological replicates.

G Representative images of sh-mDia2 fibroblasts treated with Epox (10 μM) or vehicle and stained with MitoTracker (green) and rhodamine-coupled phalloidin (red). Bar graphs show fluorescence intensity distribution of MitoTracker relative to the highest intensity value from the perinuclear region to the plasma membrane and mean network branch quantified using MiNA toolset. *n*=22-29.

H, I Representative images showing PLA signals (red) in HDFs stained with mDia2 and MIRO1 antibodies and in the negative control (-Ctrl) without primary antibodies (H), counterstained with Hoechst (blue), either alone (H) or together with MitoTracker (green) (I).

Graphs show mean ± SEM. ns $p>0.05$, *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$ (one-way ANOVA with Bonferroni post-hoc test (E-G for network analysis), two-way ANOVA with Bonferroni post-hoc test (G for MitoTracker intensity), or unpaired Student's t-test (B, C)). Scale bars: 50 μm.

Fig. 4. Overexpression of mDia2 and MIRO1 in CAFs promotes tumorigenesis

A Expression of *MIRO1* in liver, breast and ovarian cancer stroma (CS) *vs.* stroma of respective normal tissues (NS) based on datasets GSE45001 (N=10 per group), GSE9014 (N=6 and 53), and GSE40595 (N=8 and 36).

B Single-cell expression profiles of *mDia2*/*DIAPH3* and *MIRO1* in immune cells, endothelial cells and CAFs of melanomas based on data from Single Cell Portal (Broad Institute).

C Correlation analysis between *MIRO1* and *mDia2*, *INHBA* and *TGFB1* gene expression across different cancers using TIMER2. UVM: uveal melanoma; LUAD: lung adenocarcinoma; PAAD: pancreatic ductal adenocarcinoma; SKCM: skin cancer cutaneous melanoma, BRCA-Lum: luminal breast cancer; LIHC: liver hepatocellular carcinoma. The red or blue color indicates a statistically significant positive/negative correlation (Spearman's, $p < 0.05$), respectively, and gray denotes a non-significant result.

D Kaplan–Meier survival curves based on TCGA and GTEx data. High expression of *mDia2*/*DIAPH3* and *MIRO1* in patients with liver or lung cancer correlates with poor survival.

E Representative sections from normal human skin, cSCC, and BCC stained for MIRO1. Scale bars: 100 μm. T: tumor cells.

F qRT-PCR analysis for *MIRO1* using RNA from CAFs or NFs from two SCC patients. *n*=3.

G Representative Western blot of total lysates of NFs and CAFs from patient No. 1 for MIRO1, CAF markers, and GAPDH.

H Quantification of SCC13 tumor spheroid area in hanging drop including CM from NF and CAFs. *n*=10-11.

I Mitochondrial distribution in NFs or CAFs from patient No.1. *n*=15-19.

J Representative images and bar graph showing fluorescence intensity distribution of ATP biosensor (cyto-Ruby3-iATPSnFR$^{1.0}$) relative to the highest intensity value from the perinuclear region to the plasma membrane of NFs and CAFs (patient No. 1). *n*=19.

K Mitochondrial branch length of NFs or CAFs (patient No.1). *n*=15-19.

L Representative immunofluorescence images of de-cellularized matrices obtained from NFs and CAFs (patient No.1) stained for FN1 and COL1A1 and quantification of stained area. *n*=3.

M Quantification of SCC13 tumor spheroid area in hanging drop including CM from NFs transfected with an expression vector encoding human MIRO1 (pGEM-MIRO1 "+") or empty vector (pGEM-EV "–"). The spheroid area in one control sample was set to 1. *n*=10-12.

N SCC13 cells plated on either de-cellularized matrix from NFs transfected with pGEM-MIRO1 or pGEM-EV. After 3 days, the number of Ki67-positive SCC13 cells was quantified. *n*=3.

O Representative FN1 and COL1A1 immunofluorescence stainings and quantification of stained area in de-cellularized matrix derived from NFs transfected with pGEM-MIRO1 or pGEM-EV. *n*=3.

P, Q sh-EV and sh-mDia2 fibroblasts were transfected with pGEM-MIRO1 ("+") or pGEM-EV ("–"). Expression of MIRO1 was analyzed by immunofluorescence 24 h post-transfection (P). *n*=3. Bar graph shows fluorescence intensity distribution of MitoTracker

relative to the highest intensity value from the perinuclear region to the plasma membrane (Q). *n*=6-8.

Bar graphs show mean ± SEM. ns $p>0.05$, *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$ (one-way ANOVA with Bonferroni post-hoc test (P), two-way ANOVA with Bonferroni post-hoc test (I, J, Q), unpaired Student's t-test (A, F, H, K-O)). Scale bars: 50 μm.

Fig. 5. *MIRO1* is a target of activin A-SMAD2/3 signaling

A HDFs were treated with 20 ng/ml activin A or vehicle for 6 h and analyzed for *MIRO1* expression by qRT–PCR. *n*=3.

B ChIP using lysates from activin A- or vehicle-treated fibroblasts and a SMAD2/3 antibody, and amplification of the bound DNA with MIRO1 primers (top). Pre-immune serum (IgG) was used as negative control. Alignment of the sequences within the 2-kb region upstream of the *MIRO1* gene transcription start site (TSS) of different species that harbor a SMAD2/3 binding element (SBE) (in red and italics, bottom).

C, D Representative images of sections from ear skin tumors formed by SCC13 cells with doxycycline (DOX)-inducible lentiviral overexpression of INHBA (SCC13 Act, (C)) or FST – (SCC13 FST, (D)) or transduced with EV, immunostained for MIRO1 (green) or α-SMA (red), and counterstained with Hoechst (blue). Graphs show percentage of MIRO1- relative to α-SMA-positive area (percentage of $MIRO1^+$ area in stroma). *n*=3 tumors per group. Tumors were collected 5 or 12 weeks after the initial injection of SCC13 Act or -FST. This accounts for the higher MIRO1-positivity of EV in (D) compared to (C).

E Tumors formed by SCC13 Act cells were treated *ex vivo* for 6 h with 50 ng/ml follistatin, immunostained for MIRO1 (green) or α-SMA (red), and counterstained with Hoechst (blue). Graph shows percentage of MIRO1- relative to α-SMA-positive area. *n*=4.

F, G qRT-PCR for *FST* (F) and *MIRO1* (G) using RNA collected 24 h after DOX treatment from clonally expanded HDFs transduced with empty vector (Fb EV) or with DOX-inducible expression of FST (Fb FST1: clone 1, Fb FST2: clone 2). *n*=3.

H Western blots for MIRO1 and GAPDH using total lysates of Fb FST (clone 1) and Fb EV.

I qRT-PCR for *DIAPH3* using RNA collected 24 h after DOX treatment from HDFs transduced with Fb EV or Fb FST1. *n*=3.

J Representative images of Fb-EV or -FST1 stained with MitoTracker (green) and Hoechst (blue).

K, L Fb FST1 and control fibroblasts were transfected with pGEM-MIRO1 ("+") or pGEM-EV ("–"). Expression of MIRO1 was analyzed by immunofluorescence 24 h post-transfection (K). *n*=3. Graph shows fluorescence intensity distribution of MitoTracker relative to the highest intensity value from the perinuclear region to the plasma membrane (L). *n*=8.

M Quantification of SCC13 spheroid area in hanging drops including CM from Fb FST1 and their controls transfected with pGEM-MIRO1 or pGEM-EV. The area of the spheroid in one control sample was set to 1. *n*=8.

Bar graphs show mean ± SEM. ns $p>0.05$, *$p<0.05$, **$p<0.01$, ***$p<0.001$ (one-way ANOVA with Bonferroni post-hoc test (F, G, K, M), two-way ANOVA with Bonferroni post-hoc test (L), or unpaired Student's t-test (A, C-E, I)). Scale bars: 50 μm (C-E), 25 μm (J).

Fig. 6. Knock-down of MIRO1 causes metabolic dysfunction and impaired protein secretion in primary human skin CAFs

A, B CAFs from patient No. 1 were transfected with MIRO1 (si-MIRO1) or control (si-Ctrl) siRNAs. The knock-down was confirmed by qRT–PCR (A) and immunofluorescence staining (B).

C Quantification of nuclear p53 in CAFs transfected with Ctrl or MIRO1 siRNAs. *n*=3.

D qRT–PCR for CAF marker genes and genes encoding different small GTPases using RNA from si-MIRO1 or si-Ctrl CAFs. *n*=3.

E Representative images of si-MIRO1 or si-Ctrl CAFs (patient No.1) stained for MIRO1 (red), counterstained with MitoTracker (green) and Hoechst (blue).

F Quantification of COL1-stained area in de-cellularized matrix from si-Ctrl or si-MIRO1 CAFs. *n*=3.

G Relative levels of mitochondrial superoxide based on MitoSOX fluorescence intensity in CAFs (patient No.1) transfected with si-Ctrl or si-MIRO1. *n*=3.

H CAFs (patient No.1) transfected with si-Ctrl or si-MIRO1 were analyzed for LDH release. *n*=3.

I Seahorse assay for the OCR in CAFs (patient No.1) transfected with si-Ctrl or si-MIRO1 and quantification of basal respiration, maximal respiratory capacity, and ATP production in glucose (top) or galactose (bottom) medium. *n*=5-6.

J Quantification of total proteins secreted by si-MIRO1 or si-Ctrl CAFs (patient No. 1) in glucose medium. *n*=6.

K, L Representative images of immunofluorescence stainings for FN1 and COL1A (I) and quantification of the stained area in de-cellularized matrix (J) from si-Ctrl or si-MIRO1 CAFs (patient No. 1) in glucose medium. *n*=3.

M Quantification of intracellular fluorescence in si-Ctrl or si-MIRO1 CAFs (patient No. 1) immunostained for INHBA or ACTA2. *n*=3.

Bar graphs show mean ± SEM. ns $p>0.05$, *$p<0.05$, **$p<0.01$ (two-way ANOVA with Bonferroni post-hoc test (D), unpaired Student's t-test (other graphs)). Scale bars: 50 μm (E) and 100 μm (B, K). Data shown in **Fig. 6K, L** were reproduced with CAFs from a second patient.

Fig. 7. Depletion of MIRO1 in CAFs suppresses skin tumorigenesis

A, B sh-EV or -mDia2 HDFs co-cultured for 7 days with SCC13 cells immunostained for E-cadherin (red) and counterstained with MitoTracker (green) and Hoechst (blue) (A). The mitochondrial distribution relative to the highest intensity value from the perinuclear region of fibroblasts to the interface with SCC13 cells was quantified (B). Relative distances range from 1-10. *n*=4-6.

C Representative Western blots for MIRO1, mDia2, and GAPDH using total lysates of NFs and CAFs (patient No. 1) cultured with SMIFH2 (25 μM) or vehicle. The dotted line indicates cutting of the membrane; all samples were loaded on the same gel.

D Representative images of NFs and CAFs cultured with SMIFH2 (25 μM) or vehicle and stained with rhodamine-coupled phalloidin (red), MitoTracker (green) and Hoechst (blue).

E Two-dimensional co-cultures of SCC13 cells with si-Ctrl or si-MIRO1 CAFs at day 7. SCC13 cells were identified by E-cadherin (red) staining and counterstained with

MitoTracker (green) and Hoechst (blue). The mitochondrial distribution relative to the highest intensity value from the perinuclear region of fibroblasts to the interface with SCC13 cells was quantified. Relative distances range from 1-10. *n*=12-14.

F Chemotactic transwell migration of SCC13 cells using CM from si-Ctrl or si-MIRO1 CAFs. *n*=3.

G Quantification of SCC13 spheroid area in single hanging drop including CM from si-Ctrl or si-MIRO1 CAFs. The spheroid area in one si-Ctrl sample was set to 1. *n*=6.

H Tumor volume at different time points 2 weeks after injection (*n*=4) and representative photos of 2-week-old tumors formed upon intradermal co-injection of SCC13 cells with si-MIRO1 or si-Ctrl CAFs. An inset panel indicates the area where tumor cells invade into the cartilage. Asterisk indicates cartilage; arrow indicates site of invasion.

I Representative images of COL1A1 immunofluorescence and Herovici staining of tumors formed by SCC13 cells transfected with si-MIRO1 or si-Ctrl CAFs at day 15.

J Quantification of percentage of COL1A1-positive area and curvature of fibers per field of view. *n*=3-4.

K Increase in SCC13 (co-injected with CAFs) tumor volume (mm^3) upon injection of the tumors with MIRO1-Reducer (2.5 μM per injection) or vehicle (DMSO) once every 3-4 days for 18 days. Red arrows indicate the treatment time points. *n*=5.

Bar graphs show mean ± SEM. ns $p>0.05$, *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$ (two-way ANOVA with Bonferroni post-hoc test (B, E, H, K), unpaired Student's t-test (F, G, J)).

Scale bars: 25 μm (A, D, E) and 50 μm (I).
