Author Declaration

Parkinsonism & Related Disorders is committed to proper scientific conduct and the protection of animal and human research subjects. Submission of this manuscript implies compliance with the following ethical requirements. Please affirm that you are representing all of the authors in stating compliance with these policies by checking the box at the end of this section.

1. Studies with human subjects must have been conducted in accordance with the Declaration of Helsinki. All persons must have provided informed consent prior to being included in the study.
2. Studies with animal subjects must have been conducted in accordance with the Guide for the Care and Use of Laboratory Subjects as adopted by the US National Institutes of Health and/or according to the requirements of all applicable local, national and international standards.
3. Protocols with animal or human subjects must have been approved by the relevant local committee(s) charged with ensuring subject protection. Studies that entail pain or distress will be assessed in terms of the balance between the distress inflicted and the likelihood of benefit.
4. The authors declare that the manuscript is original, that it is not being considered for publication elsewhere, and that it will not be submitted elsewhere while still under consideration for Parkinsonism & Related Disorders or after it has been accepted by Parkinsonism & Related Disorders.
5. All authors have seen and approved the manuscript in the form submitted to the journal. The authors declare that they have conformed to the highest standards of ethical conduct in the submission of accurate data and that they acknowledge the work of others when applicable.
6. All sources of financial support for the work have been declared in the Acknowledgements section of the manuscript. Any additional conflicts of interest must also be declared. Please include declarations of any consultancy or research funding received from relevant companies from three years prior to performance of the research until the time of manuscript submission. If the research is supported by internal funds, that should be stated as well.

To indicate compliance with the preceding declaration and that you have obtained agreement from all of the authors of this paper to declare their compliance as well, please place an x here: x

In cases of uncertainty please contact an editor for advice.

Dear Editor,

On behalf of all the authors, I would like to submit the manuscript entitled: "Levodopa response and motor fluctuations in beta-propeller protein-associated neurodegeneration".

Motor fluctuations and dyskinesias represent the major complications of the long-term therapy with levodopa in Parkinson's disease. Similar motor complications may also be observed in other conditions associated with substantia nigra neuronal loss.

Here, we report on a case of BPAN presenting adulthood progression with development of levodopa-responsive dystonia parkinsonism syndrome, associated with prominent and early motor complications. This might be due to the severe dopaminergic depletion in the striatum as assessed by DAT imaging and the prominent involvement of the substantia nigra by iron accumulation, whereas the striatum was less affected. The observation of severe levodopa-induced motor complications is uncommon in tauopathies and might be a disabling feature in BPAN, especially in those patients with prominent iron accumulation in the substantia nigra rather than the striatum.

All authors have approved the final article. We confirm that the paper has not been previously published, it is not under simultaneous consideration by another journal and no ghost writing by anyone not named on the author list must be included. We have received a signed release form from the patient videotaped authorizing the offline and/or online distribution of the video material.

The authors report no conflicts of interest.

I have read and have abided by the statement of ethical standards for manuscripts submitted to Parkinsonism & Related Disorders.

We hope you will consider also this manuscript to be reviewed by the Editorial Board.

Sincerely,

Dr. Antonio Emanuele Elia

42 Motor fluctuations and dyskinesias represent the major complications associated with levodopa in
1
243 Parkinson's disease (PD). We report on a case of beta-propeller protein-associated
3
44 neurodegeneration (BPAN) presenting with a young-onset levodopa-responsive dystonia
6
745 parkinsonism, who developed early motor complications after the initiation of levodopa.

1046 The patient is a 34-year-old right-handed lady, who was referred for a 2-year history of progressive
11
12 slowing of movement associated with episodes of "spasms" affecting the left leg. She gradually
1347 developed clumsiness of the left limbs, cognitive decline and social isolation. Her parents reported
14
1548 sleep talk and screaming at night, and the presence of excessive movements during sleep.
16
17
1849

19
20
2150 She was diagnosed with a young-onset parkinsonism and started levodopa+benserazide titrated up
22
23
2451 to 100+25 mg four times/day, with significant improvement in motor function. Nevertheless, after
25
2652 only four months, she developed early mild motor fluctuations and dyskinesias.

27
28
2953 Over the course of the last four years, motor complications progressed into disabling OFF-periods,
30
31
3254 characterized by severe bradykinesia, and troublesome peak-dyskinesias (causing a weight loss of
33
3455 about 10 kg) and requiring a reduction of levodopa therapy. Generalized dyskinesias significantly
35
3656 impaired walking and daily activities (video).

37
38
39
4057 Brain MRI disclosed bilateral T2* hypointensity in the globus pallidus and in the midbrain,
41
4258 involving the substantia nigra. Dopamine transporter (DAT) tomography showed a bilateral reduced
43
44 uptake in the striatum (figure). Genetic screening revealed a never described and *de novo*
4559 c.344+2T>G mutation in the WDR45 gene. Neuropathological investigation on cerebrospinal fluid
46
4760 (CSF) samples disclosed reduced levels of β -amyloid 1-40 [5226 pg/ml (7755-16715)] and β -
48
49 amyloid 1-42 [500 pg/ml (> 640)]. Conversely, A β 1-42 / A β 1-40 ratio [0.096 pg/ml (0.068-0.115)],
5061 t-tau [254 pg/ml (146-404)] and p-tau levels [23.4 pg/ml (21.5-56.5)] were within the reference
51
5262 range, and 14-3-3 protein was not found.

68 dyskinesias, as usually observed in Parkinson's disease, particularly in early onset patients. In a
69 previous study motor response to levodopa administration was described in BPAN and the duration
70 of levodopa benefit was reported to be relatively short, with early appearance of motor fluctuations
71 and quickly advancing to disabling dyskinesias [1]. This might be due to the severe dopaminergic
72 depletion in the striatum as assessed by DAT imaging, and the prominent involvement of the
73 substantia nigra by iron accumulation compared to the striatum. Hayflick and colleagues have
74 described levodopa response in 47.8% of BPAN patients, despite the duration of levodopa benefit
75 was short, with early emergence of motor fluctuations determining the discontinuation of drug [1].

76 Recent reports on BPAN patients have demonstrated widespread tau deposition, indicating that
77 BPAN is a tauopathy [2]. However, our investigation on CSF disclosed a decreased concentration
78 of A β 1-40 and A β 1-42, but normal levels of p-tau and t-tau. Studies on Alzheimer's disease (AD)
79 have in fact revealed a significant reduction in A β 1-40 CSF levels in cognitively normal elderly
80 subjects who subsequently developed AD [3]. By contrast, elevated tau levels occur in individuals
81 who already have cognitive decline, mild cognitive impairment or dementia, and correlate in part
82 with the degree of atrophy [4]. These observations suggest that A β aggregation and deposition
83 might be associated with the preclinical phase of AD, whereas changes in CSF tau levels and brain
84 atrophy might represent advanced events. According to that, we might speculate that our findings
85 could reflect an initial phase of the neuropathological mechanisms leading to the frank tauopathy
86 described in BPAN in the post-mortem report of Paudel and colleagues [2].

87 Intriguingly, the accumulation of tau aggregates typically represents a neuropathological feature of
88 patients with atypical parkinsonism usually poorly responsive to levodopa. Moreover, the
89 observation of severe levodopa-induced motor complications is uncommon in tauopathies and might

90 be a disabling feature in BPAN, especially in those patients with prominent iron accumulation in the

91 substantia nigra rather than the striatum.

92 In addition, our patient developed a sleep disturbance resembling REM behavioral disorder, which
93 is more common in synucleinopathies [5]. Parasomnias are reported in several patients with BPAN,
94 accounting up to 22% of subjects [1] These observations point out that BPAN phenotype may be
95 atypical for tauopathies, thus suggesting other potential pathophysiological mechanisms.

96 The need for a personalized management has started to be regarded as significant factor for
97 delaying and decreasing motor fluctuations on BPAN patient's quality of life. To date, there are no
98 reports on the use of deep brain stimulation to treat parkinsonism in BPAN; nevertheless, the
99 possible worsening of cognitive function in these cases dictates a personalized approach. Further
100 studies addressing dopaminergic response in BPAN might elucidate this peculiar aspect of the
101 disease.
