AIMS

The goal of this study was to compare the different results When analysing cancer incidence by sites using socio-economic Local Deprivation Indices (LDI) or the National Deprivation Index (NDI).

We will stress their different ability in identifying the incidence characteristics at different socio-economic status (SES).

Background and state of the art

The variables used for computing the LDIs and NDI came from the National Italian Census 2001.

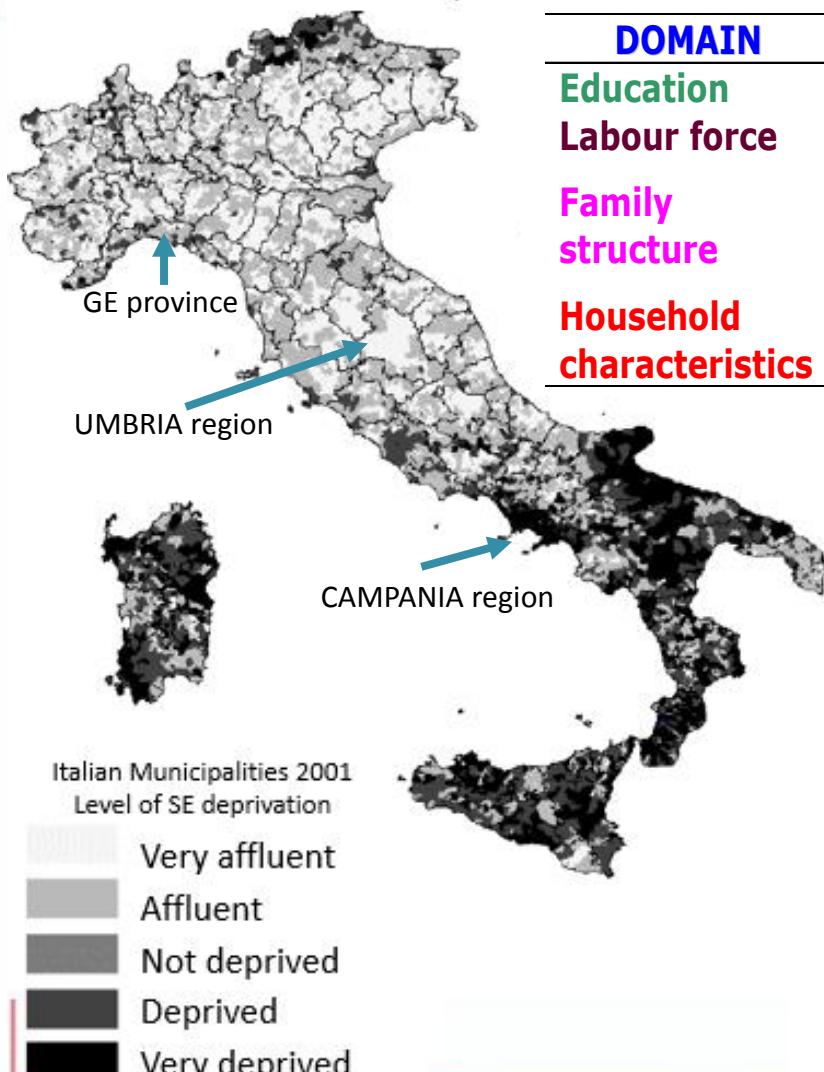

The NDI was computed for all Italian population, but in this project were re-parameterised for the areas of Genoa, Umbria and Campania.

The LDIs were computed specifically for three regional areas.

Until now we built, validated and used only the indices for Liguria (LRDI) and Umbria (UDI), while the LDI for Campania (CDI) is ongoing.

2001 National Deprivation Index characteristics

DEPRIVATION INDEX
Italian Municipalities 2001

INDEX COMPOSITION

DOMAIN	NDI 2001
Education	- % pop. with at least primary level education
Labour force	- % pop. unemployed or searching for first employment
Family structure	- % families with one parents and dependent sons living together
Household characteristics	- % rented households - No. of people by 100 mtrs ²

Building of Liguria and Umbria Deprivation Indexes -1

Demographic and socio-economic variables (DSE) for Liguria and Umbria regions were derived from census data at municipality and sub-municipality level (for Liguria we subdivided Genoa and Savona; for Umbria the cities of Perugia, Terni and Foligno).

A 1st selection of the DSE was performed by computing the Pearson's Correlation Coefficient with the SMRs of Overall Mortality; only the variables significantly correlated ($p<0.05$) were chosen for the 2nd step.

A 2nd selection was performed by collinearity tolerance check ($p<0.01$). The remaining variables were entered in a Principal Component factor Analysis (conditions: eigenvalues >1 , varimax orthogonal rotation), which synthesized the factors describing the main characteristics of the two populations.

The two Regional Deprivation Index (RDI) were computed by linear combination of factors, standardising the index on a % scale.

Building of Liguria and Umbria Deprivation Indexes -2

The municipalities and sub-municipalities were classified on the basis of distribution by quintiles of the RDIs.

In order to give a more balanced distribution of the population inside the groups, also the population of each area was considered as a criterion of classification to obtain the groups on the basis of maximum similarity of the RDI values and of the best normalized population level

So, we used the cluster discriminant analysis based on the algorithm of Agnelli, Cadeiras, Tabak, Turner and Vander-Eijden*, which allows to aggregate cases maintaining one or more clustering variables with a quite normal distribution through the generated clusters.

The reached normalization level was tested at the $p<0.05$ level.

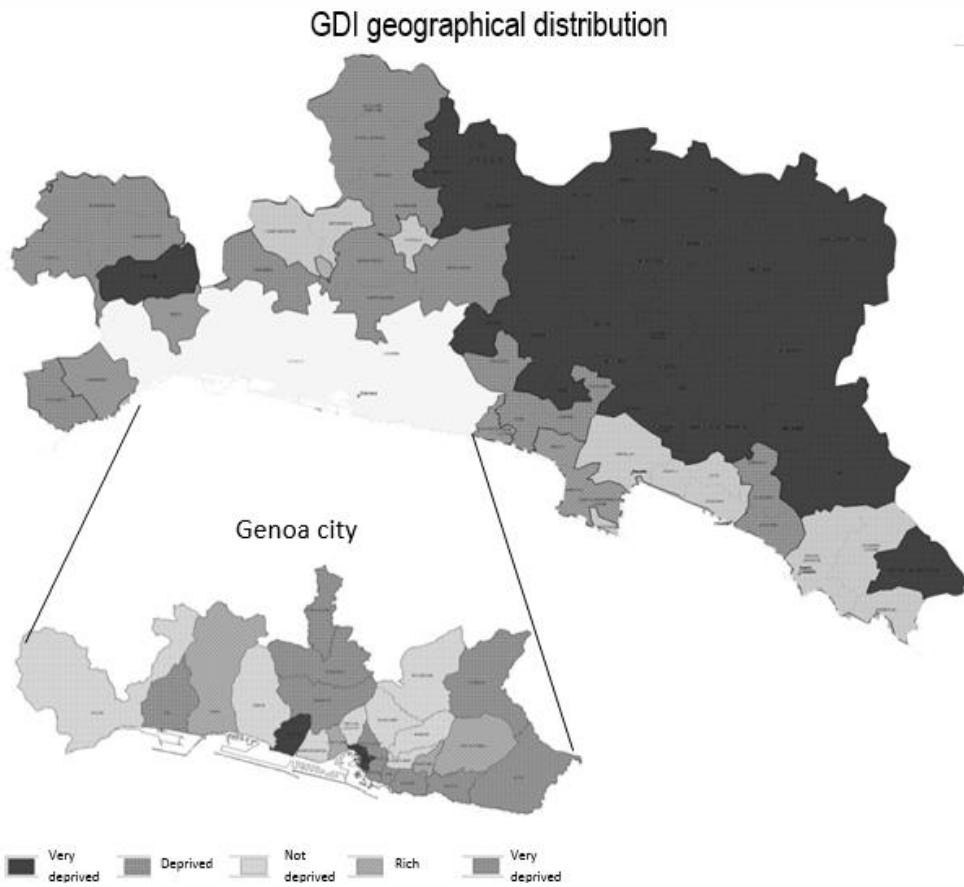

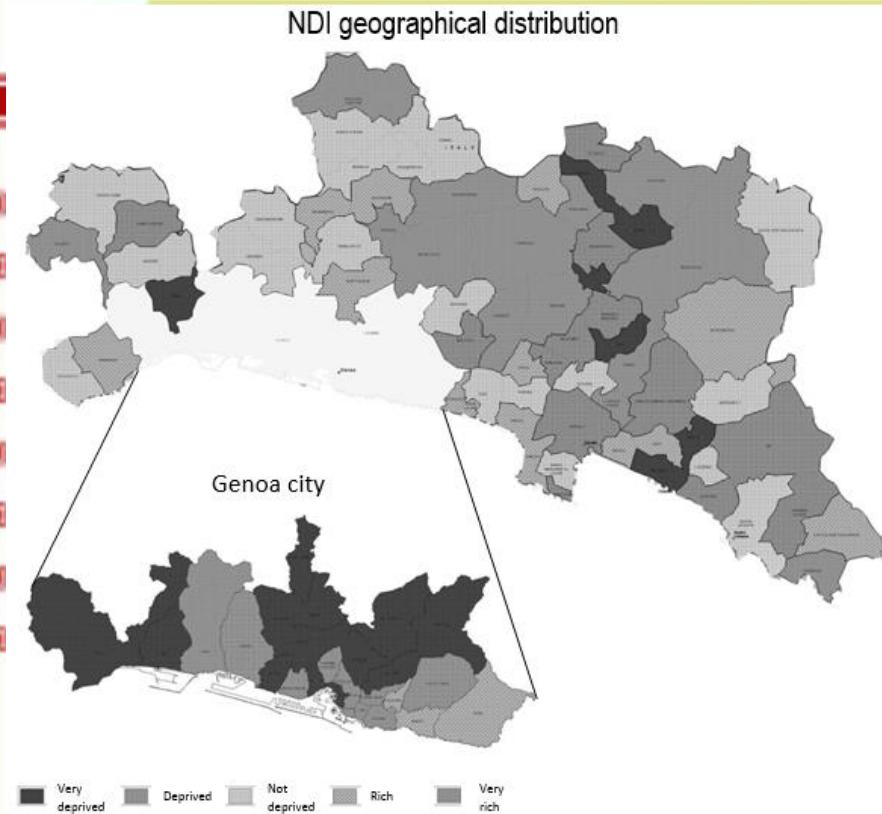

Finally, the local index for Genoa province (GDI) was obtained re-parameterising the Liguria RDI on the Genoa province population.

Variables composing the factors of the GDI and UDI

DOMAIN	2001 Genoa (GDI)	2001 Umbria (UDI)
Education	- % of high school and university degree diploma	- % of high school and university degree diploma
Labour force	- % entrepreneurs and professionals	- youth employment rate - employment rate
Family structure	- % two people families - % married people	- average age of 3-persons families - % of people born in the same municipality of residence - % of singles - N° of persons in the family
Household	- % houses with very small kitchen	- % of owned houses - % of houses with independent heating system

UMBRIA CENSUS TRACT BY UDI

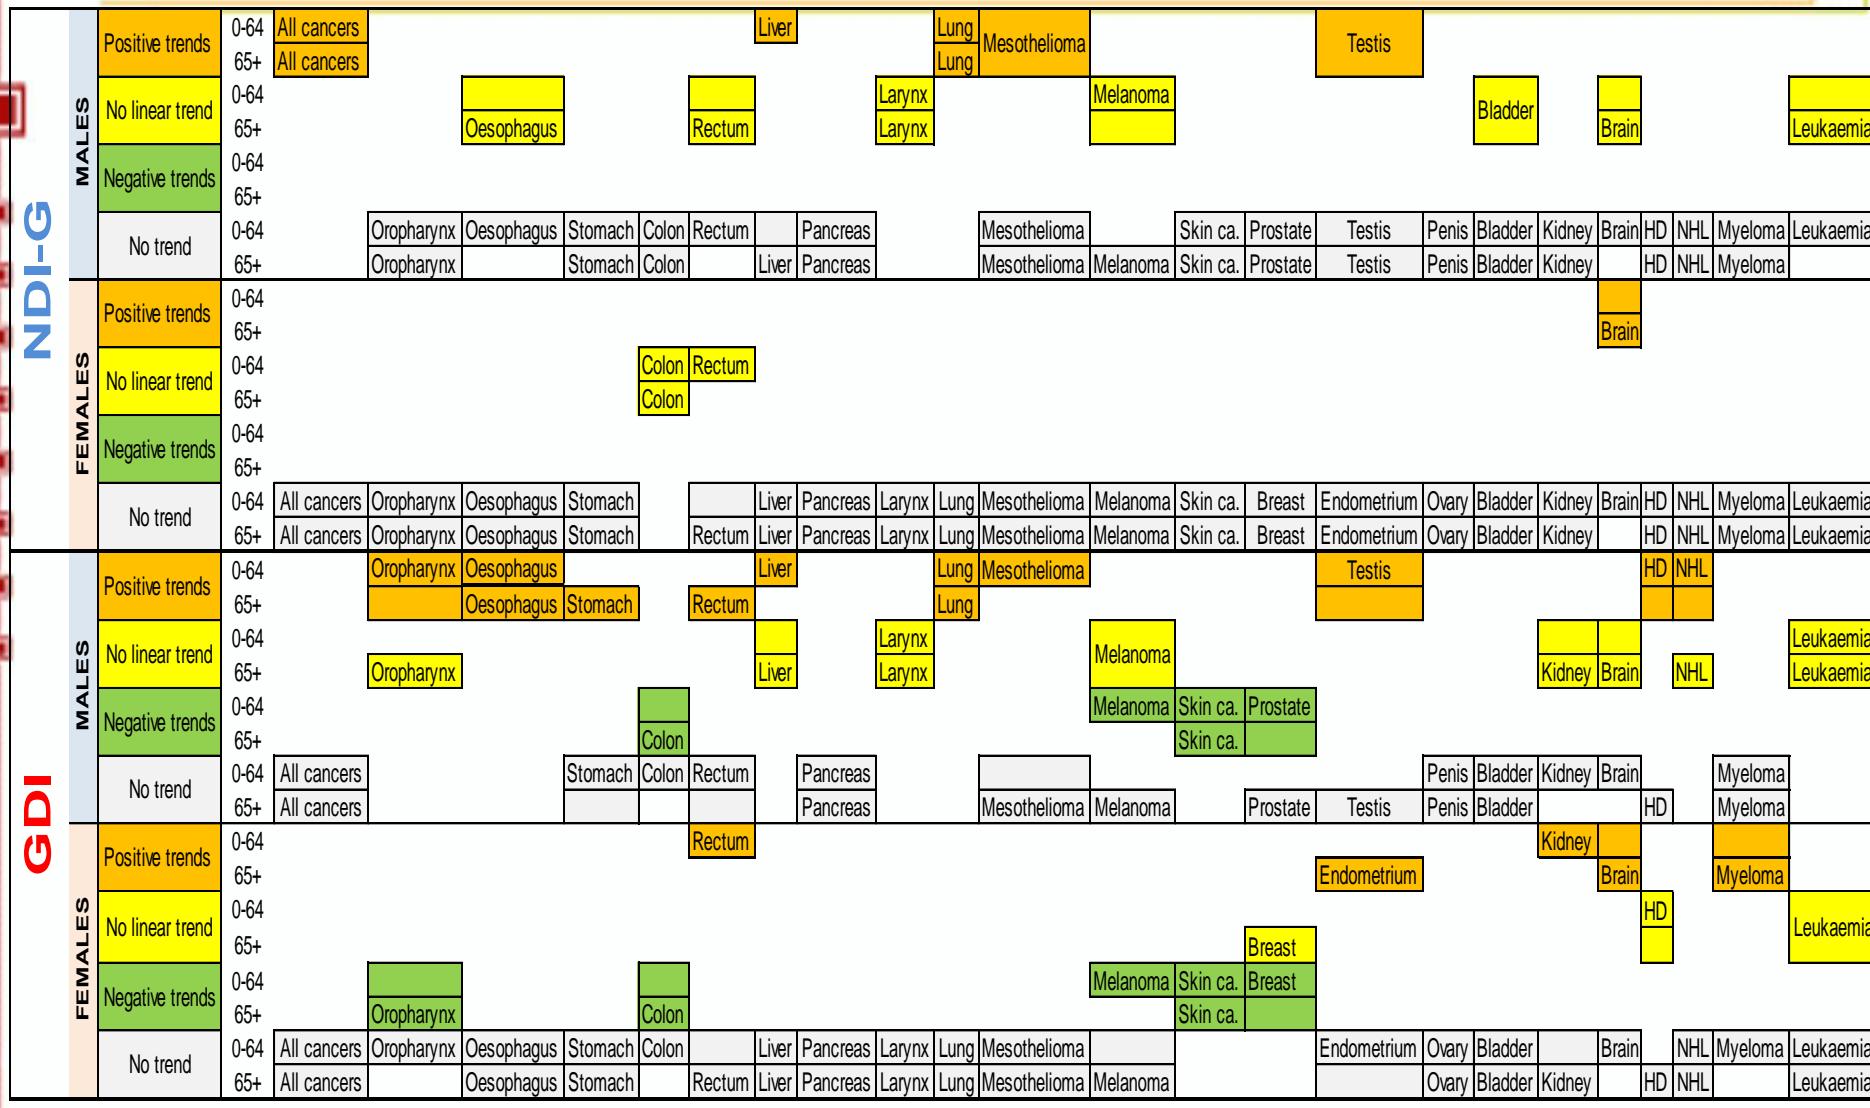

Results - 1

We have found more statistically significant associations between cancer incidence distribution by site and gender and trend of deprivation by local index, compared to the ones found by the NDI.

These associations were generally homogeneous with the results found in the international literature.

Conclusions

We propose the use of the two types of index for different public health purposes.

LDIs are able to provide specific information for an improvement of the health and social support policies and actions, identifying specific health needs in targeted groups of population.

NDI can give a more general description of the relationships between deprivation and health status, allowing a comparison among different regions and providing a validation benchmark for the LDIs.

Thank you for your attention

Umbria region incidence: 2001 - 2010

Results -2

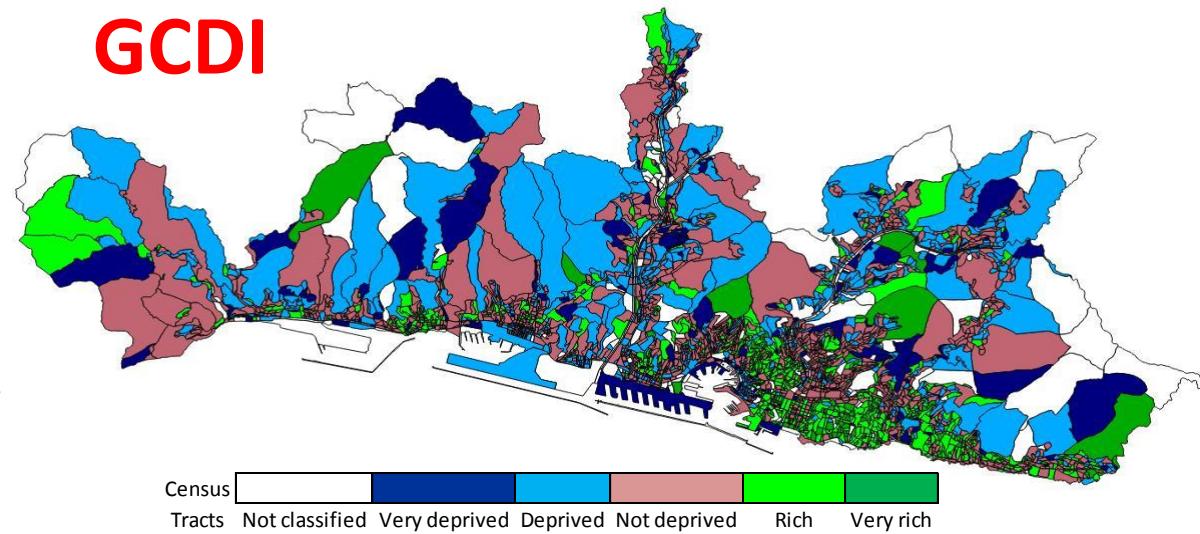

The NDIs and LDIs produced similar results where the populations were more urbanised, stressing the main feature of the NDI as descriptor of the Italian population as a whole, the elevated urbanisation (67% of Italian people were urbanised in 2001).

E.g. this happens when the NDI and the LDI were build at Census Tract (CT) level specifically for Genoa City, after the geo-referring of the 2008-2011 mortality by cause of resident at CT level.
