Welcome to the 13th World Congress of the RSAI

Dear Friends and Colleagues,

It is our pleasure to welcome you to the 2021 RSAI World Conference! On behalf of the Regional Science Association International, the Local Organizing Committee, and the Scientific Committee, we would like to thank you for joining us at this historical meeting, and for sharing your experience, research and views with all the participants.

Organized by the Moroccan Section of the RSAI, the 2021 RSAI World Conference is intended to be a major international forum for researchers and policy-makers in the field of Regional Science across the world, focusing on today's most challenging issues. The World Conference brings together more than 500 participants from 53 different countries. The papers cover all major areas of the field, with applications for a wide range of regions in the globe.

Since we have decided that the congress would run 100% online, many colleagues from the Association have joined us in an extraordinary effort to organize a high standard, inclusive, online event. Recognizing the key role played by former RSAI President, Mark Partridge, we would like to extend our sincere gratitude and appreciation for the hard work and dedication provided by all of them.

Going online has shown to bring us some opportunities. We have contacted every single national section and invited them to propose special sessions dedicated to their countries/regions. We have received positive responses from almost all sections. This is really invigorating and motivating, further developing the sense of community belongingness that may motivate a larger number of young regional scientists to engage more broadly in the Association. We now have the opportunity to have a truly global conference, with the participation of many of RSAI sections!

This World Conference is a unique opportunity to showcase some of the exceptional work regional scientists are doing all over the world. There are 35 slots dedicated to 25 national sections, in addition to an even larger number of parallel sessions, and five outstanding keynote speakers.

Going online also made possible a wider participation across the world, allowing us to minimize the number of competing sessions, to allocate time slots with time zones in mind, and to reduce drastically registration fees.

We are pleased you were able to join us, and we wish you an excellent and memorable conference! Your participation and commitment to RSAI are very important and truly appreciated. In the next days, you will all have the opportunity to grab a big picture of our Association, being exposed to different topics and approaches people are using across the world.

Please receive our warmest welcome!

Eduardo Haddad

International*

A truly World Congress

On behalf of the Moroccan Regional Science Association (AMSR) and the Regional Science Association International (RSAI), it is our pleasure to welcome you all to the 13th World Congress of the RSAI.

This last year has brought well known troubles to the whole world. At the time we are writing these words, the worst pandemic in over a century is still exerting a major toll on our every lives, among which the need to resort to online scientific events such as the one we are joining between May 25 and 28, 2021.

Yet, the RSAI took this as an opportunity to further broaden the geographical and disciplinary scope of our main global gathering. The map below shows the broad coverage of participants in this RSAI World Congress, as evidenced by the 53 Countries included in the program (proxied by Country of the institution of affiliation of the first author).

While older supranational sections (NARSC and ERSA) are as usual largely represented, we are very happy to report an important presence of PRSCO and LARSA national sections, too. Moreover, and this is among the main goals of this edition of the World Congress, we witnessed a positive feedback from many regional scientists located in African Countries where no national section of the RSAI is to date present. We hope this congress will sow seeds for the creation of new national sections, with the fundamental help of AMSR, presently the only national section active on the Continent. In the medium run, hopefully a new supranational section will emerge, including all such new sections, while also coordinating their activities.

Papers accepted to the 2021 RSAI World Congress

The RSAI World Congress is also a place of strong networking. In the next map, the intensity of co-participation for authors presenting papers accepted to regular sessions of the congress is represented with blue lines, with increasing thickness showing more frequent interactions of presenters sharing the same sessions. Blue lines cross all oceans and suggest a high propensity of exchange of ideas among regional scientists all over the world.

The last map shows with green lines that an analogous message comes from interaction of authors presenting papers accepted in special sessions during the World Conference. The geography of interactions appears relatively different, with thicker lines connecting North America and Europe, and between China and South Asia.

Beyond the pre-existing networks, we wish this Congress to be an opportunity for all of you (us!) to open new nodes, and further diffuse our discipline.

Have a safe, interesting, and productive Congress!

The RSAI World Congress Organizing Committee

Programme Overview

Tuesday, May 25, 2021	Wednesday, May 26, 2021	Thursday, May 27, 2021	Friday, May 28, 2021
			Session New Zealand 1 [05:30-07:00]
OPENING CEREMONY [08:30-09:00]			INTERVAL [07:00-09:00]
PLENARY SESSION I Keynote speech: Tawfik Mouline [09:00-09:30]			Session New Zealand 2 [9:00-10:30]
Parallel sessions 1 [09:30-10:45]	Parallel sessions 6 [09:30-10:45]	Parallel sessions 11 [09:30-10:45]	Parallel sessions 16 [09:30-10:45]

Instructions to Chairs, Presenters, and Discussants

1. Sessions are will last 1 hour and 15 minutes. Please stick to the times shown in the program. Each presentation is assigned a specific time, all expressed in the GMT+1 zone (please be sure and check how this translates into your own time zone). If you have a no-show, use the time for a discussion of the proceeding paper(s) or for a recess. Please do not shift papers to fill voids, as individuals may want to attend a particular paper.
2. The majority of sessions have 3 papers. In 3 paper sessions, each presenter is allowed 18 minutes for presentation, followed by a 5 minutes discussion. In 4 papers session, each presenter is allocated 15 minutes, followed by 3 minutes discussion. In the few 5 paper sessions, each paper should be allocated 12 minutes, with about 10 minutes at the end of the session for generic questions.
3. Hold each individual to the time available. If a speaker continues after time has expired, please let her/him know that time has expired. The audience and the other speakers will respect and support your decision.
4. Because of the limited time available, the conference assumes no formal discussion to follow presentations. However, Chairs of each session are free to organize their sessions as refereed ones, i.e. sessions where papers are assigned a discussant. In this case, Session chairs are asked to please get in touch as soon as possible with the Authors of the papers of their sessions to verify their availability to have a discussant assigned to their papers.
5. The discussant, if any, should provide a 3-minute discussion of the paper's main merits and limitations, possibly suggesting ways to address them for future reference.
6. In case the session is refereed, please adjust presentation times accordingly so as to leave room for all presenters and related discussants.

Zoom Requirements

For the meeting this year, the 2021 RSAI World Congress will restrict meeting participants to logged-in users only. This means that you must be logged in to Zoom to attend any of the sessions.

If you do not have a Zoom account, you will not be able to join the meeting.

If you try to join a session and are not logged into Zoom, you will receive the following messages:

Click on the **Sign In to Join** button. If you already have an account, log in to Zoom. If you do not have an account, you may sign up at this time.

Having a Zoom account allows you to create your own Instant Meetings or Schedule Meetings. An account also allows you to access your personal settings, where you can update your profile or upgrade your plan at any time.

How do I sign up for Zoom?

You can sign up for a free Zoom account at zoom.us/signup.

How much does Zoom cost?

A basic Zoom license is free.

Issues with logging in?

For any issue when logging in, you may write to the following email addresses, where specialized staff will assist you in the procedure:

Virtual room name	Email address
FIPE	RSAI.FIPE@gmail.com
NEREUS	RSAI.NEREUS@gmail.com

Themes

Umbrella Theme

Smart Regions – Opportunities for sustainable development in the digital era

The themes which will zoom in particular on the pressing challenges of meeting the 2030 Agenda of Sustainable Development Goals, in both developed and developing economies. As a new challenge to regional science research is caused by the emerging digital technologies and their implications for analysis, monitoring, evaluation and forecasting of spatial dynamics at all levels, the theme chosen for the congress is ‘Smart Regions- Opportunities for Sustainable Development in the Digital Era’. Therefore, the potential of spatial and temporal big data, machine learning, artificial intelligence, social media information, and of the new spatial maps emerging from digitization and robotization will be addressed by the congress as well, as these forces will have far-reaching impacts on human behaviour and interaction in space.

General Themes

RS01 - Entrepreneurship
 RS02 - Infrastructure, transportation and accessibility
 RS03 - Knowledge and innovation
 RS04 - Local finance
 RS05 - Location theory and applications
 RS06 - Methods in Regional Science and Urban Economics
 RS07 - Migration and regional labor markets
 RS08 - Real estate and housing
 RS09 - Regional and urban policy
 RS10 - Regional development
 RS11 - Rural development
 RS12 - Spatial implications of climate and environmental change

RS13 - Spatial planning
 RS14 - The spatial dimension of sustainable development
 RS15 - Theoretical and empirical urban economics
 RS16 - Tourism
 RS17 - Globalization and territorial intelligence
 RS18 - Resilience and Risk Management
 RS19 - Green economy and complexity of socio-ecosystems
 RS20 - Biodiversity, ecosystems and ecosystem services
 RS21 - Agriculture, fisheries and food security
 RS22 - Nexus: water, agriculture and energy

Special Sessions’ Themes

SS01 - Alternatives for integrating development with infrastructure provision in the global South
 Manisha Jain and Jörg Knieling
 SS08 - Subjective well-being and spatial inequalities
 Camilla Lenzi and Giovanni Perucca
 SS09 - Regional, national and supranational identities: determinants and policy implications
 Enrique López Bazo and Giovanni Perucca
 SS10 - Regions and cities at the edge of the new technological era
 Roberta Capello and Camilla Lenzi
 SS12 - SMEs/Family Businesses and Regional Development
 Lech Suwala, Rodrigo Basco and Stefano Amato
 SS16 - Smart, sustainable, resilient regions: Responses to pandemic challenges - Contributions of the Romanian Scholars
 Daniela L. Constantin and Cristina Serbanica
 SS17 - Data science, machine learning and big data for regional Sciences
 Jean-Claude Thill, Hicham Mharzi Alaoui, Said Lahssini and Hicham Hajji
 SS18 - Urban Future in the Global South
 Abdul Shaban and Tomaz Ponce Dentinho

SS19 - The spatial dimension of energy transition policies, practices and technologies
 Andrea Caragliu and Marcello Graziano
 SS22 - Regional Disparities in the EU and Hungary in the Age of Digitalization and the Pandemic
 Zoltán Gál
 SS23 - Understanding the role of Renewable Energy in the Water, Agriculture, Energy Nexus in West and North Africa
 Mariama Camara and Mary Thompson-Hall
 SS24 - Education inequality and Economic development: a regional perspective
 Amaghous Jabrane and Ibourk Aomar
 SS27 - Discontent, Hate & Intolerant Attitudes
 Alessandra Michelangeli, Alessandra Faggian and Daria Denti
 SS28 - Smart Actors for Smart Regions
 Chiara Tagliaro and Gianandrea Ciaramella.
 SS29 - Strengthening the resilience of socio-ecological systems
 Sumana Bandyopadhyay, Lakshmi Sivamakrishnan, Tomas Ponce Dentinho and Said Lahssini
 SS31 - Regional Economic Development in Asia
 Yuri Mansury and Budy Resosudarmo

SS33 - Plastic pollution and its environmental impact

Abdellatif Khattabi and Diane Pruneau

SS36 - Glocalization and Regional Development

Hideki Fukui and Shinya Ishizaka

SS38 - Resilience and peripheral areas: development patterns and policies in the borderlines

Karima Kourtit, Gabriela Carmen Pascariu, Ramona Tiganasu and Loredana Maria Simionov

SS40 - The productivity gap and the re-launch of productivity in Europe

Roberta Capello and Silvia Cerisola

SS41 - Regional perspective of the different global crisis for small countries in 21 century – case study of Croatia

Vinko Mustra

SS42 - Regional and urban resilience in a turbulent world: perspectives from Aotearoa New Zealand

Philip Morrison and Jacques Poot

SS43 - Advances in Regional Science: Contributions of Italian Scholars

Roberta Capello

SS44 - Mapping Co-Working Spaces: Spatial Patterns and Location Factors

Tüzin Baycan, Grzegorz Micek and Anastasia Sinitsyna

SS45 - Selected regional science topics in Mexico

Serena Eréndira Serrano Oswald

SS46 - Poverty and Local Economy Development in Ecuador

Fabian Vilema

SS47 - Regional Development in Sub-Saharan Africa

Tomaz Ponce Dentinho

SS48A - Arctic regions: economic, climate and epidemiologic challenges

Alexander Pilyasov

SS48B - Regional Science in Russia

Alexander Pilyasov

SS49 - Sharing Economy and Urban Sustainability in Thailand

Sutee Anantsuksomsri and Nij Tontisirin

SS51 - Sustainable Regional Development in China

Ling Xue and Jian Wang

SS52 - Regional Science in Lebanon

Nadim Farajalla and Lina Maddah Souheil

SS53 - Regional Science in Egypt

Michael L. Lahr

SS54 - Regional Science in Paraguay

Eduardo A. Haddad

SS55 - Regional Science in Angola

Tomaz Ponce Dentinho

SS56 - The Colombian Economy and its Regional Structural Challenges

Jaime Bonet

SS57 - Regional Science in Bangladesh

Md. Musleh Uddin Hasan

SS58 - Argentinean social and economic challenges

Pedro Luis Elosegui

SS59 - Labour mobility and regional development

Annekatrien Niebuhr

SS60 - Greek Regional Science

Yannis Psycharis

SS61 - Brazil Regional Science

Terciane Sabadini

SS62 - Moroccan Regional Science

Abdellatif Khattabi

SS63 - Chilean Regional Science

Yasna Cortés Garriga

SS64 - Portuguese Regional Science

Francisco Carballo-Cruz

SS65 - Urban Neighborhoods: Accessibility, Segregation, and Neighborhood Change

Neil Reid

Urban Empires - Cities as Global Rulers in the *New Urban World*

Room: Marrakech

<https://us02web.zoom.us/j/83917560314>

Organizers book editors: Edward Glaeser, Peter Nijkamp and Karima Kourtit (eds.)

The Regional Science Academy

Aims and Scope of ABC

We live in the 'urban century'. Cities all over the world – in both developing and developed countries – display complex evolutionary patterns. A recently published study, *Urban Empires*, charts the backgrounds, mechanisms, drivers, and consequences of these radical changes in our contemporary systems from a global perspective and analyses the dominant position of modern cities in the 'New Urban World'.

In this session, various contributors of the above mentioned publication will present and discuss the drastic change cities have undergone internationally from a broad perspective, and consider their emerging roles in our global network society. Contributions from renowned scholars provide advanced analytical contributions, the spatial scaling applied and theoretical perspectives on the competitive profile of urban agglomerations in a globalizing world. The works that will be presented trace and investigate the economic and political drivers of network cities in a global context, and explores the unprecedented challenges over governance that are presented by mega-cities. These also identify and map out the new geography of the emergent 'urban century'.

With contributions from well-known and influential scholars from around the world, *Urban Empires* session serves as a touchstone for students and researchers keen to explore the scientific and policy needs of cities, as they become our age's global power centers.

09:25 – 09:30 | Welcome

Peter Batey

President, *The Regional Science Academy* (TRSA)

09:30 - 11:00

Chair: Peter BATEY

- 1) **Do Urban Empires Rule the World? An Introduction**
Edward GLAESER, Karima KOURTIT and Peter NIJKAMP
- 2) **Measuring the unmeasurable: The empirics of non-geographical proximity**
Andrea CARAGLIU
- 3) **A Scientific Program on Urban Performance and Dynamics**
Roberto CAMAGNI, Roberta CAPELLO and Andrea CARAGLIU

11:00 - 11:30 | Break

11:30 - 13:00

Chair: Andrea CARAGLIU

- 4) **Defining City Size and Growth**
Michael BATTY
- 5) **In Pursuit of High-Performance Global Cities - An Extended Dea Model: For Assessing Urban Socio- Economic and Environmental Indicators**
Soushi SUZUKI, Karima KOURTIT and Peter NIJKAMP
- 6) **Metropolitan Cities: Which Development Strategies? Which New Perspectives For Improving Productivity? Which Governance Tools?**
Luigi FUSCO GIRARD

13:00 - 13:30 | Break

13:30 - 15:00

Chair: Abdellatif KHATTABI

- 7) **Seoul as an Urban Empire: Evidence from Spatial Interaction Models**
John CARRUTHERS and Su-Jung LEE
- 8) **The Changing Industrial Organization of American Megaregions**
Harrison S. CAMPBELL, Isabelle NILSSON and Neil REID

SUBJECTIVE WELL-BEING, INEQUALITIES AND THE GEOGRAPHY OF DISCONTENT IN EUROPEAN REGIONS

Giovanni Perucca, Camilla Lenzi

Politecnico di Milano, Italy

ABSTRACT

The rise of a geography of discontent in the European Union (EU) documented in recent studies highlights a strong spatial association between discontent, regional economic decline and poor occupational opportunities, suggesting that economic disparities within the EU are at the origin of some of the most recent and shocking political events as Brexit. This paper re-examines this statement by disentangling the effect on discontent of different socioeconomic disadvantage conditions at the interregional, intraregional and individual levels. Making use of a large dataset on the discontent perceived by more than 760,000 EU citizens between 2013 and 2018, our analysis confirms that a geography of discontent exists across EU regions. Nevertheless, our findings also highlight that intraregional disparities matter more for discontent and individual socioeconomic disadvantage conditions amplify further this negative effect.

EVALUATING THE POPULATION' SPATIAL ACCESSIBILITY TO PRIMARY HEALTH CARE UNITS

[Diana F. Lopes](#)¹, [João L. Marques](#)¹, [Ana L. Ramos](#)², [Eduardo A. Castro](#)¹

¹GOVCOPP, DCSPT, University of Aveiro, Portugal. ²GOVCOPP, DEGEIT, University of Aveiro, Portugal

ABSTRACT

Primary Health Care (PHC) is a key component of the Portuguese health system, representing the population's first contact level with the National Health Service. Understanding geographical imbalances in the spatial planning of the PHC is essential to reach a proper distribution that will culminate in a most effective prevention of disease progression on a large scale.

Within this context, it is critical to have a correct identification of the spatial accessibility to the primary health care units and having tools to assist analysing how to mitigate spatial inequalities. Previous studies have greatly improved our understanding of the role played by geographic distribution of health services in population health maintenance, with extensive research being devoted to the place-based accessibility theory, with special focus on the gravity-based methods (including the two-step floating catchment area (2SFCA) method).

Although they represent a good starting point to analyse disparities across different regions, the results are not intelligible for policy-making purposes. Given the weaknesses of these methods and the multidimensional nature of the topic, this study intends to: (i) highlight the main concepts and measurements of access; and (ii) exploit and propose a framework based on multiple criteria decision analysis methods and Geographic Information Systems to evaluate the population' spatial accessibility to healthcare facilities.

Regarding the latter, within the scope of the DRIVIT-UP project – DRIVIng forces of urban Transformation: assessing pUblic Policies – this study proposes a sociotechnical approach based on the UTASTAR model to build an index to evaluate the population' spatial accessibility to the Portuguese PHC units.

The starting point was to link scientific with policy-based evidence to properly define and structure the multidimensional spatial accessibility index, which unfolds in the dimensions of proximity and availability. The proximity assessment considers the travel time of individuals to the PHC units, and the mobility of populations when accessing healthcare. The availability dimension involves the coverage of PHC network in terms of human resources in health (general practitioners and nurses).

Respecting that multidimensional structure, the technical component of the proposed approach encompasses the adoption of a variant of the UTASTAR-based method, which will be able to model preferences provided by policy-makers and experts, grounded in different socioeconomic scenarios. The process of gathering the viewpoints and preferences of policy-makers and experts about spatial accessibility to PHC units constitutes the social component.

Given the current pandemic context and the limited availability of policy-makers and experts involved in this study, i.e. health administrators and health professionals, that are the frontline soldiers against COVID-19, the proposed socio-technical approach was thoroughly conceived, through the design of an interface that allows individuals to interact and emit their preferences, in a user-friendly fashion way. Also, a reduced number of judgments is required from the policy-makers and experts to avoid the risk of triggering rejection by them, without compromising the model accuracy and quality. The proposed methodology will be later applied to build an index to evaluate the population' spatial accessibility to the Portuguese PHC units.

KING LEOPOLD'S SKELETON: THE AFTEREFFECTS OF COLONIALISM ON URBAN FORM AND SPATIAL INEQUALITY IN KINSHASA, DRC

Nathan Hutson, Wise Lubanda

University of North Texas, USA

ABSTRACT

Research Idea and Approach- Kinshasa (former Leopoldville) was originally established by the Belgians for the purpose of efficiently transporting ivory and rubber back to the mother country. The urban form of the city created a spatially-determined social stratification with a small riverfront core of Gombe surrounded by a vast unplanned network of alleys and self-constructed homes housing the vast majority of the native population. Kinshasa emerged as the DRC's primate city and sole administrative center, despite its location at the far periphery of the country. The city thereby replicates spatial inequality at both the national and local level. This dichotomy is apparent in modern day Kinshasa as the historic area of Gombe is well kept with a street grid similar to that one might find in a European city featuring palatial buildings and a large golf course. Ordinary Congolese are physically and culturally separated from Gombe yet continue to view it as the symbol of success. Many of the DRC's new elite now occupy homes and spaces vacated by Belgians. This paper aims to document the ways in which Kinshasa's colonial urban form has influenced post-colonial social development in order to determine the extent to which urban form perpetuates social stratification. Methodology- The paper relies on interviews conducted with current Gombe residents, Kinshasa residents outside of Gombe, and expats in first world cities. Specific questions include whether Kinshasa residents regard Gombe as the "downtown" or the most important part of the city despite its peripheral location. Socially ascendant Kinshasa residents are asked how much importance they would assign to living in or near the colonial core for reasons of social mobility. Interviews with older Kinshasa residents chart the shifting symbolism of Gombe through the colonial period, "Africanization" phase typified by the 1972 Rumble in the Jungle match which brought Congo (Zaire) to the world stage, and the Congolese civil war in the 90s which resulted in thousands of well-off Congolese fleeing the capital. Expected Findings- While research is ongoing, the effects of colonial urban form are still felt in Kinshasa with its premise of promoting inequality between the Europeans and Africans still functioning as a class based rather than race-based separation which compounds unequal access to education, jobs, and municipal services. We predict that recent emigres will recognize Gombe's controversial role in Kinshasa's development, however we also predict that second generation emigrants will be favorably disposed to Gombe due to its "ordered", Western appearance.

**COMING OUT OF THE WOODS. DO LOCAL SUPPORT SERVICES
INFLUENCE THE PROPENSITY TO REPORT SEXUAL VIOLENCE?**

Daria Denti^{1,2}, Simona Iammarino¹

¹London School of Economics, United Kingdom. ²Gran Sasso Science Institute, Italy

ABSTRACT

Sexual crimes against women are severely underreported to the police, allowing for impunity of perpetrators. Observers suggest that a stimulus towards reporting the crime comes from nearby support services for victims of sexual offences - like refuges and advisors. Still, the evidence about the effects of nearby support on the reporting of sexual crimes remains scattered and mainly qualitative. This paper provides quantitative evidence on this effect, by exploiting the uneven geography of local support services which resulted in the UK after the introduction of the austerity program. Findings highlight a positive net effect of the provision of local support services on the victims' propensity to report. The positive effect holds also in the aftermath of a space-neutral high- impact media campaign empowering women to report sexual violence. This evidence relates to relevant policy implication, given that in some countries the austerity-driven cuts to public budgets have reduced and dispersed the local availability of support services, making digital support and/or helpline the only available options in many places.

MEASURING THE POPULATION SIZE OF CITIES IN CHINA

Yi Niu, Jinyu Wang

Capital University of Economics and Business, China

ABSTRACT

City size is a key indicator across many disciplines that study cities including planning, economics and geography, but its measures are full of difficulties and controversies, particularly in China. This paper provides another measure of city size in China, and describes its main characteristics and evolution, by using the population data at the township level, the land cover data at 30-meter resolution, as well as the satellite images of night lights. In each prefecture city's urban proper, county-level city or county, we recognize a township as urban if it has (1) at least 1 km² or 10% urban land, (2) night lights brighter than approximately 10, and we also require a city size no less than 50,000. Our preliminary results, quite different from the official data, suggest following results during 2000-2010. First, the number of cities increased from 1,115 to 1,612, and the average city size from 370 thousand to 440 thousand. Second, almost no cities shrank, while the rural areas around some cities were losing population. Third, some county-level cities and counties have large "cities" (larger than 500 thousand or even one million), while in some prefecture's city proper cities were small (smaller than 500 thousand). We will conduct similar analyses by individual regions including East-Central-West, Northeastern China, Beijing-Tianjin-Hebei Urban Agglomeration, Yangtze River Delta, Pearl River Delta, etc. We believe this paper provides more accurate description of the size and evolution of cities during China's fast urbanization.

URBAN NETWORK EXTERNALITIES AND ECONOMIC GROWTH OF URBAN AGGLOMERATION REGIONS IN CHINA

Hongming Zhang¹, Tieshan Sun^{2*}, Yuanxi Li³

¹ School of Government, Peking University, Beijing, China, hmzhang67@gmail.com; ² School of Government, Peking University, Beijing, China, tieshansun@pku.edu.cn; ³ School of Government, Peking University, Beijing, China, liyuanxi@pku.edu.cn; * Corresponding author

ABSTRACT

Urban agglomeration regions are the center of future urbanization and the engine of future economic growth in China, which are advanced spatial organizations of interconnected cities. Previous studies have analyzed the spatial form of the urban agglomeration region, but shed little light on the economic benefit from the compact urban network in the urban agglomeration region. This study first proposes a theoretical framework for urban network externality and its mechanism. The complex network method is employed to evaluate the development of urban agglomeration regions in China. Further, based on panel data from 2003-2018 of 12 urban agglomeration regions, this study has tested the hypotheses proposed. The basic result demonstrates that there is significant positive urban network externality among urban agglomeration regions. Moreover, the relationship of network centrality and economic growth takes the form of inverted U. At last, industrial structure similarity and proportion of secondary industry of central cities have a positive effect on urban network externality. These results suggest that the urban agglomeration region is indeed an efficient form to boost economic growth by urban network externalities. At the same time, appropriate network centrality can help to make the best of urban network externalities. Raising the industrial structure similarity and the proportion of secondary industry of central cities is a way to produce more urban network externalities.

KEYWORDS

Agglomeration, Economic growth, Externality, Urban agglomeration region, Urban network

1. INTRODUCTION

With the rapid improvement of transport infrastructure and information technology, the interaction between firms from different cities becomes increasingly close and frequent. Urban networks implying firm networks have been the main form of spatial organization. To put it more exactly, of a mainly horizontal and non-hierarchical nature, urban networks are systems of relationships and flows (Camagni et al. 1993), where previously independent cities with complementary functions cooperate and achieve scope economies (Batten 1995). The notion of synergy, often formulated as $1+1>2$, is another way to explain this phenomenon, which means the performance of an urban network is better than the sum of cities alone (Meijers 2005). More formally, this economic advantage of urban networks could be expressed as urban network externalities emerging from the complementary relationships and synergies in cooperative activities (Capello 2000).

Urban agglomeration regions, characterized by compact spatial organization and close economic links (Fang 2015), are the spatial carriers of urban networks. Just as the worldwide rise of mega-region discovered by Florida et al. (2008), urban agglomeration regions will also play a leading role in the future urbanization in China. The linkage intensity between cities in urban agglomeration regions is a key standard for evaluating the development of urban agglomeration regions (Fang et al. 2020), making urban agglomeration regions become urban networks by nature. Urban agglomeration regions are also the major engines for future economic growth because reciprocity caused by intense network connection between cities could bring positive urban network externalities. As proposed by Camagni et al. (2016), the key to economic growth is not the development of large mega-cities, but factors such as external linkages and cooperation network.

There have been some empirical studies on urban network externalities. The pioneering work made by Boix et al. (2007) proposed the concept of urban network externality based on agglomeration economy and established an urban growth model. They set the spatial weight matrix based on a high-tech urban knowledge network and used the panel SLX model to analyze and compare the impact of agglomeration economy and urban network externalities on employment growth. Gong et al. (2020) established a theoretical model of housing price based on urban network externalities and used the SLX model with a binary spatial weight matrix, confirming the existence of positive network spillovers in housing prices in eastern Chinese cities. Urban network externalities, though analyzed directly, should have been paid more attention to the relationship between network characteristics and regional growth.

Several attempts have been made to focus on the effects of urban networks on economic growth. Shi et al. (2020) combined an urban network approach and a spatial econometric framework to investigate the impact of indigenous factors, cross-territorial flows, and positions in the regional capital network on urban growth and estimated their spatial spillovers. Huang et al. (2020) made use of train frequency data to construct urban networks, analyzed the structure of

urban networks using complex network methods, finally examined the impact of urban network externalities on urban economic growth. Previous work has been carried out more on the city-level economic growth. However, there has been a lack of research on the urban network externalities of economic growth at the regional level, especially on urban agglomeration regions in China.

A wide body of empirical studies has been published on the spatial structure of urban agglomeration regions in China (Gao et al. 2017, Lan et al. 2019), but few endeavors have been made to the economic growth. Applying a DID estimation on panel data of Chinese cities, Li et al. (2017) showed that there's no significant labor productivity benefit in urban agglomeration regions. No wonder that they find such a result because the network connection between cities matters for economic growth rather than being part of the planning region proposed by the government. Further, Ma et al. (2019) focused on the influencing factors and mechanisms of the economic efficiency of urban agglomeration regions and checked the effects of externalities. They just compared urban agglomeration regions to cities, but the contributing role of the urban network is still neglected.

In general, the research on the urban network externalities of regional economic growth is still limited, so is the research on industrial mechanisms of such externalities. Therefore, the purpose of this study is to explore the relationship between economic growth and urban network at the regional level. Taking urban agglomeration regions in China as the study area, this study builds urban networks in each urban agglomeration region based on the industrial investment between cities, adopts complex network methods to characterize the network. Furthermore, a panel data model is estimated to test the hypotheses put forward at first.

The remaining part of the paper proceeds as follows. In Section 2, a theoretical framework is established for urban network externalities, and the hypotheses are proposed. Section 3 describes the urban agglomeration regions used for this study. The complex network methods and an empirical framework are introduced in Section 4. Section 5 analyzes the empirical results to examine the hypotheses. Finally, Section 6 provides the conclusion and policy implications.

2. THEORETICAL FRAMEWORK

2.1. From agglomeration externality to urban network externality

Compared with agglomeration externality in traditional urban and regional economics, urban network externality no longer regards cities as isolated units, but as nodes in the urban network. The interaction between urban network nodes produces urban network externality, which does not depend on geographic proximity (Camagni et al. 1993). Externality refers to the impact on the output of the firm due to the interaction between firms that occurs externally to the firm per se. Traditionally, the agglomeration externality is limited within the boundary of the city. According to the scope of agglomeration externality, it can be divided into two categories: MAR externality (localization economy) occurs in the same industry, while Jacobs externality (urbanization economy) occurs in different industries (Glaeser et al. 1992, Henderson et al. 1995). The externality that arises between firms in different cities is urban network externality, so this externality can be seen as an extension of the agglomeration externality in a larger geographical space. The main difference between these two concepts is that agglomeration externality, whose spatial scope is limited, will decay with distance, while urban network externality has no spatial scope limitations and depends on the strength of functional connections between different cities rather than geographic proximity (Burger et al. 2016).

Three mechanisms of MAR externality are labor pooling, input sharing, and knowledge spillover. Similarly, Duranton et al. (2004) summarized three mechanisms of agglomeration economy as sharing, matching, and learning. These three mechanisms occur between firms, but there is no reason to confine them to firms in the same city. In other words, these three mechanisms are also mechanisms for urban network externality generated by firms in different cities. The close connection between cities allows various factors to communicate and interact on a larger spatial scale. Therefore, the city as a network node can obtain the urban network externality from the labor pool, input sharing, and knowledge spillover in the entire urban network. The benefit of sharing, matching, and learning produced by agglomeration economy can extend to all cities in the network.

A major reason why agglomeration externality can transcend urban boundaries is the decline of transportation costs. The micro-foundation in traditional urban and regional economics is the spatial choice of economic entities. The existence of trade costs makes the spatial proximity of firms and labor an important source of the agglomeration economy. Due to market access effect and cost-of-living effect, both firms and labor will be in a self-reinforcing process of gathering to the big market (Baldwin et al. 2011). Similarly, the close connection between firms and labor is also the source of urban network externality. With the advancement of regional integration, the decline of transportation costs has made it easier for factors and commodities to flow across cities. The development of information technology has also enabled innovation activities to be carried out in different cities at the same time. The sharing of knowledge and technology has become increasingly less dependent on face-to-face communication. In addition, the emergence of urban networks is also the result of the agglomeration diseconomy. The congestion effect caused by excessive agglomeration within a single city will promote the relocation of firms. Just as firms in a city are connected due to agglomeration, firms scattered in different cities belonging to the same city network can also establish a cross-city connection through lower transaction costs. In this way, the agglomeration externality will break through the spatial scope of the traditional agglomeration economy and realize the agglomeration of firms from different cities in the urban network through network linkages.

Based on the same micro-foundation, urban network externality is the expansion of agglomeration externality in the spatial scope. That is, the unified market composed of different cities forms a larger-scale agglomeration. Urban network externality, however, has its unique mechanism at a more macro level. In traditional urban and regional economics,

increasing returns to scale is an important mechanism for large cities to produce agglomeration economies. Similarly, Alonso (1973) proposed the concept of borrowed size. It is believed that small cities can borrow the agglomeration economy of neighboring large cities, and at the same time enjoy the benefits of the small scale to avoid the agglomeration diseconomy. In this way, small cities around large cities can maintain high economic growth rates and efficiency. Burger et al. (2015) further improves the concept and measurement method of borrowing size and introduces this concept into the study of urban network externality. They believe that it is important for firms to obtain the benefits of agglomeration rather than being close to the agglomeration area. Therefore, the borrowed size can be interpreted as the network connection between different cities, which can replace geographical proximity to some extent. Therefore, intense network linkages between cities are the source of positive urban network externality. The above discussion can be summarized as the following hypothesis.

Hypothesis 1: The network linkages between cities have positive effects on regional economic growth, reflecting the positive urban network externality.

2.2. Network centrality and urban network externality

Despite the positive urban network externality proposed above, the structure of urban networks is also a critical factor that influences economic growth. The centrality of urban networks stems from the geographic agglomeration of economic activity among cities, thus the inequality between cities. Therefore, the effect that network centrality has on urban network externality, or economic growth, can be understood with the help of long-standing debate on the relationship between agglomeration (or inequality) and economic growth.

For a region in the early stages of development, it is often the case that all the cities in the region are equally at the low-income level. The emergence of one or some cities with favorable conditions is the prerequisite for the future prosperity of a region. With regional integration deepens, core cities become wealthy at the expense of peripheral cities, forming a core-periphery pattern (Krugman 1991). Even though agglomeration seems to cause a huge income gap in the static models, the growth spurred by agglomeration is strong enough to benefit both the core and periphery in a dynamic setting (Fujita et al. 2003). Despite the agglomeration demonstrated in NEG models, the growth-promoting agglomeration externalities have long been noticed (Jacobs 1985). Urban network externality is the expansion of agglomeration externality in one city to intercity interaction. The high level of network centrality means the intense interaction between the agglomeration center and its surrounding cities. The agglomeration center, on the one hand, will obtain a larger market size, which provides both the purchasing power and the labor force. On the other hand, production factors, such as capital and technology, will spill over from the agglomeration center to surrounding cities, improving the economic status of surrounding cities significantly. In this way, urban network externalities, concentrated on one core but radiating out to its periphery, will boost the economic growth of the entire region.

However, as agglomeration isn't beneficial all the way, network centrality could also be harmful to the economic growth of the region overall. As mentioned above, agglomeration enhances growth only at the very beginning of the development. In the later stages, growth will be hindered due to agglomeration diseconomies (Williamson 1965). From the perspective of the network, extreme network centrality won't bring congestion diseconomies but engender the drawback of increasing inequality between cities. Both agglomeration and inequality, as the source of network centrality, can be regarded as the accumulation of production factors necessary for growth at least in the early stages of development (Castells-Quintana et al. 2014), but limit the urban network externality beyond some critical level. As the extreme income inequality can exert negative effects on growth through some transmission channels (Castells-Quintana et al. 2017), network centrality will hamper the efficiency of interaction between agglomeration center and its surrounding cities. First, the impaired purchasing power of surrounding cities will decrease consumer demand. Second, the labor force will be largely drawn to the agglomeration center, which causes an obvious mismatch in the labor market that is unemployment in the core and vacancy in the periphery. At last, the surrounding cities cannot utilize the capital and technology from the network center, which restricts the gain from urban network externality. Therefore, in the later stages of development, further concentration in the network can also lead to the deterioration of economic growth. Based on the positive and negative effects of network centrality, we derive the following hypothesis.

Hypothesis 2: Network centrality will lead to higher economic growth in the early stages of development but lower economic growth in the later stages, implying the relationship between network centrality and economic growth has the shape of inverted U.

2.3. Industrial linkage and urban network externality

The urban network externalities originate from the economic linkage between firms from different cities, which can be represented as industrial linkage at a more macro level. Therefore, the perspective of industrial linkage is indispensable to study the mechanism of urban network externality. For the source of agglomeration externalities within a city, whether specialization or diversification promotes agglomeration has become the focus of debate (Glaeser et al. 1992, Henderson et al. 1995). MAR externality refers to the externality generated by specialized agglomeration, where knowledge spillover mainly occurs between firms within the same industry due to similar technology. Contrary to MAR externalities, Jacobs externality refers to externality brought about by diversified agglomeration, where firms from different industries generate knowledge spillover in the absence of fierce competition, which is also conducive to the collision of different ideas for innovation. However, it is not the case, because industries with too large technological gaps may have a completely different technological foundation and knowledge base, making knowledge spillover difficult.

The concept of technological relatedness, put forward by Frankel (1955), will help to illustrate the relation between industrial linkage and urban network externality. Based on technological relatedness, Frenken et al. (2007) first proposed the concept of related variety, clarifying that the diversity of products and services can promote regional economic growth because of the more inter-industry knowledge spillover. What's more, they emphasized that knowledge spillover within a region mainly occurs between related industries with similar knowledge, while only a very limited portion occurs between unrelated industries. Therefore, they divide variety into related variety and unrelated variety. The cognitive distance between related industries is not large, so that firms can more effectively share knowledge, lowering the cost of cross-industry knowledge spillover. The knowledge bases between unrelated industries are completely different, which make the process of interaction more uncertain and costly, then hinder knowledge spillover between industries.

With the concept of related variety, the impact of industrial structure similarity on urban network externality can be examined. The more similar the industrial structures between cities are, the more likely there will be related variety because only cities with similar industrial structures can have closer technological relatedness. For cities with large differences in industrial structure may have a vertical relationship of labor division similar to that in the central place theory, and possess quite different knowledge bases. Since related variety can promote knowledge spillover between firms, cities with similar industrial structures are also more likely to have knowledge spillover, making urban network externalities stronger to benefit the economic growth of the region. Therefore, we derive the following hypothesis.

Hypothesis 3: Industrial structure similarity will strengthen the urban network externality.

Industrial structure similarity is the determinant of network linkage at the regional level, but the industrial characteristics of each city are the origin that generates industrial linkage between them. Therefore, the industrial characteristics of cities can affect the urban network externality. The industrial structure is an aspect of industrial characteristics, reflecting whether the city is dominated by manufacturing or service industry. It is because of the different organizations of firms in manufacturing and service industries that they have different spatial distribution patterns, and thus, different ways of interacting with surrounding cities.

Manufacturing and service industries are important driving forces for second nature. They have different regional spatial effects: the manufacturing industry appears as a trickle-down effect and contact diffusion, while the service industry appears as a polarization effect and hierarchical diffusion. The principal reason is that the manufacturing industry has a long industrial chain, and the upstream and downstream linkages make firms dispersed in different cities to carry out the division of labor and cooperation in production activities. There will be a trickle-down effect, presenting a spatial expansion pattern of contact diffusion in neighboring areas and driving the surrounding cities to grow together. The service industry, especially one that produces intangible products, presents a pattern of centralized production and networked transmission, which makes firms concentrated in higher-level cities enjoy the benefits of the diversified urban economy. Connections between cities mainly occur between higher-level cities. There will be a polarization effect, presenting the spatial centralization pattern and weakening the development of surrounding cities.

Moreover, according to the phenomenon of vertical disintegration in industrial organizations, when the market expands, the upstream branches of some companies will be separated from the downstream branches to take advantage of specialization and scale effects (Stigler 1951). This phenomenon has been tested by empirical data in the manufacturing industry (Holmes 1999). Each link in the vertical value chain, with large differences in the requirements of the quality and cost of production factors, has its own optimal geographic locations. Therefore, the manufacturing industry, especially firms' production with a high degree of standardization and modularization, has a significant trend of vertical disintegration. For a region, the industrial characteristics of the central city determine the interaction pattern of the whole region, thus influence the urban network externality. The following hypothesis is then derived.

Hypothesis 4: For the central city of a region, a higher ratio of the manufacturing industry will strengthen the urban network externality.

3. STUDY AREA

Our analysis takes urban agglomeration regions (UARs) as the study area, which are put forward by the Chinese government. The concept of urban agglomeration region we use here is the synonym for urban agglomeration, city cluster, city group, megalopolis, and mega-region in the literature studying China. Since urban agglomeration, though adopted by the majority, can be regarded as the city per se, we employ the concept of urban agglomeration region to emphasize the nature of the region composed of a group of cities.

China 14th Five-Year Plan (2021-2025) states that the development of urban agglomeration regions is the basis for advancing the new-type urbanization, and urban agglomeration regions are going to be the core areas of economic growth and high-quality development. The high importance of urban agglomeration regions has been gradually tested in practice, and the government has therefore kept clarifying its role in Plans. "Urban agglomeration region" was formally proposed in the 11th Five-Year Plan in 2005, which firstly regarded developing urban agglomeration regions as the main form of promoting urbanization. In 2016, the 13th Five-Year Plan first put forward the spatial scope of 19 urban agglomeration regions. Recently, 14th Five-Year Plan in 2020 emphasized that central cities and urban agglomeration regions are the source of high-quality development, which can promote the carrying capacity for the economy and population to enhance the national economic efficiency.

It is worth noting that the latest Five-Year Plan points out the significance of promoting the integrated development and optimizing the internal spatial structure of each region to form multi-center, multi-level, and multi-node urban networks within urban agglomeration regions. The network form is the basic feature of a mature urban agglomeration region, due

to the compact space organization and close economic ties. Most urban agglomeration regions in China, except the top three (Beijing–Tianjin–Hebei, Yangtze River Delta, and Pearl River Delta), however, have not formed a close network connection. This means that “urban agglomeration regions” in China is mostly a planning concept rather than a practical regional type. Urban agglomeration regions, including mature and immature ones, exactly provide the various samples to investigate the impact of urban networks on economic growth.

According to data availability, we select 12 out of 19 urban agglomeration regions that contain over 4 cities to study their advancement of urban networks. The 12 selected urban agglomeration regions are mainly distributed in the east and middle of China (Figure 1), which represents the geographical difference of economic development level in China.

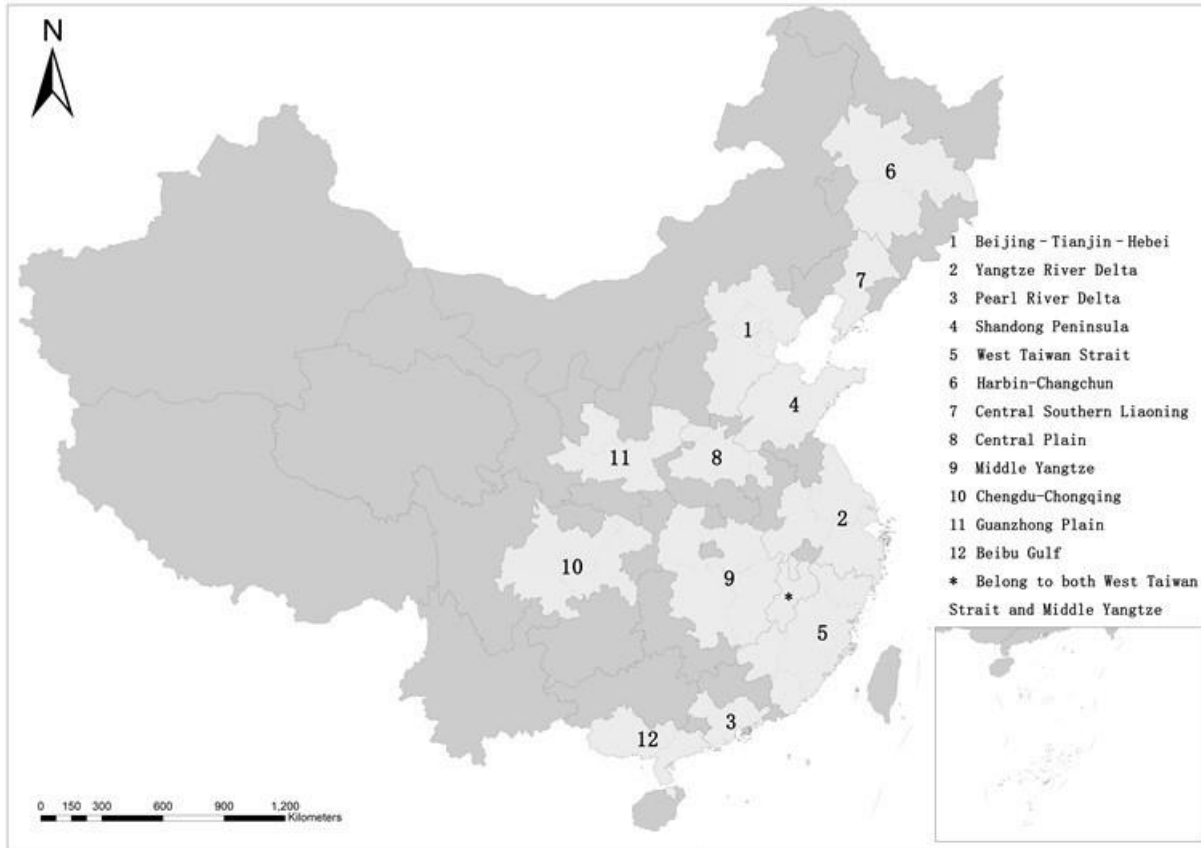

Figure 1: The distribution of 12 urban agglomeration regions in China

These urban agglomeration regions consist of 181 cities (57.34% of the total in China) at the prefectural level or above, with a total area of 2233163 km² (20.91% of the total in China). In 2018, they carried a population of 948.73 million (60.6% of the total population), and they created a GDP of 74.3315 trillion yuan (73.19% of total GDP) with the per capita level 20.43% higher than the national level (Table 1). Urban agglomeration regions with only 20% land and 60% people produce 70% GDP because the close network linkages among cities increase the economic efficiency. These cities optimize resource allocation through urban networks, expanding the scope of agglomeration externality and creating urban network externality.

Table 1: Socioeconomic status of 12 urban agglomeration regions in 2018

UAR name	GDP (10 ¹² yuan)	Population (10 ⁶)	Area (km ²)	GDP per capita (yuan)	Number of cities
Beijing–Tianjin–Hebei	8.4359	101.26	218545	83310	13
Yangtze River Delta	17.8642	131.75	214001	135592	26
Pearl River Delta	8.1048	35.86	54963	226014	9
Shandong Peninsula	7.6866	99.69	156160	77105	16
West Taiwan Strait	5.8728	96.50	272891	60858	20
Harbin-Changchun	2.5430	44.07	279380	57703	10
Central Southern Liaoning	2.1633	28.66	82348	75483	9
Central Plain	3.6454	78.46	99648	46462	13
Middle Yangtze	8.3201	131.23	343981	63401	28
Chengdu-Chongqing	5.7515	110.16	239548	52210	16
Guanzhong Plain	2.0617	45.24	161949	45572	11
Beibu Gulf	1.8822	45.85	109749	41052	10
Total	74.3315	948.73	2233163	77851	181
Percentage (%)	73.19	60.66	20.91	120.43	57.34

Notes: Yingtan, Fuzhou (Jiangxi), and Shangrao belong to both West Taiwan Strait and Middle Yangtze.

4. METHOD AND DATA

4.1. Complex network method

This paper uses complex network methods to evaluate the network development of urban agglomeration regions. There are two aspects of the urban network to measure: compactness and centrality. Traditional measures on social networks are designed for binary networks. Nevertheless, our networks of investment are weighted in nature, implying that the weights of ties are as essential as the number of nodes. In addition, the change of investment overtime should be captured. Therefore, measures for weighted networks are introduced.

The compactness of a network is the source of urban network externality, which has two indicators that reflect it in complementary ways. One is average investment intensity. The other is the clustering coefficient. The average investment intensity of an urban agglomeration region is the average value of the investment between all city pairs including ones with no investment data for some year, which can measure the contact strength produced by the entire urban agglomeration region. However, the average investment intensity is just a measure of interaction level that cannot consider network features, hence the need for an indicator to reflect the compactness in the view of the network.

The clustering coefficient refers to the density of triplets of nodes in a network. A triplet is defined as three nodes that are connected by either two (open triplets) or three (closed triplets) ties. A triangle contains three closed triplets, each of which is centered on a node. The clustering coefficient is defined as the number of closed triplets (or 3 times the number of triangles) divided by the number of all triplets (including open and closed). It was first proposed by Luce et al. (1949), and the formula of the standard clustering coefficient is

$$clu = \frac{\sum \tau_{\Delta}}{\sum \tau} \tag{1}$$

where $\sum \tau$ is the total number of all triplets, and $\sum \tau_{\Delta}$ is the total number of closed triplets. The coefficient takes values between 0 and 1. In a completely connected network, all triples are closed, and the clustering coefficient is 1.

One of the main drawbacks of the standard clustering coefficient is that it cannot be applied to weighted networks. As a consequence, networks with different distribution of weights, which reflects the different likelihood of nodes being connected, may turn out to be the same clustering coefficient, making the analysis of network structure biased. To overcome the limitation, Opsahl et al. (2009) generalized the clustering coefficient to the weighted network, explicitly capturing the weight attached to ties. The triplet value can be defined as the arithmetic mean of the weights of all ties that make up the triplet. This is the simplest way to calculate the triplet value. Therefore, the clustering coefficient for the weighted network can be generalized to

$$clu = \frac{\sum \tau_{\Delta} \omega}{\sum \tau \omega} \tag{2}$$

where ω is the triplet value, $\sum \tau_{\Delta} \omega$ is the sum of all closed triplet values, and $\sum \tau \omega$ is the sum of all triplet values. This generalized clustering coefficient still ranges between 0 and 1. In a completely connected network, this generalized clustering coefficient is also 1. Accordingly, the generalization reveals the relative importance of triplets in a network after taking weights of ties into account. If the closed triplets have higher values, the clustering coefficient tends to be larger, which is more factual.

The above two indicators are measures for compactness of the network, but the network structure remains to be portrayed, which is also a factor to influence economic growth. To characterize the centrality of a network, the node centrality should be computed first. Then, a descriptive statistic of node centrality can be applied to obtain network centrality. The closeness centrality of one node reflects the distance of a node to all other nodes in the network. This measure depends on the length of the shortest paths among nodes in the network, so how to define the shortest distance determines the measure of closeness centrality. In a binary network, which treats all edges equally (Freeman 1978), the length of the shortest path is defined as the minimum number of ties linking two nodes. Newman (2001) used the shortest path algorithm proposed by Dijkstra (1959) to generalize close centrality to weighted networks. Opsahl et al. (2010) further suggested that both the tie weights and the number of intermediary nodes should be incorporated at the same time, thereby proposed the length of the shortest path dis_{ij} between two nodes i and j as

$$dis_{ij} = \min \left(\frac{1}{(w_{ih})^{\alpha}} + \dots + \frac{1}{(w_{hj})^{\alpha}} \right) \tag{3}$$

where α is a positive tuning parameter. When $\alpha = 0$ or $\alpha = 1$, the proposed measure is the same as the one obtained in the binary network or with Dijkstra's algorithm. For $0 < \alpha < 1$, a shorter path with weak ties is favored over a longer path with strong ties, where the number of intermediary nodes is relatively more important. Let $\alpha = 1/2$ here. The closeness centrality of node i that generalized to weighted networks is

$$cloc_i = [\sum_j dis_{ij}]^{-1} \tag{4}$$

In binary networks, the graph centrality can be obtained by the sum of differences between the largest value of point centrality and all others over the possible maximum of such sum (Freeman 1978). The extreme example of this possible maximum is the graph that takes the form of a star. Hence, the standard measure is a comparable ratio. Unfortunately, there's no possible maximum in weighted networks. Then, we proposed a similar comparable measure that utilizes closeness centrality mentioned above, which captures the average level of differences between the maximum and others. The formula is expressed as

$$cen = \frac{\sum_{i=1}^n (cloc_{max} - cloc_i)}{n-1} \tag{5}$$

where n is the number of nodes in the network, $cloc_{max}$ is the maximum of closeness centrality.

4.2. Empirical strategy

Using urban agglomeration regions in China as the empirical setting, we will test the theoretical hypotheses in Section 2 with a panel model.

To test hypothesis 1, our baseline model estimates the impact of network linkage on economic growth among urban agglomeration regions. The baseline model is a fixed effect regression model that is as follows

$$\ln Y_{it} = \alpha_0 + \alpha_1 \ln Net_{it} + \alpha_2 \ln X_{it} + \mu_i + \varepsilon_{it} \tag{6}$$

where $\ln Y_{it}$, as the dependent variable, is the logarithm of output for urban agglomeration region i at time t , $\ln Net_{it}$, as the explanatory variable, is the logarithm of network linkage, and $\ln X_{it}$ is the control variable including production factors and others. At last, μ_i is the unit fixed effect, and ε_{it} is the error term.

To test hypothesis 2, the variable of network centrality needs to be added to the baseline model. Because the inverted U relationship will be tested, both the linear term and the quadratic term of network centrality should be added. Then, the model is

$$\ln Y_{it} = \alpha_0 + \alpha_1 \ln Net_{it} + \alpha_2 \ln Cen_{it} + \alpha_3 \ln Cen_{it}^2 + \alpha_4 \ln X_{it} + \mu_i + \varepsilon_{it} \tag{7}$$

where $\ln Cen_{it}$ is the logarithm of network centrality for urban agglomeration region i at time t .

To test hypotheses 3 and 4, we need to generate interaction terms to capture the moderating effect. After interacting industrial structure similarity of urban agglomeration region and industrial structure of the central city with network linkage, we get these two models

$$\ln Y_{it} = \alpha_0 + \alpha_1 \ln Net_{it} + \alpha_2 \ln Net_{it} \times \ln Sim_{it} + \alpha_3 \ln X_{it} + \mu_i + \varepsilon_{it} \tag{8}$$

$$\ln Y_{it} = \alpha_0 + \alpha_1 \ln Net_{it} + \alpha_2 \ln Net_{it} \times \ln Ind_{it} + \alpha_3 \ln X_{it} + \mu_i + \varepsilon_{it} \tag{9}$$

where $\ln Sim_{it}$ is the logarithm of industrial structure similarity for urban agglomeration region i at time t , and $\ln Ind_{it}$ is the logarithm of the industrial structure of the central city in the urban agglomeration region i at time t .

4.3. Data sources and variable definition

City-level economic data is drawn from China City Statistical Yearbook from 2003 to 2018. The number of patents granted comes from the China National Intellectual Property Administration. The investment data is the newly-increased investment by firms from the industrial and commercial enterprise registration database, which can be aggregated to the city level. All the data is filtered to keep the cities within the urban agglomeration regions. Based on the above data sources, this study constructs balanced panel data of 12 urban agglomeration regions for 16 years from 2003 to 2018, with a total of 192 observations.

The dependent variable, the output of urban agglomeration regions, is obtained from the aggregation of city-level output. The core explanatory variables, including average investment intensity, clustering coefficient, and closeness centrality, are constructed with the complex network method introduced in Section 4.1 based on the investment data between cities. Other control variables that are also aggregated to the urban agglomeration region level comprise capital, labor, technology (represented by the number of patents granted), total college attendance, foreign direct investment, and the percentage of GDP of secondary industry.

As for industrial structure similarity, we adopt the indicator proposed by UNIDO (United Nations Industrial Development Organization), which is

$$sim_{12} = \frac{\sum_k s_{1k} s_{2k}}{\sqrt{\sum_k s_{1k}^2 \cdot \sum_k s_{2k}^2}} \tag{10}$$

where sim_{12} represents the industrial structure similarity coefficient of city 1 and city 2, s_{1k} , s_{2k} represent the share of industry k in the total output of city 1 and city 2, respectively. Therefore, when the industrial structure of the two cities is completely the same, the value of sim_{12} is 1; when the industrial structure of the two regions is completely different, the value of sim_{12} is 0. We take the average of industrial structure similarity coefficient between all city pairs in an urban agglomeration region as the industrial structure similarity, which is

$$sim = \frac{\sum_{i \neq j} sim_{ij}}{n(n-1)/2} \tag{11}$$

where sim is the industrial structure similarity of an urban agglomeration region, and n is the number of cities in this urban agglomeration region. The proportion of secondary industry of central cities is represented by the percentage of GDP of secondary industry, where central cities selected are the cities with the highest average closeness centrality in their urban agglomeration regions in the sample period. As can be seen from Table 2, central cities in each urban agglomeration region are also the most developed cities, which control the resource allocation and act as the source of capital and investment.

Table 2: Central cities in each urban agglomeration region

UAR name	Central city
Beijing-Tianjin-Hebei	Beijing
Yangtze River Delta	Shanghai
Pearl River Delta	Guangzhou
Shandong Peninsula	Ji'nan
West Taiwan Strait	Xiamen
Harbin-Changchun	Harbin
Central Southern Liaoning	Shenyang
Central Plain	Zhengzhou
Middle Yangtze	Wuhan
Chengdu-Chongqing	Chengdu
Guanzhong Plain	Xi'an
Beibu Gulf	Nanning

Note: Descriptive statistics are generated for all variables as Table 3 presented.

Table 3: Variables and descriptive statistics

Name	Description	Mean	SD	Min	Max
Dependent variable					
ln_y	Logarithm of output	19.26	0.875	17.11	21.30
Explanatory variable

cluster	Clustering coefficient	0.734	0.194	0.136	1
closeness	Closeness centrality	0.045	0.026	0.006	0.113
Moderating variable					
gdp2p_cen_75q	Proportion of secondary industry of central city above 75 quantile	0.188	0.391	0	1
gdp2p_cen_80q	Proportion of secondary industry of central city above 80 quantile	0.141	0.349	0	1
simc_75q	Industrial structure similarity above 75 quantile	0.339	0.474	0	1
simc_80q	Industrial structure similarity above 75 quantile	0.271	0.446	0	1
Control variable					
ln_k	Logarithm of capital	18.68	1.049	15.82	20.79
ln_l	Logarithm of labor	6.659	0.612	5.435	8.116
ln_t	Logarithm of patents	8.121	1.536	4.382	11.51
ln_stu	Logarithm of College student	14.07	0.589	12.27	15.18
ln_fdi	Logarithm of foreign direct investment	13.63	1.199	10.45	15.75
gdp_2p	Proportion of secondary industry	0.480	0.054	0.335	0.588

Notes: Each variable has 192 observations.

5. EMPIRICAL RESULTS

5.1. Network characteristics of urban agglomeration regions in China

Network development is one critical criterion for evaluating the maturity of urban agglomeration regions. We will show the network characteristics across the year studied and the evolution to compare these urban agglomeration regions. The results of the compactness of urban networks are summarized in Table 4 and Table 5. As shown in Table 4 and Table 5, there's no doubt that the top three urban agglomeration regions, namely Beijing-Tianjin-Hebei, Yangtze River Delta, Pearl River Delta, keep the top 3 regardless of the indicator used. What's more, there's a huge gap between the top 3 and the fourth, which also demonstrates the development of these three urban agglomeration regions far surpasses the others. What is unexpected is that Yangtze River Delta ranks third place for both because the number of cities included is twice that of Beijing-Tianjin-Hebei and three times that of Pearl River Delta. As for others, we can divide them into two groups. One group is more compact, including Central Southern Liaoning, Shandong Peninsula, Chengdu-Chongqing, and Central Plain. The other group is less compact, including Harbin-Changchun, Guanzhong Plain, Beibu Gulf, and Middle Yangtze. Differing from the relatively stable ranks of these 8, West Taiwan Strait is less compact for average investment intensity but more compact for clustering coefficient. This implies that despite the weakness of the linkage strength, West Taiwan Strait has a more compact network structure. For the evolution of compactness, there is a clear trend of rapid growth for both of the indicators, suggesting the cities in urban agglomeration regions become progressively closer to form urban networks.

Table 4: Annual mean of average investment intensity

UAR name	Number of cities	Mean of 2003-2018	Mean of 2003-2007	Mean of 2008-2012	Mean of 2013-2018
Pearl River Delta	9	177416	18235	54902	412161

Harbin-Changchun	10	0.1809	0.1026	0.1055	0.3089
Guanzhong Plain	11	0.1635	0.0635	0.1062	0.2947
Beibu Gulf	10	0.1328	0.0000	0.1355	0.2412

It's not enough to see the compactness of urban networks alone, since network centrality is still an essential part of the assessment. The higher network centrality indicates the network development is more polarized, but the lower indicates the network development is more balanced. According to the theory illustrated in Section 2.2, there is an inverted U relationship between the network centrality and economic growth. It is in line with our expectations that the top three urban agglomeration regions rank 5th, 7th, and 11th respectively in the middle of Table 6. The measure of closeness centrality is also influenced by the number of cities. Urban agglomeration regions with more cities tend to present a lower level of network centrality. Nonetheless, ones with utterly high or low network centrality are indeed in poor economic status. For the evolution of network centrality, the top three urban agglomeration regions experience paralleled surge, implying that they were in the left part of inverted U. The group with higher compactness mainly presents the trend of first falling and then rising, while the group with lower compactness mainly displays the trend of declining all the way. The difference in the evolution of network centrality shows that various urban agglomeration regions have their own optimal network centrality base on their condition.

Table 6: Annual mean of closeness centrality

UAR name	Number of cities	Mean of 2003-2018	Mean of 2003-2007	Mean of 2008-2012	Mean of 2013-2018
Beibu Gulf	10	0.1264	0.2074	0.1146	0.0687
Harbin-Changchun	10	0.1097	0.2646	0.0541	0.0270
Guanzhong Plain	11	0.0743	0.1319	0.0608	0.0374
Central Southern Liaoning	9	0.0587	0.0623	0.0492	0.0637
Pearl River Delta	9	0.0574	0.0498	0.0574	0.0637
Central Plain	13	0.0526	0.0607	0.0401	0.0562
Beijing-Tianjin-Hebei	13	0.0467	0.0340	0.0386	0.0641
Chengdu-Chongqing	16	0.0399	0.0353	0.0324	0.0500
Shandong Peninsula	16	0.0386	0.0264	0.0330	0.0535
West Taiwan Strait	20	0.0327	0.0616	0.0252	0.0148
Yangtze River Delta	26	0.0232	0.0164	0.0216	0.0301
Middle Yangtze	28	0.0124	0.0191	0.0062	0.0120

Taking compactness and centrality both into account, we can exhibit a more explicit classification of these urban agglomeration regions. As can be seen from Figure 2, the clustering coefficient and the closeness centrality are both employed to show the diversity. Similarly, we can still divide them into three groups the same as above. The most

remarkable group locates in the bottom-right corner, composed of the top three urban agglomeration regions. This group not only has the most compact urban networks but also evolves with a relatively balanced pattern, indicating that the compactness and balance of the network are the signs of maturity for urban agglomeration regions. The second group, Central Southern Liaoning, Shandong Peninsula, Chengdu-Chongqing, Central Plain, and West Taiwan Strait included, locates in the middle-lower part, whose networks are also relatively balanced but less compact than the top three urban agglomeration regions. The economic development of this group is also better than the last group including the remaining urban agglomeration regions. The last group as the worst developed mainly locate in the upper-left corner, presenting a loose and polarized network.

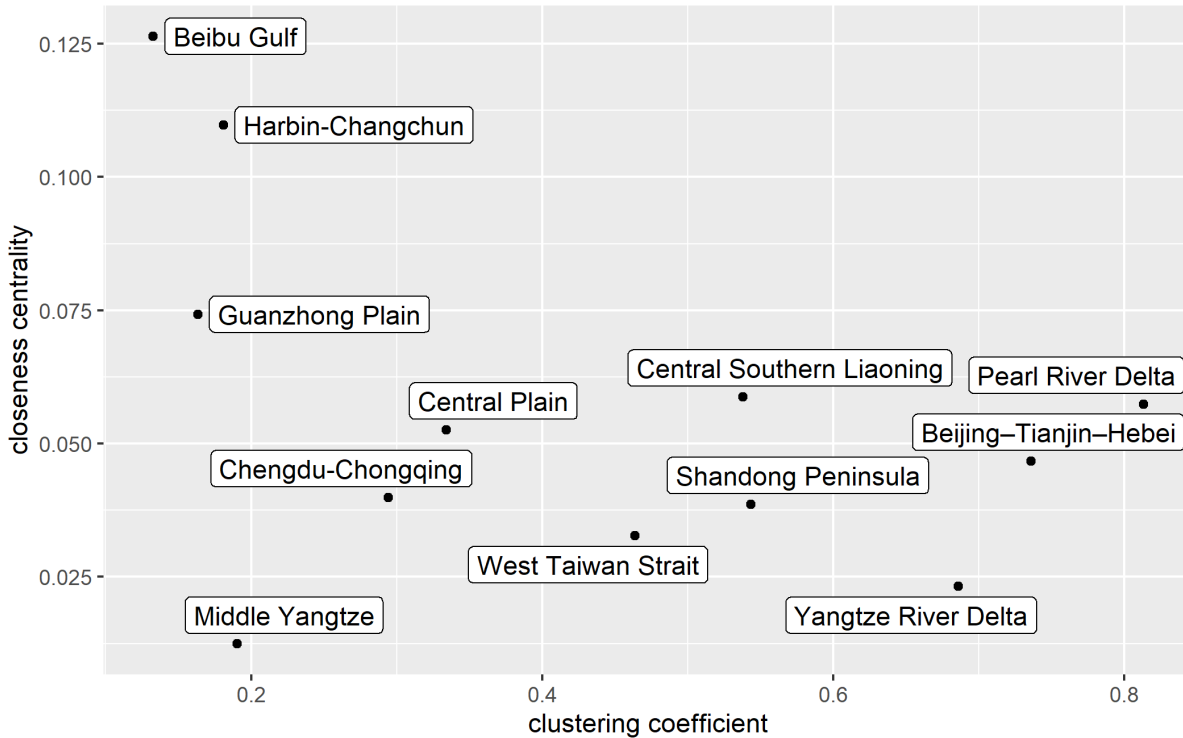

Figure 2: Classification of UAR by clustering coefficient and closeness centrality

5.2. Urban network externality of economic growth

The result estimated from the baseline model (Equation 6) is presented in Table 7. Average investment intensity and clustering coefficient both have a positive effect on economic growth at least at the 5% significance level, indicating that there are significant positive urban network externalities on the economic growth of urban agglomeration regions. Hence, hypothesis 1 is confirmed, which provides the foundation for further investigation.

Table 7: Estimates of urban network externalities

Dependent variable: ln_y	Average investment intensity	Clustering coefficient
ln_minv	0.0448*** (0.0138)	
cluster		0.1449** (0.0595)
ln_k	0.2096*** (0.0274)	0.2199*** (0.0277)

gdp2p	0.4177* (0.2305)	0.3246 (0.2291)
Constant	8.6682*** (0.7105)	8.7040*** (0.7198)
Observations	192	192
R-squared	0.9823	0.9819

Notes: (1) ***, **, * indicate significance level at 1%, 5%, 10%, respectively. (2) Standard errors of parameter estimates are reported in parentheses.

Network linkage represented by average investment intensity and clustering coefficient is just one aspect of urban network externality. Network Centrality also influences the effect of urban network externality. From Table 8 we can see that the coefficients of network linkage are still positive at least at 10% significance level after adding the variable of network centrality expressed as Equation 7, implying that the compactness of network linkage is a different factor from network centrality. The linear term of closeness centrality is positive at 5% and 10% significance level respectively, while the quadratic term of closeness centrality is negative both at 10% level, indicating that there is an inverted U relationship between the closeness centrality and economic growth of urban agglomeration regions. Hence, hypothesis 2 is also confirmed. Considering the different significance levels, the coefficient of the linear term is more significant than the quadratic term, revealing that the majority of urban agglomeration regions in China are still on the upward slope at the present stage. In other words, urban agglomeration regions with a higher degree of network centrality tend to be more developed.

Table 8: Estimates of urban network externalities with network structure

Dependent variable: ln_y	Average investment intensity	Clustering coefficient

Notes: (1) ***, **, * indicate significance level at 1%, 5%, 10%, respectively. (2) Standard errors of parameter estimates are reported in parentheses.

5.3. The impact of industrial linkage

We have just confirmed that there are positive urban network externalities among urban agglomeration regions, but little is known about how urban network externalities work. Given urban networks are constructed based on the industrial investment between cities, the industrial linkage between cities is no doubt the underlying mechanism of urban network externality. In light of the concept of related variety, we will examine the moderating effect of industrial structure similarity among cities within urban agglomeration regions in Equation 8. As shown in Table 9, all the interaction terms of industrial structure similarity and network linkage are positive at least at 5% significance level, implying that industrial structure similarity has a positive moderating effect on the urban network externality. Hence, hypothesis 3 is confirmed. Moreover, viewing the change from 75 quantiles to 80 quantiles, we discover that the coefficient of the interaction term is decreasing, suggesting that the excessive similarity may lead to competition that damage the reciprocity for cities.

Table 9: Moderating effect of industrial structure similarity

Dependent variable: ln_y	Average investment intensity		Clustering coefficient

Industrial structure similarity represents the possibility of industrial linkage, but the industrial characteristics of cities should be the final decisive factor that determines the industrial linkage between cities. Especially, the industrial characteristic of central cities will shape the pattern of the industrial linkage. It can be seen from the results in Table 10 that all interaction terms between the proportion of secondary industry of central cities and network linkage are positive mostly at 5% significance level or above, implying that proportion of secondary industry of central cities has a positive moderating effect on urban network externality. Hence, hypothesis 4 is confirmed. Interestingly, for average investment intensity and clustering coefficient both, the coefficients of interaction terms become larger and more significant from 75 quantiles to 80 quantiles, which manifests that central cities that specialize more in the secondary industry indeed form closer industrial linkages with surrounding cities.

5.4. Heterogeneous effects

It is validated that there are positive urban network externalities across urban agglomeration regions in China through the period of 2003 to 2018, but heterogeneous effects remain to be investigated. The primary distinction among urban agglomeration regions in our sample is the number of cities incorporated. As the number of cities troubles the comparison of the network characteristics mentioned in Section 5.1, urban network externality will work dissimilarly among urban agglomeration regions of different scales. To examine whether the scale will influence the urban network externality, we define that the ones with 16 or more cities are large scale and the others are small scale. Table 11 shows that the coefficients of network linkage in large-scale ones are positive at 5% significance level, while the coefficients in small-scale ones are below 10% significance level. The results, where coefficients in large-scale ones are larger and more significant, indicate that urban agglomeration regions with more cities tend to produce stronger urban network externalities. Although urban agglomeration regions with fewer cities seem to be closer from the network perspective, there is a threshold of scale that makes urban network externality works.

Table 11: Heterogeneous effect of scale

Notes: (1) ***, **, * indicate significance level at 1%, 5%, 10%, respectively. (2) Standard errors of parameter estimates are reported in parentheses.

Since China has undergone great changes in economic development, the formation of urban agglomeration regions also takes time. We divide the period into two parts, namely period 1 (from 2003 to 2010) and period 2 (from 2011 to 2018), to investigate the time effect. As shown in Section 5.1, the compactness of urban networks is increasing gradually with time. A similar result is presented in Table 12 that the coefficients are not significant in period 1 but positive at 5% significance level. This implies that with urban networks become tighter, urban network externalities become stronger and more prevailing. From another point of view, urban network externality takes effect more obviously in the later period, suggesting that urban network externality is more critical to the economic growth of urban agglomeration regions in recent years.

6. CONCLUSION

The main goal of this study is to determine the role of urban networks on the economic growth of urban agglomeration regions. The contributions of our study are twofold. On the one hand, we evaluate the development of urban agglomeration regions using the complex network method. From the view of compactness and centrality, the top three urban agglomeration regions are undoubtedly the most mature. Other urban agglomeration regions can be divided into two groups based on the network development. As time goes on, urban networks in urban agglomeration regions become increasingly compact, but network centrality presents various trends according to the property of urban agglomeration regions.

On the other hand, we established a theoretical framework of urban network externality, and empirically investigated the urban network externality on the economic growth. Based on the theory of agglomeration externality, we introduced the concept of urban network externality and proposed the relationship between network centrality and economic growth. Furthermore, we explained the underlying mechanism of urban network externality working through industrial linkage. The empirical results supported the hypotheses proposed, which can be summarized along the following four lines. First, there were positive urban network externalities on economic growth across urban agglomeration regions. Second, the inverted U relationship of network centrality and economic growth was found. Third, both the industrial structure similarity and the proportion of secondary industry of central cities could strengthen the urban network externalities. Finally, the larger and more significant urban network externalities were found in large-scale urban agglomeration regions and recent years.

These results suggest that urban networks play a significant role in regional economic growth. Accordingly, we will discuss the policy implication from three aspects as follows. First, embedding as many as possible cities into urban networks and intensifying the linkage within urban networks can be helpful to economic growth for both developed and developing countries, because urban network externality can exploit the unfulfilled potential of economic growth. The organization of cities in the form of a network is also efficient and sustainable. Governments should encourage the cross-city cooperation of firms, accelerate the flow of all production factors and break down the barriers between cities by increasing the input in transportation and information infrastructure. Second, keeping a certain degree of network centrality can make the best of urban network externality. More specifically, for underdeveloped urban agglomeration regions, it is beneficial to promote the dominance of central cities, since such a network structure will take full advantage of the agglomeration economy for the lack of resources. For urban agglomeration regions with more maturity, network centrality maintained at a moderate level can do best for economic growth, which should also be adjusted dynamically according to the status of urban agglomeration regions. Third, reinforcing the industrial linkage is one critical way to exert urban network externalities. Proper industrial structure similarity will facilitate industrial linkage due to the common knowledge base. Besides, central cities with a higher ratio of the secondary industry also tend to interact more with surrounding cities. Hence, central cities shouldn't concentrate on the tertiary industry excessively for fear of isolation from the surrounding cities.

YOUNG HIGH-TECH FIRMS AND MARKET INTRODUCTION OF SUSTAINABLE ENERGY SOLUTIONS

[Marina Geenhuizen](#), [Razieh Nejabat](#)

Delft University of Technology, Fac. Technology, Policy and Management, Netherlands

ABSTRACT

The paper deals with a specific type of young high-tech firms, namely spin-offs from universities. Universities act as cradles of invention, and their spin-off firms attempt to bring (part of) these inventions to market. Increasingly, the new products, processes and services deal with sustainable energy solutions. However, the extent in which such solutions reach the market and the kind of risk-related factors young firms encounter and influence survival, are hardly known and understood. The paper aims to clarify market introduction by focusing on empirics of firms' risk-taking behavior related to strategic choices, competences and interaction with (national) ecosystem conditions. We use a unique dataset of almost 110 university spin-off firms in Northwest Europe and a small selected sample from this set. 60 per cent of the spin-offs are able to reach the market with their invention, most of them in the first five years of their lives. Wind-energy provides the best chances, as compared to e.g. solar PV and advanced biomass. In-depth results suggest high probability of quick market introduction in 'Innovation Leader' countries, like Sweden and Denmark, if combined with employing rich collaborative networks. A second set of favourable influences includes a practical mind-set of the entrepreneurs and accessing substantial investment capital. In contrast, strong risks tend to be connected to activity in fundamental inventions, highly specialized technology, weakly developed (sub) markets, poorly built networks and short refunding time of substantial investment. In the paper, such risks are connected to survival rates. The study contributes to literature on market introduction of sustainable energy solutions, risk-taking in rigid socio-technical systems, and firm survival.

DETERMINANTS OF NEW FIRM FORMATION IN JAPAN: NEW METHODS FOR THE ANALYSIS OF ENTREPRENEURSHIP

[Akira Kiminami](#)¹, [Lily Kiminami](#)², [Shinichi Furuzawa](#)²

¹ The University of Tokyo, Tokyo, Japan, akira@mail.ecc.u-tokyo.ac.jp; ² Niigata University, Niigata, Japan, kiminami@agr.niigata-u.ac.jp; ³ Niigata University, Niigata, Japan, furuzawa@agr.niigata-u.ac.jp

ABSTRACT

There have been many studies conducted on the factors of the new firm formation because it is an economic activity that revitalizes the regional economy and is also one of the important factors for regional economic development. However, new analysis methods are required since the factors of new firm formation are generally divided into entrepreneurship and entrepreneurial environment, and entrepreneurship itself is difficult to be grasped directly. The purpose of this study is to capture entrepreneurship in the new firm formation rate in Japan and clarify its components through factor analysis. The analysis methods used in this research are as follows. First, we perform a factor analysis of the fixed-effect model using two-point panel data of the Economic Census to explain the new firm formation rate of each prefecture in the country. Secondly, the entrepreneurship is indirectly grasped by the measured fixed effect, and an index of entrepreneurship at prefectural level is created based on the analysis results. Thirdly, we create indexes of attitudes for new firm formation, social capital, diversity, tolerance, and business network at the regional level based on economic and social statistics. Fourthly, the components of entrepreneurship at the regional level are clarified by analyzing the relationship between entrepreneurship and the above indexes. Finally, we derive policy implications that contribute to the promotion of new firm formation based on the analytical results.

KEYWORDS

Entrepreneurship, New firm formation, Panel data analysis

1. INTRODUCTION

The new firm formation is an economic activity that stimulates the regional economy and is one of the important factors for economic development, but there is a large regional disparity in the level of its activity. It is reported that the new firm formation rate is very low in Japan among developed countries internationally and that the disparity in the new firm formation rate among prefectures is more than twice as large as in Japan (Small and Medium Enterprise Agency 2020). The factors that determine the new firm formation rate can be broadly classified into demand, supply, and other factors for new businesses, and these factors are thought to bring about the regional disparity in the new firm formation. Amongst, entrepreneurship is regarded to be the main factor in the "other factors" and to play an important role in the startup of a new business. However, entrepreneurship itself is difficult to be grasped directly. In this research, after reviewing the previous studies, we propose a new analytical method to understand the impact of entrepreneurship at the regional level based on fixed effects in a panel data analysis of the new firm formation rate. In addition, we clarify the factors that influence the new firm formation and the components of entrepreneurship by applying the above method to prefectural level data and derive policy implications for promoting new business startups from the aspect of entrepreneurship.

2. SURVEY OF PREVIOUS STUDIES

2.1. Quantitative studies on new firm formation

Many previous studies have focused on the regional disparities in entrepreneurship and attempted to identify the factors affect new firm formation. In particular, there has been a large body of quantitative analysis studies, mainly in the United States and Europe. Table 1 summarizes some of the variables, causal variables, and measurement methods for new firm formation in previous studies.

Armington and Acs (2002) conducted a multiple regression analysis of the effects of regional economic factors on new firm formation in the U.S.A. and found that firm sizes, industry groups, growth rates of income and population, management (management/labor force), unemployment rate, and education affect the number of new businesses per labor force. Parajuli and Haynes (2017) conducted a spatial panel data analysis for New England, U.S.A., and found that population density, deposit balance, firm size, income growth, public schools, and unemployment rate affect the rate of new firm formation. By estimating a spatial Durbin model for Italy, Piacentino et al. (2017) showed that population growth, innovation (patents), population density, age structure, withdrawal rate, unemployment rate, industry specialization, number of commuters, and national voting rate affect the number of new firms per capita. On the other hand, Lee et al. (2004) introduced indicators of creativity and diversity of the population in addition to general factor variables as factors affecting new firm formation.

Table 1: Examples of quantitative studies on new firm formation

	Variable of new firm formation	Explanatory variables	Estimation method
Armington and Acs (2002)	New firms / labor force	Establishment size, Establishment size, Industry intensity, Income growth; population growth, Share of proprietors, Unemployment rate, No high school degree, College graduates	Multiple regression analysis
Parajuli and Haynes (2017)	Logarithm of single-unit firm birth	Population density, Public enrollment per capita, public enrollment per capita and savings institutions, , Ratio of establishments with 50 or CB more employees to establishments with less than 10 employees, Unemployment rate, Population growth rate, Per capital personal income growth rate	Spatial panel analysis
Piacentino et al. (2017)	New firms / Population	Population growth, Innovation (Patents per capita), Urbanization, Population density, Age distribution, School dropout rate, Unemployment rate, Industrial specialization, Endowment of services, Incoming workers, Voter turnout	Spatial analysis
Lee et al. (2004)	New firms / Population	Creativity Index, Diversity Index, Melting Pot Index, Human capital, Population, Income growth rate, Patents per capita, Population growth rate	Multiple regression analysis
Okamuro and Kobayashi (2005)	New firms / Total firms	Population growth rate, Manufacturing industry wage, Unemployment rate, Graduate rate, Professional-technical job ratio, Household with owned house ratio, Ratio of professional and technical workers, Firm density, Manufacturing industry ratio, Average size of firms, Transportation, Public services expenditure per capita	Multiple regression analysis
Komoto (2007)	New firms / Total firms	Firm closure rate, Unemployment rate, Household growth rate, Growth rate of taxable income, Ratio of aged 65 and over, Commercial land prices, Wages, Ratio of service industries, Ratio of professional and technical workers	Panel data analysis
Kiminami et al. (2019)	New firms / Total firms	Ratio of person who wants to startup ratio, Ration of person who wants to prepare for startup, Population density, Average income, Unemployment rate, Social capital	Structural equation modeling

In recent years, there has been an increasing number of studies on new firm formation in Japan. Okamuro and Kobayashi (2005) have developed a model that explains the regional new firm formation rate by demand factors, cost factors, human capital factors, financing factors, industrial concentration and structure factors, and other factors. Komoto (2007) found that the factors affect new firm formation are those as follows: firm closure rate, unemployment rate, growth rate of household income, growth rate of taxable income, population over 65 years old, land price of commercial land, wages, ratio of service industries, and ratio of professional and technical workers to workers, etc. Furthermore, Kiminami et al. (2019) introduced structural equation modeling to analyze the impact of the desire to startup, readiness to startup, population density, income, and unemployment rate on new firm formation using the data of Japanese prefectures.

2.2. Studies on entrepreneurship and economic development

Instead of focusing on the rate of new firm formation, some previous studies related to new business startups pay attention to people's entrepreneurial activities, entrepreneurial attitudes, and personal attributes. This type of studies usually use the data from Global Entrepreneurship Monitor (GEM) (Honjo 2015; Hundt and Sternberg 2016). In the GEM, global surveys have been conducted according to the framework shown in Figure 1, where entrepreneurship is viewed as an interrelationship of individual entrepreneurial activities (attitudes, behaviors, and motivations) and their social, cultural, political, and economic backgrounds. Among them, Honjo (2015) found that the weak awareness of entrepreneurship in Japan leads to the weak entrepreneurial activities, but as for those who have the necessary knowledge, skills, and experience, the likelihood of starting up a business is higher than others.

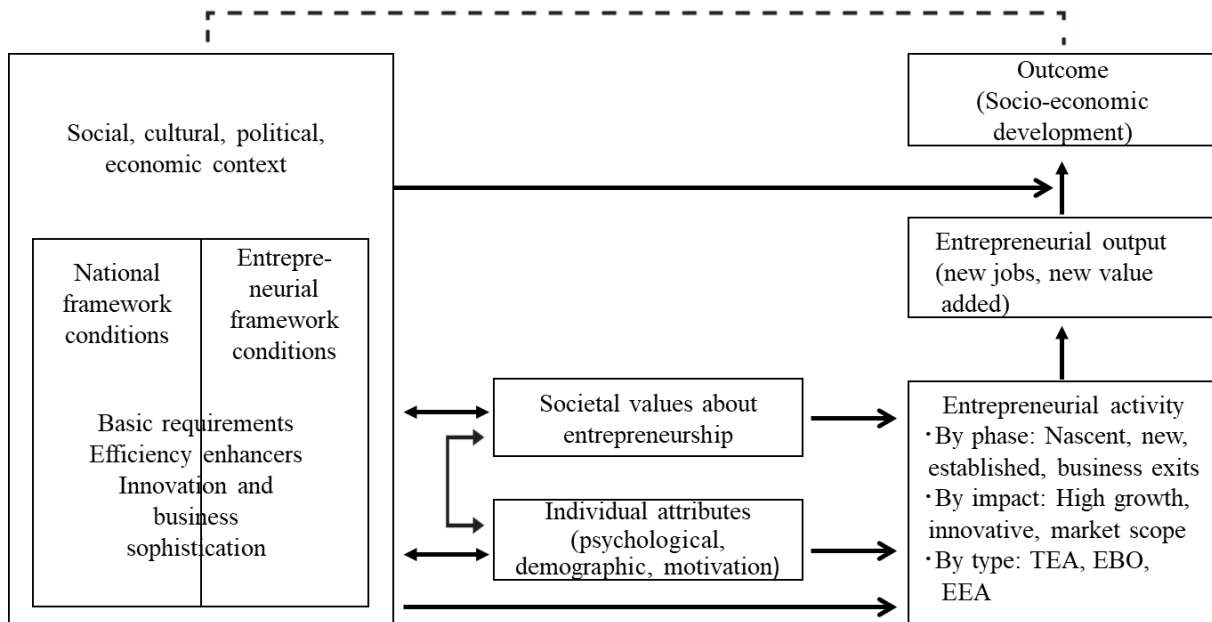

Figure 1: Analysis framework of Global Entrepreneurship Monitor (GEM)

Source: Global Entrepreneurship Monitor (2019).

On the other hand, Harada (2005) analyzed the effect of economic variables on entrepreneurial consciousness called "latent entrepreneurship" in Japan, using the panel data by prefecture. Furthermore, using the individual data from "Employment Status Survey" (Ministry of Internal Affairs and Communications), Matsuda et al. (2016) analyzed the factors of entrepreneurial attitudes in Japan. However, the impact of economic conditions on entrepreneurship is considered to be a long-term rather than a short-term. Besides, there was few studies on the relationship between individual entrepreneurship and the actual startup of a new business.

Due to a new business startup is to produce new economic activities, the demand and supply factors that directly affect the creation of the business are undoubtedly to be focused. Furthermore, "other factors" that affect new business startups, especially entrepreneurship should be distinguished from the demand and supply factors. In this study, we conduct panel data analysis using the variables of demand and supply conditions for new firm formation and consider the fixed effects calculated from the analysis as the outcomes of entrepreneurship specific to the region.

Although, Komoto (2007) calculated the magnitude of the fixed effects of "support measures for business start-up by prefectural governments," "the awareness of residents toward business start-up," etc., the analysis from the view of entrepreneurship was not sufficiently conducted. Besides, Parajuli and Haynes (2017) used the panel data analysis for new business startups using the variables related to human capital, such as the proportion of professional and technical workers and education, as proxy variables for entrepreneurship. Another approach is to consider entrepreneurship in a broad sense as an outcome that cannot be explained by demand and supply factors, such as in the analysis of the factors that contribute to the diversification of farm management in Japan (Kiminami et al. 2020), in which they used the method of fixed effects of panel data analysis as the outcomes of entrepreneurship at the regional level.

And the outcomes of entrepreneurship are assumed to be determined by the factors such as social, cultural, political, and economic backgrounds, the awareness of residents toward startups and the social capital in the region. A modification of GEM framework and the variables used in the empirical analysis for explaining the differences in new firm formation among regions in Japan are shown in Figures 2.

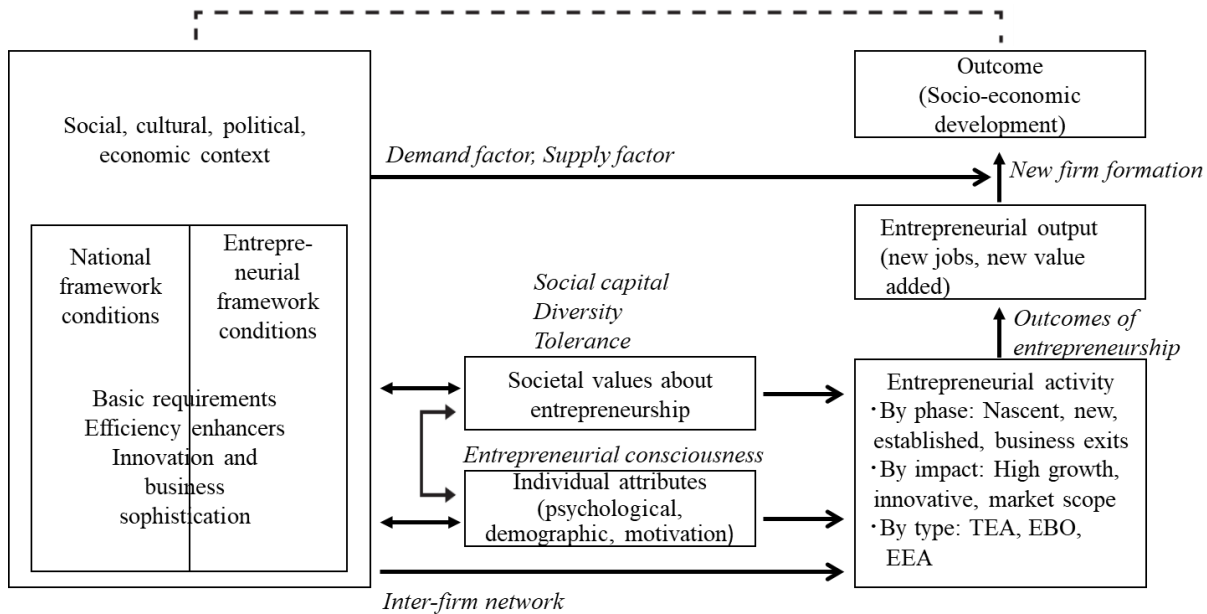

Figure 2: Areas of analysis in this study

Social capital is "the features of social organization such as trust, norms, and networks that improve social efficiency by promoting cooperative behavior" (Putnam 1993). Due to different functions in connecting actors, social capital can be roughly divided into bonding type and bridging type. Bonding type of social capital has the functions of linkage between homogeneous actors in a social organization, which generates trust, cooperation, and unity within the organization. These functions are thought to promote new business, but they may also lead to exclusiveness and suppress new business. On the other hand, bridging type of social capital has the function to form a consensus by sharing and exchanging information among groups with various interests, and is thought to promote new business, which is a network of heterogeneous actors and social organizations.

Peir'o-Palomino (2016) measures the impact of social capital on economic growth for European cities and finds that the impact on economic growth is non-linear and that the effect varies by region and time. The results of Yodo (2005) show that "normality" has a positive impact on regional economic growth, while "trust" has no significant impact.

Kiminami et al. (2019) built a model assumed causal processes among the variables, different from most of previous studies that added various types of social capital to the factor variables for new firm formation without considering the complex interrelationships among them,

Diversity includes what is represented by statistics such as gender, age, nationality, and employment status, but also deeper things that cannot be represented by statistics such as values, personality, job attitude and ability (Ishikawa 2014). METI (2012) states that in order to break through the stagnation of the Japanese economy, it is important to increase diversity and create innovation.

As for gender diversity, World Economic Forum (2020) pointed out that gender parity has a fundamental bearing on whether or not economies and societies thrive and calculated Global Gender Gap Index of each countries in the world. In 2020, Japan ranks 116th out of 153 countries in terms of gender parity, making it a country with an extremely large gender gap. In particular, Japan's economic participation and opportunity index is not only low, but also shows a further decline in ranking in recent years. The European Institute for Gender Equality (2019) also states that closing the gender gap will create jobs, produce competitiveness, and contribute to economic development. Dai et al. (2019) reported that gender diversity has a positive impact on innovation, including the study on new venture teams. Also, the study on the relationship between creative class and sustainable development of regions by Furuzawa et al. (2019) has revealed that gender diversity and tolerance are important.

With respect to ethnic diversity, Jiang et al. (2020) found that ventures with ethnically diverse founding teams tend to realize higher returns in the U.S.A. On the other hand, Ramasamy and Yeung (2018) conclude from their international comparative study that ethnic diversity has a negative impact on innovation and that cultural diversity has a positive impact.

3. ANALYTICAL MODEL AND METHODS

From the results of the previous studies, the factors affect new firm formation can be classified into demand factors, supply factors, and other factors. While variables of demand factors include population density, income growth rate, etc., variables of supply factors include labor force, unemployment rate, capital, land price, firm size, and industry composition, and variables of "other factors" include individual and organizational entrepreneurship and social capital. As for the variables related to individual entrepreneurship, human capital such as educational background and percentage of professionals, as well as awareness of startup of a business are used. Moreover, we use firm density and

industrial agglomeration as variables of organizational entrepreneurship since they represent networks among firms and organizational activities.

Generally, theoretical model is rarely presented in most econometric studies on the determinants of new firm formation rate. However, the theoretical model for the choice between self-employed or employee by Talyer (1996, 1999) seems very useful in the study of new firm formation. It is assumed that an individual will take the one with a higher expected utility while facing the choice between becoming self-employed (SE) through starting up a business or becoming an employee (E) through getting a job, as shown by the following.

$$E(U_{SE}) = f(\theta, k, r, D, X)$$

$$E(U_E) = g(w, X)$$

Where, the expected utility from self-employed $E(U_{SE})$ is a function of entrepreneurial ability θ , available capital k , interest rate r , level of demand in the economy D , and individual preferences X . Similarly, the expected utility from employee $E(U_E)$ is a function of wage w and X . If $E(U_{SE}) > E(U_E)$, self-employed will be chosen. And if $E(U_{SE}) < E(U_E)$, employee will be chosen. Among the variables that determine $E(U_{SE})$ and $E(U_E)$, k , r , D , and w are variables of the economic environment, θ is a variable of entrepreneurship, and X is a variable of personal attributes. Besides, both self-employed and employee are facing risks affected by economic environment. For example, if unemployment rate is high, employees are facing the risk of losing job and $E(U_E)$ becomes zero.

Therefore, it is assumed that changes in the economic environment affect the expected utility through k , r , D , w , and risk in a short run, and affect expected utility through θ and X in a long run. However, social and cultural environment is thought to have a long-run effect on entrepreneurship and a short-run effect on the expected utility for business startup. Moreover, it is supposed that there is also a feedback from individuals' choice for self-employed or employment to the economic environment. Replacing the choice of self-employed with that of the startup of a new business, we can set the economic model for the determinant factors of the startup of a new business.

4. UNDERSTANDING THE OUTCOMES OF ENTREPRENEURSHIP

The explained variable used in the panel data analysis is the rate of new firm formation. The explanatory variables are the rate of income growth, the ratio of working-age population, population density, unemployment rate, the ratio of tertiary industry, and patents. The definitions and levels of each variable are summarized in Table 2. The data for explained variables are the years of 2014 and 2016. Since the data for the dependent variable is based on the number of new businesses startup in the past two years, the years of 2012 and 2014 were used for the explanatory variables.

Table 2: List of variables used in panel data analysis

Variable	Definition	Year	Average	Min.	Max.
NFR	New firm formation rate: Number of new firm/Total number of firm (%)	2014	7.9	5.9	12.2
		2016	5.5	4.1	8.3
POD	Population density: Population/Livable area (person/ km ²)	2012	1,369	246	9,506
		2014	1,365	244	9,609
IGR	Income growth rate: Growth rate of per capita income (%)	2012	-0.2	-7.3	8.8
		2014	0.5	-3.3	4.4
WPR	Working-age population ratio: 15~64 years old / Population (%)	2012	61.2	57.3	67.5
		2014	59.6	55.6	66.2
UER	Unemployment rate: Unemployed/Labor force (%)	2012	4.0	2.5	6.8
		2014	3.3	5.4	2.3
TER	Tertiary industry ratio: Gross output of tertiary industry/ Total (2011price)(%)	2012	69.5	54.8	86.5
		2014	68.7	54.3	86.2
PAT	Patents: Number of patents registered/ 100,000 population	2012	72.1	5.7	874.2
		2014	57.5	3.8	706.9

NFR: 2014 Economic Census for Business Frame, 2016 Economic Census for Business Activity (Ministry of Internal Affairs and Communications); POD: Population Estimates (Ministry of Internal Affairs and Communications), National Survey of Urban, Town and Village Areas (Ministry of Land, Infrastructure, Transport and Tourism); IGR, TER: List of Japanese Prefectures by GDP (Cabinet Office); WPR: Population Estimates (Ministry of Internal Affairs and Communications); UER: Labor Force Survey (Ministry of Internal Affairs and Communications); PAT: Population Census (Ministry of Internal Affairs and Communications), Japan Patent Office Annual Report (Japan Patent Office)

The results of the panel data analysis for the rate of new firm formation are summarized in Table 3. As a result of testing the fixed effects model, the Pooled model and the random effects model, the fixed effects model was supported. According to the results of the fixed effects model, the ratio of working-age population, unemployment rate, and patents have a strong influence on the rate of new firm formation, and the signs of the coefficients are as expected. The coefficient of population density is negative, but not significant. In general, the higher the population density, the greater the demand, so the sign of the coefficient is expected to be positive, however Delfmann et al. (2014) pointed out that a higher population density also has a negative effect.

Table 3: Results of panel data analysis (Explained variable: NFR)

5. FACTORS AFFECTING ENTREPRENEURSHIP OUTCOMES

Next, we will analyze the factors that affect the fixed effects measured by the panel data analysis. In other words, instead of the demand and supply factors, "other factors" for new firm formation will be grasped. However, "other factors" discussed in this study are the individual entrepreneurship, inter-firm networks, social capital, diversity and tolerance, and the corresponding proxy variables are summarized in Table 4. Since the fixed effects are derived from the analysis of new business startups during the period of 2012-2016, the percentage of applicants for startups and firm density are based on the data of 2012.

Usually, proxy variables are used as variables for social capital by prefecture in previous studies, here we use an index created from the results of a large-scale questionnaire survey conducted in 2015 (Research Group on Mechanisms and Activation of Local Activities 2016).

Table 4: List of variables used in the analysis of factors affecting fixed effects

Variable	Definition	Year	Average	Min.	Max.
FIE	Score of fixed effect		-51.72	-62.00	6.56
ENT	Prospective entrepreneurs ratio: Person who wants to startup / Aged 15 years and over (%)	2012	0.83	0.54	1.62
FID	Firm density: Firms / Livable area (/ km2)	2012	63.1	10.9	516.5
BON	Bonding index	2015	0.33	0.23	0.42
BRI	Bridging index	2015	0.23	0.20	0.29
GEG	Gender gap: Male-female gap of self-employed and executive ratio (%)	2012	12.6	8.0	17.7
FOR	Ration of foreigner: Foreigners / Population (%)	2012	1.17	0.28	3.10
SUI	Suicide ratio: Suicides / Population (%)	2012	0.21	0.17	0.27

ENT, GEG: Employment Status Survey (Ministry of Internal Affairs and Communications); FID: Economic Census, Population Census (Ministry of Internal Affairs and Communications); BON, BRI: Study Group on Mechanisms and Activation of Community Activities (2016); FOR: Population, demographics, and number of households based on the Basic Resident Ledger (Ministry of Internal Affairs and Communications, Statistics on Foreign Residents (Ministry of Justice); SUI: Population, demographics, and number of households based on the Basic Resident Ledger (Ministry of Internal Affairs and Communications), National Center of Neurology and Psychiatry, "Regional Statistics of Suicide Deaths for Suicide Prevention 1983-2012.

Following trends in the percentage of prospective entrepreneur those who wish to start up a business by age, gender, and type of business are shown in Table 5. First, among those aged 25 and over, the order of the percentage of those who wish to start up a business is as follows: unemployed > additional job (employed) > job change (employed). However, in the case of those aged 15-24, the order is additional job (employed) > unemployed > job change (employed), and it is considered that many students are included in the unemployed.

Although, the percentage of men who want to start a business is higher than that of women in all age groups, in the age groups of 25-54, who are unemployed, the percentage of women who want to start a business is higher than that of men (Table 6). It suggests that gender gap in employment affects the awareness of startups.

Table 5: Ratio of those who want to startup (%)

	Additional job (employed)		Job change (employed)		unemployed	
	Male	Female	Male	Female	Male	Female
Total	1.44	0.53	0.96	0.39	1.23	0.58
15~24 years old	0.86	0.34	0.81	0.31	0.62	0.34
25~34years old	2.00	0.68	1.43	0.64	4.23	1.56
35~44years old	2.07	0.79	1.27	0.54	5.38	1.78
45~54years old	1.61	0.61	0.95	0.34	5.27	1.60
55~64years old	0.75	0.30	0.63	0.19	2.31	0.68
65~74years old	0.45	0.10	0.26	0.15	0.76	0.19
Over 75years old	0.14	0.07	0.06	0.02	0.28	0.03

Source: Employment Status Survey 2012 (Ministry of Internal Affairs and Communications)

Table 6: Composition of those who want to startup (%)

	Additional job (employed)		Job change (employed)		Unemployed	
	Male	Female	Male	Female	Male	Female
Total	34.92	9.73	23.37	7.14	13.48	11.35
15~24 years old	1.40	0.57	1.33	0.51	1.55	0.78
25~34years old	8.98	2.34	6.42	2.21	1.99	2.14
35~44years old	12.17	3.33	7.44	2.27	2.24	3.42
45~54years old	7.84	2.34	4.65	1.31	1.93	2.18
55~64years old	3.53	1.00	2.97	0.63	2.70	1.87
65~74years old	0.91	0.13	0.51	0.19	2.16	0.80
Over 75years old	0.09	0.03	0.04	0.01	0.91	0.16

Source: Employment Status Survey 2012 (Ministry of Internal Affairs and Communications).

The correlation coefficients among the variables are shown in Table 7. The ratio of prospective entrepreneurs (ENT), firm density (FID), and the ratio of foreigners (FOR) are positively correlated with fixed effects (FIE), with firm density having a particularly strong positive correlation. Bonding index (BON), bridging index (BRI), gender gap (GEG), and suicide rate (SUI) are negatively correlated.

Table 8 summarizes the correlations between each variable and the fixed effects. The results generally show the expected signs, but the bridging index and suicide rate were not significant. For the bonding index, both positive and negative signs were possible, but the sign was negative.

Table 7: Correlation coefficient between variables

	FIE	ENT	FID	BON	BRI	GEG	FOR	SUI
FIE	1.000	<u>0.635</u>	<u>0.975</u>	<u>-0.483</u>	-0.238	<u>-0.326</u>	<u>0.591</u>	-0.220
ENT		1.000	<u>0.650</u>	<u>-0.625</u>	-0.205	-0.245	<u>0.407</u>	<u>-0.309</u>
FID			1.000	<u>-0.495</u>	-0.226	<u>-0.297</u>	<u>0.621</u>	-0.201
BON				1.000	<u>0.523</u>	<u>0.368</u>	-0.143	0.190
BRI					1.000	<u>0.372</u>	-0.188	-0.012
GEG						1.000	<u>-0.540</u>	0.238
FOR							1.000	<u>-0.321</u>
SUI								1.000

Note: Double underline and underline mean statistically significant at the 1% and 5% levels, respectively.

Table 8: Correlation coefficient with FIE (score of fixed effect)

Variable	Expected sign	Result
ENT	+	+
FID	+	+
BON	+ / -	-
BRI	+	0
GEG	-	-
FOR	+	+
SUI	-	0

Note: +, -, and 0 in the result column indicate positive correlation, negative correlation, and no correlation, respectively, at the 5% level of statistical significance.

6. CONCLUSION

The following conclusions were drawn from the results of the above-mentioned analysis. First, it became clear that supply factors such as the working-age population, the unemployment rate, and patents have strong influences on new business start-ups. This implies that policies promoting new business start-ups should be combined with the policies promoting the availability of labor and innovation creation. On the other hand, demand factors do not have a significant impact, suggesting that the new firm formation that meets demand is not sufficiently progressing in Japan.

Next, the regional differences in the fixed effects as the level of entrepreneurship were larger than the regional differences in the rate of new firm formation. This means that the factors of entrepreneurial awareness, inter-business networks, social capital, diversity and tolerance that are inherent in the region are more important. In particular, the influence of inter-business networks is the strongest, which induces new business start-ups and lead to further agglomeration of firms. Therefore, when considering policies to promote new businesses, it is necessary to consider not only policies directly related to industries but also policies to increase the level of entrepreneurship in the region (Kiminami et al. 2020).

However, there remain several issues in the study. First, the interrelationships among the factors that constitute entrepreneurship need to be explored and clarified. Second, the variables related to entrepreneurship policies implemented in each region need to be introduced and evaluated, and the industry-specific analysis based on industrial characteristics need to be developed.

FACTORS THAT INFLUENCE ON THE ENTERPRENUERIAL INTENTION OF UNEMPLOYEES IN COVID-19 TIMES

Grace Carolina Guevara-Rosero, Bernardo Alquina, Marcela Guachamin

Department of Quantitative Economics, Escuela Politécnica Nacional, Ecuador

ABSTRACT

Currently, the COVID-19 pandemic has caused many changes both in health and economic terms. In Ecuador, the existent harsh economic situation was agravated with an increase of the unemployment in 9 percentage points from 4% by 2019, to 13.3% by June 2020. Given this scenario, people who fell into unemployment and already unemployed people might see the entrepreneurship as a viable option to maintain or increase their income. In the Ecuadorian case, in which most of microentrepreneurs have a survival perspective, existent and new unemployees may have a defensive attitude to escape unemployment. Then, microentrepreneurship plays as a "refuge effect" (Vivarelli, 2004; Thurik et al, 2008). Therefore, the research question is: what are the factors that drive unemployed people to undertake their own business? Do these factors differ across types of unemployess, namely, existent unemployees and new unemployees due to COVID-19?. To answer to these questions, data from a national survey undertaken by the educational institution Escuela Politécnica Nacional of Ecuador during the pandemic is used. This database accounts for 3,868 observations. To determine the probability of enterprenuerial intention, a Probit model is estimated for two types of unemployed people, namely existent unemployees and new COVID-19 unemployees. Sociodemographic characteristics, family conditions and financial aspects are considered as explanatory variables. Among the sociodemographic variables, we have sex, age, level of education, income level, the nationality, whether the person accounts for medical insurance and civil status. Among the family conditions we have the number of members in the family and number of income perceptors. Regarding the financial conditions, we consider the debt, the savings, necessity of credit and financial knowledge. Finally, the variation of income level due to the pandemic is included. The results show that the underlying motivations of entrepreneurial intentions vary across existent and new unemployees. For instance, the level of education influences in opposite directions. As the level of education increases, the entrepreneurial intention also increases for COVID-19 unemployees but reduces for existent unemployees. This result could indicate that unemployees in the context of a crisis use their human capital in entrepreneurship to improve their situation. The number of income perceptors reduces the entrepreneurial intention for COVI-19 unemployees, as there exists more mechanisms of consumption smoothing. This aspect is not significant for existent unemployees. Interestingly, the necessity for credit increases the intention of entrepreneurship for both types of unemployees. In this sense, policies that boost entrepreneurial activity by generating differentiated credit products for identified groups of people, are needed. The variation of income due to the crisis influences only on the entrepreneurial intention of existent unemployees. In this line, it is important to create opportunities through training and promote an optimal environment for entrepreneurship.

CRIME AND CHINESE AID PROJECTS IN GHANA

[Michael Appiah-Kubi](#)

School of Economics, Xiamen University, China

ABSTRACT

The impacts of Chinese aid in Africa have been the focus of recent studies, suggesting a high probability of elite capture and political patronage. It should make residents in the projects' vicinities feel neglected since the intended benefits that may accrue from the projects are not likely to trickle down to them. The paper examines the impact of Chinese aid projects on criminal activities in Ghana. Using a geo-referenced dataset of subnational allocation of Chinese projects which is geographically matched with 10,797 respondents of Afrobarometer surveys for Ghana, we implement a difference-in-difference identification strategy to capture the impact of living near vicinity of projects under implementation at the time of the survey against areas where a project will be implemented in the future. The results suggest that living near projects under implementation makes residents prone to be burglarized but less likely to be physically attacked. There is no equivalent pattern when considering projects financed by other donors.

IMPACT EVALUATION OF VOCATIONAL TRAINING FOR PEOPLE WITH PHYSICAL DISABILITIES ON EMPLOYMENT OPPORTUNITIES

Leni Marlina¹, Evi Noor Afifah²

¹Government of Rejang Lebong Municipal, Bengkulu, Indonesia. ²Department of Economics, Universitas Gadjah Mada, Indonesia

ABSTRACT

This study examines the impact of vocational training, specifically for people with physical disabilities, who carried out in the Balai Besar Rehabilitasi Vokasional Bina Daksa (BBRVBD), also known as National Vocational Rehabilitation Center (NVRC), towards increasing employment opportunities for people with disabilities. By using pooled cross section data from 2014-2017 and probit model data analysis techniques, this study validates the hypothesis that there is a positive impact of vocational training on increasing employment opportunities for persons with disabilities, higher in 43.32% significant at alpha level 1 %. The level of education also has a significant positive impact on the level of 1% increasing the chance of being accepted to work for people with disabilities by 2.03%. There are 6 types of vocational skills held, the most accepted in work opportunities are sewing skills, followed by graphic design skills, computers, electronics, automotive, and metal work.

EDUCATION EXPENDITURE AND ECONOMIC GROWTH IN SOUTHEAST ASIA

Farisa Puspita Adila, Evi Noor Afifah

Department of Economics, Universitas Gadjah Mada, Indonesia

ABSTRACT

The purpose of this study is to analyze the influence and direction of the causality between education expenditure and economic growth in Southeast Asia. This study used panel data from 11 countries in Southeast Asia in a period of 17 years. The method of analysis used in this research includes unit root test, panel cointegration test, model panel, and error correction model test. The results of this study during the period 2000-2016 indicate that there is a positive and significant effect between education expenditure, physical capital, and labor on economic growth in Southeast Asia in the long term. In the short term, only education expenditure and physical capital has a positive and significant effect on economic growth. Meanwhile, based on the Granger causality test, it was found that there was a unidirectional effect of economic growth on education expenditure. Furthermore, this research proves that human capital plays an important role in influencing economic growth in Southeast Asia.

ABSTRACT

Von Hippel et al. (2011) proposed a new innovation paradigm that emphasizes the role of consumers as innovators. In this paradigm, innovation consists of three phases: consumers develop new products for themselves, other consumers evaluate and improve them, and producers enter when market potential is clear. Moreover, Christensen et al. (2019) categorized innovations into three types: sustaining innovations, efficiency and market-creating innovations. They pointed out that while all innovations are important to keeping an economy vibrant, one type in particular 'market-creating innovation' plays a significant role, providing a strong foundation for sustained economic prosperity because innovation is also a process of organizational learning with dynamic changes in collective cognition.

The current study examines the direction of innovation in Japan's rice policy and rice industry from a long-term perspective based on the consideration of 'backcasting' (Robinson 1982). To this end, we introduce the methods of SEM (structural equation modeling) and cognitive map based on questionnaire survey targeting Japanese consumers for hypotheses verification in the research. The following results were obtained from the analytical results.

First, the demand conditions for market-creating innovation in Japan's rice industry are in place and rice consumption will increase if the innovation that meets the potential needs of consumers occurs. Second, innovation-oriented policies or market-creating innovation strategies to change the cultural beliefs, including the perception of producers and consumers about rice cultivation, rice products and the way of rice eating are required. Specifically, Japanese rice market should be transformed from a short tail to a long tail (Anderson 2006). In the long tail part, consumers who are oriented toward innovation will play a central role in discovering new types of rice products, inheriting the food culture related to rice, and creating shared value through communicating and organizational learning with producers and stakeholders.

KEYWORDS

Market-creating innovation, Rice industry, Backcasting, Long tail, Japan

1. INTRODUCTION

Generally, food demand is affected by prices, income, preferences (including food culture), information and policies (Hansen 2013). Figure 1 shows the long-term trend of rice supply per capita in Japan. It peaked at 118.3 kg/per capita in 1962 and has declined to 53.0 kg/per capita in 2019. Figure 2 shows the changes in the rice purchase volume per capita and rice price (both in nominal and real term) from 1963 to 2019. Rice purchase volume per capita has continued to decrease from 86.5 kg in 1963 to 20.9 kg in 2019, although the rate of decline has become gradual in recent years. Alternatively, the price of rice (in real terms) was on an upward trend while increasing and decreasing until the 1970s, and after having been flat in the 1980s, it has turned to a downward trend since the mid-1990s.

Note: Supply quantity (Net food).

Source: MAFF Food Balance Sheet. 2019 is a rough estimate value.

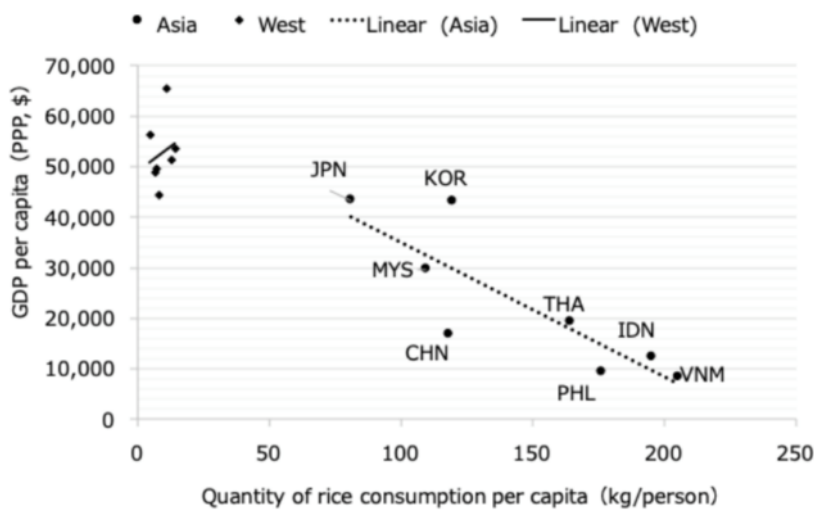

Figure 1: Annual rice consumption per capita

Source: Ministry of Internal Affairs and Communications "Family Income and Expenditure Survey", "Consumer Price Index"

Figure 2: Trend of rice price and annual purchasing quantity per capita

Here, we give an overview of the current state of rice consumption in Japan from the perspective of international comparison. To consider differences in preferences (food culture), an analysis will be conducted using cross-section data by country for the two groups. That is, the Asian group whose staple food is rice and the Western group whose staple food is other than rice. Looking at the relationship between per capita rice consumption and income (Fig. 3), it is shown that rice consumption is lower in high-income countries than in low-and-middle-income countries in Asian group. However, rice consumption is slightly higher in high-income countries in Western group. In addition, Japan has the lowest rice consumption among Asian countries. South Korea, whose income level is almost the same as Japan, consumes more rice than Japan. From this, it is considered that besides income other factors such as prices, preferences, information, and policies give the influences on rice consumption in Japan and South Korea.

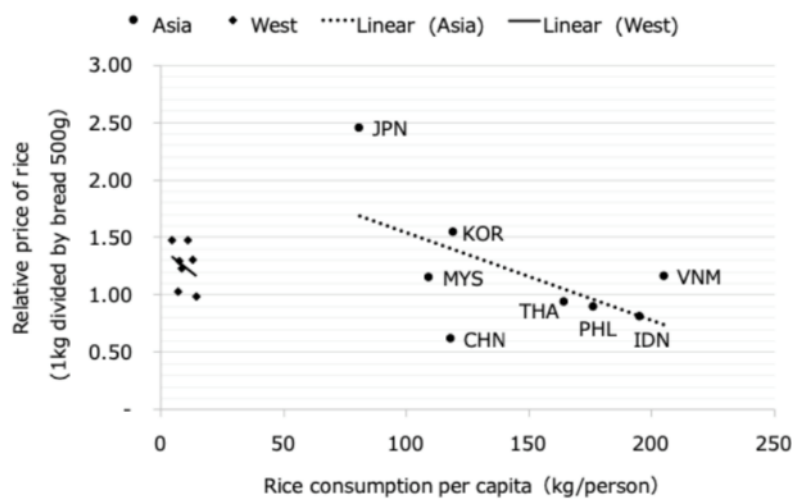

Note: Quantity of rice consumption is "rice and products". Asia group includes Japan(JPN), China(CHN), Indonesia(IDN), Malaysia(MYS), Philippines, PHL), Korea(KOR),Thailand(THA), Vietnam(VNM). West includes USA, UK, Italy, Australia, Canada, Germany, France.

 Quantity of consumption (2018) is collected from FAO HP "FAOSTAT New Food Balances" <http://www.fao.org/faostat/en/#data/FBS> (2020/12/28 Accessed)
 GDP per capita is collected from World Bank "World Development Indicators". <https://data.worldbank.org/indicator/> (2020/12/28/ Accessed)

Figure 3: Quantity of rice consumption and GDP per capita

Next, looking at the relationship between rice consumption and rice prices, the variation in rice prices is small in Western group, while it is large in Asian group (Fig.4) . In addition, it is clear that the higher the rice price, the lower the consumption in Asian group. Moreover, the price of rice in Japan is the highest, and it deviates significantly upward from the approximate straight line. This could be considered that the level of rice consumption in Japan is affected not only by rice price but also by other factors such as food culture, information, and rice policies, etc.

Note: Quantity of rice consumption is "rice and products".
Source : Same as Fig.3

Figure 4: Quantity of rice consumption and relative price of rice

The purpose of this study is to examine the direction of innovation in Japan's rice policy and rice industry from a long-term perspective based on backcasting thinking¹. First, in Chapter 2, selective literature reviews on innovation policy and market-creating innovation are conducted. It also explains the analytical framework, hypotheses, and analytical methods for the research. In Chapter 3, the hypothesis will be verified by the analysis of the results from the questionnaire survey to consumers. Finally, we derive policy implications for the sustainable development of the Japanese rice industry based on the analytical results.

2. LITERATURE REVIEW AND HYPOTHESIS

2.1 Innovation policy and market-creating innovation

Innovation policy is relatively new to the agenda of policy makers, and its interest has risen rapidly since the mid-1990s. It has been categorized into three types (Edler and Fagerberg 2017): "Mission-oriented policy" (Ergas 1986), which provides new solutions to specific political issues; "Invention-oriented policy," which focuses on the R&D/invention stage and leaves the exploitation and diffusion stage to the market mechanism; "System-oriented policies," which focuses on the interactions between different parts of the system recently. In Innovation Policy Review by the OECD (2020)², it provides a comprehensive assessment of the innovation systems of individual members of partner countries and provides specific recommendations for policies that affect the performance of innovation.

However, as Edler and Fagerberg (2017) specified, the market failure argument, which is invoked as a rationale for public funding has the problems of policy failure, perfect knowledge, and the linear model. Hence, it is seen difficult to justify the design and implementation of innovation policies broadly. As the responsibility for the different components of the system is distributed across different areas of government, a 'holistic' perspective on policy (Edquist, 2011) as well as an effective coordination between different parts of government (such as the ministries responsible for knowledge creation, skills-production, finance, and so on) are necessary for understanding such a systemic innovation policy (Braun, 2008;Fagerberg, 2016a).

Alternatively, von Hippel et al. (2011) proposed a new innovation paradigm that emphasizes the role of consumers as innovators³. In this paradigm, innovation consists of three phases: consumers develop new products for themselves, other consumers evaluate and improve them, and producers enter when market potential is clear. Therefore, it is necessary to consider consumers as active actors in the processes of innovation creation and dissemination and conduct research and analysis starting from the consumption/demand side.

Moreover, Christensen et al. (2019) categorize innovation into three types: sustaining, efficiency, and market creating. It insists that "All innovations are important to keep the economy vibrant, but especially market-creating innovation plays an important role and is a strong foundation for sustainable economic prosperity" because market-creating innovations transform culture. The institution of a society reflects the culture and values of the people of that society, institutional change needs to be elicited by cultural transformation. Therefore, simply introducing a system is not effective in promoting economic growth and sustainable development.

2.2 Japanese rice industry and innovation

1 The backcasting method defines a desirable future (what it should be and what it should be), shares it with the people concerned, and thinks about what to do from the present to connect it to the desired future. It is one of the planning methods for identifying policy and programs and (Robinson 1982).

2 OECD Review of Innovation Policy (<https://www.oecd.org/sti/inno/oecd-reviews-of-innovation-policy.htm>)

3 Consumer innovator is defined as a person who had innovated in software products or physical products from scratch or improving an existing for non-work purpose within the last three years.

The pioneering study of Hayami and Ruttan (1985) presented an induced innovation model for explaining agricultural development from two aspects: technological innovation and institutional innovation. In the technological innovation of rice cultivation in Japan, the accumulation of technology and knowledge by the veteran farmers, the selection at the agricultural experimentation site, and the dissemination of the technology through the farmer's organization play a major role. In the institutional innovation, the function of the village that can realize the formation and maintenance of land improvement capital as a local public good (in the theory of social capital: the bonding-type of social capital) played an important role (Hayami 2000, Hayami / Godo 2002, pp. 106-107).

Uraki (1986) used the framework of complex science to analyze the changes in the Japanese social life surrounding rice. He emphasized that technological innovation in rice cultivation under the Basic Agricultural Law was "technological innovation without independence" (or blind technological innovation) by the old-fashioned peasants. He also pointed out that creative destruction had not occurred because the innovation in this period was not based on modern capitalist motivation and consciousness structure.

Alternatively, rice in Japan is being differentiated and branded according to various qualities. Although the quality of rice was strongly influenced by the grade depending on the place of origin and variety, it was formed by various factors (Fuyuki 2014). Saito (2010) clarified the characteristics of regional brands and mentioned strategic issues and the importance of brand management. Suzuki and Kiminami (2009) clarified the current status of regional collective trademark registration, and Takita and Kikuchi (2012) analyzed the effects of rice quality, production area, and variety on consumption by conjoint analysis. In addition, rice differentiated and branded by farming methods that take biodiversity into consideration has also appeared. Taie (2012) and Taie (2013) have described public goods as the quality of the environment with respect to "creature mark rice." In addition to clarifying the economic characteristics of rice, it analyzed price premiums from the perspective of product differentiation under monopolistic competition.

Moreover, the conventional consumer choice theory in economics has been extended to allow for factors such as the cost of gathering information, imperfections in the perception of information and limitations to consumers' cognitive powers in gathering and processing information. As argued by Anderson (2006) that e-commerce and other new technologies improve efficiency by encouraging the entry of new producers and innovations, creating a "long tail" of niche products while reducing the market share of previously popular products. According to the result from an empirical analysis conducted by Kiminami et al. (2021) on the rice retail market (especially the e-commerce market) in China, the retail rice market is undergoing dynamic change in which the externalities of consumption in the two-sided market are modernized and sustained through cumulative market feedback. Alternatively, Kendall and Tsui (2011) studied the strategic interaction between hits and niches in their pricing, entry, and innovation decisions using a model of competition under the product differentiation and generalized cost structure. They pointed out that industries in which firms innovate low variable/high fixed cost technologies tend to move toward superstar effects, while those where firms innovate low fixed cost/high variable cost technologies tend to move toward long tail effects. Therefore, the ability of policy to improve market efficiency is limited by the knowledge that policymakers hold regarding the cost structure and other parameters of the affected industries. Zilberman et al. (2019) addressed the importance of policy design that does not diminish entrepreneurship in the food and agriculture sector.

Although there have been increasing interest in the sustainable diets in the area of scientific research recently, there are few policy studies on it. Because the relationship between sustainable diets and adjacent social issues (eg, fair trade, animal welfare, sustainable agriculture, social acceptability etc.) is unclear, and it is difficult to uniformly evaluate and discuss eating habits. There can be various transitional routes in a specific diet because it is susceptible to individual tastes and cultural influences (Burlingame and Dernini 2012).

In addition, Kiminami et al. (2020) analyzed the relationship between Japan's rice policy and innovation in rice cultivation so far. It pointed out that rice prices maintained by the production adjustment policy suppressed consumers' original demand for rice and caused rice consumption decrease. In addition, major innovations are difficult to be created due to the existing cultural beliefs dominate the political and social domains of the system although rice production adjustment policy has been officially abolished.

2.3 Hypothesis and analysis method

Based on the results of the above literature review, the following hypotheses are set in this study.

Hypothesis 1 "Innovation can stimulate Japanese consumers' demand for rice"

Hypothesis 2 "Consumers require a strategy to induce an innovation in the rice industry that contributes to the sustainable development of agriculture and rural areas."

In the following chapter, to verify Hypothesis 1 and Hypothesis 2, the analysis of rice demand function, covariance structure analysis (SEM) and cognitive map analysis will be conducted using the data of household survey by the government and authors' original questionnaire survey. Furthermore, we will propose policies for the realization of sustainable development (SDGs) of Japan's rice industry introducing a backcasting model based on the analytical results.

3. HYPOTHESIS VERIFICATION

3.1 Measurement of rice demand function

The demand function of rice is measured to clarify the self-price elasticity of demand, cross-price elasticity, income elasticity, and trends in rice consumption by using time-series data. The demand function of rice is expressed by Eq. (1).

$$Q_r = f(P_r, P_b, P_n, P_o, Y)(1)$$

Here, Q_r is the annual purchase quantity of rice per capita, P_r is the rice price, P_b is the price of bread, P_n is the price of noodles, P_0 is the price of market goods other than rice, bread and noodles, and Y is the amount of annual consumption expenditure per capita.

Of these, the annual purchase quantity of rice (Q_r), rice price (P_r), bread price (P_b), noodles price (P_n), and annual consumption expenditure (Y) are collected in the Ministry of Internal Affairs and Communications “Household Survey.” Data for workers’ households from 1963 to 1999, and for two-or-more-person households from 2000 to 2019. The purchase quantity of rice and consumption expenditure are divided by the number of household members and converted to per capita. For the prices of other market goods (P_0), the Ministry of Internal Affairs and Communications “Consumer Price Index” is used (2015 = 100). The descriptive statistics for each variable are shown in Table 1.

Table 1: Descriptive statistics of variables

	Variables	Unit	Mean	S.D.	Minimum	Maximum
Dependent variable	Annual purchase quantity of rice per capita	(kg/person)	40.7	17.0	20.9	86.5
Independent variable	Rice price (real term)	(yen/kg)	464.9	75.4	330.6	598.9
	Bread price (real term)	(yen/100g)	45.5	1.7	40.4	50.1
	Noodles price (real term)	(yen/100g)	53.1	5.8	38.8	64.8
	Annual consumption expenditure per capita (real term)	(yen/person)	1,021,878	200,796	508,215	1,210,546

Equation (2) shows the specification model that uses a log-log type to measure the rice demand function. To clarify the trend effect, the trend term (Trend: 1963 = 1, 1964 = 2, ... 2019 = 57) is used. In addition, Prais-Winsten AR (1) regression (GLS estimation) is used to deal with the problem of series correlation of error terms.

$$\ln Q_r = \alpha_0 + \alpha_1 \ln (P_r / P_0) + \alpha_2 \ln (P_b / P_0) + \alpha_3 \ln (P_n / P_0) + \alpha_4 \ln (Y / P_0) + \alpha_5 \text{Trend} + \varepsilon(2)$$

The measurement results are as shown in Table 2. R2 is 0.996 and DW value is 1.831 (the closer it is to 2, the better), and the model has high explanatory power and good results are obtained. The following four points can be mentioned from this result. First, the self-price elasticity of rice is negative and significant, so rice demand is elastic with respect to price. As the price of rice falls, the quantity of rice purchased may increase. Secondly, the elasticity of consumer spending is negative and significant, indicating that rice is an inferior good as a whole. Thirdly, the cross-price elasticities of bread and noodle were not significant, respectively. Regarding bread and noodles, it cannot be said that their price changes have not influenced changes in the amount of rice purchased, and it can be said that they are not substitutes for rice. Fourthly, the sign of the coefficient of the trend term was negative and significant. Rice purchase volume is declining as a trend.

Table 2: Result of measurement of rice demand function

	Coefficient	t-value	
Rice price: $\ln (P_r / P_0)$	-0.219	-3.760	***
Bread price: $\ln (P_b / P_0)$	-0.184	-1.460	
Noodles price: $\ln (P_n / P_0)$	-0.007	-0.100	
Annual consumption expenditure per capita: $\ln (Y / P_0)$	-0.418	-5.740	***
Trend term: <i>Trend</i>	-0.019	-16.740	***
Constant	10.102	15.040	***
rho	0.548		
R2	0.996		
DW value	1.831		

3.2 Questionnaire survey analysis

A web-based questionnaire survey was conducted to clarify the conditions for the increase in rice consumption and consumers’ preferences for rice policy. The investigation was outsourced to Cross Marketing Co., Ltd., and conducted from September 8th to September 9th, 2020 after designing the original questionnaire. Samples in the survey are collected based on their ratio to the census in sex, age (7 categories from 18 to 79 years old), and place of residence (Hokkaido/Tohoku, Kanto, Koshinetsu, Tokai, Kinki, Chugoku, Shikoku, Kyushu/Okinawa). The number of collected samples is 1,805. In the following, 1,387 samples were used in SEM analysis, excluding 418 samples who answered “I do not know/do not want to answer” when asked about income.

As a variable preparation used in the analysis, principal component analysis was performed for the answers to the question regarding rice consumption motives (reasons for eating rice and related products as staple foods) (Table 3). The cumulative contribution ratio up to the second main component is 45.4%, which is generally a good result. Since the score of the first principal component is positive in all items, it can be interpreted as diversity-oriented (high-low). The second principal component can be interpreted as functionality-oriented (high-low) because positive and the large items

of the score are “because it is delicious,” “because it is easy to store,” and “easy to eat,” while the negative and large items of the score are “because I want to save time for cooking and tidying up,” “because it is a request of my family/cohabitants,” and “because it is cheap.” For the variable of rice consumption motive, the score of each principal component was used.

Table 3: Results of PCA about motives for rice consumption

	1st component	2nd component
Because it is delicious	0.22	0.52
Because it is a request of my family / cohabitants	0.23	-0.40
Because it is cheap	0.29	-0.38
Because it has a lot of eating way	0.48	0.03
Because I want to save time for cooking and tidying up	0.34	-0.54
Easy to eat	0.49	0.25
Because it is easy to store	0.48	0.27
Cumulative contribution ratio	29.0%	45.4%
Interpretation of components	Diversity oriented (high-low)	Functionality-oriented (high-low)

Here, we use Structural Equation Modeling (SEM or covariance structure analysis) to identify the relationship between consumers’ preferences, constraints, and purchasing behavior for clarifying the process of formation of the needs for rice, and their influence on consumers’ preferences for rice policy. Fig. 5 shows the framework of covariance structure analysis, and Table 4 shows a list of explanatory variables and descriptive statistics.

It is assumed that consumer attributes (social economic attributes) and consumption motives influence consumers’ independence (consumer’s innovation orientation, self-determination of rice purchase), and conditions for rice demand (conditions for increasing rice consumption) are affected by consumer’s independence. Furthermore, consumers’ independence and the conditions for rice demand also influence their policy preferences. However, socio-economic attributes such as sex, age, and income are set as control variables in the research.

Regarding consumers’ preferences for rice policy, three potential variables are assumed as: protection policy (production adjustment, customs duty), innovation policy (scale expansion, new technology, new usage method of rice) and sustainability policy (environmental conservation, communication between producers and consumers, human resource development of manger). Demand conditions for increasing consumption (excluding “do not increase”) are classified into two latent variables: the explicit needs (price, taste) and the implicit needs (information, environment, packaging, safety, health, variety).

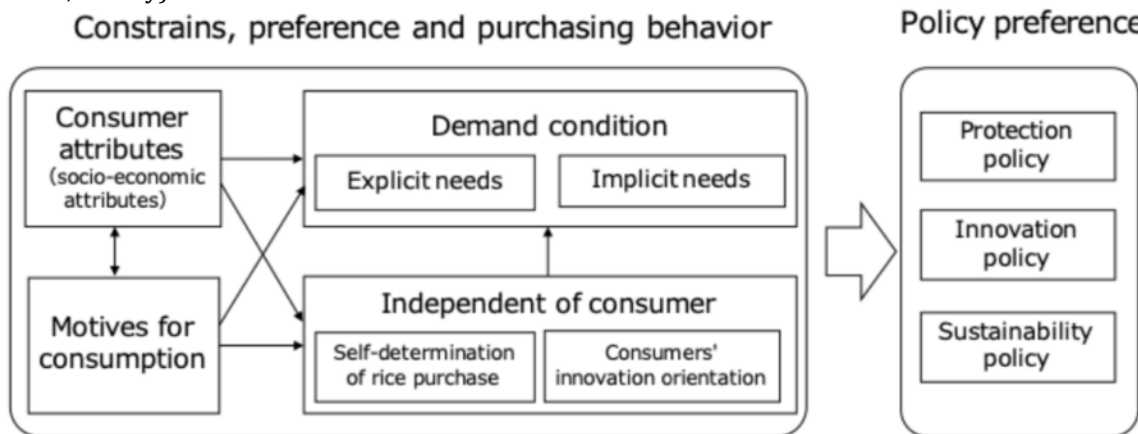

Figure 5: Framework of SEM analysis

Table 4: Explanation and descriptive statistics of variables

Components of Variable	Name of variables	Explanation	Mean	Minimum	Maximum
Socio-economic attributes	Sex	Female: 0, Male: 1	0.51	0	1
	Age	18-19 years old: 1, 20s: 2, 30s: 3, 40s: 4, 50s: 5, 60s: 6, 70s: 1	4.51	1	7
	Income	0 to less than 3 million yen: 1, 3 to less than 5 million yen: 25 to less than 7 million yen: 3, 7 to less than 10 million yen: 40 to 10 million yen or more: 5	2.62	1	5
Motive for consumption	Diversity-oriented	Score of 1st principal component (Reason for eating rice and rice-related products as staple food)	0.65	0	2.53
	Functionality-oriented	Score of 2nd principal component	0.45	-0.94	1.07
Consumers' innovation orientation	Innovation	I don't like it at all: 1, I don't like it very much: 2, Neither: 3, I like it a little: 4, I like it very much: 5	3.01	1	5
Self-determination of rice purchase	Decision	I don't think so: 1, I don't think so much: 2, I can't say either: 3, I think so a little: 4, I think so: 5	3.59	1	5
Conditions for increasing rice consumption	Price	Condition: Price range goes down (not applicable: 0, applicable: 1)	0.39	0	1
	Taste	Condition: Tastes better (not applicable: 0, applicable: 1)	0.38	0	1
	Information	Condition: Information on production method is clarified (not applicable: 0, applicable: 1)	0.09	0	1
	Environment	Condition: Environmentally friendly (not applicable: 0, applicable: 1)	0.10	0	1
	Package	Condition: Packaging etc. becomes attractive (Not applicable: 0, Applicable: 1)	0.03	0	1
	Safety	Condition: Higher safety (not applicable: 0, applicable: 1)	0.16	0	1
	Health	Condition: Good for health (Not applicable: 0, Applicable: 1)	0.28	0	1
	Diversity	Condition: You can eat in diversified ways (not applicable: 0, applicable: 1)	0.15	0	1
Not increase	No more increase (not applicable: 0, applicable: 1)	0.27	0	1	
Policy preference	Production adjustment	Policy to adjust productions to keep prices high (Not good at all: 1, not very good: 2, neither: 3, a little good: 4, very good: 5) Same below	2.83	1	5
	Customs duty	Policy to impose tariffs on imported rice	3.34	1	5
	Scale expansion	Policy to encourage scale-up to reduce costs	3.53	1	5
	New technology	Policy to encourage the introduction of new technologies (ICT, etc.) to improve efficiency and stabilize quality	3.76	1	5
	New utilization	Policy to promote rice production for new utilization method (rice flour, etc.)	3.71	1	5
	Environmental conservation	Policy to encourage the introduction of environmentally friendly production methods (organic farming, etc.)	3.80	1	5
	Interaction	Policy to encourage interaction between producers and consumers	3.59	1	5
	Development of manager	Policy to promote the human resource development of managers for rice farms	3.86	1	5

Figure 6 and Table 5 summarize the path diagram and the estimated coefficients of the results. The model fit is relatively good (CFI = 0.766, RMSEA = 0.079). The results clarified that consumers' innovation orientation and self-determination of rice purchases influence each condition for increasing rice consumption, and these conditions affect consumers' preference for rice policy. Socio-economic attributes used as control variables here (sex, age, income) and rice consumption motives (especially diversity-oriented) also influence these processes to some extent. The following important points are obtained from the estimation results.

First, there are few answered that they will not increase rice consumption any further among consumers who are highly innovation-oriented and highly self-determined in purchasing rice. This means that consumers who are particular about rice and are innovation-oriented can increase the consumption of rice if some conditions are met. Second, consumers with explicit and implicit needs for rice prefer sustainability and innovation policies, and innovative consumers particularly prefer innovation policies. Therefore, Hypothesis 1 "Innovation can stimulate consumers' demand for rice" is supported.

3.3 Cognitive map analysis

In the next, we will analyze the data of free-form questions in the items of the questionnaire survey (see Appendix 2). Specifically, the cognitive structure of consumers is visualized using co-occurrence network analysis (3-5 keywords are given by each respondent to the questions about <what is required for Japanese rice> and <what is required for Japanese

rice cultivation and agriculture / rural areas>. The co-occurrence network is a diagram in which the relationships of words appearing in common (co-occurrence relationships) are displayed by circles and lines. It is thought to be effective to analyze the co-occurrence relationships of the keywords obtained from the free association method to structure the potential factors and concepts. The software of KH Coder (Higuchi 2014) was used in this research, and 1,805 samples were used for the analysis. A data cleaning was conducted in the analysis, such as the unification of notation fluctuations (conversion of hiragana into kanji), the designation of forced extraction of words ("local production for local consumption," "new rice," "pre-washed rice"), the designation of unused words ("none," "nothing in particular" and "I can't think of anything").

From the results of the analysis, the consumers' cognitive structure regarding <what is required for Japanese rice> can be classified into four factors (Fig. 7-a): (1) economic efficiency (competitiveness), (2) environmental conservation, (3) sociality (safety/security, health), and (4) diversity. In addition, the consumers' cognitive structure regarding <what is required for rice cultivation, agriculture and rural areas in Japan> It can be organized according to the four elements of (Fig. 7-b): (1) economic efficiency (competitiveness), (2) environmental conservation, (3) sociality (safety and security) , and (4) the attractiveness of rural areas. Taken together, these supported our hypothesis (H2) that "Consumers require a strategy to induce an innovation in the rice industry that contributes to the sustainable development of agriculture and rural areas".

Furthermore, Fig. 8 shows the policy proposals for inducing innovation based on the 'backcasting' thinking. The goal of policies is set as 'sustainable agricultural and rural development', and the four long-term objectives are set as: 'competitiveness', 'efficient use of resources/environmental conservation', 'quality improvement of food market' (sociality/diversity), and 'formation of local attractiveness'. These long-term objectives are also closely linked to medium-term targets such as 'cost reduction', 'quality improvement/stability', 'market diversification', 'human resources development', and 'regional resource development'. In other words, it is important to embody each element in the actions when devising rice policy such as identifying the implicit needs of consumers and residents, cultivating entrepreneurs and managers, reviewing the direction of R&D, and trust formation through cooperation among stakeholders.

Figure 7-a: Co-occurrence network analysis about <What is required for Japanese rice>

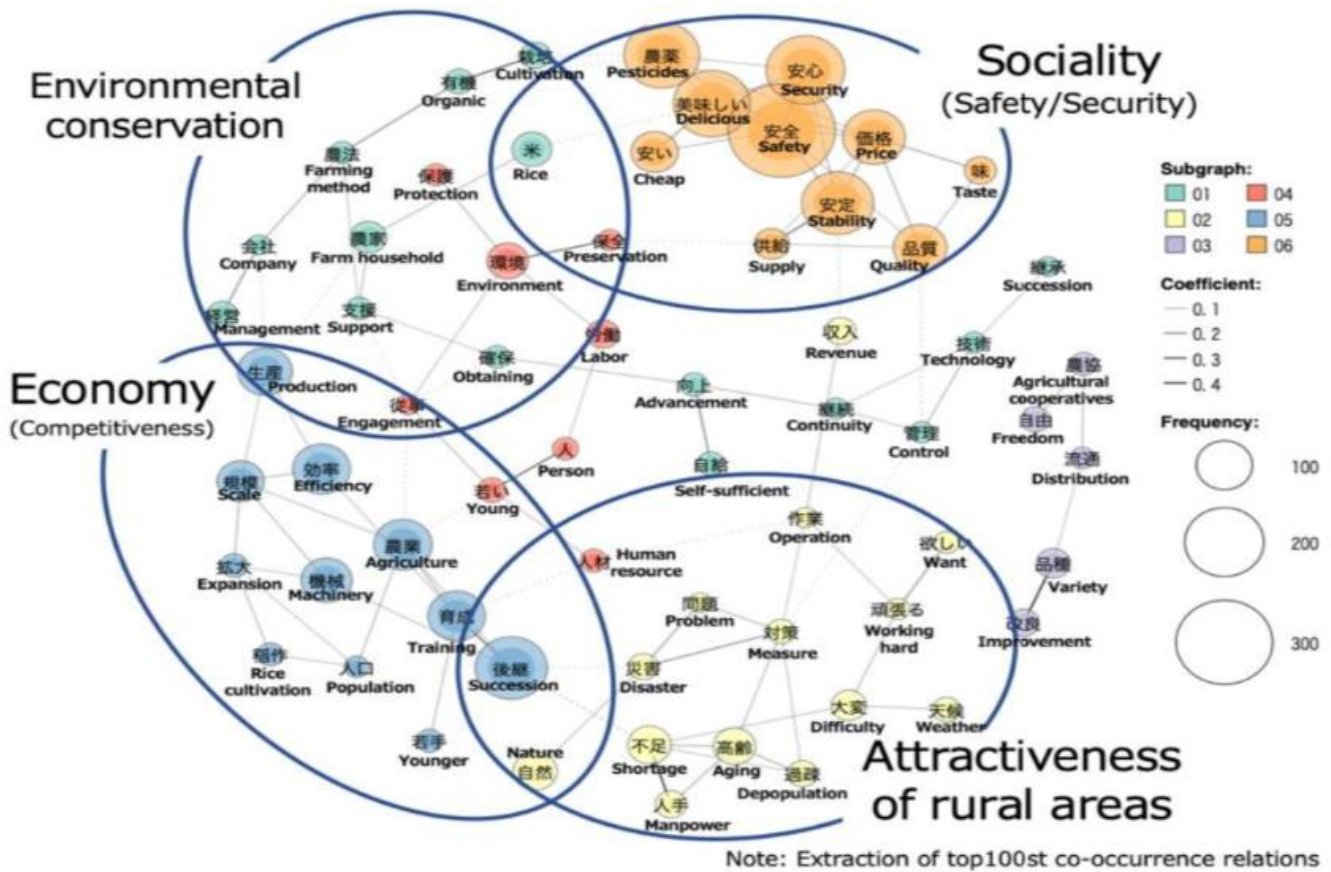

Figure 7-b: Co-occurrence network analysis about <What is required for rice cultivation, agriculture and rural areas in Japan >

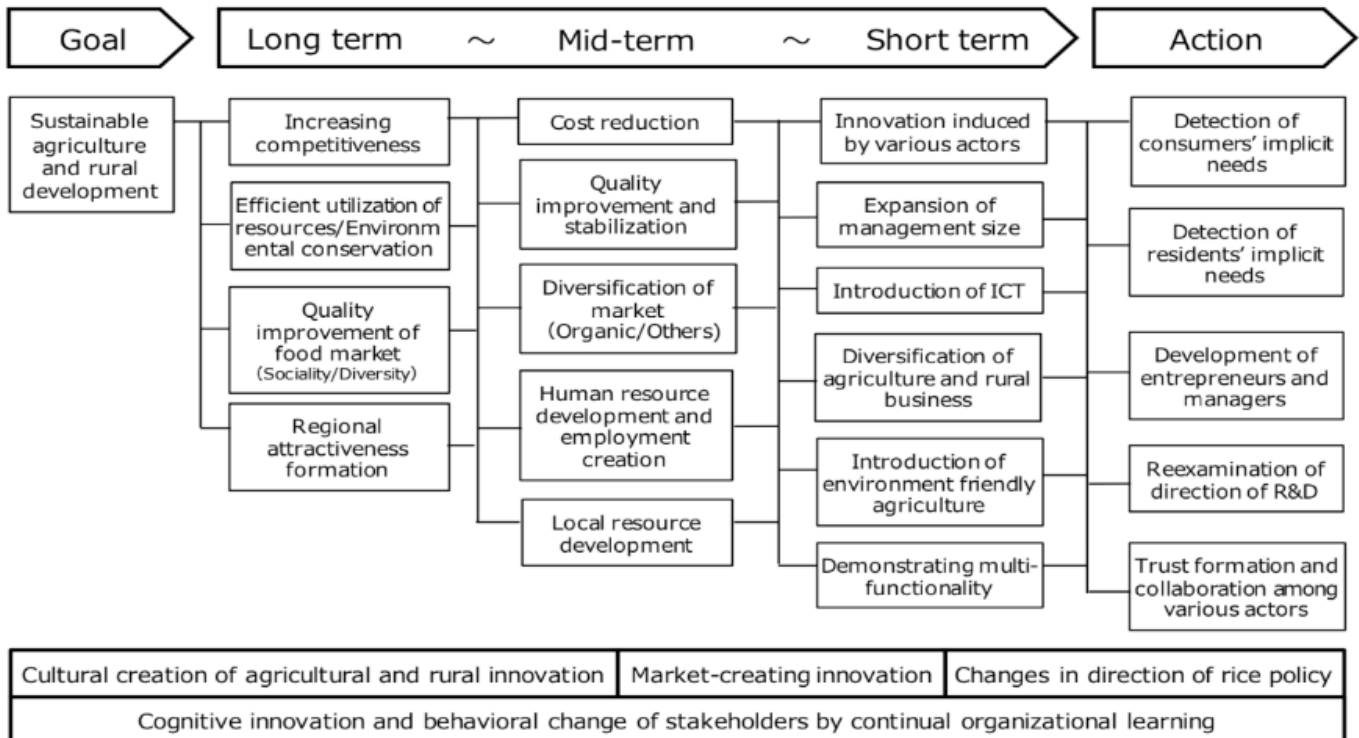

Figure 8: Policy proposals about rice policy for inducing innovation

4. CONCLUSIONS AND POLICY IMPLICATIONS

This study draws the following conclusions based on the above analytical results. First, if the innovation that meets the potential needs of consumers occurs, it may increase rice consumption, and the demand conditions for market-creating innovation in the Japanese rice industry are in place. This means that innovation-oriented policies or strategies to change

their cultural beliefs (common prior expectations as mutual knowledge of social, economic and technical characteristics) for rice industry, agriculture and rural areas are expected by consumers.

Suppose, in the Japanese rice market so far, the head part is small and the tail part is not a long tail but a short one (Fig. 9-a). There are products in the volume zone that meet the actual needs such as deliciousness, savings, and brands, but they are not satisfied enough. In addition, the short tail part is the current niche market, which consists of implicit needs (health, safety, environment) and value-oriented (usage/experience) areas. It might be possible to develop the market by expanding the head and creating a long tail through the strategy of market-creating innovation (Fig. 9-b). In the long tail part, innovative consumers will play a central role in creating shared value and inheriting rice culture in addition to the values in use and experience, through communication with other stakeholders by discovering new types of rice products and new ways of rice eating. To that end, in addition to the market expansion related to actual needs, innovation policy for rice industry emphasizing on implicit needs such as health, safety, and the environment is important. Furthermore, attention to the viewpoint of consistency between individual element of targets and objectives related to sustainability, and the exertion of synergistic effects is also important in the innovation strategy.

ABSTRACT

Generally, social enterprises are facing with a trade-off between economic efficiency and sociality so called “duality” or “dual mission” problem. One of the management strategies to solve duality problems is considered to enlarge the effectiveness of the business, while complementing management resources through the formation of cooperative networks with external organizations.

The purpose of this study is to clarify the mechanism of social innovation induced by inter-organizational network of social enterprises in Japan. First, the analytical framework and hypotheses are set based on the selective literature review of existing studies on social enterprise theory and organizational network theory. Second, structural equation model (SEM) is applied to the piece vote data at organizational level in two prefectures of the “Social Business Network Survey (2010 METI Regional Revitalization Countermeasure Survey)”. Third, case studies are applied for the advanced intermediate organizations in the two prefectures to verify the hypotheses.

Based on the analytical results, the following three hypotheses are verified: the organizational attributes and business areas of social enterprises influence the formation of inter-organizational networks (Hypothesis 1), diversity and collaborative network formation promotes empathy with related entities and cooperation with social enterprises (Hypothesis 2), and intermediate organizations affect the structure and function of network and promote the induction of social innovation (Hypothesis 3). In other words, the formation of inter-organizational networks of social enterprises promotes the induction of social innovation through changes in the collective cognition of the region. Therefore, policy implication drawn from this research suggests enhancing the diversity and collaboration of social enterprise networks in order to promote sustainable regional development through the resolution of regional social issues.

KEYWORDS

Social enterprise, Effect of network, Analysis at organizational level, Japan

1. INTRODUCTION

According to a survey by the Cabinet Office of Japan (2015), the number of social enterprises in Japan has reached 205,000, its value added is 16.0 trillion yen (3.3% of the total economy), and the number of its paid employees is 5,776,000(13.2%). In general, social enterprises face a trade-off between economy and sociality (called the “duality” or “dual mission” management problem). In order to solve these duality problems, social enterprises can enhance the effectiveness of their businesses while supplementing the management resources such as human resources, knowledge / information, and funds through the formation of a collaborative network with external organizations. However, most of the research on the influence of network formation in social enterprises is to grasp the actual situation by a qualitative approach, and research by a quantitative approach has not progressed.

Therefore, this study clarifies the mechanism by which network formation between organizations in social enterprises induces social innovation in Japan. First, we will set an analytical framework and hypotheses based on selective literature review on social enterprise studies and organizational network theory. Second, we will verify hypotheses through applying SEM (Structural Equation Modelling) by using a piece vote data of the “Social Business Network Survey (2010 Ministry of Economy, Trade and Industry Regional Revitalization Measures Survey)”, and also analyzing the advanced intermediate organizations. Finally, based on the above analytical results, we will derive policy implications for sustainable regional development through the development of social enterprises.

2. LITERATURE REVIEW AND HYPOTHESIS SETTING

2.1 Previous research on social enterprises and inter-organizational networks

Kaneko (2013) stated that the development phase of social entrepreneurship in Japan can be classified into three periods from the beginning of the 20th century to the half of 1970s, from 1975 to 2000, and after the 2000s, and pointed out that recent development reflects a strong market orientation and innovation approach in addition to sociality. However, many social enterprises face economic problems such as financial management (Larrata et al. 2011). For example, the Ministry of Economy, Trade and Industry(METI) (2008) has clarified the issues faced by social enterprises: (1) lack of PR to consumers and users, (2) securing of working capital, and (3) unestablished operating system due to lack of human

resources. On the other hand, Suzuki (2009) has identified methods for improving profitability such as (1) improvement of customer value, (2) cheap procurement of management resources, and (3) expansion of business domain.

Regarding the quantitative analysis of social enterprises⁴, Hoogendoorn et al. (2010) reviewed 31 empirical analyses and pointed out that there are three shortages: (1) lack of robust hypothesis-testing analysis, and (2) lack of diversity in research design, and (3) analysis of a small sample size. On the other hand, Matsunaga (2012) clarified that social entrepreneurship and inter-organizational networks improve the management efficiency of social enterprises by using a probabilistic frontier model for Japanese social enterprises. However, it pointed out that there still analytical issues such as how to measure social entrepreneurship, the possibility of estimation bias due to under formulation, and the small sample size. Stevens et al. (2014) also found that, social missions are associated with interest in altruistic values, normative identities and social goals while economic missions are strongly associated with egoistic values, utilitarian identities, and interest in economic goals through a quantitative analysis of social enterprises in the United Kingdom. In addition, a trade-off between the level of social missions and that of economic missions was observed. Research on the measures to achieve both missions at a high level is called for.

In addition, Briggstock et al. (2010) clarified that diversity management especially with harmony and financing in social enterprises leads to organizational innovation and performance improvement through comparative analysis of cases. It also pointed out that network diversity is extremely important for small organizations usually having a low level of internal diversity. From the network with general companies, these small social enterprises can get the merit of searching for excellent practices, partners, human resources, funds, etc.

Although, exerting a collective impact through the formation of collaborative networks between organizations is important in order to induce social innovation (Kania and Kramer 2011)⁵, empirical quantitative analyses are scarce. On the other hand, the Cabinet Office of Japan (2016) proposes specific evaluation tools and describes the social impact as “social and environmental outcomes as a result of projects and activities, including short-term and long-term changes.” It also proposes to quantitatively and qualitatively grasp the outcomes, judge the value of the business and activities, and make improvements as necessary. Furthermore, in the evaluation of social impact, it is pointed out to be important to achieve the two objectives of (1) fulfilling accountability, (2) learning and improving (evaluation with wide participation and collaboration of stakeholders). Therefore, it can be said that it is effective to understand social innovation as a dynamic process that causes cognitive changes and further enhances the results of the innovation through social impact assessment together with the collaboration of various stakeholders⁶.

2.2 Hypothesis and analysis method

Based on the above literature review, this study sets the analytical framework and hypotheses shown in Figure 1. Hypothesis 1 is, “Organizational attributes / regional conditions and business domains (social issues) of social enterprises influence the formation of inter-organizational networks of social enterprises”. And, Hypothesis 2 is “Diversity of networks of social enterprises and formation of collaborative networks with related entities change the collective cognition of the region by promoting empathy and collaboration between actors”. Finally, Hypothesis 3 is, “The intermediate support organizations influence the structure and function of inter-organizational networks of social enterprises, and promote the induction of social innovation”. We assumed that the formation of inter-organizational networks of social enterprises promotes the induction of social innovation and contributes to the sustainable development of the region. In other words, in this research, the cyclic process of the three elements of social entrepreneurship, network formation and social impact and the self-reinforcement loop through the intermediate support organization is regarded as social innovation.

⁴ For example, Furuzawa et al. (2021) compare the factors affecting the innovativeness of start-ups between social enterprises and general enterprises in Japan by focusing on the entrepreneurial motives, management ability, management strategy internal labor management system and network.

⁵ Collective impact means that cross organizational activity belonging to multiple different actors work together to create impact by solving social issues. Kania and Kramer (2011) have the following five conditions: (1) Common Agenda, (2) Shared Measurement Systems, (3) Mutually Reinforcing Activities, (4) Continuous Communication and (5) Backbone Support Organizations.

⁶ There are various definitions of social innovation, but in this study, it is regarded as a process through cognitive changes due to organizational learning. See, for example, changes in mental models in systems thinking in Meadows (2008) and organizational learning theory in Senge (2006).

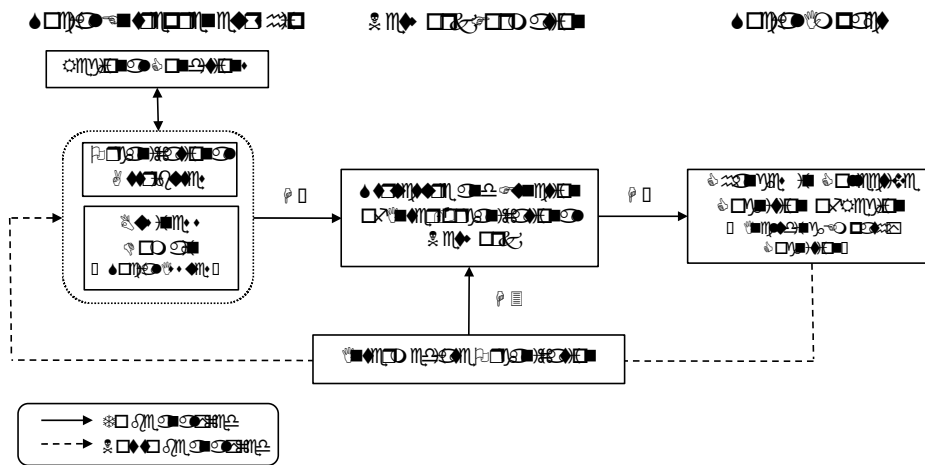

Figure 1: Analytical framework

The data used to verify Hypothesis 1 and Hypothesis 2 is a piece vote data of the “Social Business Network Survey” (2010 Ministry of Economy, Trade and Industry Regional Revitalization Measures Survey) conducted by the Ministry of Economy, Trade and Industry as an investigation entity. The survey areas are Aichi prefecture and Niigata prefecture (The investigation period was from November 2010 to January 2011).

The main reason for selecting the two regions is that they are advanced regions of social enterprises in Japan. The features of each are as follows. First, Aichi Prefecture formulated the “Community Business Support Guidelines” in 2006 and is the first in the country for support measures related to the social enterprises. On the other hand, in Niigata Prefecture, there is a need to foster social enterprises in the recovery process from disasters (Chuetsu earthquake, Chuetsu-oki earthquake, flood damage). In addition, the socio-economic situation (population density, aging rate, per capita prefectural income, number of NPO certified) is close to the regional average outside the metropolitan area.

This survey is characterized by (1) a participatory survey involving intermediate support organizations in the survey process, (2) surveying the scope and content of social business networks, and (3) disclosure of the survey process. In this survey, three conditions are specified as the scope of social enterprises⁷. The first is sociality, with the mission of coordinating with the community, utilizing local resources, and solving social issues, and supporting or being supported by the community. Secondly, it is business-oriented, has year-round activities and independent business income, and employs one or more paid employees on a full-time basis. Thirdly, it is innovativeness (developing a new business model that does not exist in the area of activity).

Furthermore, to verify Hypothesis 3, a qualitative analysis will be conducted on the cases of representative intermediate support organizations from the viewpoints of financial sustainability and social impact. The organization on female entrepreneurship in Aichi prefecture, and the organization on the support for community businesses for regional planning in Niigata prefecture are analyzed respectively. For the analysis, we mainly use the business reports and financial statements, information on websites. For the case of Niigata prefecture, the results of interview survey with a representative in the organization are also used.

2.3 Analytical regions

Table 1 summarizes the statistical indicators for the economic and social environment⁸ of Niigata and Aichi prefectures. For comparison, the average value of 47 prefectures is shown in the table. According to this table, compared to the prefectural average, it is low performance in Niigata prefecture in terms of demographics (high population decline rate, low birth rate, excess migration), opening / closing of business (low opening rate), human capital (low percentage of university / graduate school graduates), creative class (low percentage of professionals, engineers, and writers), and tolerance (low percentage of foreigners, high suicide rate).

On the other hand, Aichi prefecture has high performance in terms of demographics (high population growth rate, high total fertility rate, excess transference), economy (high per capita income), opening / closing (high opening rate), human capital (high percentage of university graduates and graduate school graduates), creative class (high percentage of engineers), and tolerance (high percentage of foreigners). However, there is a gender gap in both regions (the gender gap in regular salaries is large and the relative wages of female are low). In addition, the non-profit sector (number of certified NPO corporations per population) is below the prefectural average in both regions. Thus, Niigata prefecture relatively has many economic and social challenges.

⁷ In addition, in this survey, if either sociality or business feasibility is not met, it is not considered as SB, and the target is set (preparation of the primary list of survey targets). In the questionnaire that SB is explained that “businesses trying to solve social issues by utilizing business methods (community business, social business, etc.)”.

⁸ Furuzawa et al. (2020) analyzed the impact of creative class, tolerance and gender gap on the economic development of cities in major cities in Japan.

Table 1: Economic and social environment of the target area

Division	Indicator	Unit	年	Niigata Prefecture	Aichi Prefecture	Average of 47 Prefectures
Population	Total population	(person)	2015	2,304,264	7,483,128	2,704,144
	Ratio of population under 15	(%)		12.0	13.8	12.7
	Ratio of population aged 65 and over	(%)		29.9	23.8	28.3
Demographics	Rate of changes in population	(%)	2015	-0.68	0.26	-0.43
	Rate of natural increase and decrease	(%)		-0.52	0.02	-0.35
	Total fertility rate			1.44	1.57	1.53
	Im-migration rate (Japanese)	(%)		-0.29	0.11	-0.16
Urbanization	Population per habitable area	(person/km ²)	2015	508	2,505	1,358
Economy	Prefectural income per capita	(1,000yen/person)	2015	2,778	3,677	2,874
Industrial Structure	Primary industry	(%)	2015	1.6	0.4	1.7
	Secondary industry	(%)		29.5	42.3	29.7
	Tertiary industry	(%)		68.9	57.2	68.6
Entry/Exit	Entry (Opening) rate	(%)	2015	3.1	6.1	4.7
	Exit (Closing) rate	(%)		3.4	4.0	3.7
Human capital	University /graduate school graduates (ratio to population)	(%)	2010	8.8	14.7	11.8
Creative class	Professionals (ratio to workers)	(%)	2015	1.3	1.6	1.7
	engineer(")	(%)		6.8	8.6	7.9
	Writer / artist / entertainer (")	(%)		0.9	1.2	1.2
Gender gap	Gap of salary (25-29 years old)	(Female/Male)	2008	0.88	0.90	0.88
	Gap of salary (35-39 years old)	(Female/Male)		0.73	0.76	0.73
Tolerance	Ratio of foreigners	(per 100,000)	2015	502	2,220	994
	Ratio of suicide	(per 100,000 people)		22.0	16.0	18.8
Non-profit sector	Number of certified NPO	(per 100,000)	2015	30.1	25.6	38.8

Note: Due to data restrictions, data for university and graduate school graduates are used in 2010, and the ratio of female average regular salary to male regular average salary is for 2008.

The opening rate and closing rate are secondary quotes from Fig. 1-2-10 of the Small and Medium Enterprise Agency "Part 1: Trends of Small and Medium Enterprises in 2016" and "White Paper on Small and Medium Enterprises in 2017".

https://www.chusho.meti.go.jp/pamflet/hakusyo/H29/h29/html/b1_2_1_2.html

The original material is the Ministry of Health, Labor and Welfare "2015 Employment Insurance Business Annual Report", which is defined as follows.

1. Entry (Opening) rate = Number of establishments newly established in employment relationship in the current year / Number of applicable establishments on average in the previous year x 100
2. Exit (Closed) rate = number of business establishments whose employment relationship disappeared in the current year / average number of business establishments in the previous year x 100
3. Applicable business establishments are business establishments that have an insurance relationship for labor insurance related to employment insurance (Article 5 of the Employment Insurance Law).

3. RESULT OF ANALYSIS

3.1 Covariance structure analysis

3.1.1 Data preparation and variable setting

In this study, 259 samples (78 in Niigata prefecture and 181 in Aichi prefecture), out of a total of 370 samples (115 in Niigata prefecture, 255 in Aichi prefecture) are used for the analysis because it can obtain information about the number of paid full-time employees, sales (previous year), ordinary income (previous year), business contents and importantly connected organization.

First, the principal component analysis was applied in order to make variables on the business domain (See Table 2). The cumulative contribution ratio up to the third principal component is about 38.0%. In the first principal component, the factor loading of "1. Insurance / medical / welfare", "2. Support for independence of persons with disabilities, the elderly, homeless, etc." and "3. Support for child-rearing" is positive and large. In the second principal component, the factor loading is positive and large in the order of "8. Safety and security", "7. Environment", and "9. Traffic". Finally, in the third principal component, the factor loading of "11. Industrial promotion", "10. Tourism", and "14. Support for other community business / social business" are positive and large. Thus, it can be interpreted that the first principal

component represents a welfare-oriented business domain, the second principal component represents an environment / safety-oriented business domain, and the third principal component represents a regional development-oriented business domain.

Table 2: Results of principal component analysis about business domains

	Ratio	1 st Component	2 nd Component	3 rd Component
1. Insurance / Medical / Welfare	37.5%	0.523	-0.053	0.086
2. Support for independence of persons with disabilities, the elderly, homeless, etc.	29.7%	0.468	-0.065	0.103
3. Support for child-rearing	18.9%	0.261	-0.084	-0.093
4. Education / Human resource development	25.5%	-0.195	-0.146	-0.452
5. Culture / Art / Entertainment	10.8%	-0.146	-0.367	-0.154
6. Sport	6.9%	-0.125	-0.207	-0.443
7. Environment	15.4%	-0.253	0.472	-0.190
8. Safety and security	9.7%	-0.102	0.595	0.097
9. Traffic	1.2%	0.048	0.277	0.135
10. Tourism	5.4%	-0.215	-0.321	0.412
11. Industrial promotion	7.3%	-0.237	-0.156	0.438
12. Regional revitalization and planning	44.8%	-0.377	-0.082	0.189
13. International exchange and cooperation	4.2%	-0.124	-0.010	-0.184
14. Support for other community business/social business	6.6%	-0.164	-0.006	0.233
Cumulative contribution ratio		16.9%	27.9%	38.0%
Interpretation of components		Welfare-orientation (high-low)	Environment& Safety-orientation (high-low)	Regional development-orientation (high-low)

Note: "Others" is excluded.

Next, the principal component analysis was applied to the response about the relationships with importantly connected organizations (See Table 3). The cumulative contribution ratio up to the second principal component is about 53.3%. In the first principal component, the factor loadings of all the related items are positive and have the same sign. As for the factor loadings of the second principal component, "2. Receiving the provision of opportunities to improve ourselves, such as learning places and consultations", "3. Receiving support about informational aspects such as bridging with the outside and providing know-how" and "1. having a collaborative relationship such as conducting a project together" are positive, while "7. Receiving financial supports such as subsidies, donations, and investments and loans", "6. Receiving physical support for goods and activity locations", and "5. Having a business relationship with suppliers, sales destinations, business outsourcing, etc." are negative. Thus, the first principal component can be interpreted as representing the level of network diversity(high-low), and the second principal component can be interpreted as representing the type of network (collaborative –economic).

Table 3: Results of principal component analysis on inter-organizational networks

	Ratio	1 st Component	2 nd Component
1. Having a collaborative relationship such as conducting a project together	54.1%	0.371	0.179
2. Receiving the provision of opportunities to improve ourselves, such as learning places and consultations	42.0%	0.422	0.425
3. Receiving support about informational aspects such as bridging with the outside and providing know-how	43.2%	0.470	0.375
4. Demonstrating specialized skills etc, and Receiving labor	19.6%	0.482	-0.086
5. Having a business relationship with suppliers, sales destinations, business outsourcing, etc	26.5%	0.191	-0.394
6. Receiving physical support for goods and activity locations	17.3%	0.336	-0.468
7. Receiving financial supports such as subsidies, donations, and investments and loans	16.7%	0.287	-0.514
Cumulative contribution ratio		33.2%	53.3%
Interpretation of components		Diversity of Network (high-low)	Type of Network (Collaboration-Economy)

Note: "8. Others" is excluded. For the analysis, "the number of selections of each relationship content from 1 to 7 / the number of organizations with important connections" was used.

The variable settings used for the covariance structure analysis (Structural Equation Modelling) are as shown in Table 4. Regional dummy variable (Niigata prefecture =1), and the number of full-time employees (paid) are used for regional attributes and organizational attributes respectively. For the variables of the business domains and the inter-organizational network, the scores of each principal component is calculated from the results in Tables 2 and 3. Finally, empathic cognition is taken up as an index showing changes in collective cognition in the region. Then, it is set that the

latent variable of empathic cognition is composed of two observed variables: the ratio of connected organizations that are recognized as social enterprises, and the ratio that strongly empathizes with them.

Table 4: Variable setting

	Variables	Content	Average	Minimum	Maximum
Regional conditions	Regionality (Niigata dummy)	0:Aichi Prefecture, 1:Niigata Prefecture	0.30	0.00	1.00
Organizational attributes	Full-time employee (person)	1:0~10, 2:11~30, 3:31~100	1.16	1.00	3.00
Business domain	Welfare-orientation (high-low)	Score of 1st component (Table 2)	0.05	-0.83	1.25
	Safety & Environment-orientation (high-low)	Score of 2nd component (Table 2)	-0.08	-0.77	1.07
	Regional development-orientation (high-low)	Score of 3rd component (Table 2)	0.01	-1.08	1.04
Inter-organizational network	Diversity of network (high-low)	Score of 1st component (Table 3)	0.83	0.00	2.56
	Type of network (collaboration-economy)	Score of 2nd component (Table 3)	0.15	-0.80	0.98
Empathy cognition: Latent variable	Social enterprise	0 to 1: Number of organizations recognized as social enterprises ÷ Number of organizations with important connections	0.29	0.00	1.00
	Empathy	0 to 1: I strongly sympathize with the efforts of the group ÷ Number of groups with important connections	0.43	0.00	1.00

3.1.2 Results of covariance structure analysis

Figure 2 and Table 5 summarize the path diagram and estimated coefficients of the results. The model fits well because the fitting indicators (CFI = 0.959, RMSEA = 0.039) shows good results. The following points can be seen from the results. For Hypothesis 1, the number of full-time employees has a negative and significant effect on network diversity. This can be interpreted that small scale social enterprises form an inter-organizational network because management resources are scarce. In addition, regionality (Niigata Prefecture dummy) has a negative and significant effect on the network type (collaborative-economic). As for the relationship between business domains and networks, the social enterprises of welfare-oriented and regional development-oriented have a positive and significant influence on the type of network. Furthermore, positive and significant correlations were observed between organizational size and welfare-orientation of business domain, between regionality (Niigata prefecture dummy) and regional development-orientation, and between welfare-orientation and regional development-orientation. On the other hand, negative and significant correlations were observed between regionality and welfare-orientation, and between welfare-orientation and safety & environment-orientation. Therefore, it can be said that the selection of business domains determines the type of inter-organizational network. From the above results, Hypothesis 1 “Organizational attributes / regional conditions and business domains (social issues) of social enterprises influence the formation of inter-organizational networks of social enterprises” was supported.

Next, with regard to Hypothesis 2, network diversity and network type (cooperative-economic type) have a positive and significant effect on empathic cognition. And a positive correlation is observed between the diversity and type of network. Therefore, it can be seen that the formation of inter-organizational networks of social enterprises promotes empathy and cooperation among social enterprises. Based on the above results, Hypothesis 2 “Diversity of networks of social enterprises and formation of collaborative networks change the collective cognition of the region by promoting empathy with related entities and cooperation with social enterprises” was supported.

Table 5: Results of covariance structure analysis

		Coefficient	p-value	
Diversity of network	Regionality (Niigata)	-0.045	0.480	
	Full-time employee	-0.124	0.073	*
	Welfare-orientation	-0.026	0.567	
	Safety & Environment-orientation	0.041	0.578	
	Regional development orientation	0.003	0.964	
Type of network:	Regionality (Niigata)	-0.083	0.073	*
Collaboration-Economy	Full-time employee	-0.035	0.490	
	Welfare-orientation	0.069	0.042	**
	Safety & Environment-orientation	-0.038	0.476	
	Regional development orientation	0.094	0.088	*

Empathy cognition	Diversity of network	0.205	0.000	***
	Type of network: Collaboration-Economy	0.148	0.004	***
Latent Variables				
Empathy cognition	Social Enterprise	1.000	Constraint	
	Empaphy	1.078	0.000	***
Covariance				
Diversity of network	Type of network: Collaboration-Economy	0.040	0.000	***
Regionality (Niigata)	Full-time employee	-0.017	0.148	
Regionality (Niigata)	Welfare-orientation	-0.093	0.000	***
Regionality (Niigata)	Safety & Environment-orientation	-0.003	0.808	
Regionality (Niigata)	Regional development orientation	0.022	0.040	**
Full-time employee	Welfare-orientation	0.060	0.000	***
Full-time employee	Safety & Environment-orientation	0.005	0.591	
Full-time employee	Regional development orientation	0.004	0.696	
Welfare-orientation	Safety & Environment-orientation	-0.025	0.091	*
Welfare-orientation	Regional development orientation	0.030	0.042	**
Safety & Environment-orientation	Regional development orientation	0.001	0.915	

Note: "*", "**", and "***" indicate that there is a statistically significant difference at 10%, 5%, and 1%, respectively.

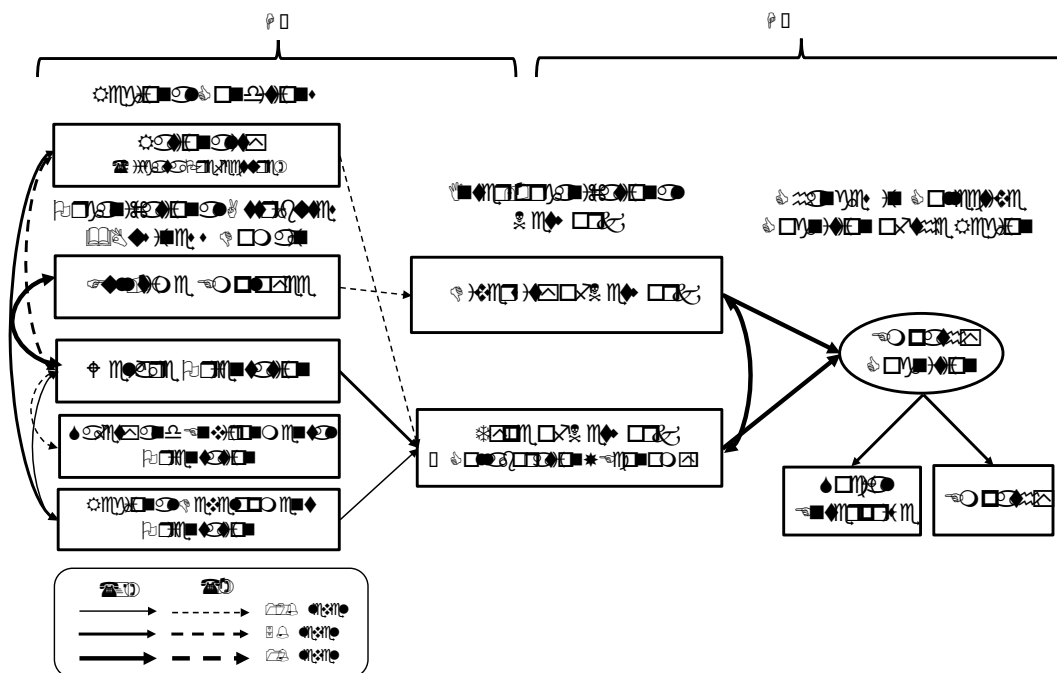

Figure 2: Path diagram of the impact of inter-organizational networks on social enterprises

3.2 Case analysis of intermediate support organizations

3.2.1 Case of Aichi Prefecture

“Entrepreneurship Support Net” was officially established in 1998, and specified non-profit in 1999 for the purpose of supporting female entrepreneurship. Its predecessor organization had been established in 1992 by the late Mieko Sekido who was a high school teacher and a director of the Meikin Co-op (Consumer Cooperatives). As for the number of members, there are 26 individual formal members, 11 organizational formal members, and 23 supporting members (as of the end of R2.5). Its main business is to support entrepreneurial activity matching one’s situation through entrepreneurship education, consultations, lectures and training, etc.

Regarding the financial aspect (Figure 3), it has secured certain scale of revenue and various sources of income. The total income is on the rise, reaching about 20 million yen in FY2019. The main breakdown of the income (FY2019) is commissioned business revenue (87.5%), business revenue (9.7%), membership fee (2.7%), and donation (0.1%). In addition, contract consultation and business support accounts for about 80% of business revenue. Looking at financial sustainability, the rate of return fluctuates significantly, but remains positive (about 5%) for the entire period (6 years). Moreover, the net property / income ratio and payable period are high and the financial aspect is stable.

Figure 3: Financial sustainability of Entrepreneurship Support Net

Next, regarding social impact, it is important in three points in the efforts of “School of Entrepreneurship”, as a main business (see Table 6). The first is to support the start-ups of small business and social enterprises mainly for people who have difficulty in achieving self-actualization in the current social structure. For example, it is emphasized in the purposes of the organization “For those who have a handicap in financial independence and self-actualization under the current social and economic structure, including female to start a job as another unemployed way of working (start-up), to carry out a business to disseminate the necessary knowledge for the purpose of ... to support self-actualization, and to contribute widely to the promotion of the interests of society as a whole” (extracted from the purpose of the articles). Secondly, the entrepreneurial business fields of graduates cover various fields such as food, child-rearing, disability support, community development, specialized skills, and elderly support. It also focuses on creating networks between graduate entrepreneurs, and also expanding their social impact by supporting the formation of collaborative and highly diverse networks. Thirdly, from 2004 to the present, the “School of Entrepreneurship” has been held for 16 terms (16 years) and continues to produce a large number of entrepreneurs. Therefore, it can be judged that social and environmental changes and collective cognitive changes in the region are brought about to some extent in the medium to long term.

Table 6: Social impact of “Entrepreneurship Support Net”

Item	Main initiatives
(1) Support for network formation (high collaboration & diversity)	Involvement of various actors in entrepreneurial schools and seminars Publication of PR magazine “Yale” Collaboration by contract management of consortium
(2) Promotion of social entrepreneurship	Opening and management of entrepreneurial schools (multiple areas in Aichi and Fukushima prefectures, online) Creating diverse entrepreneurial fields and networks for graduates
(3) Medium- to long-term long term social impact	Accumulation of activities by opening 16th term of entrepreneurial school Creation and dissemination of “Community Business Guidebook”

Source: made from the entrepreneurship support net website (<https://npo-kigyo.net/>) and annual business report.

3.2.2 Case of Niigata Prefecture

The “Tsukisara Partners Center (hereinafter referred to as TPC)” located in the Iwafune area of Niigata Prefecture, is the intermediate organization for the purpose to support community planning through community business development. It is an organization that has developed based on the support window for residential activity established in June 1999 based on the “New Plan for Hometown Creation in Niigata”, a regional revitalization project by Niigata Prefectural government. It became a specified non-profit organization in March 2002. Currently, there are 35 regular members and 76 supporting members (as of the end of June, 2020). Based on partnerships with residents, companies, and government, TPC supports social entrepreneurs and NPOs by promoting various coordination, planning, research, etc. in seven main business fields: supporting residents’ activities, community business support, community development coordination, support and development for product and market development, and regional tourism, information transmission and reception, and inspection acceptance.

TPC has supported 79 individuals and groups in about 7 years after the start of the business, and half of them have started new businesses (e.g. facility to experience and sell traditional textiles, cafeterias at closed schools, doburoku brewing, etc.). Because of its high reputation, it has received the Minister of Internal Affairs and Communications Award in 2007, Hometown Creation Grand Prize and Group Award in 2015, and Regional Revitalization Grand Prize in 2017.

Regarding the financial aspect (Figure 4), it secures the various sources of income and the stabilized revenues. The total incomes of the TPC fluctuated significantly in the 2000s, but stabilized in recent years. It reaches about 23 million yen in FY2019. The main breakdown of income (FY2019) is business revenue (98.2%), membership fee (1.6%), subsidy revenue (0.2%), etc. (for specified non-profit activities). The community development support (about 60%), and instructor dispatching/inspection acceptance (about 30%) account for 90% of business revenue. Looking at financial sustainability,

the average rate of return had been almost zero in the 2000s, but has become positive since the latter half of the 2010s. At the same time, the ratio of net assets to revenue also improved. It is considered that the accumulation of the management know-how has improved TPC's financial sustainability.

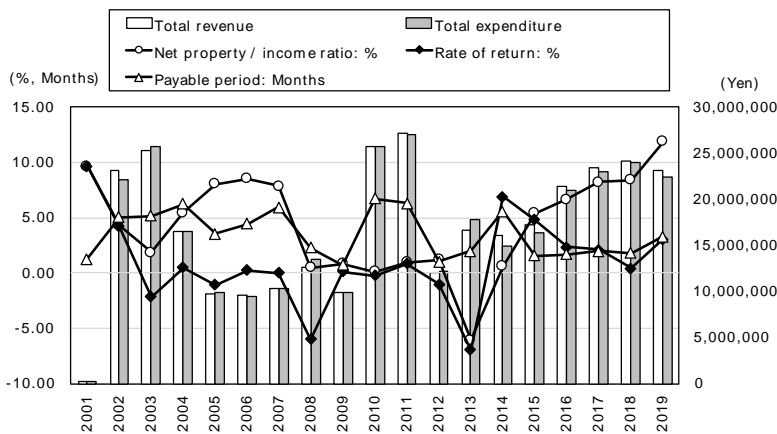

Figure 4: Financial sustainability of TPC

Next, regarding the social impact, there are three important points: supporting the formation of collaborative and diverse networks and promoting start-up of social enterprises, continual business development, and presenting development model of intermediate support organization. First, it constructed a model house in Kajimachi, Murakami city as a collaborative activity space of citizens by collaboration with Togashi Works Co., Ltd. There are a large number of citizen groups and organizations to use this space (The number of people is 1,723, the number of groups is 26, and the number of uses is 180 in 2019). Residents' collaboration is increasing through its continuously dispatching instructors, planning and managing the meetings for training and exchanging as well as conducting and analyzing residents' questionnaires. In addition, through collaboration with local companies it promoted the diversity of networks by developing products that make use of art created by disabled people. Second, by opening and operating a contact point for supporting residents' activities for more than 15 years, the active participation of young people of the next generation is increasing, and medium-to long-term social impact is being created. Third, TPC initially started as regional promotion project in Niigata Prefecture, but has reached the stage where it can develop its business independently through the accumulation of management performance and accumulation of know-how. The growth process of such an intermediate support organization is of great valuable in that it presents one of the development models that can be referred to in other regions in fostering social enterprises and promoting network formation under the initiative of the government in the initial stage.

Table 7: Social impact of TPC

Item	Main initiatives
(1) Support for network formation (high collaboration & diversity)	Cooperation for the management of town bases Community development coordination Sending and receiving information
(2) Promotion of social entrepreneurship	Support for residents' activities with community business at the center of community development
(3) Medium- to long-term long term social impact	Continuous support such as consultation, mediation, and information provision by residents' activities support desk (grassroots activities continued for 15 years or more) Creation and dissemination of "Tsukisara-ryu CB training technique" and "Book on collaboration book" Promotion of youth participation

Source: made from TPC's website (<https://www.tsukisara.org/>) and annual business report.

Finally, Table 8 summarizes the strengths and weaknesses of each network entity as seen by TPC, based on the results of interview survey (interview for secretariat was conducted in August, 2014). Due to the characteristics of TPC as an intermediate support organization, it has networks inside and outside the region, and has accumulated know-how on regional development. However, while it faces the issue of securing stable operating costs, which is a common issue for many NPOs (at the time of the interview survey).

Next, regarding the evaluation of the strengths and weaknesses of the connected network destinations, the local government is evaluated as having creditworthiness, the small and medium-sized private enterprises are evaluated as have a strong awareness of regional contribution, and the residents are evaluated as the cohesion within each region. On the other hand, the weaknesses are the vertical administrative system and lack of participation from the planning stage in the government, obstacles in awareness of cooperation with NPOs in private companies, and lack of cooperation between regions. Therefore, there is a possibility that social impact can be enlarged by improving the quality of networks with increased diversity and collaboration.

Table 8: Strengths and weaknesses of each network entity from the perspective of TPC

		Strength	Weakness
Self-evaluation on TPC		[Inside and Outside network of the region] [Community development know-how] There is both quantity and quality of information. The ability of connoisseurs has also been gradually cultivated. Initially, we asked a well-known expert to teach, but now we can choose with our own eyes.	[Lack of stably securing operating costs] It is necessary to deal with supporters and revenue sources separately, but donations are not collected well (members). [Problems with how the organization Works] There are things I want to do and things I should do, and it is difficult to balance the two.
Network	Local government	[Creditworthiness (inside and outside the region)] The Prefectural Regional Promotion Bureau has a budget. However, since the key person has changed in recent years, the impact of the change in the person in charge cannot be ignored.	[Vertical administrative system] There are many cases where TPC is more familiar due to lack of information sharing and collaboration between departments. I try to play a bridging role. [Lack of participation from the planning stage] In some cases, even the projects commissioned by the local government may be refused, and in that case, a counter-proposal will be presented. We are working to promote participation from the planning stage.
	Private enterprises	[Many SMEs have a strong awareness of regional contribution] Although they think about the area well and shows their understanding, it cannot expect too much from the financial aspect because their business environment is harsh.	[Obstacles in awareness of cooperation with with NPOs] In some cases, they feel guilty about making money in collaboration with NPOs. Since it is difficult to encourage companies to contribute to the local community in terms of CSR, we are promoting private-private partnerships based on the idea of CSV (creating shared value).
	Residents	[Good cohesion within each region] There is active participation when holding workshops. In rural villages, residents cooperate with the voice of the president and ward mayor.	[Lack of cooperation between regions with different temperaments] The temperament is completely different among the mountains, the sea, and the town. In the center, the consciousness of samurai and tradesmen still remains in the elderly generation, and the consciousness of rivals is strong even among the villages.
	NPO	[Exercise of incorporation (partial)] The number of incorporated NPOs is 12 to 13, which is small. This is also because there are few merits of incorporation and it is not recommended so much.	【Bipolarization】 Organizations with poor actual activities and organizations with poor activities are becoming more polarized.

3.2.3 Summary of case analysis

From the above, intermediate support organizations in both regions selected the business domain in line with the social issues of the region. And sustainable management is conducted through the accumulation of know-how and learning. And these intermediate support organizations contribute to increasing diversity and collaboration in the formation of networks between organizations. In addition, it promotes collective cognitive changes through organizational learning through fostering and collaborating with social enterprises as well as fostering empathy with related entities in the network. Therefore, “intermediate support organizations influence the structure and function of social entrepreneurship and inter-organizational networks of social enterprises, and promote the induction of social innovation (Hypothesis 3)” was supported.

4. CONCLUSIONS AND POLICY IMPLICATIONS

This study clarified the mechanism of social innovation through the analysis of inter-organizational networks of social enterprises. Specifically, through covariance structure analysis of inter-organizational networks of social enterprises, it is clarified that the organizational attributes and business domains of social enterprises influence the formation of inter-organizational networks (Hypothesis 1) and diverse and collaborative network formation promotes empathy with related entities and cooperation with social enterprises (Hypothesis 2). In addition, through the case studies of intermediate support organizations, it clarified that these organizations promote the induction of social innovation (Hypothesis 3) in the study regions. From this, it can be said that by appropriately designing the formation of inter-organizational networks of social enterprises, it is possible to promote the induction of social innovation as the exertion of social impact through changes in the collective cognition of the region. Therefore, in order to promote sustainable regional development through solving regional problems, policy that supports to enhance the formation of diverse and collaborative network is required.

However, to conduct research to evaluate the performance of social innovation in the region using the method of social impact assessment, and to analyze the impact of regional social institutions on the development of social entrepreneurship will be our future research agenda.

**ON THE WORKING IN BORDER THINKING TO DIGITALIAN FROM
“JIKOCHULIAN”:AN EMPIRICAL ANALYSIS IN “DIGITAL SOULFULLIAN”
ERA**

Kazuyoshi Hayama

JAPAN, Japan

ABSTRACT

This paper is about border thinking to digital thinking and analog thinking in “the DIGITAL SOULFULLIAN” era that means people who survive the predicament era about digitization.

In the wake of the Corona(COVID-19) disaster, which is already a year old (from the first wave to third wave or third silent wave means between third wave and next wave of the COVID-19), now, the use of ICT has been promoted in various aspects such as industry, medicine, and education. Japan is in the midst of a major change in social life with ICT technology. The significance of this paper is that Japan's social life is about to change drastically, and as a sustainable city, it is very significant for future digitized Japan to consider and analyze the turning point of innovative thought.

Digitization of information in all of its forms is one of the most developed things of the twentieth century. In Japan, Information as the business resource gets more important in addition to the conventional three business resources, human, goods, and money, trends. The era has begun when it is impossible to establish a business management strategy without an information strategy. The problems of "information literacy" and "digital divide" in the early days of information technology are the essence of relative disparities, and with the co-evolution of information and communication technology, business organizations, and business models, the boundaries of information disparities are advancing of information capabilities, it is important things. It has been fifteen years since the author has advocated the Novel theory “Information and Business Study” that the Information resource is as the core of four business resources since 2006. However, at least for this fifteen years, digital transformation is the biggest problem behind Japan's economy and companies, it still has not changed by leaps and bounds about digital in Japan. So in this paper discussed the question is Why hasn't this changed in the Japanese mind yet, whether we are now “ANALOGIAN” means pure analog thinking, “DIGITALIAN” means pure digital thinking or “JIKOCHULIAN” means the thought that both analog and digital information are important by interview survey and literature survey. This paper concluded that one person of United States appears to have DIGITALIAN thinking, but they are JIKOCHULIAN thinking in current Japanese citizen mind.

In the future, it is important to analyze other cases and when is the singularity from JIKOCHULIAN to DIGITALIAN, different of regional in the world, $\min.0 \geq A$ and $0 \geq B$, and $\max 1 \leq A, B$ and so on about after the third wave and third silent wave of COVID-19 on risk society by the General and Unification study perspective in the future.

REGIONAL INNOVATION POLICY FOR INNOVATION UPGRADING OF LOCAL SEMS

Hidegori Shigeno¹, Taisuke Matsuzaki¹, Yasushi Ueki², Masatsugu Tsuji¹

¹Kobe International University, Japan. ²IDE-JETRO, Japan

ABSTRACT

This paper addresses the following two new perspectives on the innovation ecosystem in a region; (i) focusing not only on innovation, but also on upgrading innovation; and (ii) empirically analyzing the effectiveness of local innovation policy aiming promotion of innovation in regional SMEs. This analysis attempts to identify how policy affects internal innovation capability which creates innovation. Thus, the **RQs** are summarized: RQ1: What are factors inside the firm to promote innovation upgrading?; RQ2: Whether and how local innovation policy is effective to innovation upgrading?

This study is based on a questionnaire survey to 1,324 SMEs conducted in 2014 in the *Hanshin* area, Japan. The stage of innovation upgrading was classified into four depending on whether technology used and market targeted are existing or new. This study defines the stages of upgrading as follows: Stage 1: Develop products with existing technologies for existing markets; Stage 2: Develop products with new technology for existing market; Stage 3: Develop products with existing technologies for new markets; Stage 4: Develop products using new technologies for new markets.

Since the outcome variable is defined as four categories, an ordered probit model was employed for empirical analysis. The explanatory variables consist of firm's characteristics such as the number of employments, R&D investment ratio to sales, and practicing open innovation, and factors promoting innovation contains sources of ideas, problem solving ability, HRD, business development strategies.

This study also analyzes the effect of six policies of Hyogo prefectural government for upgrading; 1) Hyogo Manufacturing Academy; 2) Hyogo Industrial Cooperation Coordinator Council; 3) Industrial location Support System; 4) Hyogo Prefecture COE Program Promotion Project; 5) Financing System for SMEs; and 6) Support SMEs via the Internet.

An ordered probit model obtained the following factors and questions were significant to upgrading: Sources of idea; Invented inside the firm based on market trends; Problem solving; Ask advice or conduct joint R&D to universities or public research institutions.; HRD; Provides higher jobs to workers and aims to elevate their potential; Business development strategy; Emphasizing areas utilizing experiences of technology and R&D.

For policy evaluation, two cross terms became significant, which are (i) "Hyogo Manufacturing Academy*Arrange the environment which provides higher jobs to workers and aims to elevate their potential" and (ii) "Hyogo Industrial Cooperation Coordinator Council*Arrange the environment which provides higher works to workers and aims to elevate their potential." Thus, the policies enhance upgrading via the HRD of SMEs.

The Hyogo Manufacturing Academy has training courses to nurture workers of the next generation by succession of technical skills. SMEs also stress on HRD which includes various schemes combining OJT and OFFJT. The Academy provides OFFJT programs which are complimentary to the HRD schemes inside SMEs. This is a reason why the Academy plays an important role.

MACHINE LEARNING APPLICATION TO PREDICT FOREST FIRES IGNITION RISK IN THE MEDITERRANEAN REGION (NORTH-WEST MOROCCO)

Hicham Alaoui¹, Assali Fouad¹, Hicham Hajji²

¹Climatic and Forest Risk Management Center, Morocco. ²IAV, Morocco

ABSTRACT

This scientific paper explores the spatial predictability of forest fire ignitions in the mediterranean region (North- west of Morocco). The geographic information system was used to locate 704 forest fires recorded between 2002 and 2018. Using 20 human and biophysical variables, the building of dichotomous prediction model (Fire or No Fire) was developed using 3 classification models namely: the binary logistic regression, the random forest and XG-Boost. Data analysis provide relevant information to understand the human factors, climate, topography and vegetation type, affecting forest fire ignitions processes in the study area. A random sample of observations (60%) was used to build the model and external observations (40%) have been reserved for testing the ability of the model to predict forest fire ignitions. The explanatory variables included in the model, report on the impact of factors related to (1) human action represented by localities with high frequency of fires and accessibility (roads and trails), (2) topoclimatic, including, temperature, relative air humidity and slopes and (3) biological, namely the type of fuel, (pine and cork oak trees, Matorral, ...). The 3 types of machine learning models (binary logistic regression, random forest and XG Boost) have shown very interesting results in terms of forest fire predictability by correctly classifying an average of 85% of the sample reserved for the model training and data validation. The forest fire ignitions probability maps produced could operationally improve the alerts processes, the lookout posts positioning and the early intervention against fires by the units in charge of initial attacks.

AN ASSESSMENT OF DROUGHT VULNERABILITY AMONG HOUSEHOLDS WITH TEMPORARY MIGRANT MEMBERS AND HOUSEHOLDS WITHOUT TEMPORARY MIGRANT MEMBERS: A COMPARATIVE STUDY ACROSS DIFFERENT INCOME AND SOCIAL GROUPS IN RURAL INDIA

Badsha Sarkar

TERI School of Advanced Studies, India

ABSTRACT

In recent times, India is witnessing a significant growth in terms of both the vulnerability to climate change as well as the volume of seasonal migrants simultaneously. One of the several ways through which the climate change is supposed to impact India is the increasing frequency and intensity of droughts. India which to a large extent is dependent on the monsoonal precipitation pattern for recharging its vast drainage networks is also a country with a huge volume of workforce dependent directly on the rainfed agricultural system. A volume of field investigations has emerged which has shown a variety of migration behaviours among the different population groups, distinguished by their respective social and economic characteristics, under a given drought situation. At the same time there is also a debate between the narratives of migration as an adaptive strategy or a failure to adaptation during a given climatic hazard especially in the academic arena. Therefore, a policy choice between migration prevention and migration support under a drought situation needs to be properly backed by empirical evidences. These evidences are very small in size for the Indian population. In this direction, the present paper investigates the drought vulnerability among households with temporary migrant members and households without temporary migrant members in rural India across different income and social groups. Vulnerability is defined as a function of exposure, sensitivity and adaptive capacity following Intergovernmental Panel on Climate Change (IPCC) Assessment Reports. Household level sensitivity and adaptive capacity indicators are identified from India Human Development Survey 2011-12 (IHDS-2) which are merged with the district level drought exposure data collected by India Meteorological Department (IMD). Weights are assigned to the variables by principal component analysis and composite indexes are calculated for exposure, sensitivity, adaptive capacity and the overall drought vulnerability.

INTERDEPENDENCIES BETWEEN SPATIAL PLANNING AND THE MINING LAISSEZ-PASSER IN CITIES, THE CASE OF ECUADOR

[Karl Heinz Gaudry](#)^{1,2}, [Danilo Ibarra](#)¹, [Carla Carabajo](#)¹, [Katty Marin](#)¹

¹Instituto de Investigación Geológico y Energético (IIGE), Ecuador. ²Centre for International Migration and Development (CIM/GIZ), Germany

ABSTRACT

Addressing urban planning as shared-resource is tied with the 'tragedy of the commons'. Since UN-Habitat III, Ecuador has embraced the opportunity for urban sustainability. However, while the *right to the city* is constitutionally anchored since 2008, the integration of strategic sectoral plans and their spatial link remains unclear. Aiming at a better understanding on how sectoral plans, particularly mining, are spatially articulated to spatial planning instruments, we review the existing planning instruments as well as those from the mining sector. Next to the mining city of Zaruma, our desktop research combined with stakeholder and expert interviews, showed a vacuum in articulating sectoral planning with urban spatial planning instruments. Instead of interpreting wrong-will from the mining sector, we suggest further research on existing planning instruments that accommodate underground with surface land-use planning.

POPULATION CONCENTRATION, SOCIO-ECONOMIC DEVELOPMENT AND PERCEPTION OF CORRUPTION IN THE CAPITAL OF LATIN AMERICAN COUNTRIES

Suzana Quinet Bastos, João Frederico Martins Baêta Guimarães, Fabio Gama

Federal University of Juiz de Fora, Brazil

ABSTRACT

The relationship between population concentration in the capital of a nation, where the powers that govern it are located, and the socioeconomic development of the region, is an issue that involves a double assessment, since this population can affect the country's decision-making center both positively and negatively.

The main work that seeks to investigate the influence of population concentration in capital cities in socio-economic development and, mainly, in corruption, is by Campante and Do (2014), in which the authors seek to answer whether the isolation of the capitals of the American states contributes to less control over public authorities and, consequently, a higher level of corruption.

For the authors, isolated capitals are associated with less accountability. For this, they investigate two spheres of accountability, which are the role of the media and the electoral process. With respect to the media, they show that newspapers provide greater journalistic coverage with regard to state policy when the population is close to the capital, that is, the spatial distribution influences this issue. With less media scrutiny and less voter involvement, an isolated capital paves the way for a stronger role for money in shaping political outcomes.

In addition, for Campante and Do (2014) the low degree of accountability affects the final provision of public goods. This is because states with isolated capitals seem to obtain unsatisfactory results in terms of education, public welfare and health. Thus, low accountability, as a result of the isolation of the capital and, consequently, of corruption, impacts on the quality of governance.

And it is precisely this aspect that we intend to deal with in this work: how much does isolated capital allow corruption and affect the socioeconomic development of countries? In this context, we want to assess whether the location of the capital in a region with a high concentration of the population can be an indication of greater public control, that is, less corruption, greater human development and less inequality, and, consequently, greater socio-economic development. The region of analysis is Latin America and the data are for the years 2017 and 2018.

Analyzing the results, it was possible to notice variations in the correlation coefficients of the different socioeconomic development indicators with the population concentration in the countries' capital.

The issue of social inequality measured by the GINI index is the most distant in terms of the correlation of population concentration in the capital. The intermediate factor is the Human Development Index, which is weakly correlated with population concentration in the capital. Finally, the index of greatest significance is the corruption perception index. The results seem to indicate that the population concentrated in the same city as the policy makers, are subject to more significant scrutiny, and thus corruption tends to be milder.

URBAN STRUCTURE TO DETERMINE A EQUITABLE REGIONAL GROWTH TOWARDS HUMAN EQUITY: CASE STUDY IN CHÍA-BOGOTA, COLOMBIA

Vasco Barbosa¹, Monica Suárez², Jorge Cerdas³

¹University of La Sabana, Engineering Faculty, Colombia. ²Colombian School of Engineering Julio Garavito, Colombia.

³Geographic Engineering Department, University of Santiago de Chile, Chile

ABSTRACT

The evolution of land use occupancy at present in the different cities of the world is very high. Particularly, in developing countries, large cities are the main attractor centers of activities, therefore, the social component associated with this trend is very important. Thus, the constant modification of land uses, economic instability and environmental factors, as also social behaviour changes of big cities' inhabitants characterize the current urbanism. So the question arises how does the urban spatial structure and organization contribute to an inclusive and equitable socio-spatial evolution, considering the challenges of urban growth with climate change?

The case study is located on the northern limit of Bogotá's city, characterized by large volumes of mobility especially of a functional type (work-study-residence). Due to the rapid expansion of the peripheral areas in Global South, this research will help to understand and manage two urban areas that tend to come together in the future as an urban continuum. Therefore, the aim of this research is to define optimal locations and adequate urban growth areas, ensuring socio-spatial equity and mitigating impacts on climate change.

As a methodology, is proposed an analysis of urban morphology and an analysis of the (social) intensity on uses of activities and infrastructure, which allows characterizing the urban structure itself and identifying the appropriate mobility corridors for the implementation of new growth areas. The space syntax analysis is focused on the logic of urban space based on human behaviour (Hillier, B., 2005) which allows to know the connectivity, integration, choice and intelligibility parameters, to understand the global structure of the urban network (Ahmed et al, 2014; Liu et al, 2018). This method could be applied to other urban areas, however, some adjustments to the spatial context are necessary. The (social) intensity analysis of spatial structure, integrates the mobility flows and the social characteristics of the study area with environmental factors (Ericson et al, 2020). The main data to be used will be the urban mobility axes (vehicle and pedestrian) through transformation into axial maps, land uses and classification of the social strata based on plot structure of the urban space.

As a result (based on the relationship between urban structure and social infrastructure), they are expected to consider the degree of entropy and spatial asymmetry, as well as to determine the optimal urban growth areas and to fit the United Nations urban development goals. One of the main discussions should be the identification of social urban structure that could be helpful to public policy of land use planning, as a new finding. This public policy on a municipal scale, as an instrument is one of the most important in urban space and the results obtained can support the policy in a more equitable and adequate management when it is necessary to select or delimit new areas of urban growth. The study should conclude with evidence of suitable allocating urban expansion areas which will allow better efficiency of urban land as a limited resource.

OVERCOMING MARGINALITY: GRASSROOTS REDEFINITIONS OF URBAN FUTURES IN THE LATE SOCIALIST HAVANA

Oskar Lubiński

University of Warsaw, Poland

ABSTRACT

The aim of this paper is to explore competing and uncertain urban futures of Havana constituted through small grassroots initiatives and infrastructures, as well as large scale commercial-investments. Recent years have brought a proliferation of community projects that tend to be small grassroots initiatives aimed at helping marginalized communities and creating opportunities within the respective neighbourhoods for work, leisure and improving the quality of life.

On the basis of ethnographic fieldwork conducted in the course of 9 months between 2018 and 2020 I intend to answer the questions on how competing through grassroots initiatives and navigating the informal economies *habaneros* envision and create their futures. At that time I spoke to various community leaders and inhabitants of informal settlements regarding their everyday lives and opportunities, problems that the communities were facing etc. Rampant rise of inequalities and limited possibilities of accessing hard currency outside of the tourist economies forces many Cubans, especially younger ones to seek possibilities outside of Cuba and longing to emigrate in order to make a living. Others choose to work in the informal economies, also engaging in the illegal activities. This is where community projects come in with the intention of creating opportunities for other futures within Cuba.

The position of Havana as an economic, political, cultural and touristic hub of Cuba constitutes it as a city of contested futures. As a result of the need to readjust Cuban economy after the fall of its main trade partner, the Soviet Union, Havana has become a place of massive investments geared mostly towards improving tourist infrastructure. This shift along with nation-wide economic crisis led to massive migrations towards the Cuban capital that the neglected through decades urban infrastructure was not able to sustain, producing a rampant rise of informal housing, as well as informal economies, that were only reinforced by the dismantling of socialist economies in the 1990s.

At the same time, Havana is experiencing consequences of environmental decline with water reserves drying out, pollution of rivers, deforestation and rising amount of waste. Although the Cuban government was fast to jump on the bandwagon of environmental protection through actions of reforestation, promotion of alternative sources of energy, permaculture schemes etc. these discourses were not always put into practice. In many cases it is community projects and other non-state actors that fill the void created by the state and engage in urban gardening, environmental care and social help.

The paper takes a closer look about how such projects employ global and local discourses and practices of overcoming marginalization and fostering development into the broader ideological debate of defining socialist Cuba in a late socialist setting. This approach broadens the existing body of work that focused primarily on the emerging entrepreneurial markets by taking a closer look of construction of new "solidarities" and community work in the context of the absent state increasingly market-reliant Cuba.

THE AICOVID19 PANDEMIC VULNERABILITY INDEX FOR BRAZILIAN MUNICIPALITIES: A MACHINE LEARNING APPLICATION WITH GRADIENT BOOSTED TREE MODEL

Rogério Pereira¹, Erick Giovanni Sperandio Nascimento²

¹ State University of Bahia, Centro: Santo Antônio de Jesus, Brazil, ropereira@uneb.br; ² CIMATEC/ SENAI, Rio Vermelho: Salvador, Brazil, erick.sperandio@fieb.org.br

ABSTRACT

This study approaches the spatial distribution of the deaths of COVID-19 pandemic to valAIcovid-19 Pandemic Vulnerability Index for the Brazilian municipalities. We focus on COVID-19 deaths of March 01 to April 25, 2020, to build the index and the spatial probability distribution for deaths in the municipalities. We use artificial intelligence in a machine learning process, called the Gradient Boosted Tree method. The data was collected in the Health Ministry of Brazil and the results show that the coronavirus largely will affect the southeast, south, and Midwest, however, others hotspots will expect in a few regions.

KEYWORDS

Covid 19, Vulnerability Index, Machine Learning.

1. INTRODUCTION

The coronavirus surprised the world in 2020, reaping countless human lives, and driving a lot of researchers to forecast the deaths for many regions of the world. One method to predict some of the consequences of this sickness is the Pandemic Vulnerability Index because it permits the prediction of the spatial probability distribution of deaths. At the moment, this initiative innovates a lot because will be possible to calculate for the first time the index using the number of true deaths to COVID19.

Assuming this objective, we build the AICOVID19 Pandemic Vulnerability Index for Brazilian municipalities, adapted from DeCAPRIO (2020). First, we collect the aggregated coronavirus deaths for the period of March 20, to April 25, 2020, and next elaborate the Pandemic Vulnerability Index by one artificial intelligence, called to Gradient Boosted tree method. We collect some mortality risk variables of the illness, proxies of the wealth, and the health system in the cities (AHMAD et al (2020); AHMAD et al (2020a); and, DECAPRIO (2020)). We suppose that the structure of urban city's and the industrialization process may reflect the path of the coronavirus infection will occur. It shows us that when larger is the infrastructure, likely more infectiously will be the region.

This study is organized into four main sections. In section 2, we provide a survey of the multiple health forecasting models. Section 3 deals with the analysis of the Vulnerability Index, assuming the artificial intelligence recommendations. Section 4, shows the main results; and in the last section, we present the final remarks.

2. THE HEALTH FORECASTING MODELS

The health studies of pandemic outbreaks looking for a medical perspective to control given illnesses, and attention is giving to the containment measures, the diagnosis, the treatment of patients, and the development of vaccines. Ferguson et al. (2020) assume that the information required by public health experts comes from a wide variety of epidemic models, where estimate transition rates between exposed (S) infected (I) and recovered (R) or dead. Then, these transition rates depend on the disease's features and your transmission processes, and the containment measures. To Wynants et al. (2020), there are many ways to structure these models: Markov frameworks (Liu, 2020), simulation models (Ferguson et al., 2006; Halloran et al., 2008), artificial intelligence estimates (Ozturk et al., 2020), multivariate analysis (Xie et al., 2020), vulnerability indexes (DeCaprio et al., 2020) or meta-analysis (Wynants et al., 2018).

According to Maher (2020), Shinde et al. (2020), and DeCaprio, (2020), the health forecasting techniques consider assisting governments in designing better strategies to confront pandemics. The studies on health focused on big and slow-moving health outcomes such as infant mortality. Given that the COVID-19 presents a fast-moving, sudden shock in the health systems [GREER et al. (2021)], the forecasting will be more difficult and doesn't exist some past knowledge about this viral pandemic. However, the results of these studies are useful for multiple purposes like controlling the spread of COVID-19 locally, reducing the spread of COVID-19 for a specific region, deciding its impact, building the vulnerability index, and/or establishing a correlation between the environmental conditions (metrological conditions) [MAHER (2020)]. These surveys together represent the main ways for assessing the health impacts of pandemic outbreak [SHINDE et al. (2020); ZHOU F. et al (2020); and, WANG, T. et al. (2020)].

Maher (2020) argues that the interplay of social and health risk factors will be important when considering where to focus relief efforts. Because COVID-19 is a novel disease that has evolved into a pandemic, then we shall focus our analysis

on the component to better understand the distribution of hospitalization and mortality risk, analyzing the industries and geographical space. To Greer et al. (2021), by spring 2020, COVID-19 exposed gaps in public health systems and social policy structures in different countries. The NPIs and TTIS systems were the core of the successful efforts of governments to manage the pandemic⁹ 10.

Besides, Fekete (2009) assumes that the choice of variables to compound the vulnerability index needs some validation to find whether the Social Vulnerability Index without direct relation to disaster impact or hazard parameters is valid. Next, they indicate three advantages to use the validation when evaluating the social index of the pandemic. However, we believe that validation for the AICOVID19 pandemic vulnerability index seems difficult due the social-economic importance of the COVID19 outbreak deaths [ACHARYA and PORWAL (2020)]. Then, we assume that the pandemic vulnerability index appears more to the social economic costs to municipality returns at the same economic development background before the COVID19 deaths occurred.

These studies use features according to Acharya and Porwal (2020) in social, demographic, economic, health, and epidemiological aspects. They used a similar methodology developed by Flanagan, by the CDC to compute social vulnerability indices for each census tract in the USA. To both authors, Flanagan's social vulnerability index includes four domains: social-economic status (comprising income, poverty, employment, and education variables), household composition and disability (comprising age, single parenting, and disability variables), minority status and language (comprising race, ethnicity, and English language proficiency variables), and housing and transportation (comprising housing structure, crowding, and vehicle access variables). The authors remember that a similar methodology was also used by the Surgo Foundation to calculate their COVID-19 Community Vulnerability Index (CCVI). The objective here is the interpretation of the pandemic vulnerability index according to until Jun, 2021, COVID19 deaths. The graphic view shall be careful, looking for inconsistency.

Next, according to Maher (2020), approximately 80% of the US workforce has at least one health risk factor for the COVID-19, and approximately 11% of the US workforce is over 60 with at least one additional COVID-19 risk factor. Therefore, the hypothesis that better planning may also increase the return on investment for public policy seems to be the first best policy to follow, keeping essential businesses functioning in high-risk industries and preventing avoidable deaths from COVID-19 [SHINDE et al. (2020); ZHOU F. et al (2020); and, GREER et al. (2021)]. To Greer et al, (2021), countries that implemented swift responses such as robust testing and efficient contract tracing fared better in these first months of the pandemic.

On August 14, 2020, the pandemic resulted in 3,224,876 confirmed cases and 105,463 deaths in Brazil [GREER et al. (2021)]. The Global Health Security Index believe too that Brazil has a comfortable position in Latin America, been ranked with the best score between these countries (59.7 out of 100). However, Greer et al. (2021) affirmed yet that by the winter of 2020, the Infections were rising rapidly in the southernmost states and most regions of the center-west in the country, showing that Brazilian authority efforts to contain the virus to urban and other hotspots were failed.

3. METODOLOGY

The Gradient boosted tree models are a machine learning method that demonstrates fairly robust [MAHER (2020)]. The idea of boosting came out of the idea of a weak learner can be modified to become better, [BROWNLEE (2018)]. This author believes that the boosting hypothesis was the idea of filtering observations, leaving those observations that the weak learner can handle and focusing on developing new weak learns to handle the remaining difficult observations. To Brownlee (2018), the statistical framework cast boosting as a numerical optimization problem where the objective is to minimize the loss of the model.

Different authors assume that as possible to use the loss function of a mean squared error and the classification in the logarithmic loss form. The decision trees used to give us the output real values for splits and whose output can be added together allow subsequent model outputs to be added and next will be possible to correct the residuals of these predictions. These authors assume too that a gradient descent procedure can be used to minimize the loss when adding trees. To Brownlee (2018), gradient descent is used to minimize a set of parameters, where after calculating error or loss, the weights can be updated to minimize the next error term.

The Gradient Boosting method assumes to "teach" the model $\hat{y} = F(x)$ to minimize the mean square error (SME), $\frac{1}{n} \sum_i (\hat{y}_i - y_i)$, where "i" is the training set, and "n" is the number of observations. This method uses the function $F_m(x) = F_{m-1}(x) + \sum_{j=1}^m \gamma_{jm} 1R_{jm}(x)$ to permit the adjustment by adding the second term on the right side of the equation. Then, minimizing the mean square error (SME) imply that the algorithm solves $\gamma_{jm} = \underset{\gamma}{\operatorname{argmin}} \sum_{x_i \in R_{jm}} L(y_i, F_{m-1}(x_i) + \gamma)$. Therefore, we calculate the optimum, and removing the feature importance ranking.

9 Greer et al. (2021) assume that "NPIs are public health actions to slow or stop the spread of disease that do not involve vaccines or medicines; included hand washing, social distancing, travel restrictions, school closures, restrictions on businesses or closures of activity in places or sectors ("lockdowns"), mask mandates, and restrictions on working and socializing". To other hands, "the TTIS systems are a package of interventions: testing extensively (to find people with the virus), contract tracing (to find out whom they might have infected and from whom they caught it), isolation (keeping infected people away from the public and opportunities to infect others), and support (ensuring that infected people have what they need to isolate, e.g., income, food, support for dependents while their caregivers were in isolation, a secure place to live)".

10 The decisions about the official causes of death introduce discrepancies in the real data, which make it difficult to compare across contexts. Furthermore, "some metrics that are useful for epidemiological purposes have been misused during the pandemic", [GREER et al. (2021)].

We admit a proxy variable that assumes the municipality where occur deaths to coronavirus to be equal to one, $y = 1$, and 0, ever not occur deaths to the virus. Besides, we collect data containing 20 variables following DeCaprio (2020), Zhou et al (2020); Wang et al. (2020); Byhan and Fenichel (2020); and, Brownlee (2018). We use 10 % to the test sample, remaining 90% to the training sample. For the outliers' tests, we use the Z-count, removing 832 from the total of 5570 municipalities, which appear in color white in Figure 1. Next, the feature importance was calculated, for the test and training samples. Finally, we build the index of each municipality.

4. MAIN RESULTS

The AICOVID19 Pandemic Vulnerability Index uses the deaths and the number of cases of COVID19 registered adding up until April 25, 2020. All variables are presented in Table 1. The variables used follow Acharya and Porwal (2020). We use to the social-economic variables: the population proportion of firms in 2018; the per capita GDP in the year of 2019; the proportion of CNPJ registered firms in the year of 2018; the proportion of CEI registered firms in the year of 2018; the per capita taxes in the year of 2019; and, the proportion of CEApf registered firms in the year of 2018. To the Demographic variables, we choose: the population proportion of births in the year of 2019; the average of elderlies in Hospital Intensive Treatment in the year of 2019; and the average of black elderlies in Hospital Intensive Treatment in the year of 2019. To the Housing and hygiene conditions variables, we use only the population proportion of mothers with 15 years old 2019. For the Availability of a health care public hospitals variables, we adopt the Mortality rate of the year of 2019; the population proportion of General Hospitals in the year of 2018; the municipality population proportion of health professionals in the year of 2018; the population proportion of males death in hospitals in the year of 2019; the population proportion of health establishments in the year of 2018; and, the Mortality rate in hospitals in the year of 2019. Finally, the Epidemiological variables: the population proportion of COVID19 cases until April 2020; the population proportion of male deaths in the year of 2019; the municipality population proportion of COVID19 deaths in the year of 2020; and, the population proportion of individuals in Hospital Intensive Treatment in the year of 2019.

The feature importance ranking by the test and the training samples present in the Table 1 too. We observe that the share of new coronavirus cases is the first feature of ranking. Next, the features of the share of male deaths occurred in 2019, and the share of registered firms in 2018. If the locality produces spillover effects to the regional economy suggests that the COVID19 risk is high in this locality. The results point out that the strategies to the pandemic will be better evaluated by the regions where the productive activity presents. In these regions, the disease spread needs attention.

Table 1. Variables and Importance Ranking for the AICOVID19 Pandemic Vulnerability Index: test and training samples

Variables	Test	Training
# of COVID 2020 cases	0,87066425	1,58764069
# of 2019 male deaths	0,043044185	0,060209933
# of firms in 2018	0,038559674	0,069158036

5. SPATIAL DISTRIBUTION OF VULNERABILITY AND THE COVID-19 OUTBREAK

The interpretation of pandemic vulnerability index distribution and the comparisons with the COVID19 deaths shall be careful. The spatial distribution of the AICOVID Index on April 25, 2020, is on the right side of Figure 1. This vulnerability index represents the economic costs that the locality will assume to recover the economy to the levels before the pandemic outbreak. The municipalities that present a high vulnerability index will suffer more to return to economic patterns before the pandemic for each new dead the location will have.

In the right side of the Figure 1, we shows the spatial distribution of COVID-19 deaths occurs until Jun, 2021, this is, one year after the spatial distribution of AICOVID-19. The states with more deaths until Jun, 2021, are Rio de Janeiro, São Paulo, Minas Gerais, Rio Grande do Sul, and Paraná (Ministry of Health of Brazil, 2021).

Figure 1. The Spatial Distribution of AICOVID19 Pandemic Vulnerability Index (Apr 2020) and the Number of Deaths by COVID19 (Jun 2021) in Brazilian Municipalities

Source: IBGE Cidades, Ministério da Economia RAIS, and Secretaria Estadual de Saúde, Brazil, 2020. Elaborated by Author.

There are four possible outcomes when comparing the vulnerability index and the number of deaths from COVID-19 in Brazil, 2020. First, the municipality has a low vulnerability, and there are few deaths. In Figure 1, we can see many locations in the northern region (Amazonas, Pará, Acre, among others) and others in the Northeast of Brazil. The states that have most municipalities in the North region are Pará (144) and Amazonas (62). In 2019, the average per capita GDP ranged between 10.11 and 21.99, and the mortality rate ranged between 0.002 and 0.004 in this region. The proportion of deaths among men in 2019 ranged from 0 to 0.002. The registered firms in 2018 ranged from 0.001 to 0.018 among municipalities. Besides, the general hospitals' proportion ranged from 0 to 0.000001. We conclude that the region does not present high values for the features of vulnerability.

In the second result, the municipality is highly vulnerable, and there are few deaths. This group seems to be a successful case of policies to contain the disease outbreak. Analyzing Figure 1, we observe that this is the case of municipalities in some states in the Midwest of Brazil (Mato Grasso, Mato Grasso do Sul, more precisely). The states that have most municipalities in the Midwest region are Goiás (245) and Mato Grosso (224). In 2019, the average per capita GDP ranged between 17.8 and 81.12, and the mortality rate ranged between 0.00 and 0.002 in this region. The proportion of deaths among men in 2019 ranged from 0.0007 to 0.004. The registered firms in 2018 ranged from 0.014 to 0.029 among municipalities. Besides, the general hospitals' proportion ranged from 0.00001 to 0.0001. We conclude that the region presents high values for features of vulnerability.

In the third result, the city has a low vulnerability, and there are many deaths. This result is the case in many of the locations in Northeast Brazil. The states that have most municipalities in the Northeast region are Bahia (417) and Piauí (224). In 2019, the average per capita GDP ranged between 9.41 and 18.89, and the mortality rate ranged between 0.00 and 0.003 in this region. The proportion of deaths among men in 2019 ranged from 0.002 to 0.005. The registered firms in 2018 ranged from 0.003 to 0.008 among municipalities. Besides, the general hospitals' proportion ranged from 0.00001 to 0.00004. We conclude that the region does not present high values for features of vulnerability.

Finally in the fourth and alarming result, the municipality is highly vulnerable, and there are many deaths. This result is the worst of all and fully alarming. The cities in the Southeast and South regions are in this group. The high AICOVID19 vulnerability is related to the fact that this region is highly industrialized and shows high per capita income (See Table 1). The states that have most municipalities in the South and Southeast region are Minas Gerais (853) and São Paulo (645). In 2019, the average per capita GDP ranged between 18.08 and 34.418, and the mortality rate ranged between 0.00 and 0.004 in this region. The proportion of deaths among men in 2019 ranged from 0.000 to 0.007. The registered firms in 2018 ranged from 0.019 to 0.032 among municipalities. Besides, the general hospitals' proportion ranged from 0.000023 to 0.000061. We conclude that the region presents high values for features of vulnerability.

The actual moment is not favorable to Brazilians. We believe that the future seems worst, according to the results: the pandemic vulnerability, the high number of deaths, and the spatial distribution between the municipalities. In addition to the high number of COVID-19 deaths, we assume that the location of occurrences will affect the country's economic final result. The situation presented by the AICOVID19 pandemic vulnerability study indicates that the Brazilian policymakers will need to be more strategic, strengthening the supply chains most important in the regions where deaths by COVID19 will most affect the productive activities. Besides, the results presented by Coronavirus contamination process may be reversed with the economic growth, if the damage caused by the COVID19 deaths becomes smaller in addition to new policies focused on economically resilient supply chains.

5. FINAL REMARKS

The present study suggests predictions about the progress of coronavirus in Brazil during 2020 and the first months of 2021. We observe that the spatial distribution of COVID19 deaths is closing to the spatial distribution of the AICOVID19 Pandemic Vulnerability Index. We focus the importance of this discovery for the pandemic progress in the country.

The strong urban industrial activity characteristics will be more prone to COVID19. The impact on the workforce will be large as possible in these cities. To Maher et al. (2020) similar occur in the EUA where the results show that the highest risk is in the Midwest and the lowest in the Intermountain West and West Coast.

According to Greer (2021), governments put their entire economies into the equivalent of a medically induced coma. In Brazil, the most vulnerable COVID-19 workers are found in the biggest urban centers, where the essential jobs are. Besides, "vaccination campaigns had yet to start in most places in the world, and there was great uncertainty about when vaccine clinical trials would be complete and the vaccines would be authorized for use" [GREER et al. (2021)]. Moreover, without social policies to support lower-income and vulnerable populations, health policies to promote social distancing cannot be fully effective and are likely not sustainable long enough to end the epidemic in a country. This is pointed here in the AICOVID19 Pandemic Vulnerability Index to Brazil. We conclude for more attentive to the large industrial centers are the public policy managers fewer impacts of the pandemic in Brazil will be noted. This seems to be the main conclusion drawn in the AICOVID19 Pandemic Vulnerability Index.

CONNECTING SMART SPECIALIZATION, THE GREEN TRANSITION AND SOCIO-ECONOMIC RESILIENCE. AN EMPIRICAL TEST

[Cristina Maria Serbanica](#)

Constantin Brancoveanu University, Pitesti, Romania. The Bucharest University of Economic Studies, Romania

ABSTRACT

Smart specialization (RIS3) has been formally introduced as integral part of the 2014-2020 programming period of the European Cohesion policy to enable each European region prioritize investments in research, development and innovation and develop the its unique place-based competitive advantages. For the 2021-2027 programming period, the Cohesion Policy has the ambition to take the smart specialization strategies "one step further" and contribute to a "smarter Europe", through innovation, digitization, economic transformation and support to small and medium-sized businesses. Meanwhile, smart specialization is now expected to embark into a process of widening and support the ambitions of the new European Green Deal and the global Sustainable Development Goals. Sustainability appears at the top of the Smart specialization agendas, while the "smart directionality" towards the green transition is recognized as an overriding strategic priority. The Covid 19 pandemic adds an additional layer in the prioritization process and a new narrative for smart specialization at the EU level. The post-Covid RIS3 is now expected to support socio-economic recovery and resilience and to reduce vulnerability to shocks; "no places and no people should be left behind in the EU". Within this frame of reference, the purpose of this paper is to question how a region can better mix, in an integrated smart specialization strategy, the ambition to move towards innovation-driven productivity growth, green transition (environmental protection), stability and inclusiveness. This is particularly challenging for the lagging-behind regions, with less developed research and development systems, where the impact of innovation on growth is estimated to be much weaker that in the core regions. To illustrate the case, we use empirical evidence from Romania, a "modest innovator" according to the European Innovation Scoreboard, which faces serious environmental pressures and social challenges. On this account, we intersect a measure of economic and technological specialization and an index of environmental and social pressures. The index will capture at least the following indicators: energy use and air emissions intensities by NACE Rev. 2 activity, structural change in employment (2010 - 2020) and the resistance to Covid pandemic (i.e. change in the number of employees between December 2019 and December 2020). Our investigation is meant to enhance understanding on how to manage the trade-offs between different sustainability dimensions and create synergies between policy objectives.

ECONOMIC CRISIS AND NEW FIRM CREATION IN ROMANIA. INSIGHTS FROM STATIC AND DYNAMIC SPATIAL PANEL MODELS

Zizi Goschin^{1,2}, Mihai Antonia¹, Horia Țigău¹

¹Bucharest University of Economic Studies, Romania, zizi.goschin@csie.ase.ro; ²Institute of National Economy, Bucharest, Romania

ABSTRACT

Entrepreneurship has a key role in the transformation of Romanian economy and society, influencing economic development by putting innovative ideas to practice and creating new jobs, and by enriching the quality of life and human existence as well. Entrepreneurship dynamics depends upon a series of local and national economic factors, but is also affected by the international environment, like the current COVID - 19 pandemic. Statistic data show that new businesses are created at a slower rate during an economic crisis, when the economic climate is harsh and business opportunities scarce. Nevertheless, there are local differences in the reaction to crises, and new business formation tends to decline with variable intensity from one region to another, even in the same country.

The crises are acting like a trigger for some opportunity-driven entrepreneurs and resilient regions can thrive even in times of crisis or recover faster after the depression. Given the scarcity of regional statistical data regarding the economic effects of COVID-19 pandemic, we draw mainly from the lessons of the precedent major crisis, namely the 2007-2009 Great Recession, for assessing the likely economic effects of the current crisis on new firm births. We focus on the interval between 2007 and 2020, aiming to investigate the impact of economic crisis and the difficulties generated by COVID-19 pandemic to new business formation in Romania, and to determine if the response to crises is shaped by location. This research extends the empirical debate in Țigău and Antonia (2020) on the determinants of new business formation in Romania.

In order to capture spatial interactions, as well as spatial short- and long-term effects, the method employed in our analysis relies on the estimation of various static and dynamic panel models. We tested the potential impact of a large variety of social and economic indicators on new firm creation and found that the most consequential factors of influence are the employment rate, unemployment and education. Our results convey a powerful policy message for both national and regional decision-makers. We believe that, while putting to test the entrepreneurial initiative, the current crisis might act like a catalyst that leads to innovation and reshaping our economy and society.

THE IMPACT OF COVID 19 PANDEMIC ON HEIS – RESPONSE STRATEGIES FROM ROMANIAN UNIVERSITIES

Romana Emilia Cramarencu, Monica Burca Voicu

Babes Bolyai University, Cluj Napoca, Romania

ABSTRACT

The negative impact of COVID 19 pandemic on global health systems is a dramatic one. Nevertheless, the pandemic triggered plenty of vulnerabilities of the world economy, international labour markets, as well as educational systems. Moreover, important new trends should be identified, along with determinants that will certainly impact and reshape the future framework and economic environment related to educational processes and policies, labour force markets, consumer behaviour patterns, economic public policies, capital investments, etc. Despite the vulnerabilities revealed by the global health crisis, significant opportunities will occur, and sound interventions will be needed. That is why we consider that there is a stringent need for the educational systems to be able to adapt fast to the new realities and to implement correct, innovative and efficient response strategies in order to promote instruments and mechanism for flexible, dynamic and yet relevant, sustainable and trustworthy educational environment for all the implicated parties generating access, balance and equity for all the implicated parties to the process.

According to UNESCO's data, in March 2020, due to global lockdowns, 82.8% of total enrolled learners (pre-primary, primary, lower-secondary, upper-secondary and tertiary education levels) in 166 country-wide closures were directly affected by no access to in person education. One year later, in February 2021, the situation is improved, with 12.7% of total enrolled learners in 28 country-wide closures directly affected. Still, the international educational systems are confronted with problems related to digitalisation, access to support programs for vulnerable learners, reduced mobility for international students and teaching staff, reduced number of scientific events, reduced number of outreach activities in local communities, etc.

The present article aims to focus on the impact of the global health crisis on education, with a special attention paid to HEIs (higher education institutions) in Romania. We intend to identify and analyse response measures, as well as strategic approaches adopted by Romanian universities, in a comparative analysis with other models identified as being relevant for the investigated context, from the abrupt switch to online education, to support mechanisms for both students, teachers and administrative staff. We intend to sketch profile of those HEIs that are undertaking a responsible, accountable and resilient approach on the education in these challenging times.

NEW FIRM FORMATION DURING UNCERTAINTY. A REGIONAL ANALYSIS OF ROMANIAN NEWBORN FIRMS DURING 2020

Alina I. Popescu

The Bucharest University of Economic Studies, Romania

ABSTRACT

The paper investigates the regional dynamics of new firm formation in the Romanian counties during the 2020 year which was marked by the coronavirus pandemics. After an initial period of slowed down firm formation that ended with the sudden fall of the registration of newborn firms during the lockdown month of April, the new firm formation activity registered a significant increase in the months that followed until the end of the year 2020, at even a greater formation rate than that of same month of the previous year. We look at the economic activities by NACE code that attracted the most newborn firms during pandemics. Further on, we calculate a score of technological and knowledge intensity at county level based on the economic activity sector of newborn firms in 2020. Results show an average score of medium-low technological and knowledge intensity according to the main economic activity of the newborn firm in 2020 in Romania.

FISCAL RESILIENCE OF RUSSIA'S REGIONS

[Anna Mikhaylova](#)

Russian Presidential Academy of National Economy and Public Administration, Russian Federation. Institute for Public Finance Reform, Russian Federation

ABSTRACT

Currently, the Russian Federation does not have a methodology to determine the degree of fiscal resilience of regions. There are certain elements that make it possible to state the presence of problems in the regional budget system (high level of public debt, budget deficit, high share of intergovernmental fiscal transfers in budget revenues). However, these elements do not line up into a single system for assessing regional fiscal sustainability, or resilience.

The report was prepared as part of the implementation of the state task of the RANEPA for 2021.

The methodology for assessing the debt sustainability of Russian regions applied by the federal government reflects their creditworthiness, provides flexibility and correctly differentiates regulatory measures depending on the amount of debt. However, it does not fully take into account the institutional and economic aspects, which reduces the consideration of the risks of budgetary sustainability at the regional level.

Federal measures of influence against regions that have exceeded the established limits of debt sustainability go far beyond the immediate sphere of debt and affect the area of overall fiscal sustainability. They concern not only the issues of debt policy, but also the choice of directions and volume of expenditures and other parameters of the budget. This gives practical relevance to the search for an answer to the question of whether debt sustainability indicators adequately reflect the state of fiscal sustainability of Russian regions.

In order to quantitatively characterize the budgetary sustainability of the constituent entities of Russia and to test the hypothesis on the differentiation of the concepts of budgetary and debt sustainability, we have developed the corresponding indices - fiscal sustainability index (FSI), and debt sustainability index (DSI).

The regional fiscal sustainability index (FSI) developed by us has an integral character, includes 20 indicators and takes into account the institutional and economic aspects.

Grouping according to the calculated FSI data, carried out on the basis of one-dimensional cluster analysis, made it possible to distinguish three groups of regions of Russia. The results of the grouping indicate that it is undesirable to link federal regulatory measures that restrain the budgetary independence of regions with purely debt indicators.

At the same time, in the existing system of federal regulation of debt sustainability, it is more effective to focus federal measures at high debt levels exclusively on the sphere of debt policy. The absence of additional restrictions on regional spending could have a positive effect on the overall fiscal stability of Russia in the medium and long term.

BETWEEN PATH DEPENDENCE AND INNOVATIONS: DETERMINANTS OF TECHNOLOGICAL ENTREPRENEURSHIP IN THE RUSSIAN REGIONS.

Stepan Zemtsov, Alexander Mikhaylov

Russian Academy of National Economy and Public Administration, 84 Prospekt Vernadskogo, Building 9, Moscow, Russia, zemtsov@ranepa.ru, mikhaylov-aa@ranepa.ru

ABSTRACT

High-tech startups provide organic implementation of technological innovations in the contemporary economics. Through startups entrepreneurial ecosystems are adapting to the changes caused by technological progress. For the Russian Federation startup activity has brought an important opportunity to reduce regional socio-economic disparities and negative effects of resource extraction dependency. The coronavirus pandemic has made the importance of startup activity even more vital for future economic recovery.

Spatial patterns of high-tech startups in Russia show a tendency for a significant concentration in particular regions. The analysis of entrepreneurial statistics for the last decade shows us that technological entrepreneurship is partially related on factors typical for the majority of SMEs (local market volume, purchasing power, characteristics of entrepreneurial ecosystems) and partially for the high-tech economics (localization of other high-tech SMEs and special human capital). Some tendencies resemble more comprehensive specifics of Russian startups.

The paper aims to study the aspects of regional differentiation of startup activity in Russia and reasons which have formed its contemporary conditions. We use econometric analysis of quantity of new high-tech companies in combination with 22 statistical indicators representing different sides of regional socio-economic situation. It helps us to shed light on complex interrelationships among them and extinguish the factors of the most importance for the new high-tech firms, which include levels of human capital development, ICT infrastructure availability majorly corresponding with the phenomenon of "path dependence" of regional socio-economic development trajectories. Nevertheless, patent activity and availability of banking support have turned less significant.

According to the findings and the context of socio-economic disparities among Russian regions, we provide recommendations for the regional authorities in order to make the local conditions more suitable for technological entrepreneurs and increase the startup activity levels.

KEYWORDS

Russian regions, technological entrepreneurship, startup activity,

1. INTRODUCTION

Startup activity is rightly considered one of the key elements of the innovative development of the modern economy. The venture capital sector contributes to the relatively rapid selection and diffusion of innovations in society, which significantly favors economic activity - for example, in the United States, about half of the total productivity growth is accounted for by startups (OECD, 2020).

The coronavirus pandemic has become a challenging test for the venture capital industry around the world. According to the international project Startup Genome, 72% of young hi-tech companies experienced declining revenues; 60% of surveyed firms responded to this challenge by reducing the number of employees or reducing wages (Startup Genome, 2020). The volume of transactions in the venture capital sector in the first months of 2020 in the world as a whole decreased to the level of 2018. In some developed countries, its decline turned out to be even more pronounced - for example, in the USA it reached a minimum over the past 7 years (Teare, 2020).

The researchers note that the socio-economic consequences of the coronavirus pandemic will not become critical for the venture capital sector - rather, they will lead to its reformatting. The growing difficulty of moving the founders of young companies, investors and business angels provokes some increase in the disunity of local entrepreneurial ecosystems; the combination of this trend with the globalization of the world economy allows us to conclude that these ecosystems will have more prerequisites for both cooperation and competition with each other. A special role in each of them will be played by the operating conditions, institutional environment, economic specialization of these ecosystems and a number of their other characteristics.

The Russian venture capital industry has not remained apart from global trends. Nevertheless, the Russian case is characterized by its own specificity of startup activity, which is well shown by the current research of the Startup Barometer. It is articulated that 50% of young companies surveyed by the vc.ru portal were unable to receive the desired assistance during the coronavirus pandemic, since their industry field was not included in the official list of the mostly affected economic activities. Nevertheless, 65% of startups in the sample plan to raise funds from investors in the near future, and 41% of companies intend to hire 1 to 5 new employees (Startup Barometer, 2020). In addition, due to the high heterogeneity of the country's socio-economic development, it can also be assumed that different constituent

entities of the Russian Federation will be able to adapt to new conditions to varying degrees. In general, it will be necessary to create new and rethink the existing mechanisms for supporting the venture capital sector, taking into account the factors that determine the degree of success of the emergence of such firms in different regions of the country. The purpose of this work was to highlight and analyze these factors taking into account the specifics of the socio-economic situation of the regions of the Russian Federation.

2. THEORETICAL FRAMEWORK

The theoretical side of the study of start-up activity in the regions of the Russian Federation is associated with the need to resolve several important issues presented below.

First of all, it is necessary to clarify what is meant by the concept of "startup". Despite its widespread use in journalistic and consulting publications, there is no single definition of this concept in scientific thought. As a rule, it means a newly created (in most cases - up to 1 year) firm, largely controlled by its immediate founders (founders), presenting a new high-tech product on the market and possessing intellectual property rights to it (Robehmed, 2013). An important distinguishing characteristic of a startup is usually its high growth potential in the short or medium term: it is assumed that the product presented by the startup can be relatively easily scaled up and implemented in the global market or the markets of other countries.

Another important characteristic of startups, as a rule, is the high riskiness of doing business. Risks can be either external (lack of funding or difficulty in obtaining it, lack of knowledge and competencies for doing business of this kind) or internal - lack of entrepreneurial experience, difficulty in teamwork, etc. (Gonzalez, 2017; Evers, 2003). According to statistics, about 80% of such companies are closed already at the initial stages of project implementation (Hyder, Lussier, 2016).

There is no official definition of the concept of "start-up" at the federal level in Russia these days. This concept, however, is found in departments supervising the activities of high-tech firms in certain regions: for example, the Government of the Moscow Region considers a startup to be "a legal entity that, within 3 years from the date of its registration, has implemented its innovative projects and whose main purpose of activity is the promotion of innovative technologies"

As an operational definition, it was decided to name as "startup" a firm of high- or medium-tech activities created during current calendar year and having a non-zero revenue volume. The last refinement is required to remove the so-called. "Fly-by-night companies", the goals of which are different from those positioned by the majority of "real" startups.

The second question concerns the factors that most significantly affect the success of a startup. Similar factors, like risks, are divided by many researchers into internal and external. The former include the personality traits of entrepreneurs (Stuetzer et al, 2013), as well as the various categories of skills required to run a company. The latter are related to the general context of the socio-economic situation in the country, region or city where the entrepreneur is located (Del Bosco, 2019; Partridge et al, 2019).

An important role is played by the ratio of "demand" and "supply" of entrepreneurial services in society. The first is usually formed by the presence and volume of a local market in which a potential entrepreneur can find his niche. The second is the desire of such a person to conduct business. It often depends on the culture of the business environment and aspects of the position of entrepreneurs in society (Verheul et al., 2002); sometimes the "offer" of entrepreneurial services is formed by force - during crises and other periods of rising unemployment for some people, such activities become an alternative to working as employees (Verheul et al. 2002).

Many researchers assign a fundamentally important role to the characteristics of the educational level of the population (Armington, Acs, 2002; Breitenecker, 2007). It seems that universities, research centers, and research departments of large companies, which require highly qualified personnel, are often places of birth for new firms (Novotny, 2008). Agglomeration effects are often referred to as important groups of factors (Beaudry, Schiffauerova, 2009; Audretsch, Fritsch, 1994; Fritsch, Kristalova, Wyrwich, 2019), in particular - the density of companies of firms from similar sectors of the economy, as well as the characteristics of the firms themselves - the average company size, the share of small and medium-sized enterprises in the economy, the presence and organization of entrepreneurial ecosystems (Quan, Acs, Stough, . Startups are particularly sensitive to formal and informal institutions and norms (Aparicio et al, 2016; Fuentelsaz et al, 2015) operating in the economy. Some researchers also highlight general patterns of the specifics of institutional conditions characteristic of developing countries, such as the severity of the "path effect" (Calá, 2014). The presence of specialized programs of state financial support and infrastructure - business incubators, accelerators, funds and other mechanisms for stimulating start-up activity - has a beneficial effect on the development of the venture capital sector (Breitenecker, 2007).

Based on a review of theoretical sources, three hypotheses can be proposed for an empirical study of startup activity in the context of Russian regions:

1. It is impossible to single out the factors that determine the differentiation of start-up activity in the regions of the Russian Federation. A possible reason for the implementation of this hypothesis may be the lack of data for building a representative model, the absence of a significant relationship between the considered indicators and the dependent variable, or, on the contrary, the complexity of the nature of this relationship.
2. The distribution of start-up activity by regions of the Russian Federation depends on factors similar for foreign countries (recall that these include the level of education of the population, agglomeration effects, general entrepreneurial activity, and characteristics of the institutional environment and the availability of financial support
3. The distribution of startup activity depends on some other processes that can be identified in the course of empirical analysis.

3. NEW HIGH-TECH COMPANIES IN RUSSIA: OVERVIEW OF THE CURRENT SITUATION

Figure 1. Dynamics of changes in the number of new high-tech firms in 2015-2020

Source: RUSLANA.

Generally, the dynamics of the number of new high-tech companies in recent years can hardly be called favorable (Figure 1). Since the mid-2010s, the number of such firms in Russia has been steadily decreasing - from 17.5 thousand units in 2015 to 11.6 thousand units in 2019. Since 2016, the rate of organization, or “fertility” of firms (the number of new companies created per 1,000 existing ones) has become less than the liquidation rate (the same rate as the closure of firms). In January-September 2020, the coefficients were just over 5 and 12 units, respectively. This situation can be called extremely negative for the country's economy: according to OECD statistics, even a one-time reduction in the number of new firms by 20% leads to a decrease in employment by 0.7% over the next three years.

The sectoral structure of the distribution of start-up activity is as follows (Figure 2). About half of Russian startups can be classified as knowledge-intensive services in the B2C and B2B categories. It seems that firms of this type have suffered quite badly during the coronavirus pandemic due to the significant importance of personal communication of employees for conducting business, but subsequently they were able to digitize most of the business processes.

On the contrary, the manufacturing sector accounts for less than 12% of new high-tech companies, although its share in the total revenue of Russian startups exceeds 45%. The information technology sector practically does not stand out against the background of other areas: it accounts for slightly less than a fifth of the total number of all startups, and about 8% of the total revenue.

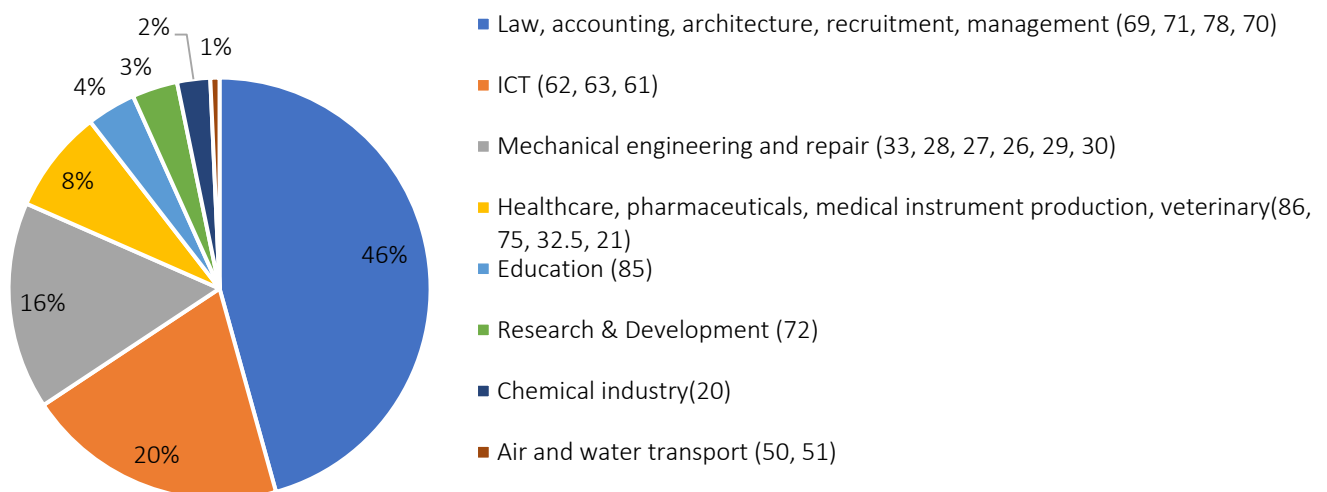

Figure 2: Sectoral structure of Russian startups according to – Russian classification of economic activities

Source: authors' calculations based on RUSLANA data.

Startup activity is extremely unevenly distributed in the regional context (Figure 3). Approximately every fourth new high-tech company emerging in the country is created in Moscow. Moscow, St. Petersburg and the Moscow region together concentrate about 40% of the number of such firms, and ten leading regions in terms of start-up activity (including the Sverdlovsk region, Novosibirsk region, Tomsk region, Nizhny Novgorod region, the Republic of Tatarstan, etc.) concentrate about 58% of such companies. By the number of new high-tech companies, the largest urban agglomerations (Moscow, St. Petersburg), regions of presence of important research centers (Novosibirsk and Tomsk regions) and the localization of large manufacturing companies (Vologda region, the Udmurt Republic) stand out in relation to the number of labor force.

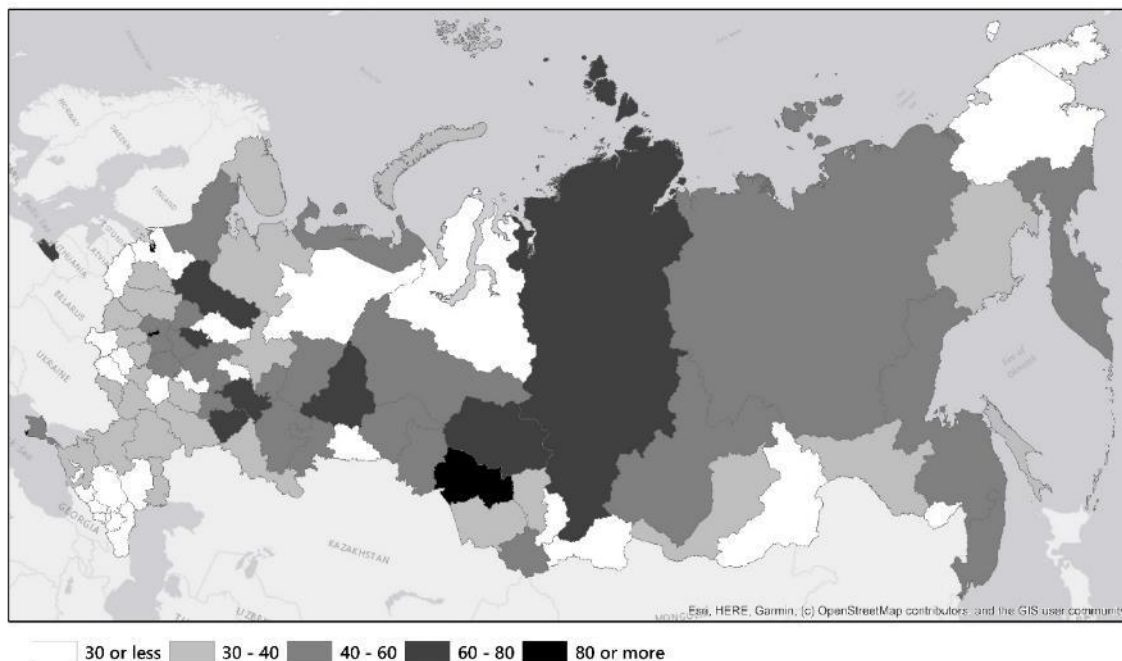

Figure 3: The average number of new high-tech firms in regions of Russia per 1,000 workforce in 2010-2018

4. FACTORS OF REGIONAL HETEROGENEITY OF STARTUP ACTIVITY LEVELS

Basing on the hypotheses formulated earlier, we decided to compile a relatively broad list of seven factors that potentially explain the distribution of startup activity in the regions of Russia. The generalized equation of the econometric model has the following form:

$$startup = const + \beta_1 \times education + \beta_2 \times rndpot + \beta_3 \times inst + \beta_4 \times support + \beta_5 \times infr + \beta_6 \times market + \beta_7 \times economy$$

In which:

- *startup* - selected dependent variable;
- *education* - the level of education of the population (human capital);
- *rndpot* - scientific and technical potential;
- *inst* - characteristics of the institutional environment;
- *support* - characteristics of state support;
- *infr* - level of infrastructure provision
- *market* - market potential;
- *economy* - characteristics of the structure of the economy;
- *const* is a constant.

Each of the selected factors included one or two variables, depending on the results of the analysis of paired correlations of indicators. The list of variables considered in the work is presented in Table 1.

Table 1. List of factors and variables used in the compilation of the models

Factor	Variable
Education level of the population (<i>education</i>)	Share of employed urban dwellers with higher education in the population,%
	Average number of years of education per person
	Number of students per 1000 people population, people
Scientific and technical potential (<i>rndpot</i>)	Share of internal expenditures on research and development in GRP,%
	The number of potentially commercialized patents for inventions per 10 thousand employed people
Institutional environment (<i>inst</i>)	RAEX investment risk index, points
	Aggregate index of provision of the region with banking services, points
Information and communication infrastructure (<i>infr</i>)	Share of organizations using Internet access at a speed of at least 2 Mbps, in the total number of organizations,%
	Share of persons (households) with access to the Internet,%
State support of startup activity (<i>support</i>)	The level of state financial support for start-ups by development institutions for 10 thousand employed people
Market potential (<i>market</i>)	Income minus the subsistence minimum per month per person, rubles
	The amount of money income of the population minus the subsistence level, RUB billion
	Available markets, RUB trillion,
Economy structure (<i>economy</i>)	Share of high-tech, medium-tech and science-intensive industries production in GRP,%
	Share of agricultural production in GRP,%
	Share of mining industry production in GRP,%
Entrepreneurial environment (<i>sme</i>)	Average number of employees in the firms of the high-tech sector, people
	The share of organizations using the Internet to place orders for goods and services, in the total number of organizations,%
	Average annual unemployment rate,% according to the ILO methodology
	Micro and small enterprises per thousand workforce
Spatial aspect (<i>spat</i>)	Interregional GRP, RUB million
	Population of the regional center, thousand people

Source: authors' calculations based on Rosstat, EMISS, Rating Agency "Expert" (RAEX) data.

The number of new high-tech companies was selected as a dependent variable in the work, reduced to a relative form by dividing by 1,000 people in the workforce, from 2010 to 2018.

Table 2. Factors explaining regional differences in startup activity (OLS models)

Factors	Models

Notes:*p-value<0,1; **p-value<0,05; ***p-value<0,01. All variables are logarithmic. Robust standard errors.

Consider the results of empirical analysis in the context of the previously identified hypotheses. The first hypothesis can be rejected: despite the not very accurate explanatory ability of the models, during the analysis it was possible to identify a number of significant relationships. The third hypothesis can also be rejected: there is also no need to talk about some fundamental difference in the distribution of startup activity in Russia relative to foreign countries. In connection with the above, it would be logical to confirm the second hypothesis.

It seems that the following factors play a key role in the distribution of startup activity across the regions of the Russian Federation:

1. Concentration of human capital. A large number of start-ups appear in regions where the proportion of people potentially possessing the necessary worldview and skills necessary to found their own high-tech company is higher. This conclusion is confirmed by the high significance of such variables as the proportion of highly educated city dwellers and the number of university students per inhabitant.
2. The quality of the institutional environment. Startups are very sensitive to the formal and informal aspects of the regional specifics of doing business, which is confirmed by the high significance of the RAEX investment index variable.
3. Availability of external funding. It is often extremely difficult for a young high-tech company to develop at its own expense, and therefore needs access to external capital. It seems that bank borrowings are becoming a key source of external financing for many Russian startups.
4. Availability of effective demand. The purchasing power of the region's residents is becoming a significant factor in the development of start-up activity - recall that most Russian young high-tech firms operate in the B2C format or interact with companies whose clients are private households.

The results of the analysis showed that in order to increase the number of high-tech startups created, it is necessary to promote investment in research and development, as well as to increase the concentration of human capital by creating incentives in the field of education. Particular attention should be paid to aspects of commercialization of patents and R&D results. In addition, it is necessary to improve the institutional conditions for doing business at the regional level, for example, by reducing the barriers to registering firms, developing a specialized infrastructure to support start-up activities.

5. RECOMMENDATIONS FOR FURTHER STARTUP ACTIVITY SUPPORT

Basing on the identified factors of distribution of startup activity, the following recommendations can be proposed for adjusting measures to support the venture capital sector in Russia.

1. Wide implementation of the concept of "entrepreneurial universities". Since the level of human capital development is of particular importance for increasing start-up activity, it is necessary to improve the conditions for creating new firms in the places of its concentration. Potential measurements may include entrepreneurship training programs based on the concept of a three-tier university-wide elective in innovative entrepreneurship, helping students develop or form core competencies in the entrepreneurial sphere, expansion of forms of legal interaction between universities and businesses, and formation of a university entrepreneurship ecosystems in the most promising universities (including individual courses, MBA, entrepreneurship centers, business incubators, technology valleys, associated grants and innovation vouchers, patenting and commercialization centers, etc.)
2. Improvement of access to funding for startups. Generally speaking, grant support for start-up entrepreneurs through additional capitalization of relevant development institutions with the development of specialized competitions in the most important areas, similar to European initiatives, is particularly important for Russian case. Also, creation of cooperative programs of public and private venture funds is suggested, as well as assistance in establishment intrapreneurship (inner-corporate venture entrepreneurship) funds in large companies, especially state-owned ones.
3. Improvement of startup access to potential markets. Majorly, it requires further reduction of the "digital divide" in Internet access and digital skills, and support of entrepreneurial ecosystems in the digital field. It seems, especially in the context of coronavirus pandemic, that the development of the digital sphere will lead to the most favorable impact on the technology start-up sector.
4. Overall improvement of the doing business conditions. It is difficult to overestimate the importance of the team in the early stages of the startup's formation. Therefore, decisions related to attracting and retaining highly qualified personnel in Russia, increasing the number of students in key areas are especially relevant, as well as mentoring programs for startup founders. Particular attention should be paid popularization of start-up activities in society, especially among scientific communities: in many countries with the most developed venture capital sphere commercialization of patents has become one of the most important startup activity drivers, whereas in Russia, according to our calculations, the role of patent commercialization is low.

We suppose that measures proposed above can significantly improve the current position of Russian startups, especially during the coronavirus pandemic, and help to reduce interregional inequality in start-up activity in Russia.

ABSTRACT

After the 2020 shock, many countries are looking for new sources of growth. Entrepreneurship has been declared one of the priorities in Russia; new support tools have been introduced since 2010. A significant interregional disparity of institutional environment and business development remains. Therefore, we aimed to identify determinants of small business development in the Russian regions. According to econometric results, household incomes, access to international and interregional markets, and capital availability can be the most significant factors. Small business density is lower in regions with a high crime rate because of greater investment risks. Internet-access is also positively significant for SMEs development as it provides new market niches. State support in the form of tax breaks and holidays can have a positive effect, but this impact is limited. Regional tax incentives, tax audits and special economic zones are insignificant if we consider the general institutional environment. The identified factors can help to understand the trends and policy opportunities of entrepreneurship policy in Russia.

entrepreneurship, entrepreneurial ecosystem, institutions, market potential, unemployment, SME support, Russian regions, panel data.

1. INTRODUCTION

The unpredictability of macroeconomic processes is increasing in the world as shown by 2020. This is due natural, social and other risks, and global technological changes. In particular, accelerated automation and digitalization (industry 4.0) are leading to radical economic transformations and threatening an employment decrease in large manufacturing industries and public sector (*Schwab, 2017; Acemoglu & Restrepo, 2017; Zemtsov, 2020*). Many countries are looking for new sources of growth. Transition to entrepreneurial economic model can be one of the adapting tools (*Audretsch, Thurik, 2000; Zemtsov et al., 2019*). This requires appropriate policy changes, including business climate improvement, incentives for business cooperation, and more significant role of small and medium enterprises (SME) (*Djankov et al., 2002; Djankov et al., 2009*). This could form favourable conditions for the entrepreneurial capital to play an important role in the economic growth (*Audretsch, Keilbach, 2004; Urbano et al., 2019*).

Small business and entrepreneurship development in Russia were declared as one of the state priorities in the 2010s (*Arshed et al., 2020, p.100-118*). The relevant federal Strategy was adopted in 2016 although it didn't provide a full implementation plan but a short roadmap for a few years (*Kudrin et al., 2019, p. 543-563; Zemtsov et al., 2020*). Later the national project for SMEs development was introduced in 2018, updated in April 2021, and became a leading document till 2024 (*Kudrin et al., 2021, p. 279-290*). The goals set in the documents to significantly increase the share of SMEs in GDP and in employment seems too optimistic and unlikely to be achieved. However, a number of tools have been introduced on federal and regional level (*Arshed et al., 2020; Zemtsov et al., 2020*): the bureaucratic procedures reduction, the public services digitalization, different tax benefits, tax and other inspections reduction, special economic zones, regional tax incentives and tax holidays. As a result, Russia rose from 124th place in 2010 to 28th in 2020 in the Doing Business ranking. Unfortunately, the rating assesses the business climate for the whole country only in two regions: Moscow and St. Petersburg.

In Russia, a consistent interregional disparity of institutional environment and business development remains (*Baranov et al., 2015; Barinova et al., 2018*). The Russian regions differ significantly in geographic location, population density, welfare and economic situation (*Zubarevich, 2013*). In fact, these differences lead to formation of several stable types of entrepreneurial ecosystems with different levels of business costs, access to capital, markets and labour (*Zemtsov, Tsareva, 2018; Zemtsov, Baburin, 2019*). Corresponding differences in entrepreneurship development have persisted for decades and even centuries (*Zazdravnykh, 2019; Fritsch et al., 2019*). Nevertheless, regional business inequality is still weakly addressed in the policy (*Chepurenskiy, 2012; Yakovlev & Zhuravskaya, 2013; Chepurenskiy & Vilenskiy 2016; Arshed et al., 2020*). There is a lack of coordination of the regional SME support measures. Most of the regions are subsidized (*Alexeev, Chernyavskiy, 2018*) and don't have sufficient budget capabilities for entrepreneurship policy.

Therefore, the share of SMEs in the Russian economy remained steadily low and is unlikely to increase from 20,6% of GDP in 2019 to 32% in 2024 as planned (*Arshed et al., 2020; Zemtsov et al., 2020*). Despite the efforts and declarations, the role of public sector and state corporations is still much higher in Russia than in most similar post-socialist countries (*Abramov et al., 2017; Sauka, Chepurenskiy, 2017; OECD, 2018*). The prevalence of the informal economy, high crime rates remain acute in certain southern regions (*Rochlitz, 2017; Mannila & Eremicheva, 2018*). Moreover, the 2020 pandemic

and the corresponding anti-epidemiological measures, in particular the suspension of many service businesses, had a significant negative impact on SMEs in most of the regions (Parrot et al., 2020; Zemtsov et al., 2020; Kudrin et al., 2021). Shrinking household incomes in 2020 and in last 6 years also directly affected the decrease in demand for goods and services of small businesses (Kudrin et al., 2021; Barinova & Zemtsov, 2020). At the same time, pre-crisis and anti-crisis development of digital platforms, online services, and remote employment has contributed to SMEs persistence and stimulated start-ups activity in the Internet sector, especially in developed entrepreneurial ecosystems of large agglomerations (Kudrin et al., 2021; Zemtsov et al., 2019).

The goal of this research is to identify determinants for small business development in the Russian regions. Considering the above, we were interested in how persistent regional differences in access to markets, capital and labour, institutional disparities, digital inequality, as well as federal and regional support measures, affect small business density. Previous studies on the Russian case have rarely considered the whole complex of described factors, moreover, they paid little attention to the large set of new policy measures introduced in 2010s. Understanding the influence of these factors in the pre-crisis period may contribute to an efficient post-crisis entrepreneurship policy.

We reviewed relevant empirical studies, then, formed hypotheses; we tested them on available statistical data on the Russian regions and, at the end, discussed the results.

2. LITERATURE REVIEW

Numerous studies demonstrate two main approaches to assess the rate of entrepreneurship development in regions and countries. *The first approach* is based on identifying the share of entrepreneurs, entrepreneurial intentions and other characteristics of established business owners or nascent entrepreneurs (Reynolds et al., 2002; Verheul et al., 2002; Van Stel et al., 2007; Chepurensko, 2010; Bosma & Schutjens, 2011; Alvarez, & Urbano, 2011; Estrin & Mickiewicz, 2011; Estrin et al., 2013; Stenholm et al., 2013; Aparicio et al., 2016; Nielsen, 2014; Verkhovskaya & Aleksandrova, 2017; Dvouletý, 2018; Urbano et al., 2019). The data are based on population surveys. The disadvantage of this approach is the complexity of collecting primary information, inaccessibility of representative data for the Russian regions in dynamics. Moreover, the results of the polls are subject to various kinds of distortions (Bosma, 2013; Chepurensko, 2010). *The second approach* involves statistics on the number of small and medium-sized firms, new firms, self-employed, firms' birth rate, etc. (Storey, 1991; Reynolds et al., 1994; Storey, 2003; Fritsch, & Falck, 2007; Fritsch, 2013; Stephens, Partridge, 2011; Cravo, Gourlay & Becker, 2012; Yakovlev & Zhuravskaya, 2013; Barinova et al., 2018; Zemtsov & Tsareva, 2018; Zazdravnykh, 2019; Fritsch et al., 2019). The density of businesses per capita can be considered an indirect indicator of the entrepreneurship development. In general, more businesses are created by more entrepreneurs.

According to the second approach, we used the number of small businesses per 1000 labour force participants, or small business density, as a proxy for SME sector development and as an indirect indicator of entrepreneurial activity. Alternative measures have significant drawbacks. The dynamics of firms' birth rate can contain data on fly-by-night companies, at the same time, does not consider their mortality (Obraztsova, & Chepurensko, 2020). The data on business owners in the Russian regions is available only for one year (Chepurensko et al., 2017) and does not allow identifying dynamics factors. Moreover, in a number of regions there is a high proportion of necessity-driven entrepreneurs (Aleksandrova & Verkhovskaya, 2016), which distorts the results. An indicator describing small business development is also preferred for policy recommendations in Russia.

Cross-disciplinary researches of entrepreneurship have economical, sociological, psychological and other aspects (Bygrave & Hofer, 1991, Fritsch & Storey, 2014). Therefore, it is challenging to develop a theoretical model (Verheul et al., 2002, Nielsen, 2014, Denisenko, 2011, Blanchflower & Oswald, 1994, Carree & Thurik, 2003, Schmitz, 1989, Braunerhjelm et al., 2010). Usually several groups of entrepreneurship determinants are distinguished: demand for goods and services of SMEs (GDP per capita, incomes at al.), labour supply for SMEs (unemployment), general institutions and government support (Verheul et al., 2002; Nielsen, 2014; Fritsch & Storey, 2014). These factors are well studied in many countries (Bais et al., 1995; Verheul et al., 2002; Lee et al., 2004; Spencer & Gómez, 2004; Aidis, 2005; Van Stel et al., 2007; Sternberg, 2009; Alvarez & Urbano, 2011; Bosma & Schutjens, 2011; Fritsch, 2013; Stenholm et al., 2013; Stuetzer et al., 2014; Aparicio et al., 2016; Urbano et al., 2019). We have distinguished a separate group of studies on post-communist cases (Smallbone, & Welter, 2001; Aidis, 2005; Estrin et al., 2006; Estrin & Mickiewicz, 2011; Smallbone, & Welter, 2012; Sauka & Chepurensko, 2017), where special attention is paid to various trajectories of transition from a planned to a market economy, the influence of the state and informal sectors on business. The institutional environment of transition economies is characterized by the shortage, weak and uneven development of a necessary market and financial institutions, as well as the presence of obsolete norms. A number of studies are devoted to certain aspects of the entrepreneurship development in Russia: institutional environment (Djankov et al., 2005; Bruno et al., 2013; Aleksandrova & Verkhovskaya, 2016; Verkhovskaya & Aleksandrova, 2017), high regional variation (Chepurensko et al., 2017; Obraztsova, & Chepurensko, 2020), and persistence of firms and self-employed location choices (Zemtsov & Tsareva, 2018; Fritsch et al., 2019; Zazdravnykh, 2019; Jayet et al., 2021). However, there are significantly fewer works that investigate the impact of a wide range of regional characteristics, including government support, on the SMEs development (Yakovlev & Zhuravskaya, 2013; Barinova et al., 2018).

In recent years, significant differences in the interregional variation in entrepreneurship have been explained by the entrepreneurial ecosystem concept (Acs et al., 2017; Audretsch & Belitski, 2017). According to the systematic approach, business agents interact with each other in a specific environment and form sustainable networks (Stam, 2015). At the same time, agents perform different functions and occupy different market niches by analogy with natural ecosystems. Another approach involves identification of ecosystems' stakeholders: large firms, universities, research institutions,

venture funds, regional authorities, etc. Thus, the paper (*Isenberg, 2011*) explores the goals of business agents, their functions and connections. Another approach involves the study of the basic conditions and resources of business development (*Sternberg, 2009*). To conclude, the ecosystem approach involves the study of regional basic characteristics, business environment and agents' networks. The latter can be indirectly measured through the density of specialized institutions (venture capital funds, business incubators, special economic zones, etc.) that ensure the interaction of business agents. High business density can also be a proxy of high potential network connectivity. To formulate research hypotheses and select variables, we consider several groups of determinants in more detail.

2.1 Unemployment or supply of labour

Unemployment is a traditional factor in empirical estimates. On the one hand, high unemployment is an indicator of disadvantageous economic situation, it leads to the lower demand and higher business risks. Therefore, the unemployment rate in a region may have a negative impact on SMEs. On the other hand, high unemployment rate may increase the number of small businesses as it exceeds labour supply, lowers labour costs, and encourages necessity-driven self-employment (*Storey, 1991, Verheul et al., 2002, Fritsch & Falck, 2007*). Necessity-driven entrepreneurs are those who start an enterprise, because they have no other income-generating opportunities. In this case, a variable with a lag of one year is most often used, as it takes time for the labor market adjustment.

2.2 Market access or demand for SMEs' services and goods

Studies on new economic geography demonstrate that size and concentration of economic activity significantly influence regional development (*Jacobs, 1969; Fujita et al., 2001; Hanson, 2005; Zemtsov & Smelov, 2018; Lavrinenko et al., 2019*). In areas with a high diversity and concentration, there are more opportunities for entrepreneurship due to proximity of new and diverse ideas, knowledge, technologies and larger markets. Average incomes and market potential, population density, are usually used in empirical studies.

Population density (particularly in urban areas) can have an ambiguous effect on the entrepreneurship (*Verheul et al., 2002*). On the one hand, high population density guarantees high demand and provides access to markets, business infrastructure, skilled labour, the possibility of cooperation between new and sustainable firms, the effect of knowledge spillovers (*Reynolds et al., 1994; Fritsch & Falck, 2007; Bosma & Schutjens, 2011*). On the other hand, a high concentration increases competition and creates higher entry barriers (*Bais et al., 1995*).

Access to markets is essential for the development of mass entrepreneurship (*Hanson, 2005; Zemtsov & Baburin, 2016; Zemtsov & Tsareva, 2018*). The traditional indicators of local demand are household's incomes or GDP per capita. The higher the average income is, the greater the demand for new SME's products and services is. *Brown et al. (2008)* analysed the dynamics of new enterprises' creation in the Russian regions. The results show that firms are created and are more likely to survive during 5–10 years, mainly in regions with high market potential. Isolated and hard-to-reach regions are losing businesses. Note that the literature usually considers almost exclusively domestic markets without the influence of other countries, although many businesses in Russia are based on importing goods.

2.3 Institutional factors of entrepreneurship

Institutions are 'game rules' in society, or restrictions that determine the interactions between people (*North, 1990*). Institutions can be formal (regulations, contracts, procedures, etc.) and informal (culture, values, social norms adopted in society). Formal institutions reduce transaction costs with officially established rules, while informal ones reduce the level of uncertainty in the individual decision-making (*North, 2005*). Formal institutions can be changed over a short period of time, as opposed to the informal ones (*Williamson, 2000*).

The institutional factors influence the individual decision making to become an entrepreneur (*Aparicio et al., 2016*). Baumol's concept of productive and unproductive entrepreneurship described a mechanism between entrepreneurial behaviour and institutional environment (*Baumol, 1993b; Belitski et al., 2021*). Favourable business climate encourages productive opportunity-driven entrepreneurship (*Aparicio et al., 2016*). Moreover, informal norms such as corruption, perceptions of success, social trust, may have even higher impact than the formal ones. The absence of many formal institutions in developing and transition countries stimulated the emergence of various informal ties, agreements (nepotism, corruption), which in turn opened the way for various types of crimes, political entrepreneurship, and shadow economy (*Tonoyan et al., 2010*). All of these factors reduce social trust and, accordingly, create insurmountable barriers to productive entrepreneurship. An enterprise requires significant investments in fundraising, competence and industrial relations (*Anokhin & Schulze, 2008*). It is unreasonable for entrepreneurs to develop complex businesses that can be easily lost. The studies on the Russian case revealed a significant negative impact of political institutions, including corruption, restrictions on media freedom, length of governors' terms on the entrepreneurship development (*Shurchkov, 2012; Yakovlev & Zhuravskaya, 2013; Bruno et al., 2013*). At the same time there is a lack of papers studying such factors as access to finance, legal environment, administrative burden, and SME support policy.

Access to finance. Many researchers (*Kuzilwa, 2005; Nielsen, 2014; Barinova et al., 2018*) underline the essential role of finance access, bank credits availability for SMEs development. The lack of funding or a high interest rate is the main obstacle for many potential entrepreneurs, especially in developing countries (*Aparicio et al., 2016*), and thereby it reduces SME's development. *Aparicio et al. (2016)* use the percentage of adult population that has at least one credit in a private bank as a proxy for finance access. *Nielsen (2014)* suggests to use the percentage of the population who personally provided funds for a new business. The alternative indicators are: the degree of financial instruments' diversity, the number of investment companies and the interest rate on loans.

Legal environment. The legal environment, considering protection of private property and other business rights, has a direct impact on small business density (Anokhin, Schulze, 2008; Xheneti, Bartlett, 2012; Yakovlev, Zhuravskaya, 2013). Deficiencies in legislation and weakness of law enforcement agencies create conditions for rampant corruption and high crime rate. These factors influence a decision to become an entrepreneur, the willingness to legalize business activity, and the likelihood of business expansion.

2.4 Government policy

Public policy may significantly affect small businesses (Spencer, Gómez, 2004; Djankov et al., 2002) through regulation, tax incentives, and different forms of direct public support.

Regulations. Many papers (Aidis, 2005, Djankov, 2009, Klapper et al., 2006, OECD, 2011, Nielsen, 2014, Djankov et al., 2002, Aparicio et al., 2016, Alvarez, Urbano, 2011, Van Stel et al., 2007) state that a large number of business registration and other procedures adversely affect the willingness of potential entrepreneurs to start businesses. The empirical evidence (Van Stel et al., 2007; Djankov, 2009) became the basis for policy changes all over the world. Governments reduced regulation and simplify it in order to stimulate new business development (Aparicio et al., 2016). Alvarez and Urbano (2011) emphasize that in 2007 and 2008, simplifying the new company's registration was the most popular reform. In Russia, the supervisory inspections of enterprises are a significant administrative burden to SMEs development (Barinova et al., 2018). According to (Russian Union of Industrialists and Entrepreneurs, 2016), 93.6% of surveyed companies underwent scheduled inspections and 54.2% of surveyed companies underwent unscheduled inspections.

Taxes. A high tax burden increases the cost of starting a business, thus reducing the willingness to become entrepreneurs (Djankov et al., 2010). For example, the introduction of a progressive marginal tax rate in the USA lowered the probability of becoming self-employed for upper-middle-income households by about 20 percent (Gentry, Hubbard, 2000). On the other hand, Bruce and Mohsin (2006) conclude that different kinds of taxes (federal income, payroll, capital gains, corporate income, and estate) have significant but small effects on self-employment activity.

Public support. To help entrepreneurs reduce the start-up risks, many governments pursue special SME support policy. This policy involves the adoption of legislation acts, protecting entrepreneurs, and establishment of special programs that provide financial support to entrepreneurs and create business friendly environment (Spencer & Gómez, 2004). The impact of state support on small business development is ambiguous, since empirical studies often underestimate the «screening effect» when the strongest firms are supported (Reynolds et al., 1994; Storey, 2003). As Chepurensko (2012) notices with the reference to Lerner (2009), the most adequate programs are often implemented in rich countries with the Anglo-Saxon legal tradition. Negative public opinion and low confidence in the state support in Russia and other developing countries may decrease possible positive effects of the SME' programs (Yakovlev & Avraamova, 2008).

One of the most popular support tools is the creation of territories with special entrepreneurial regimes, for example, special economic zones. In recent years, dozens of similar tools have been created in Russia (Sosnovskikh, 2017). For example, special economic zones provide tax incentives for their residents, the possibility of duty-free trade, and infrastructure. They can create a large number of new supplier companies serving residents. Until recently, there have been few assessments of the impact of such a policy on small business (Zeng, 2010).

2.5 Digitalization

Digitalization may be an important factor, influencing small business development at a regional level. The introduction of digital technologies during current technological change leads to a significant minimization of transaction costs due to electronic workflow, “uberization” of services. Digital platforms such as Uber, Alibaba, Airbnb, etc. dramatically expand market entry opportunities. For example, the development of the Alibaba platform for product distribution has allowed the creation and scale-up of millions of small firms worldwide (Jin & Hurd, 2018). In fact, enterprises now can reach subcontractors, suppliers and customers from all around the world. The resources of small firms for customizing products and services have significantly increased.

Thus, regional digital inequality rate (digital divide) can be one of the barriers for SMEs development (Nambisan, 2017; Zemtsov et al., 2019). There are several forms of digital divide (Scheerder et al., 2017), resulting in an uneven access to ICT infrastructure, uneven abilities for Internet usage and to business digitalization. The 2020 pandemic increased the role of digitalization, as many businesses that used to operate offline have been closed. On the contrary, those who have transferred their employees to remote work, have created webpages or use digital platforms to process orders online, are successfully developing (Kudrin et al., 2021). So, the government can influence the entrepreneurship development through services' digitalization, reducing digital divide and providing digital platforms expansion.

In 2020 the world got a new factor of SMEs development – COVID-19. A number of researchers try to predict the effects of pandemic. Forey et al. (2020) predict long term development of innovative entrepreneurship in medicine and the growth in R&D funding. Kuchler et al. (2020) highlight an ambiguous role of such institutional factor as social capital, as higher social interactions may increase business risks but higher business ties may help to adapt. Many researches were devoted to the government actions during pandemic. Anti-epidemiological restrictions on trade, tourism and other services had a strong negative impact on many businesses. In Russia, the number of SMEs decreased by 4.3% (Kudrin et al., 2021). Although governments sought to compensate it by concessional loans, payroll subsidies, tax breaks and other measures (IMF, 2020). (Zemtsov et al., 2020) provides a detailed overview of public measures, explaining why direct financial support can be used in developing countries only in emergency cases like pandemic. Traditional support measures require significant budgetary resources, but often do not solve the business problems, since a small number of firms are covered; support may not be received by those firms that are in need; supported firms may crowd out other

firms. In states with weak institutions of public control (independent media, NGOs, etc.) direct financial support can create new institutional traps: corruption, “privileged” companies, rental behaviour, business distrust to the state, etc. The review allowed us to determine the set of the most significant variables for analysis. Our data does not include the period of the pandemic, but we tried to relate our findings to the new situation

3. RESEARCH HYPOTHESES

According to the purpose of our research and literature review, we formulated the following hypotheses about the influence of institutional and other regional factors on small business in Russia. In our opinion, these factors lead to formation of different types of regional entrepreneurial ecosystems in Russia.

1. *Market access* (or size of potentially available markets) is a significant positive factor in determining the demand for small business services and products. It should be higher in the Russian regions near large metropolitan areas with higher population density and wealthier households, and in border and coastal regions near large countries with better export and import opportunities. At the same time, the density of small businesses can be lower in remote and sparsely populated areas (Northern Russia) due to high transport costs. The geographical position of the Russian regions differs significantly.
2. *Unfavourable regional business environment*, that is a set of institutions, such as legal environment, access to finance or administrative burden, may significantly reduce small business density. Entrepreneurs strive to reduce their transaction costs and potential risks, so they register their businesses in specific regions, regardless of real placing.
3. *Proactive regional authorities* are able to affect entrepreneurial ecosystem development through various incentives, primarily related to lower taxes. Entrepreneurs tend to start and maintain businesses in more favourable tax conditions, which increase small business density in certain regions.
4. In recent years, the number of small businesses has been growing due to digital economy expansion, or *digitalization*. For instance, digital platforms provide access to any consumers in the world. A higher level of Internet access in a region provides more digital opportunities for small businesses and better access to new markets, as well as stimulates the development of new online services and start-ups.

4. ECONOMETRIC MODEL AND DATA

To test our hypotheses, we proposed the following econometric model (Eq. 1).

$$SBdensity_{it} = const + \alpha_1 * market_{it} + \alpha_2 * institutions_{it} + \alpha_3 * support_{it} + \alpha_4 * digital_{it} + \alpha_5 * controls + \varepsilon_{it}, \quad (1)$$

where

i – a Russian region (from 1 to 83; the Republic of Crimea and Sevastopol are excluded; but in some specifications more regions are skipped due to missing data); *t* – year (2008-2018);

SBdensity – number of micro and small businesses per 1,000 economically active population, or workforce participants, in a region;

market – availability of markets;

institutions – institutional factors (legal environment, access to finance, administrative burden);

support – federal and regional support measures for SMEs (tax benefits, reduced tax rates, special economic zones, tax holidays);

digital – percentage of individuals with access to the Internet;

controls – income per capita (or one-year lagged GDP per capita) and one-year lagged unemployment (as control for demand, economic situation in general and supply of potential nascent entrepreneurs).

Numeric variables are log transformed. We use panel data: annual values of indicators for the period 2008-2018 in 83 regions of Russia. The main source of data is the Federal State Statistics Service (Rosstat). The open data of the Central Bank of the Russian Federation and the authors' calculations are also used. Description of variables and data sources are given in Table 1. See descriptive statistics and correlation matrix in table 2 and 3.

Table 1. Description of the variables and data sources. Data on 83 regions, 2008-2018, unless otherwise specified

Factor	Variable	Description	Source
Dependent variable			
Entrepreneurship development	Small business density	Number of micro and small businesses (legal entities with full-time employees up to 100) per 1,000 economically active (employed) population (in other words: per labour force participants)	Rosstat ¹¹
Control variables			
Demand, economic situation in a region and supply of potential nascent entrepreneurs	Income per capita	Monthly income minus subsistence minimum (average value for the 12 months), rubles per person *82-83 regions. Data on the Chechen Republic is available since 2010.	Authors' calculations according to Rosstat ¹²
	GDP per capita	Gross regional product per capita, thousand roubles in constant 1998 prices *82 regions. No data on the Chechen Republic.	Authors' calculations according to Rosstat ¹³
	Unemployment	Unemployment rate on average per year according to the methodology of the International Labour Organization, in percent	Rosstat ¹⁴
Independent variables			
Market access (or agglomeration effects)	Market potential	The volume of available markets, trillion rubles in constant prices	Authors' calculations
	Population density	Population per 1 square km, individuals	Rosstat ¹⁵
Institutional factors	Banking Index (Access to finance)	Index of regional banking services availability *79-80 regions. No data on the Nenets Autonomous Okrug (AO), Khanty-Mansi AO, Yamalo-Nenets AO. Data on the Chechen Republic is available since 2012.	Central Bank of the Russian Federation reports ¹⁶
	Crimes (Legal environment)	Number of crimes per 1,000 economically active (employed) population in a region	Rosstat ¹⁷
	Tax inspections (Administrative burden)	Number of field tax inspections by the Federal Tax Service (FTS) per 1 thousand of the total number of enterprises in region	Unified Interdepartmental Statistical Information System in Russia ¹⁸
Support for SMEs	Tax benefits	The total amount of tax benefits (for income tax, property tax, transport tax and land tax) per one organization, rubles. *Data on SME support (subsidies) are available only since 2012. Accordingly, we use them for the period 2012-2018.	Federal Tax Service ¹⁹
	USN reduced tax rates	Presence of regional tax incentives (reduced tax rates) for USN payers. USN is a simplified taxation system for SMEs in Russia. A binary variable that takes on the value 1 if additional reduced rates for USN taxpayers were introduced in a region and 0 otherwise (0 if "there weren't any USN tax incentives in the region" and 1 if "there were USN tax incentives in the region").	Data on Regional Legislations ²⁰
	Tax holidays	Presence of tax holidays for Sole Proprietorship in a region. A binary variable that takes on the value 1 if tax holidays for Sole Proprietorship were introduced in the region and 0 otherwise (0 if "NO tax holidays" and 1 if "tax holidays were introduced").	Data on Regional Legislations ²¹
	SEZ	Number of special economic zones in a region. A discrete variable that takes on the values 0, 1, 2, or 3, depending on the number of SEZs in the region, i.e 0 if "No SEZ" and 1 or 2 or 3 for the number of SEZ if "SEZ exists".	Special Economic Zones ²²
Digitalization	Internet	Percentage of individuals (households) with access to the Internet *82-83 regions. Data on the Chechen Republic is available since 2014.	Rosstat ²³

Table 2. Descriptive statistics

	Variable	Obs	Mean	Std. Dev.	Min	Max
1	Small business density, enterprises per 1,000 people	913	23.215	11.003	2.453	77.604
2	Income per capita, rubles per month	911	14982.101	8918.925	1608.3	64395.571
3	GDP per capita (1 year lag), thousand rubles in constant 1998 prices	902	35.285	41.281	3.974	355.548
4	Unemployment (1 year lag), %	913	7.565	5.63	.8	53.3
5	Market potential, trillion rubles	913	20.356	10.865	4.134	58.582
6	Population density, individuals per 1 square km	913	126.732	632.122	.069	4831.105
7	Internet, % of population	907	50.206	20.113	0	88.7
8	Banking Index, Index from 0 to 2	876	.801	.218	.15	1.94
9	Crimes, per 1,000 people	913	31.981	11.698	5.293	92.258
10	Tax inspections, per 1,000 enterprises	913	12.115	9.956	.458	105.116
11	Tax benefits, rubles per one organization	913	62404.25	179076.17	0	4128604.8
12	USN reduced tax rates, binary variable	913	.496	.5	0	1
13	Tax holidays, binary variable	913	.313	.464	0	1
14	SEZ, discrete variable	913	.242	.475	0	3

The geographical distribution of small and medium-sized enterprises (SMEs) in Russia has been developing for the last 30 years. During this period several sustainable types of entrepreneurial ecosystems have formed (Zemtsov & Tsareva, 2018; Zemtsov & Baburin, 2019). Small business density is higher in the regions with the largest agglomerations: St. Petersburg, Novosibirsk, Perm, Moscow, Yekaterinburg, Kazan, Tyumen, etc. (Zubarevich, 2015) (Fig.1), with favourable institutional environment: Tatarstan, Moscow, St. Petersburg, Krasnodar, Tyumen regions (Baranov et al., 2015; Barinova et al., 2018), as well as with an advantageous geographical position near large foreign (Kaliningrad and Sakhalin regions, Primorsky, Khabarovsk and Krasnodar regions, Karelia) and regional markets (Yaroslavl, Ivanovo and Ryazan oblast) (Zemtsov & Tsareva, 2018; Zemtsov & Baburin, 2016). It is lower in the northern and the far eastern part, where transport and energy costs are high, as well as in the south, where the share of the informal economy is higher and the business environment is worse.

A proactive support policy is being pursued in regions with lower risks for investors, and better access to markets and capital for small businesses: Moscow, St. Petersburg, Novosibirsk, Samara, Belgorod, Kaliningrad, Voronezh regions, Tatarstan and others. In regions with mostly manufacturing SMEs (Tomsk, Ulyanovsk, Ryazan, Tula, Krasnoyarsk regions), there are prerequisites for the formation of high-tech clusters. In several southern regions, the high share of the informal sector is related to a low development of formal institutions, low level of trust between agents, and corruption.

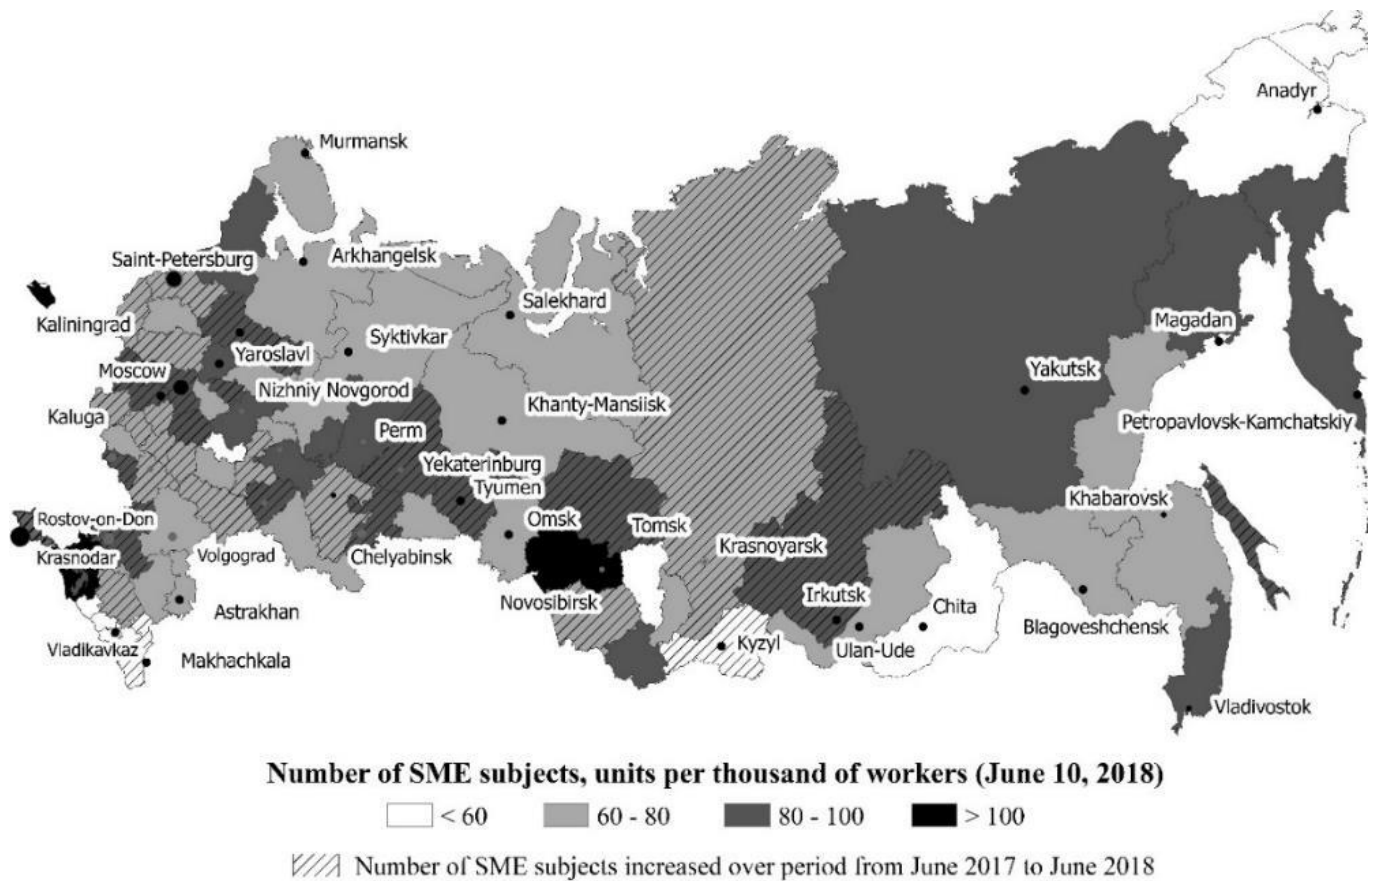

Figure 1. The number of small and medium-sized businesses per labour force

Therefore, when conducting entrepreneurial policies in large developing countries, such as Russia, it is essential to consider inter-regional differentiation and local factors. We used a wide range of variables to assess the determinants of the above-mentioned differences.

First of all, we were interested in the influence of demand on SME's products and service in a region on SMEs development. Households income or GRP per capita were used to estimate it. We used income per capita minus subsistence minimum because of the significant differences in living wages between the Russian regions. Besides it is important for business development to estimate how much consumers can spend additionally on the purchase of new goods and services, entertainment, tourism, etc. But in some specifications, due to the strong correlation between the variables of interest and income per capita, we had to use the alternative indicator, GRP per capita. It was one year lagged to solve potential endogeneity problem (*Dejardin & Fritsch, 2011*).

We included the unemployment rate (one year lagged) into regressions to control on labour supply and necessity-driven entrepreneurship. Note that in the 90s many businesses were founded due to high unemployment and lack of other alternatives; it can be the case for many regions nowadays. For example, more than 70 thousand workers were fired from 'AvtoVAZ', the largest car manufacturer in Russia, after the automation of production in 2010s (*Zemtsov, 2020*); a large part of them became a necessity-driven self-employed: taxi-drivers, car repairmen, retailers, etc. There was a government program to subsidize the opening of a new business. We had to omit the variable in some specifications due to the strong correlation.

We needed to assess total market access for SMEs in a certain region. Market potential was calculated as a cumulative indicator which includes gross regional product (GRP) of a region as well as weighed by distance GRP of other Russian regions and weighed by distance GDP of other countries (*Zemtsov & Baburin, 2016*). This approach implies that the market access can increase, if the neighbouring regions or countries are developing, even if the domestic region is not. In other words, the closer a firm is to a larger market, the higher is its ability is to sell products, services (export) and to buy equipment, components, raw materials, goods and services (import). In Primorsky Krai (Vladivostok) (Figure 1), high small business density can be explained by import and trade of Chinese (light industry products, electronics) and Japanese (automobiles) goods. Market potential strongly correlates with tax inspections and tax holidays that is why in some regressions we had to replace it with another market concentration indicator - population density, which measures only intraregional market access.

In Russia, banking capital remains the main source of SME's additional cash flow (after its own profits) because of weak development of venture financing. To assess the access to finance we used the cumulative index of bank services availability. The index characterizes regional bank infrastructure density per capita: credit institutions availability, deposits' volumes, etc. (*Barinova et al., 2018*). The higher the density of banking institutions and bank capital in a region are, the lower the credit interest rates for small businesses can be. Note that the interest rates have dropped significantly since the crisis year of 2015 in Russia, but bank loans are still less affordable for small companies than for the large ones

(Kudrin et al., 2021). In recent years, the formation of a system of state guarantees for obtaining loans, as well as subsidizing interest rates, could play a certain positive role in reducing rates for small businesses (Zemtsov et al., 2020). To assess the informal rules and formal regulations in a region, we used the ratio of a number of crimes to labour force. Crime is higher in regions with a high proportion of the informal sector, with a weak state. Crime increases the risks of a business and reduces its density.

We used the number of tax inspections per organization to assess administrative burden and related business costs. The number of tax audits has been declining in Russia as a result of a series of legislative acts, but differences between regions are still serious (Zemtsov et al., 2020). In some cases, inspections are used as a tool to put pressure on business and even as a form of political entrepreneurship.

We used a set of variables, primarily related to a reduction in the tax burden, to assess the efforts of federal and regional authorities to improve the business climate. For many years, high taxes were mentioned by entrepreneurs as one of the main barriers to small business development, along with low demand (Kudrin et al., 2021). The total amount of tax benefits (for income tax, property tax, transport tax and land tax) per one organization shows federal and regional tax breaks for businesses. Regional tax incentives (reduced regional tax rates) for a simplified taxation system for SMEs (USN) and tax holidays for Sole Proprietorship shows to what extent the regional authorities are interested in stimulating small business. It is well known from a literature review that countries and regions compete through tax regimes (Djankov et al., 2010).

We also considered special economic zones. We use the number of such zones in a region as an indicator of proactive regional policy. Distribution of special economic zones was determined by the choice of the federal government, but depended on proactive actions and the persistence of the regional authorities. The attraction of large corporations was supposed to facilitate the formation of small service companies around special economic zones.

Going back to econometrics, the basis of our model contains three variables: income per capita (or GRP per capita), unemployment and market potential (or population density). Due to the high correlation (see Table 5 in Appendix), we did not simultaneously include the following variables in the model:

- Income per capita and Internet. To test the significance of the Internet, we will include GRP per capita instead.
- Market potential and tax inspections. To test the significance of inspections, we use population density to control for agglomeration effects, instead of market potential.
- Market potential and tax holiday. To test the significance of tax holiday, we use population density, instead of market potential.
- Unemployment and banking index. We don't insert these variables into one model.
- Audits and Internet. We don't include them into one model.
- Audits and Tax holidays. We don't include them into one model.

Table 3. Correlation Matrix. All variables are log transformed except binary and discrete.

5. RESULTS

We evaluated models with fixed and random effects (table 4-5) for verification purposes. According to the Hausman test, we should give preference to fixed effects estimations²⁴ but we also used a number of time-invariant variables, which required random effects.

²⁴ The random effects model is useful when it is possible to believe that all objects are extracted randomly from some general population. This assumption is not entirely correct for a sample of the Russian regions. For country or regional samples fixed effects estimation are commonly used (Dougherty, 2011).

According to our estimations, if household incomes in a region is lower by 1%, then the number of small enterprises per workforce participants is lower by 0.35-0.58%, depending on other regional factors. The local markets demand is one of the most essential factors, because most SMEs sell their goods and services in local markets. Effect of alternative measure, GRP per capita, has a similar effect – 0,27-0,44. The self-isolation regime, introduced due of the coronavirus pandemic in April 2020, has led to a serious loss to the SME sector, because of the demand decline (*Kudrin et al., 2021*).

The impact of unemployment on the small business density insignificant, as its effect on lower incomes is already directly considered in the model. However, a 1% increase in unemployment in previous year may lead to an 0.1-0.16% increase in the number of small firms this year but mostly in regions with constantly better access to capital and markets. If corresponding variables are not included in the models, then unemployment becomes a negative factor. This is the effect of necessity-driven entrepreneurs (unemployment push). The unemployment rate in Russia in 2020 increased by 20% from 4.7 to 5.9% (*Kudrin et al., 2021*). During the crisis, employment centres in Russia actively offered various programs for starting a business and learning entrepreneurship. This could help increase the number of small businesses and self-employed in 2021.

It always seemed that foreign markets would not affect small enterprise development in such large countries like Russia because most of the small firms are oriented to local markets. However, a 1% reduction in market potential, which considers the global market influence on demand, may lead to a decrease in the number of small firms (per workforce participants) by 0.16-0.31%. In 2020, the borders of Russia and most other countries were closed for a significant period of time, which limited the possibilities of export-import operations, especially in the service sector. The global economy declined by 4,3% in 2020 (*UN, 2021*), which may corresponded to similar market potential reduction. It may accordingly lead to 0.36-0.45% decline in small firms' density.

Table 3. Fixed effects estimation results for 2008-2018

Fixed effects estimation results. Included 83 cross-sectional units. Time-series length = 5-10. Dependent variable: Small business density – Number of micro and small businesses (with full-time employees up to 100) per 1,000 economically active (employed) population in a region. Robust (HAC) standard errors. All variables are log-transformed.

The access to finance is another essential factor. The banks, facing high risks of non-return in 2020, may decrease its activity, which leads to bank service availability decline. According to our estimates, if a region has 1% higher banking accessibility index, it may lead to a 0,26-0,48% higher small firms' density. There are no available data for 2020, but the portfolio of SME's loans in 2020 grew by 22.6% compared to 2019 - up to 5.8 trillion rubles (Kudrin et al., 2021) because of the need for money during the period of self-isolation and income decline. The interest rate on a loan decreased from 12% in 2019 to 7.6% in 2020 for microbusiness, from 9.12% to 6.4% for small businesses due to government subsidies for banks. Note that the development of banking services has a positive effect on the density of small businesses only with expanding markets, which was not observed in 2020. Therefore, in this case, the growth of lending should be considered as a forced measure to avoid bankruptcy of small businesses, and if the economy does not recover in 2021, these bankruptcies and outstanding loans will be more difficult to avoid.

A low crime rate can also act as a proxy to the average level of trust in a region (highly correlated variables). And trust determines the possibilities of using new banking and other online technologies; it helps to build a sustainable entrepreneurial ecosystem with various connections. If the crime rate in a region is 1% lower, then the density of small businesses will be higher by 0.23-0.31%.

The number of field tax audits per firm turned out to be insignificant if we consider other institutional variables. There has been a substantial reduction in the total number of inspections in the recent years (Zemtsov et al., 2020), so they may no longer have a significant impact on small business density but still may affect established medium-sized companies. The tax support is positively significant. In a region with tax holidays, small business density is 0.11-0.25% higher. And 1% growth in regional tax incentives may increase small business density by 0.14-0.22%, but it is insignificant considering other characteristics of business climate. Tax breaks are less important: a 1% increase in the amount of tax benefits per firm may lead to a 0.014-0.018% increase in the number of small firms. This is due to the fact that many of these concessions are targeted at large business, and its development, in turn, can stimulate the growth of the number of small firms in a limited way.

In general, the density of small business is higher in regions with special economic zones, but if we consider all the institutional characteristics, the variable turns out to be insignificant. This is due to the fact that special economic zones were created in regions with already better conditions and proactive regional authorities.

Another important factor for small business development is Internet access in a region. The online sphere includes e-commerce, online services, and digital platforms for retailers. The Internet access will be especially important during and after the pandemic. A 1% increase in the proportion of households with the Internet access may lead to a 0.1-0.16% increase in the number of small firms (per workforce). Moreover, this value was calculated for previous periods, when only 42% of firms used the Internet to sell goods, and the online market accounted for 2% of the total retail. After the 2020 crisis, these figures are supposed to grow significantly.

6. CONCLUSION AND DISCUSSION

The regional factors of SMEs development are usually underestimated. Most politicians and researchers share the opinion about their importance. However, in practice, some government initiatives, e.g. setting up online cash registers or issuing anti-crisis subsidies through an online application, are implemented without considering regional costs and availability difference. Therefore, there is a need for differentiated and diversified regional SME policy.

In our work, we confirmed the influence of factors traditionally used in the literature (demand, unemployment, population density), but also proposed a number of new significant variables.

In confirmation of the first hypothesis, we showed that better potential access to regional and foreign markets is a positively significant factor for SMEs development. Accordingly, a decline in the global economy or trade barriers can have a disastrous effect on entrepreneurship, for example, through a reduction in imports. This influence will be especially high in the border and coastal regions.

The institutional environment is especially relevant SME development factor for transition economies, such as Russia. Firstly, small companies are more vulnerable due to their lack of substantial financial, human and other resources; there were no entrepreneurs and open markets in the USSR. Secondly, entrepreneurs in Russia often lack business experience. Thirdly, they do not have consistent access to all essential formal institutions. Consequently, small firms are often forced to use their family ties or friends of their co-founders, and are not always perceived trustworthy. According to the second hypothesis, we have shown that the high crime rate in a region reduces small business' density, while wide access to banking capital, on the contrary, increases it. High crime rate can be perceived by entrepreneurs as a threat to their security from both criminals and unscrupulous officials. The availability of banking services can be an indicator of low interest rates due to bank competition. It is a proxy for the capital access, which contributes to entrepreneurship development.

State support in the form of tax breaks and holidays may have a positive effect on small firms' density, but this impact is limited. The administrative burden and special economic zones are not significant factors compared to the general business climate. Note that, according to earlier estimates, only 9% of entrepreneurs have ever received government support in Russia (*Kudrin et al., 2018*). It can be argued that the general conditions of an entrepreneurial ecosystem are significantly more important than state support measures, and, accordingly, these measures are not able to radically change the situation in regions with weak ecosystems in the south, north and east of Russia (*Zemtsov, Baburin, 2019*). Moreover, many Russian firms usually move to the shadow economy during a crisis and large firms are split into small ones for the tax optimization and to regulatory reduction. This begs the question, if state support does not usually have a significant impact on the SMEs' dynamics in Russia, can it influence it during the crisis.

Previously, it was believed that Internet access cannot be a significant factor of SME's development, since the share of online retail does not exceed 2% in Russia and most of the companies do not sell products and service online. Our calculations show the significant role of digitalization in the 2010s. And it can be a survival factor for the companies in 2020 and after. Online businesses in Russia demonstrated growth or the smallest rate of decline even during the period of self-isolation (*Kudrin et al., 2021*).

An attempt to forecast the development of small business in a crisis period based on previous trends is debatable, since these trends and dependencies could radically change. However, our results appeared to be close to real estimates. According to our calculations and factors forecasts for 2020, with a 4,3% reduction in world markets (*UN, 2021*), a 3.5% drop in household incomes (*Kudrin et al., 2021*), a 3.3% decrease in the number of small firms is possible. According to the Federal Tax Service of the Russian Federation, there were 4.3% decline in the number of SMEs during 2020 (*Kudrin et al., 2021*). Substantial decrease in the number of small firms may lead to a long-term decline in regional development (*Reynolds et al., 2002; Wong et al., 2005; Gonzalez-Pernía & Peña-Legazkue, 2011; Acs et al., 2012; Sadyrtdinov et al., 2015; Urbano et al., 2019*). According to (*Zemtsov, Smelov, 2018*), a 4,3% decrease in the number of small firms may lead to a 0.22 to 0.67% decrease in GRP, which explains part of 3,35 drop of Russian GDP in 2020 (*Kudrin et al., 2021*). Nevertheless, it is necessary to clarify that these estimates are rather speculative in nature, and their verification is possible only after several years, when the corresponding statistics will be available.

Despite these limitations, the identified factors in a general sense may help to verify the measures taken by the governments. First of all, it would be advisable to pursue a demand support policy. This implies provision of "salary" bank loans, subsidies to cover the salaries, etc. The digitalization of all public services becomes relevant, including the online access to tax payments, subsidies, access to public procurement, etc. It is also important to support the business digital transformation. It is essential to maintain favourable institutional environment and the level of trust, especially among the entrepreneurs, to keep them motivated and encouraged to do business. In the long term, improving market access by developing infrastructure, lowering transport tariffs and removing institutional barriers at the border will also help small business development.

In our opinion, the proposed model considers the most significant factors, but it requires expansion and further verification. There are some determinants which are not reflected in the current paper. We used some indicators of

human capital (for example, average number of education years of workforce) that were found to be insignificant or led to multicollinearity. It seems to us that this is due to the fact that the indicator does not consider the quality of education. A search for alternative metrics is needed. We have not found a suitable indicator for assessing the connectivity inside an entrepreneurial ecosystem. It is also necessary to search and test other indicators of entrepreneurship.

However, the results obtained allow us to see general patterns for Russia and create the basis for future discussions. For example, to what extent identified relations are typical for all regions? How well can the proposed model predict the decline (or growth) in the number of small companies in a specific region? The models (Tables 4-5) describe well the situation on average (LSDV $R^2 > 0.98$), but for each specific region there is a large share of other factors (Within $R^2 = 0.51-0.58$). At the same time, some variables of state support worsen the quality of the models, which may be a reminder of manual or stochastic mechanisms of its distribution between regions. Anyway, there are a few questions here for further research.

THE SANDWICH OF RUSSIAN SPACE: HOW DIFFERENT SPACES DIFFERENTIATE THEMES IN REGIONAL SCIENCE

Nadezhda Zamyatina¹, Ruslan Goncharov², Alexandra Poturaeva¹, Alexander Pilyasov¹

¹Lomonosov Moscow State University, Russian Federation. ²Higher School of Economics, Russian Federation

ABSTRACT

The paper shows the inseparable connection between the topics of the main centres of Russian regional science and the properties of the space that they are studying. The diversity of the thematic structure of research centres is derived from differences in economic geographical and geopolitical position, sectoral structure of the economy, age of economic development of the studied areas of the Russian space. However, the most important factor differentiating Russian space is the density of economic activity, which determines the level of development of the territory. Within the Russian space, significant undeveloped territories of the North, the Arctic, Siberia, and the Far East are of particular interest, in which extensive buffer zones are distinguished between the main settlement zone and low-density periphery. They constitute the essential specificity of the Russian space. Another feature is the presence of colossal “ownerless” spaces that are outside the influence of any nearby major centre and therefore are forced to focus on the federal capital, Moscow.

EFFECT OF TARIFF LIBERALIZATION ON MEXICO'S WAGE DIFFERENTIAL

Mary Arends-Kuenning¹, Kathy Baylis², Rafael Garduño-Rivera³

¹University of Illinois at Urbana-Champaign, USA. ²University of California, Santa Barbara, USA. ³Universidad Panamericana, Mexico

ABSTRACT

This paper studies how the North American Free Trade Agreement (NAFTA) affected wage differentials within Mexico considering internal migration. In low-skilled, labor-abundant developing countries, trade liberalization should theoretically increase the wage of low-skilled workers, decreasing income inequality. However, anecdotal evidence indicates that NAFTA increased the gap between rich and poor in Mexico, and empirical evidence is mixed (Hirte et al., 2020; Brühlhart, 2011; Bosch and Manacorda, 2010; Nicita, 2009; Chiquiar, 2008 & 2005; Hanson, 2007; Gonzalez-Rivas, 2007). Because trade may affect wages differently across regions within the country, accurate measures of wage effects must incorporate internal migration, otherwise apparent wage convergence or divergence might only reflect a geographic resorting of workers.

To study the effect of NAFTA on migration we first predict the probability that an individual will migrate based on the potential growth in municipal Gross Value Added (GVA) associated with tariff reductions from NAFTA. Because migration and wage outcomes are jointly determined, and likely both related to unobservable individual characteristics, we instrument for migration using local crop yield shocks, specifically corn, which have been shown to influence migration yet are unlikely to affect wages in the manufacturing, retail or service sectors in urban areas except through labor supply. Next, in a second stage, we estimate a wage equation as a function of trade, demographic and household characteristics, together with the previously instrumented probability of migration. By analyzing trade openness and distance to the border, we find that workers closer to the US-Mexico border get a higher wage than their counterparts far away. But this spread diminishes as tariffs fall, after NAFTA. Further, we find that men with low wages get a boost from NAFTA in their wages while NAFTA has a negative effect for those with high wages. Thus, trade liberalization appears to have decreased wage differentials.

This paper offers the following contributions: First, to our knowledge, this is one of the first studies to consider the effect of trade on wages while explicitly controlling for migration. Second, we correct for the potential endogeneity of internal migration and wages by using a two stage least squares (2SLS) instrumental variable estimation. Third, by comparing low vs. high wage earners, we explore which workers gained and lost from trade. Fourth, we include the latest population census (2010) to observe long-run wage changes after NAFTA and ask whether wage differentials persist as the economy adapts to trade. The results of this research can help identify those barriers facing individuals and regions that limit their ability to benefit from trade. Thus, this research can help identify the areas of social investment and infrastructure investment that may help smooth wage inequality. Further, by identifying those regions and individuals who have benefited and lost from trade, this information can be used to target compensation. Finally, using this estimation approach, regional governments can anticipate migration and wages in their region, and adjust local development plans accordingly.

ASPIRATION OF MIGRANTS AND RETURN TO HUMAN CAPITAL INVESTMENT

Sucahyo Dwi Husada, Evi Noor Afifah

Economics Department, Universitas Gadjah Mada, Indonesia

ABSTRACT

Migrants are known having higher aspiration than non-migrants. In the previous studies, migrants are believed adjusting their aspiration to the new income to that of a new reference group. One conventional explanation stated that if the gap of aspiration is higher than the change of income, migrants will be trapped on hedonic treadmill phenomenon. Furthermore, migration can be viewed as a process of human capital investment. Migrant assume cities can be viewed as a place to accumulate human capital. So that by doing migration, migrants will be experienced an increase of aspiration. This study will test the phenomenon of changes in migrant's aspiration through both theoretical approaches using IFLS data 2007 and 2014. This study uses a variable that constructed by the different of migrant's current perception welfare level with 5 years to come perception and estimated using OLS, Ordered Logit and Village Fixed Effect method. The result show that the phenomenon of change in migrant's aspiration can be explained through both theoretical approaches. This study also proved the existence of hedonic treadmill phenomenon in migration activity.

**WOMAN SHOULD NOT BE AFRAID TO WORK: THE STUDY OF
MATERNAL EMPLOYMENT'S IMPACT ON CHILDREN'S EDUCATIONAL
ACHIEVEMENT IN INDONESIA**

Wahyuningtyas Puspitasari^{1,2}, Evi Noor Afifah¹

¹Department of Economics, Universitas Gadjah Mada, Indonesia. ²Provincial Government of the Special Region of Yogyakarta, Indonesia

ABSTRACT

As the increasing of women participation in labour market for the last 20 years, many women in Indonesia have double status, being a mother and a worker at the same time. The effect of maternal employment to their children still becomes a debatable issue around society and researcher. This study analyses the effect of Indonesia maternal employment on the children's achievement in primary education. Using the 2nd-5th wave of IFLS (Indonesian Family Life Survey), about 1445 children have been used as sample research. National exam score of mathematics and Indonesia language from grade 6 (elementary school) and grade 9 (junior high school) has been used for the dependent variables. Maternal employment status is taken when children in elementary school entry age. Pooled cross section regression model is used to analyze this dataset. This study found that maternal employment status has a significant effect on children's achievement on Indonesian language score both of elementary or junior high school but it doesn't have a significant effect on mathematics regardless of any grade. Working mothers at this age have changed the quantity engagement time with children to the quality engage time. Internal factors such as higher motivation or existence of role model also become the reasoning of the positive result. Government and the private sector should formulate a regulation that can increase the parenting room and expand the development early education. Except asking help from the grandparents or relative's help to substitute their role, enrolling children to the kindergarten or early education could be a solution for working mother to avoid the disadvantage of their maternal employment status.

THE IMPACT OF INCOME GAP TO MIGRATION DECISION IN INDONESIA

[Nazala Syahru Rachmawati](#)¹, [Evi Noor Afifah](#)²

¹Coordinating Ministry for Economic Affairs, Indonesia. ²Department of Economics, Universitas Gadjah Mada, Indonesia

ABSTRACT

Migrants make their decision whether to move or to stay are based on various motives such as financial or non-financial motive. Todaro, in his migration model said expected income of migration take a big part in migrants decision making. They are tend to move if their expected income after migration exceed their income in current place. The higher is this income gap, the higher migrants propensity. We are trying to test the prediction of Todaro model for Indonesian study case. But, this research model have several problem like selection bias because information about expected income are available only after individual has already migrated. To overcome this problem, we use two-step Heckman to correct selection bias in the model. The main objective of this research is to analyze the determinants of migration in Indonesia and the impact of income gap on migration decision. This study shows that income differences affect the decision to migrate by households in Indonesia based on IFLS data.

ABSTRACT

Housing has always been a constant of the morphology of cities, whose presence is the scenario against which urban life gains visibility. Housing has implications with the definition of social relations and the standardization of cultural values on the growing urbanization process, in which housing corresponds to the highest percentage of the housing market supply and is one of the main local, regional and national economies. Housing is a matter both local and global.

According to World Cities Report 2016, the housing function corresponds to more than 70% of land use in most cities and determines density and urban form. For this reason the housing issue must be placed at the heart of urban policies, especially with regard to the phenomenon of urban sprawl, which is seen as one of the biggest challenges for sustainable planning of the territory.

In view of the dichotomy between the constraints of urban expansion and the benefits of scale economies, strongly anchored in housing production, it is today required that city public policies be able to adapt housing production to transformative processes resulting from the accelerated growth of cities, taking into account the following key factors:

- a) The concept of urbanization simultaneously as a process of urban self-expansion and as a way of life, in the context of a new socio-spatial order;
- b) The awareness that the city where we will live in the future is already being modeled by spatial planning and the building of the present;
- c) The city as space-time creation and the urbanization as a way of life result both from man's ability to transform the environment that he inhabits, so the attributes of the built environment are key considerations, which require the most high architecture design standards of buildings and public spaces.

In the very deed of the construction, we must have present the social and cultural references that intervene in the relationship between space and man. If house building emerges as inevitability, what we build and how we build has currently reflected the preferences of the Real Estate industry more than the views of an architecture and urbanism committed to issues related to the social cohesion and the right to the city.

The New Urban Agenda UN-Habitat III (2016) puts us in charge of the idea that building and making cities are inseparable actions. For this reason, spatial planning acquires a growing role as a reference instrument for new governance structures to deal with problems and divergences of conduct in real estate markets.

KEYWORDS

Architecture, housing, space as commodity, urbanization.

1. INTRODUCTION

For the Romans the concept of the city is a "mobile" artifact in its essence. The reference to a Roma *mobilis*, forming the representation of an *imperium sine fine*, of which Virgil spoke, finds today full correspondence in the macro-territorial typologies of contemporary cities.

This mobility can only succeed if it is associated with the idea of *civitas augescens*, an ever-growing city, which is to say, "the programmatic characteristic of the *civitas* is to grow, there are no *civitas* other than *augescens*, which expand, which "de-lire" (Cacciari 2009: 15-16)". It should be noted here that the world 'lira' corresponded to the ceremonial groove, traced as a sign that delimited the Roman city. *Delirium* means, consequently, to leave the lira, to go beyond the city limits. This vision of a city in constant growth is of interest to our study, since European cities - as a place to live and a place of business - continue to develop from the Roman position, since we conceive the city as a place where people come to live and accept the same law, i.e. the same urban policy.

The progressive concentration of population in our cities, the result of demographic dynamics translating changes in social contexts, has been directly reflection in the expansion and complexity of urban tissues. One of Jane Jacobs (1961) seminal contributions "was the conception of the contemporary cities as «problems of organized complexity», namely problems with many variables that nevertheless interrelated into an organic whole (cfr. Theodosis 2015: 288)".

The interrelationship of these variables and the understanding of the phenomenologies associated with them can find an explanation in Christopher Alexander's article "A City is not a Tree". In his classic article, Alexander argued for the need to understand the city as a semi-lattice instead of a tree structure. "The tree structure was identified with the hierarchical

organization, functional zoning, and the separation of land uses. (...) The semi-lattice structure instead represented the complexity of the overlapping activities in mixed-use urban areas, an urban model that Alexander strongly advocated against the simplicity of the tree structure (Theodosios 2015: 288)".

To explain the functioning process of each one of these systems, Christopher Alexander gives as an example the relationships of personal knowledge that are established in a traditional society and those that characterize the current social structures, saying that "In a traditional society, if we ask a man to name his best friends and then ask each of these in turn to name their best friends, they will all name each other so that they form a closed group. (...). But today's social structure is utterly different. If we ask a man to name his friends and then ask them in turn to name their friends, they will all name different people, very likely unknown to the first person; these people would again name others, and so on outwards. There are virtually no closed groups of people in modern society. The reality of today's social structure is thick with overlap - the systems of friends and acquaintances form a semilattice, not a tree (Alexander 1965)".

In addition to the idea of a *civitas augescens*, characterized by its morpho-social *delirium*, we need to add the idea of a *civitas mobilis*, to which we previously referred. It is no longer about addressing the mechanism of urban expansion that evolves without limit and is confused and mixed with the rural territory itself that it progressively occupies, but brings to our theme of study another characteristic of our current societies - that most human activities generate mobility.

Mobility has become a key element of human activity, particularly in urban areas by playing a central role in prosperity and social cohesion. Its relationship with the housing production is crucial due to the infinite number of variables that as to be introduced in to the city planning.

Indeed the articulation between the two concepts, *civitas augences* and *civitas mobilis* finds in the production of housing a common denominator that must be taken into account in the planning of our cities. According to World Cities Report 2016, the housing function corresponds to more than 70% of land use in most cities and determines density and urban form. For this reason the housing issue must be placed at the heart of urban policies, especially with regard to the phenomenon of urban sprawl, which is seen as one of the biggest challenges for sustainable planning of the territory.

2. HOUSING PUBLIC POLICY AND REAL ESTATE

Despite all the negative social and economic impacts resulting from the 2008 financial crisis, according to eurostat housing statistics 2019, housing ownership, using indebtedness, has remained the main option and today represents the most common form of occupation in the European Union (EU-28).

When the people occupying the dwellings are also their owners, the investment usually corresponds to a significant part of their income and is a determining factor in the financing of their habits. In turn, "real estate financing represents a significant amount of financial institutions in many European countries (...) and investments in residential properties have a great weight in the investment portfolios of real estate companies (Suarez 2009: 8)".

In addition to speculation, the rise in house prices, which in the Portuguese case has been occurring since 2014, it has given rise to a new Real Estate boom and an increase in demand by investors (national and international) especially in the central areas of Lisbon and Porto cities, which may be related to several other factors:

- i. The housing rental market liberalization in 2012, mainly as a result of the publication of Law No. 31/2012 of August 14, which revises the legal regime of urban leases, liberalizing it and amending the Code of Civil Procedure and Law No. 6/2006 of February 27.
- ii. The publication in 2014 of the new exceptional and temporary regime applicable to the rehabilitation of buildings, Decree-Law No. 53/2014 of April 8 (meanwhile repealed by Decree-Law No. 95/2019 of July 18), which came from the compliance with some rules provided for in special regimes related to construction, such as accessibility, energy efficiency, structural security, etc.;
- iii. The significant increase of tourists using the Local Accommodation, strongly encouraged by the publication of Decree-Law No. 128/2014 of August 29, which approves legal regime for the operation of local accommodation establishments. In view of the reduction in tourist activity, due to the situation, many local lodges are currently being transferred to the traditional rental market;
- iv. And yet the creation of a very favourable tax regime for non-habitual residents, which contributed to increase the demand for housing properties.

The above is revealing the complex relationship between the Real Estate market and public housing policies. This relationship depends, to a large part, on the process of urban system recomposition and the different stages of the cyclical model of changes that occur in cities, namely the relationship between housing and the urban fabric, given that it is its most constant element (Marques 2021).

2.1 Real Estate as a protagonist

The media are revealing support of the almost daily transformations that come to occur in the housing production and its strong link to Real Estate markets, highlighting in their advertisements or opinion articles, the most diverse types of relationship between supply and demand for housing or the city. Let's look at some examples.

In THE IRISH TIMES de 5 May 2021, an article of Ciarán Hancock entitled "**Evidence does not support case for shared-equity housing scheme**", refers "It is one of the curious things about life in Ireland that property developers and the construction industry here openly tell us that it's just not financially viable for them to build houses that people can afford to buy".

In another article, published in *Yahoo!finance* (5 May 2021), Ethan Wolff-Mann hypothesizes that "**High demand for housing combined with low inventory has heated up the market - boosting property values and leading some to**

wonder if we're in bubble territory". The answer is given in the same article by Vishwanath Tirupattur, Morgan Stanley strategist, who wrote in a note to clients this week informing that "We have strong conviction that we are not experiencing a bubble in US housing".

Another news item published in The Guardian de 8 May 2021, with the title *"White-hot housing market has Merseyside suburb at fever pitch"*, special emphasis is given to the suburban single-family housing market: "The Merseyside town of Wallasey has over the past year recorded a bigger rise in asking prices than any town or city in Britain, according to the listings site Rightmove. And it's family homes with gardens – a popular choice during lockdown – that have become must-have assets."

On June 18, 2017 Vítor Andrade, economics coordinator of the newspaper Expresso, published an article entitled: *"There are 60 to 70,000 houses in Portugal that do not sell for the simple reason that no one wants to buy them"*. The justification for this situation was given by the article's author: "They are located mainly in suburban areas of large cities, inserted in a poorly achieved and poorly functional urbanism, in neighbourhoods served by poor quality accessibility and with severe parking difficulties. The buildings are of poor quality, the interior of the houses is poorly divided and the areas are generally ungenerous."

Several other examples could be presented here on housing and city issues. It is important, however, to retain how clearly this news matched with the statistical data, such as those presented in the next chapter.

2.2 The Portuguese case: statistical data

The Portuguese National Institute of Statistics (INE) regularly publishes an edition of the Housing Price Statistics at the local level based on data of an administrative nature (see www.ine.pt, option Products, Statistical Data, Data Base). The published figures refer to the median of the sales prices/square meter of family accommodation (€/m²). Unless otherwise indicated, the median is determined in the annual period ended in the reference quarter of this publication, eliminating possible seasonal effects on price behavior and thus allowing to increase the geographical detail of the presentation of results.

2.2.1 Quarterly results 2020

In the 3rd quarter of 2020, the median price of family accommodation in Portugal was 1168 €/m². This represents a reduction compared to the 2nd quarter (-1.6%) but an increase compared to 3rd quarter of 2019 (+7.6%). The evolution of the annual rate of change between the 2nd and 3rd quarter of 2020, from 9.4% to 7.6%, shows the slowdown in the pace of growth in house prices, as in the previous quarter. Figure 1 shows that the most common pattern recorded in 12 of the sub-regions was a median value of house prices and an annual rate of change lower than the country's values, noting that, in this group, seven sub-regions recorded a reduction in prices in the 3rd quarter of 2020, compared to the same period of the previous year.

As a result: *Seven NUTS III recorded annual reduction sums of house prices, but sub-regions with prices higher than the national value – Algarve, AML, Madeira and AMP – recorded homologous growth higher than in the country (+7.6%).*

Figure 1: Median value and annual homologous rate in median value of sales per m² of family accommodations, Portugal e NUTS III, 3^oT 2020

Fonte: INE, I.P., Housing price statistics at the local level.

Figure 2, representing municipalities with more than 100,000 inhabitants, shows that for 10 of the 24 municipalities there was a slowdown in housing prices (municipalities below the bisector of the annual growth rate in the 2nd and 3rd quarter of 2020). Of these 10 municipalities 6 belonged to the Metropolitan Area of Lisbon and only one to the Metropolitan Area of Porto (Matosinhos). In the case of the municipality of Lisbon, the homologous variation in the 3rd quarter of 2020 was even negative (-1.8%).

In nine of the 24 municipalities with more than 100,000 inhabitants, the price slowdown between the 2nd and 3rd quarter of 2020 was higher than the national standard (-1.8 p.p.), having been particularly marked in Amadora (-9.3 p.p.), Cascais (-8.9 p.p.) and Lisbon (-8.1 p.p.). Between the 1st and 2nd quarter of 2020, 10 municipalities had recorded a homologous slowdown higher than in the country (-5.0 p.p.).

Above the bisector, stand out among the 13 municipalities that verified an acceleration of prices between the 2nd and 3rd quarter of 2020, Almada (+12.5 p.p.), Porto and Funchal (both with +10.5 p.p.).

As a result: *Lisbon was the only one of the 24 municipalities with more than 100,000 inhabitants with a homologue contraction in house prices (-1.8%) and nine others also recorded a slowdown in prices.*

Figure 2: Change rates in the median value of sales per m² of family accommodation, Portugal e municipalities with more than 100,000 inhabitants, 2^oT 2020 e 3^oT 2020.

Fonte: INE, I.P., Housing price statistics at the local level.

2.2.2 Quarterly results (last 12 months ended in the reference quarter)

In the 3rd quarter of 2020 (last 12 months), the median price of family accommodation in Portugal was 1160 €/m², increasing +2.0% compared to the previous quarter and +10.1% compared to the homologous quarter. The median house price remained above the national value in the Algarve (1711 €/m²), Lisbon Metropolitan Area (1586€/m²), Madeira Autonomous Region (1307 €/m²) and Porto Metropolitan Area (1192 €/m²). In the period under analysis, 47 municipalities presented a median price higher than the national value, located mostly in Algarve sub-regions (14 in 16 municipalities) and Lisbon Metropolitan Area (15 out of 18). The municipality of Lisbon (3375 €/m²) recorded the highest price in the country. There were also values in excess of 1500 €/m² in Cascais (2747 €/m²), Oeiras (2312 €/m²), Loulé (2226 €/m²), Lagos (2018 €/m²), Porto (2016 €/m²), Odivelas (1958 €/m²), Albufeira (1951 €/m²), Tavira (1924 €/m²), Faro (1758 €/m²), Loures (17 €53/m²), Lagoa (1720 €/m²), Almada (1695 €/m²), Funchal (1686 €/m²), Vila Real de Sto. António (1656 €/m²), Amadora (1611 €/m²), Matosinhos (1584 €/m²), Aljezur (1578 €/m²), Portimão (1520 €/m²) and Silves (1512 €/m²), two more municipalities than in the previous quarter.

As a result: *Twenty municipalities, located mostly in the Algarve and Lisbon Metropolitan Area, recorded house prices above 1500 €/m².*

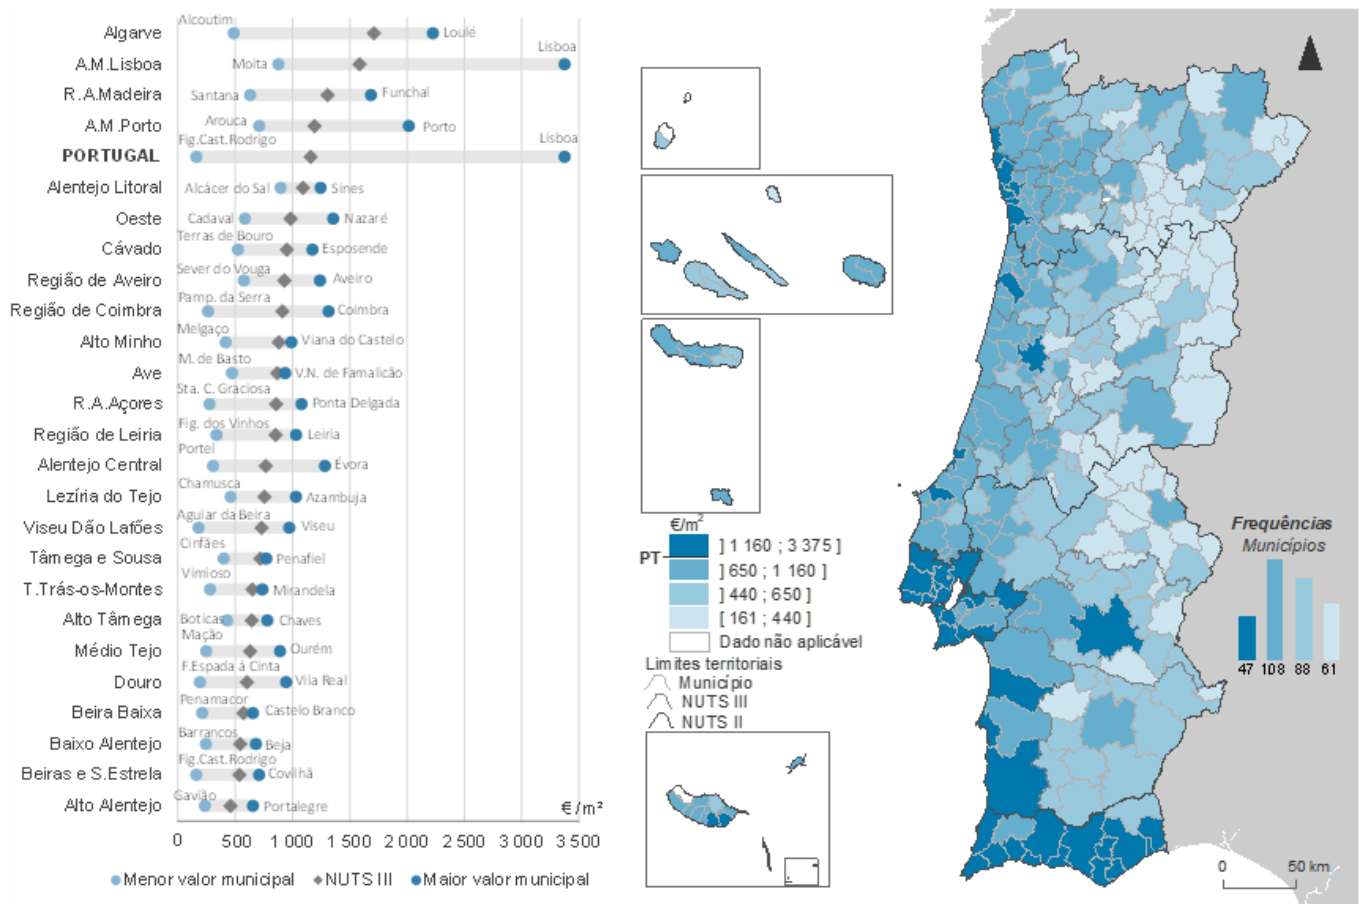

Figure 3: Median value of sales per m² of family accommodation, Portugal, NUTS III and municipalities, 3rdT 2020

Fonte: INE, I.P., Housing price statistics at the local level.

2.2.3 Quarterly results, values per parish for cities with more than 200,000 inhabitants (Lisbon and Porto)

As can be seen in Figure 4, in the 3rd quarter of 2020, three of Lisbon's 24 parishes recorded median prices for the sale of accommodation in excess of €4,500/m²: Sto António (5540 €/m²) – which includes Av. da Liberdade and adjacent areas – Sta Maria Maior (5372 €/m²) – which includes the Castelo and Baixa/Chiado area – and Misericórdia (4963 €/m²) – which includes the Bairro Alto and Cais do Sodré area. The parishes Santa Maria Maior, Estrela, Sto António, Misericórdia, Arroios and Alvalade recorded a median price above the value of Lisbon city (3375 €/m²) and variation rates, compared to the homologous period, more expressive than that observed in the city (+5.3%).

The parishes of Sta Clara, Beato, Olivais, Benfica, Marvila, Penha de França, Ajuda, Campolide, Alcântara, Carnide, São Vicente and São Domingos de Benfica recorded, in the 3rd quarter of 2020, prices and variation rates lower than those of the city of Lisbon, highlighting this set the parishes of Ajuda (-8.1%), São Vicente (-4.9%), Beato (-3.6%) and Marvila (-2.8%) house prices compared to the homologous period. (See Figure 4 and 6)

As a result: Only six of the 24 parishes of Lisbon with homologous contraction of house prices: Ajuda, Campo de Ourique, São Vicente, Avenidas Novas, Beato and Marvila.

Figure 4: Median value and homologous rate of median sales value per m², Lisbon and parishes, 3rdT 2020

Fonte: INE, I.P., Housing price statistics at the local level.

In the city of Porto, in the 3rd quarter of 2020 (last 12 months), the Union of parishes of Aldoar, Foz do Douro and Nevogilde, the Union of parishes of Lordelo do Ouro and Massarelos and the Union of parishes of Cedofeita, Sto Ildefonso, Sé, Miragaia, São Nicolau and Vitória stood out, for presenting a median price (2787 €/m², 2416 €/m² and 2326 €/m², respectively) above the value of the city (2016 €/m²) and a year-on-year change rate (+15.5% and both +15.3%, respectively) higher than that observed in the city (+11.9%).

The Union of parishes of Aldoar, Foz do Douro and Nevogilde recorded the highest median price in the city. The parishes of Ramalde, Bonfim and Campanhã recorded a median price (1745 €/m², 1972 €/m² and 1297 €/m², respectively) and a homologous variation (+4.1%, +7.2% and +10.9%, respectively) lower than the values recorded in the city of Porto. The Paranhos parish recorded a lower median price (1847€/m²) and a rate of variation, compared to the same period (+17.9%), higher than that recorded in the city of Porto. In the period under analysis, and as in previous quarters, the Campanhã parish recorded the lowest median price (1297 €/m²) and the Paranhos parish stood out for presenting the highest rate of variation compared to the same period (+17.9%). (See Figure 5 and 6)

As a result: *The Union of parishes of Aldoar, Foz do Douro and Nevogilde recorded the highest median price (2787 €/m²) among the seven parishes of the city.*

3. CONCLUSIONS

Contrary to what it would be expected, the pandemic crisis that during 2020 led to a recession in economic activity on a global scale does not seem to have affected the housing market. Statistical data show the existence of increasing price inflation, even when compared to year-on-year values in 2019.

The idea of a city in continuous process of expansion, which expands beyond its limit, the *civitas augenses*, acquires a new dimension linked to the notion of a Real Estate market that expands over the cities and rural landscapes, establishing new logics of appropriation and organization of both urban and rural spaces which become part of its business portfolio.

The concept of urbanization simultaneously as a process of urban self-expansion and as a way of life, in the context of a new socio-spatial order appears to be the result of Real Estate activity and not so much of an urban planning based on technical bases or scientific theories.

The city as space-time creation and the urbanization as a way of life result both from man's ability to transform the environment that he inhabits, so the attributes of the built environment are key considerations, since the city where we will live in the future is already being modeled by the building forms of the present.

A SPATIAL QUANTILE REGRESSION ANALYSIS OF HOUSING PRICES IN GERMAN REGIONS

[Elena Semerikova](#)

National Research University Higher School of Economics, Russian Federation

ABSTRACT

The aim of the paper is to identify and establish empirical facts on the determinants of real estate prices by analyzing spatial regional data. We provide empirical analysis on the panel data set of 401 German regions for the period 2004 – 2018 taking into account their relative geographical location and prices. The main contribution of our paper is the analysis of determinants and spatial effects in housing prices, taking into account whether regions belong to high-prices or low-prices cluster.

The panel dimension of the analysis allows to account for regional heterogeneity, whereas spatial regional dimension catches the interaction of close-located regions: how shocks in real estate price determinants in neighbouring regions affect the housing prices level and to what extent the shock in one region is expanded to other closely located regions. Finally, spatial quantile regression reveals the differences between the high-prices and low-prices regions. Taken together they provide a unique opportunity to analyze the fundamental factors affecting real estate prices from different perspectives.

First, we investigate whether real estate prices in German regions experience spatial correlation and whether this correlation is connected to the fundamental factors of the real estate prices. We find factors from the demand and supply side that affect housing prices. The prices may be influenced by socio-economic factors, such as the share of the population with higher education, purchasing power, the quality of human capital, which affect the level of development of the region's economy and in turn affects the real estate prices. Second, we perform spatial econometric analysis, applying SDM, SAR and SEM models, completing the estimation with the spatial quantile regression.

The results of the analysis suggest that the demand-side factors increase the housing prices in most cases, supply-side GRP per capita causes the decrease. At the same time, the magnitude of commuting flows may increase as well as decrease the prices depend on where the change is happening, inside the region or in neighbouring areas. Spatial allocation of regions plays an important role in real estate pricing: regions located close to regional centres benefit from it, which is easily accounted for by spatial correlation. We also find spatial effects for the determinants: a demand change in a region affects the price also in the neighbouring regions. From the spatial quantile regression analysis, we expect that regions with higher prices are more sensitive to infrastructural or policy changes, whereas low prices regions experience a more sluggish reaction. More than that, positive spatial dependence is higher between regions with high housing prices and lower for less attractive regions.

A TERRITORIAL HOUSING COST OVERBURDEN INDEX: AN EXPLORATORY APPROACH FOR PORTUGAL

Paulo Batista^{1,2,3}, João Marques^{1,2,3}

¹Universidade de Aveiro, Portugal. ²Unidade de Investigação em Governança, Competitividade e Políticas Públicas (GOVCOPP), Portugal. ³Grupo de estudos em território e inovação, Portugal

ABSTRACT

Housing needs have been increasing their analytical complexity since the concept tends to encompass multiple dimensions. The (human) rights to adequate housing should cover entitlements such as the legal security of tenure, availability of services, materials, and infrastructure or cultural adequacy. Simultaneously, the housing market has been assigned an increasingly important role: it is the device chosen to provide decent and adequate housing while public bodies assumed a low level of intervention.

The growth of housing market prices (purchase or rent) has been accompanied by territorial and socioeconomic transformations leading to a recognized emergence of overall housing provision imbalances. In this context, the measurement of housing affordability regained new importance. Despite the existence of official measures, that are used to support some housing policies, significant limitations can be found and need to be updated – see, for instance, the housing cost overburden of produced and used by Eurostat and by the National Statistics Institute.

A classical affordability approach combines measures of the housing cost (supported by the housing prices associated with them), the households income, and the adoption of a normative threshold (such as the 0,4) to classify housing provision as affordable or not. This straightforward measure does not reflect the diversity of needs that should be considered today on housing affordability analysis. Housing needs are complex and multiple dimensional phenomena that emerge at the local scale, but housing affordability is usually obtained through national inquiry to households with limited territorial detail at the sub-national level.

Based on the data provided by National Statistical Institute (INE), it is possible to estimate housing prices and household income at the local level. This work presents the methodology of this estimation process, grounded on the spatial econometrics framework, to obtain the housing cost overburden rate at the local scale (municipality and parish levels). Moreover, estimations of housing prices and household incomes will be combined with detailed census data on houses and families to provide exploratory guidance on the role of socioeconomic characteristics and general urban transformation phenomena as territorial explanations of the imbalances in housing provision for Portugal.

The results highlight the role of intense rural-urban transformations, shaping Portugal in the last decades, as an important source of the territorial housing provision imbalances as the population migrates for urban areas both on metropolitan regions (Lisboa and Porto) or the regional and local urban centers, increasing demand and pressing prices in that locations. Simultaneously, the quick shift of the demographic structure, where aging and population decrease spreads throughout the territory, required important housing readaptations or reconstructions to satisfy the needs of the new population structure (elderly). As markets and the housing market, in particular, tends to be more inefficient when ideal equilibrium conditions are far away, the territorial housing cost overburden index presented provides important insights on the multidimensionality of affordability and its connection with the new integrated concept of housing rights.

Regular Session: RS21.1 - Agriculture, fisheries and food security

11:00 - 12:15 Tuesday, 25th May, 2021

IMPACT OF COVID-19 ON FOOD SECURITY IN SRI LANKA**Roshini Jayaweera, N.P Dammika Padmakanthi**University of Kelaniya, Sri Lanka, roshinij@kln.ac.lk, dammikap@kln.ac.lk**ABSTRACT**

The global pandemic COVID-19 has created a massive range of adverse effects on many sectors including food security in many countries. COVID-19 leads it to a prolonged food crisis reflecting the importance of new methods to prevent the present and future food crisis. Therefore, this is a situation where we need to analyse our existing food system, identifying its drawbacks and suggest a solution to sustain and de-risking the system. Therefore, the major objective of this study is to analyse the impact of COVID-19 on household food security in Sri Lanka. This objective is achieved by analysing qualitative information using descriptive statistics where required. COVID-19 effect on Sri Lankan food security through two ways: supply and demand-side shocks. The supply-side shock will arise through international trade barriers, labour shortages, and the domestic market close down in the locked-down situation. The food supply chain is affected through lack of seeds, fertilizer, and agrochemicals etc. and it will affect food availability, one of the major pillars of food security, in the long run. Demand-side shocks are raised due to lower purchasing power since sudden income loss of informal sector workers, and panic buying. More importantly, food price hikes due to lack of supply may affect the demand side shocks. Impact on food affordability and availability may severe as consumers depend more on the food market than on producing their own food. Sri Lanka should meet the needs of the most vulnerable people and must keep the food supply flowing by prioritizing the health of the workers in the sector and their outputs. The main specific recommendations for meeting the needs of the most vulnerable people is the expansion of the existing social protection programs. It is important to ensure the continuity of the agricultural supply chain so that reduce inflation. Suggestions for keeping the food supply chains uninterrupted are facilitating farmers to market the food they produce, promoting e-commerce channels, keeping the food value chain alive by focusing on key logistics bottlenecks and health of the workers, addressing trade and tax policies to keep the global trade open, and managing the macroeconomic implications. As Sri Lanka battle the health and economic crises with massive public spending, it needs to control foodflations. Governments should assess the impact of their subsidies on the balance of payments and ensure they do not lead to deficits. And also, it must ensure adequate levels of foreign exchange reserves. In the case foodflation, the government should assess the fiscal policies.

KEYWORDS

COVID-19; Food Security; Sri Lanka; Vulnerability

1. INTRODUCTION

The global pandemic COVID-19 has created and will create a massive range of negative effects. The impact of COVID-19 on food security is significant among many as it is directly related to basic human needs. Further, this unexpected situation may adversely affect achieving the second sustainable development goal (SDG): end hunger, achieve food security and improved nutrition and promote sustainable agriculture.

According to the World Food Summit (1996), food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life. According to this definition, the concept of food security consists of four pillars: food availability, access, stability and utilization. Food availability refers to the availability of sufficient quantities of food of appropriate quality, supplied through domestic production or imports. Access by individuals to adequate resources for acquiring appropriate foods for a nutritious diet. The meaning of the third pillar is the utilization of food through adequate diet, clean water, sanitization and health care to reach a state of nutritional well-being where all physiological needs are met. Stability means access to adequate food at all time.

Senanayake and Premaratne (2014) identified four types of determinants of food security: determinants of the level of food acquirement, determinants of the level of food utilization, determinants of the ability to cope with shocks to acquirement and determinants of the ability to cope with shocks to utilization. Among these four types of food security determinants, the authors focus on the third type of food security determinant as it is related to the objectives of the current study. The outbreak of the COVID-19 severely affected Asian countries and Sri Lanka is no exception. Countries took many actions such as social distancing, travel restrictions, quarantine, and isolations of villages or lockdown the entire country. Among all of these preventive measures, locking down the country for a long period is critical as it affects all the economic activities of the country. Therefore, COVID-19 affects food security also in the affected countries in many ways. All four pillars of food security are vulnerable due to COVID-19, but access to food and availability of food may affect more compared to the other two pillars. In the short run, access to food may be negatively affected as consumers' income loss due to their job losses during the COVID-19 lockdown period. If food production is affected during this period, it may affect the long-run food security by creating a food deficit. COVID-19 may lead it to a prolonged food crisis

reflecting the importance of new methods to prevent the present and future food crisis. Therefore, this is a situation where we need to analyse our existing food system, identifying its drawbacks and suggest a solution to sustain and de-risking the system.

1.1 Research Problem

The impact of the COVID-19 on food security depends on the measures taken by different countries to control the viral spread and also on the economic situation of the country. Most countries are locked down as a responsive mechanism. It adversely affects the food security of all people in different ways. Sri Lanka also locked down on 22nd March 2020 as a preventive measure and step by lifting the curfew started only two months later on 11th May 2020. Therefore, the research problem of this study is 'what is the impact of COVID-19 on the short-run and long-run food security in Sri Lanka'?

1.2. Objectives

The major objective of this study is to analyse the impact of COVID-19 on household food security in Sri Lanka. This major objective will be achieved through the below sub-objectives.

1. Identify the current food security situation in Sri Lanka.
2. Understand the vulnerability of households to become food insecure.
3. Explain how COVID-19 affects food security in Sri Lanka
4. Suggest solutions to ensure the sustainability of future food security

2. LITERATURE REVIEW

Many researchers have analyzed the impact of COVID-19 on food security in different countries from a different perspective. Kansirime et al., (2021) have analyzed the impact of COVID-19 on household income and food security in Kenya and Uganda. Data were collected from 442 responders by conducting an online survey. The food insecurity experience scale was used to analyze the food insecurity and the Probit model was employed to estimate the impact of COVID-19 on sources of income. The results indicated that COVID-19 has a negative impact on food security especially consumption of nutritious foods. As well, COVID-19 has mostly affected income-poor people and those who depend on labour income. Farmers were less likely to affect food insecurity rather than those who rely on the market. The study revealed that National Social Security has less effect on income shock and food insecurity. They recommend ensuring an uninterrupted food supply chain, structural change in social security programs, and building strong financial institutions to support the recovery of the business.

Arndt et al., (2020) have analyzed the impact of lockdown policies for income distribution and food security in South Africa by giving special reference to the role of social protection programs in assuring food security using the input-output table that expands for Social Accounting Matrix to capture the income/ expenditure flows for all economic agents. The research found that labour with low education levels is strongly affected than labour with secondary and tertiary education and food security of those groups also badly affected by lockdown. Researchers indicated that the food security of low-income households are somewhat stable since the total income of the low-income households in South Africa mainly depends on government transfer and those transfers were continued during the lockdown period.

Mukiibi (2020) has explained the lockdown effect on people's ability to secure the food needs of the urban poor in Africa. This study emphasized the importance of developing rural small-scale producers and backyard gardens. As well, he stressed the importance of implementing the 'Slow Food Gardens in Africa' project to the resilience of food security.

Mottaleb et al., (2020) have investigated the COVID-19 induced lockdown effect on food security and welfare of daily wages of non-farm and farm sector in Bangladesh based on the 2016-2017 Household Income and Expenditure Survey in Bangladesh. According to the daily per capita food expenditure they estimated that the US \$ 1 per day per household should receive as the minimum compensation package to maintain minimum food security. They further calculated that a one-day complete lockdown generates US\$ 64.2 million economic losses according to the loss of wages of daily wage workers.

Wolfson and Leung (2020) have examined the early effects of COVID-19 on food security and COVID-19 related basic needs challenges of low-income adults in the US, one of the countries that massively affect by COVID-19. Data were collected from 1478 adults using the online survey method. They found that 36 per cent of low-income adults were food secure, 20 per cent were marginally food secure and 44 per cent were food insecure. They recommended implementing comprehensive policies to ensure food security if the pandemic continues.

Lal (2020) has mentioned that pandemic has caused food insecurity in urban centres because of disruption of the supply chain, restriction of import-export barriers, and food waste because of labour shortage. He emphasized the need for the adoption of a more resilient system, reduce food waste, and strengthen local food production by promoting home gardens and urban agriculture.

Erolehin and Gao (2020) have investigated the impact of macroeconomic fluctuations on food insecurity in 45 developing countries by grouping them according to income level. They attempt to explain this gap by considering the interaction between the food security status of people and the dynamic of COVID-19 cases, food trade, food inflation, and currency volatilities. Autoregressive distributed lag method, Yamamoto's causality test, and variance decomposition analysis were performed to analyzed COVID -19 effect on food insecurity. They found that the effect of COVID-19 is noticeable in upper-middle-income economies than in the least developed countries. In high-income, developing countries availability of sided food security risks (food track restrictions and currency depreciation) were more prevalent. This research has a

high contribution to the methodology development of health crisis effects on economic parameters of food availability and food security.

Zurayk (2020) has identified the different stress on food security systematically using the database Twitter account@food pandemic that has been tracking the impact of the pandemic on food security. This database especially focused on the Middle East, East Africa, and South. The impact of the pandemic on food security has been analyzed under four dimensions such as availability, accessibility, utilization, and stability. The results have pointed out that the effect of the pandemic on all countries and all citizens is not equal.

Hossain (2020) has described the effect of the COVID-19 pandemic on the agri-food sector in Asian Productivity Organization (APO) members. Further, this study has outlined the responses and policies imposed by each member country to prevent negative impacts on food security. To analyze those objectives publicly available information was synthesized and insights from 19 individuals working in agriculture or agri-food related areas in the public or private sector or academia in APO member countries. It concluded that medium and long-term food security challenges may vary among the APO member countries. Implementation of key policies regarding agricultural input such as fertilizer, safe and quality seeds to meet seasonal crop are essential.

Ruzczyk et al, (2020) have investigated the impact of the lockdown effect on food security and related coping mechanism in two cities in Bangladesh from March to May 2020. Data were collected through telephone-based semi-structural interviews with households and key persons in the government, non-government, and community. This study has pointed out that lockdown caused to lose or low income and quality and quantity of food consumed. Different coping mechanisms such as curtaining consumption, relay on inexpensive food, increase consumption expenditure, get a loan are used to get rid of food insecurity by households. Further, this study has indicated that people who have guaranteed income and adequate saving did not affect significantly.

Marambe and Silva (2020) have analyzed the effect of the government policies implemented in the COVID-19 induced locked down period in Sri Lanka from 11th March to 11th May 2020. The policies were reviewed under three categories such as food availability, accessibility, and affordability that are the main three-part of food security.

Although many researchers have analyzed the impact of the COVID-19 effect on food security in various countries it is rarely found a study that focuses on food security in Sri Lanka. Hence, this study aims to fill this gap and find out the effect of COVID-19 on food security in Sri Lanka.

3. FOOD SECURITY SITUATION IN SRI LANKA

Food Security Situation in Sri Lanka

Food security is a concern in Sri Lanka. Sri Lanka was ranked the 64th place according to the global hunger index in 2020 with a score of 16.3 which indicates a moderate level of hunger (<https://rg/sri-www.globalhungerindex.lanka.html>). At the macro level, food security in Sri Lanka is high which records only 10.3 per cent of households were food insecure (Department of Census and Statistics (DCS, 2014). However, at the micro-level, food insecurity is a critical issue. In 2014, around 9.72 per cent of households had no food for consumption while around 4.2% of households went to sleep without having dinner (DCS, 2014). Moreover, there is a significant percentage of households who eat low-quality food (25.9 per cent) or eat inadequately (35.8 per cent) (DCS, 2014). Therefore, there are health issues such as malnutrition and stunting as a result of poor food security. As can be seen in Figure 1, a significant percentage of the Sri Lankan population is undernourished. Further, around 15 per cent of the children under five are suffering from stunting, while around another 15 per cent of children under five are suffering from wasting.

Figure 1: Trends for Indicators - 2020

Source: <https://www.globalhungerindex.org/sri-lanka.html>

This food security situation may be worsened by the COVID-19. Even though the food security situation is good in Sri Lanka, a large number of people may be vulnerable to food insecurity due to COVID-19 via less affordability and availability of food. This vulnerability is high due to several reasons. First, a significant percentage of households are not producing their own food. For example, only 61.5 per cent is doing home gardening and it goes down to 9 per cent in urban areas (DCS, 2014). Given this situation, access to food will be at risk when the food markets are closed down during the lockdown period. Second, although Sri Lanka is not highly dependent on imported food, some specific food items are imported such as wheat flour, potatoes, big onion, vegetable oil and sugar. The price of those imported foods may increase as shipments slow and their currencies plunge against the dollar. Thus, Sri Lankans' food security will be negatively affected during this global pandemic situation if the international food supply chain is disrupted. The third factor is the high food ratio. The food ratio was 34.8 per cent in 2016 and it is significantly higher in the estate sector (48.5 per cent) and among the first income decile (62 per cent) (DCS, 2016). Thus, a sudden income loss as a result of the lockdown situation will worsen food security especially in the estate sector and people in lower-income decile. Fourth is inflation. Based on the data provided by the Central Bank of Sri Lanka for the week ended 03rd April 2020, the Headline and Core inflation of the Colombo Consumer Price Index (CCPI) showed surprisingly a decline in March 2020. Based on higher food prices owing to tighter supply conditions and supply-chain disruptions is expected to drive inflation. However, weak demand and lower indirect taxes, are likely to counter inflation pressure.

4. METHODOLOGY

The impact of COVID-19 on household food security in Sri Lanka was analysed qualitatively using descriptive statistics where required. Some of the data sources are Household Income and Expenditure Survey (2016/17), labour force survey (2018, 2020), Central Bank annual reports etc. Our goal was to explore various scenarios associated with the current crisis and to then map vulnerabilities at the domestic level.

5. RESULTS AND DISCUSSION

5.1 Effect of Covid-19 on food security

COVID-19 affects food security at both the global and the domestic level. The impacts of COVID-19 effect on Sri Lankan food security through two ways: supply shocks and demand shocks. Supply-side shocks are arisen via the affected food supply chain due to international trade barriers, labour shortages in food production, processing and marketing in the locked-down situation. Further, food production will be affected by the lack of inputs such as seeds, fertilizer, and agrochemicals etc. due to trade barriers. These effects will lead to a food crisis in the future. These supply-side shocks will affect one of the most important pillars of food security. That is the availability of food. Availability of food in the short run as well as in the long run will be affected by the COVID-19. Demand-side shocks can be identified as the impact on accessibility. Demand-side shocks are related to the affordability of food due to income losses, the market closes down, long queues in the market which will create an extra risk of spreading the disease, food inflation etc. The next sections will discuss both of these supply-side and demand-side impact of COVID-19 in detail.

5.1.1 Impact of COVID-19 on Food Availability

This section will discuss the impact of COVID-19 on food production, food importation and food distribution from the supply side angle. COVID-19 would affect the whole food supply chain from the farm to the consumer, including food production, processing, distribution, and demand. Further, due to the international food supply chain is also affected by COVID-19, food imports to Sri Lanka will also be affected by this pandemic.

Food Production and Distribution

In Sri Lanka, even though the country was locked down due to COVID-19, food supply was sufficient as the government adopted timely measures to minimize the impact on agriculture. Amid rising food security concerns, the government motivated people to start their own home gardening to increase food self-sufficiency. Under the programme named 'Saubagya' (prosperity) implemented by the Department of Agriculture (DOA) provided 2 million seed packets to households with the objective of promoting a million home gardens. Further, considering the importance of labour as the major input in the agriculture sector, the government exempted people's movement for agricultural activities from quarantine curfew. In addition to these measures, the Sri Lankan government took steps to assure food security by mitigating the financial constraints in the agriculture sector. A new comprehensive Rural Loan Scheme was launched to grow some food items such as paddy, chilli, cowpea, green gram, potato and sweet potato, etc.

However, the production of food was up to a satisfactory level, increased levels of food loss and wastage due to market closure, blockages to transport routes and declined demand were visible during the pandemic lockdown period in Sri Lanka. Some of the regional wholesale vegetables markets were closed to control the spread of the virus, resulting in heavy losses to the farmers. For example, short term close down of Dambulla economic centre was a reason for wasting food. The close down of the Manning Market was also a reason for food wastage. According to the President of the All Island Poultry Association in Sri Lanka, around 5000 broiler farmers and 3000 layer farmers in the country have been significantly affected during the lockdown period. Moreover, 12000 MT of poultry meat was stuck in cold storages while another 8000MT were remaining to be harvested. The price of the chicken eggs fell drastically. However, the government arranged alternative actions to reduce this food wastage and assure the availability of food in areas where agricultural activities are not the major economic activity. For example, Sri Lanka Railway deployed special trains to transport

vegetables, fruits, grains, rice and other essential commodities. Moreover, alternative arrangements were done to procure vegetables and fruits owing to the closure of the Manning market. The government's approval of the transport of vegetables during curfew hours was helpful to minimize such losses during the latter part of the lockdown. Rice being the staple diet of the country, rice mills were declared as essential service during this lockdown period.

Another impact of COVID-19 on food production is the issues in input supply. Some farm sectors are more dependent on (seasonal) labour than others. Paddy, fruits and vegetables are more labour-intensive. Limits on the mobility of people have reduced the availability of seasonal workers for planting and harvesting in the agriculture sector especially in fruits and vegetable farming. Though the lockdown exempted farming operations and food supply chains from the beginning, implementation problems caused severe labour shortages and price collapse in wholesale markets. Given these circumstances, the government initiated a programme to procure fruits and vegetables directly from the farmers to ease the problem of limited wholesale markets (<https://www.netherlandsandyou.nl/latest-news/news/2020/06/02/impact-of-covid19-on-food-supply-chains-in-sri-lanka>).

In addition to labour, other important inputs in the agriculture sector are seed, pesticides, fertilizers, and energy. Seeds supply was not a problem in Sri Lanka at the moment. However, the concern is about the fertilizer. Even though the global availability of fertilizer is not a problem, the transport of fertilizer will be problematic. According to the newspapers and electronic media report these days, farmers in several districts complain that they have been adversely affected as a result of not receiving fertilizer and paddy seeds. The major issue related to the distribution of fertilizer is twofold: not receiving on time and sufficiently. According to the chairman of the Ceylon Fertilizer Company, Sri Lanka has sufficient storage of fertilizer for the Yala season in 2021. However, the problem will be raised in the next season. Being a country that uses chemical fertilizer much, reduction of fertilizer usage can be seen as a good thing resulted from COVID-19. However, there should be a plan and sufficient quantity of organic fertilizer.

Moreover, even though there is no data, the government restrictions on imports could trigger a shortage of veterinary medicines and other inputs leading to problems in livestock production.

Even though current food production was not much affected due to COVID-19, a significant quantity of food was wasted due to issues related to transportation, marketing and food delivery related logistics. And also due to the problems in supplying inputs for agriculture such as fertilizer, future food production will be problematic.

Impact of COVID-19 on food imports in Sri Lanka

Amidst the foreign exchange crisis, the Sri Lankan government-imposed restrictions on 156 categories of products including essential food items such as rice, grains, pasta, bakery products and liquor. The government increased the levy on imported fruits and edible nuts in April 2020. Imports of apples, oranges, grapes, pears, cherries, plums, lemon, grapefruit, peaches and some dried fruits were affected by this rule. The Department of Animal Production and Health imposed restrictions on the import of live animals, animal products and by-products as a mean of overcoming the spread of the diseases. Restrictions on food imports have mainly been imposed due to the foreign exchange crisis during this period rather than supply shocks. Further, being a trade-dependent country, effects of destruction in the global food supply chains are also inevitable. To protect the domestic customer and assure food security in the country, a presidential task force was appointed to coordinate with relevant authorities to facilitate the import of essential food items and export of some food items such as tea.

Not only the food import was affected by the COVID-19, but also the export of the food items also was affected by this pandemic. The processed food industry in Sri Lanka is one of the emerging and lucrative industries in terms of production, consumption, export and growth prospects. Processed food sector consists of Dehydrated Fruits & Vegetables, Processed Gherkins & Cucumber, Herbal Tea, Frozen meat, Sauces and Tomato ketchup and prepared foods such as Ambul Thial, Katta Sambol, and Dried Sprats etc. The industry counts more than 110 manufacturing and marketing companies. In 2016 the industry's export value was close to US\$400 million, representing about 4% of total goods exports. About 40% of micro, small and medium enterprises nationwide are involved in the sector and EDB has estimated that the sector employs more than 2 million. (National Export Strategy of Sri Lanka 2018-2022 Processed Food & Beverages Strategy) With the changes in lifestyles, more and more supermarket appearing new opportunities have emerged for MSMEs to supply value-added agricultural products and processed food items. In the recent past, a considerable number of entrepreneurs have stepped into this subsector with innovative ideas. They have been guided by NEDA and IDB and many entrepreneurs have received assistance and are being supported through various projects of the Government, Ministry and NGOs which has shown positive results. The outbreak of COVID virus is a big blow that they had to face at this development stage (Gunawardena, 2020).

Also, the export of commodities such as tea, coconut, rubber, spices and food and beverages were heavily impacted due to the pandemic. Total exports were down 26 per cent in the first half of 2020 in comparison to last year. However, some sectors are starting to see some growth after the lockdown ended. For example, in the month of June, the export of tea, coconut-based products, spices and essential oils, fish and fisheries products were up (Economy Next, 2020).

5.1.2 Impact of COVID-19 on Access to Food

The current global health problem creates many economic problems such as income inequality, unemployment, economic frustration, food insecurity, and uncertainty. The effect of pandemic badly affects the Sri Lankan economy since many industries closed and other industries also do not operate in the usual manner. As well, many people lost their jobs or reduce their working days during this period. Because of this situation, people's income was reduced and this badly affects their consumption especially for food security. So the demand-side factors that affect food security can be

explained according to several factors such that reduction of income, food shortage, and effect of social protection and relief package.

Reduction of Income

During the COVID-19 pandemic situation permeant, employees get their salary without any delay or any reduction. However, in some cases, temporary staff and daily wage workers in the public sector and the private sector lost their income or reduce their income. Informal sector workers are the highly affected group of workers. In Sri Lanka, most people are working in the informal sector. The informal sector can be defined as persons in employment who are not national labour legislation and income tax or entitled to social protection and employment benefits (DCS, 2020). Informal employment can exist in both the informal and formal sectors of the economy. In Sri Lanka, 57.4 per cent of people are employed in the informal sector (DCS, 2020). When disaggregate this according to the economic sector 89 per cent of people work in the agriculture sector and 46.7 per cent in the non-agriculture sector (DCS, 2020). Because of the lockdown situation, impose of curfew, and isolation, most people in the informal sector lost their job or reduce their income. Although it is allowed to continue agriculture activities, construction sector works according to the COVID-19 regulation because of pandemic situation people do not like to go for work or owners of agriculture sector and construction sector do not like to offer work for their workers. Because of that many people suffer from the lack of income. The following Table shows the distribution of informal sector employment by the main occupation.

Table 1: Distribution of Informal Sector Employment by Main Occupation

Occupation	Informal sector %
Chief executive, Senior official, Legislators	6.8
Administrative and commercial managers	15.7
Production and specialize services managers	44.4
Hospitality shop and related service managers	69.3
Professionals	13.8
Technical and associate professionals	23.0
Clerks and clerical support workers	8.2
Service and sales workers	41.2
Skilled agricultural forestry and fishery workers	97.2
Craft and related trade workers	72.6
Plant and machine operators and assemblers	59.0
Elementary occupation	62.6
Armed force occupations and undefined occupation	16.6

Source: DCS, 2020.

When considering the distribution of employment by the main occupation, most people work in the informal sector. Especially, most employed people in sectors such that skilled agricultural forestry and fishery, hospitality shop and related service, craft and related trade, service and sales are included for the informal sector. Since travel restrictions are imposed in most countries the workers in hospitality industries are lost their jobs since the tourism industry almost closed. Not only that many other related occupations related to the tourism industry such as craft and related trade, service that provide for hospitality industries and the person who works in executive-level are also lost their occupation. Daily wage workers also face difficulties because they lost their livelihood. As well, some companies reduce their working hours since those companies also have a negative effect. In some cases, some companies take out their labour. All these reasons affected for reduction of income of the informal sector workers.

Self-employed people are the other major category of people that suffer from negative economic impact from the COVID-19 pandemic. Self-employed people can be categorized as employers, own-account workers, and contributing family workers (DCS, 2020). The following Table shows the distribution of informal sector employment by employment status.

Table 2: Distribution of Informal Sector Employment by the Employment States

State of Employment	Informal sector
Employee	34.9
Employer	2.3
Own account workers	51.7
Contributing family workers	11.6

Source: DCS, 2020.

According to information of the above Table most of employee and self-employed are work in the informal sector. That means they are highly affected by the pandemic situation. In some cases, some self-employed industries have to be closed because of marketing problems and lack of input. Backward and forward industries also face negative economic effects because of the closure of the aforementioned industries.

A study that focuses on the effect of the COVID-19 pandemic has pointed out that approximately 60 per cent of households have lost entire last month's income and/or one-time income lost (University of Ruhuna, 2020). The negative income effect of the households causes many problems including food insecurity.

Shortage of food

The shortage of food is one of the main factors that caused food insecurity during the pandemic. Panic buying reasoned for food insecurity during the COVID-19 pandemic. Because of the lockdown situation and fear of lack of food, people rush to collect food and this leads to a shortage of food and increases in foods price. This badly affected daily wages and informal sector workers who lost their employment or reduce their income. Those groups of people don't have enough savings to collect food.

Further, most economic centres that distribute fruits and vegetables and fish markets were closed. Hence, on the one hand, those people lost their income since they could not sales their production. On the other side wastage of food is high and people suffer from lack of food. Those factors negatively affected food security especially people who couldn't get nutritious food.

Social Protection and Government Relief Package

The COVID-19 pandemic causes for loss of income of most households especially daily wage workers, informal sector workers, and temporary and contract basis employees in the private sector. Therefore, the government of Sri Lanka introduce a relief package and introduce extra social protection benefits while continue exist social protection programs to increase the purchasing power of mostly affected people and as a relief for people who affected their income-earning activities.

On 23rd March 2021, the government adviced to Central Bank Governor, and other relevant authorities including heads of all banks and leasing companies to offer these relief packages to the people. The relief package and responsible authorities as follows:

Treasury/Government/Inland Revenue

- A grace period for the payment of income tax and VAT, driving license renewal fee, water bills, and assessment tax less than LKR 15,000, be extended until 30th April 2020.
- Graduates selected for the training at divisional secretariats are offered LKR 20,000 per month.
- The benefits of Agrahara insurance scheme are doubled for the people engaged in COVID-19 prevention activities.
- Lanka Sathosa and cooperative stores were exempted from VAT.
- Bank of Ceylon has opened a special account to raise the fund for health care activities. Those who contribute to this fund granted Tax exemption and relief of foreign exchange control restrictions.
- The Government of Sri Lanka donated USD 05 million to the SAARC COVID-19 Emergency Fund.
- LKR 5000 offer for two months for financially destitute households.

Samurdhi Authority

- The Samurdhi Authority issues title certificates to Samurdhi and low-income families for issuing nutritious food items. Under this benefit rice, dhal and salt are provided on a weekly basis.
- Interest-free advanced of LKR 10,000 is offered for Samurdhi beneficiaries and Samurdhi cardholders through all Samurdhi Banks

Central Bank and other banks

- Monthly credit card bills less than LKR 50,000, are extended until 30th April 2020.
- Leasing loan repayment of three-wheeler owners is postponed for six months period.
- Loans repayment from the salaries of government employees and private sector employees is postponed until 30th May 2020.
- Personal loan repayment of less than one million borrowed from banks and finance companies is postponed for three months.
- Debt moratorium will be offered to the tourism, apparel, and SMEs for six months period.
- A maximum of 15 per cent interest rate has been stipulated for credit card domestic transactions up to LKR 50,000 and a 50 per cent reduction in minimum monthly charges.

Source: University of Ruhuna, 2020

All these reliefs benefited all people to get rid of some financial problems and manage the day-to-day activities in a difficult period. Especially because these financial relief facilities cause enhances the food security of the households.

6. CONCLUSION AND WAY FORWARD

The main objective of this paper is to analyse the effects of COVID-19 on food security in Sri Lanka using a descriptive method. The results of the study revealed that food security in Sri Lanka is moderate now and it will become worse if necessary timely actions are not implemented. Even though the food production was not affected, a significant quantity of food wasted due to marketing, transportation and other logistics. Future food security is also challenged due to the lack of input supply. Even though, food was available on the doorsteps; affordability was lower due to the reduction in the income of consumers. Income loss was mainly caused by the unemployment of the informal sector workers. Additionally, a short term food-deficit could be seen due to panic buying. To avoid all these issues related to food security in the country, the Sri Lankan government has taken several steps. Due to the effect of COVID-19, Sri Lankan households have started growing their own food at their home gardens. And the food utilization habit also changed. More homemade food is consumed and demand for outside food is reduced. In summary, availability, affordability and utilization of food—three main pillars of food security—is affected by the COVID-19.

Macroeconomic policies such as monetary policy, trade policy, fiscal policy and social security program should be changed according to the needs of the current pandemic situation to protect the food security of all consumers and the agriculture sector. Ensure the continuous supply chain, enhance the productivity of smallholders, maintain low foodflation, continues check on the health of agriculture sector employers are the other recommended policies that can

be implemented to ensure food security in a pandemic situation like COVID-19. Sri Lanka should meet the needs of the most vulnerable people and must keep the food supply flowing by prioritizing the health of the workers in the sector and their outputs. The main specific recommendations for meeting the needs of the most vulnerable people is the expansion of the existing social protection programs to assist those who didn't previously have coverage and who are extremely vulnerable due to COVID-19. It is important to ensure the continuity of the agricultural supply chain so that reduce inflation. Military mobilisation and available administrative structure can be an effective tool to distribute subsidies without spreading the virus.

Suggestions for keeping the food supply chains uninterrupted are giving smallholder farmers support to both enhance their productivity and market the food they produce, also through e-commerce channels, keeping the food value chain alive by focusing on key logistics bottlenecks, addressing trade and tax policies to keep the global trade open, and managing the macroeconomic ramifications. As Sri Lanka battle the health and economic crises with aggressive public spending, it needs to hold down inflations, especially to reduce the risk of inflating food prices. Governments should assess the impact of their relief and stimulus packages on the balance of payments and ensure they do not run deficits. And also, it must ensure adequate levels of foreign exchange reserves. In case food prices jump, they should assess the fiscal measures carefully when responding.

ACKNOWLEDGEMENT

ROLE OF AGRICULTURE ON ENSURING FOOD SECURITY IN SRI LANKA**Moksha Samarakoon¹, Roshini Jayaweera², M.M.Gunatilake³**¹MPhil Candidate, University of Kelaniya, Sri Lanka, harinisamarakoon95@gmail.com; ²Senior Lecturer, University of Kelaniya, Sri Lanka, roshinij@kln.ac.lk; ³ Professor, University of Kelaniya, Sri Lanka, gunatilake@kln.ac.lk**ABSTRACT**

Ending hunger and food security is a key challenge faced by today's world. Agriculture sector plays a major role to ensure food security of a country. Sustainable Development Goal 2 is about ending hunger, enhancing food and nutrition security and promoting sustainable agriculture. Country's agriculture and food security is strongly linked together. Examination of this link in case of Sri Lanka is important as both agriculture and food security are concerned. In one hand, productivity in the agriculture sector is decreasing and therefore the employment in this sector is also decreasing over time. On the other hand, although at the macro level Sri Lanka is food secured, image at the micro level is not good. Population growth, lack of economic and physical access to food, chronic poverty, climate changes and natural disasters, low labour in agriculture sector, lack of using technology in agriculture production, lack of infrastructure facilities, not having a proper marketing strategy, frequent pest attacks on crops, adversely affects the food security in Sri Lanka. Moreover, high dependency on import of essential food items also leads Sri Lanka into food insecurity. Severity of this dependence of imports was renowned during the Covid-19 pandemic situation. Improving agriculture is the key to combat food insecurity of the country. Increased agriculture productivity will also increase the food availability which is one of the four pillars of food security. Therefore, the objective of this research is to analyse the role of agriculture in ensuring long term food security in Sri Lanka. The research is mainly based on secondary data. Promoting investments in agriculture sector that increases food availability will have positive impacts on food security in Sri Lanka. Moreover, substantial investments in rural infrastructure facilities, new and modern technology, research and development based on agriculture productivity, using proper organized marketing strategies will contribute to the development of efficient methods of crop management and productive means of food production. National level policy on using harmless pesticides and pest control methods are also essential to secure agriculture products which will enhance food security. Improving urban agriculture, home gardening, and kitchen garden will also help to secure food security in urban areas especially during pandemics. A climate smart agriculture system is also very important to Sri Lanka as it faces frequent climate changes.

KEYWORDS

Agriculture, Agriculture Productivity, Food Security, Sustainable Development Goals

1. INTRODUCTION

Sri Lanka has been a rich agricultural country since history and it dates back more than 2500 years. The main occupation of the Sri Lankan from the ancient times was agriculture. The early agriculture were settled in the river valleys in northern and southern eastern plains and the main crop was paddy. Paddy cultivation was not only just an economic activity but also a life that shaped the society culture, religion and the economy.

Agriculture in Sri Lanka is not just composed with plantation and vegetation. There are 16 components in agriculture sector namely, growing cereals, rice, vegetables, sugar cane and tobacco, fruits, oleaginous products (coconut, king coconut, oil palm), tea, other beverage crops (coffee, cocoa), pharmaceutical crops and spices, rubber, other perennial crops, animal production, plant propagation and support activities to agriculture, forestry and logging, marine fishing and marine agriculture and fresh water fishing and fresh water agriculture (Central Bank of Sri Lanka, 2016).

Agriculture is the most important sector of the Sri Lanka which makes a significant contribution to the national economy, employment and food security. Agriculture is also the main livelihood of the majority in the rural sector and plays a key role in alleviating rural poverty of the country. A survey conducted by Sri Lanka's statistics office in 2016/2017 has found that 2.1 million households or 40% of the total was engaged in agricultural sector. (<https://economynext.com/only-1-7-pct-of-sri-lankas-farming-population-has-formal-training-survey-35078/>). Under Sustainable Developments Goals in Sri Lanka, goal no 2 is to end hunger, achieve food security and improved and promote sustainable agriculture (<http://www.statistics.gov.lk/sdg/index.php/sdg/target/2>).

Major changes to agriculture sector occurred during the colonial period starting from Portuguese, Dutch and British. During these periods different plantation crops such as tea, rubber, coffee, cashew, etc. were introduced. Before the colonial period, people in Sri Lanka were involved with cultivation of paddy and other crops that can be used for domestic consumption (Jayasinghe-Mudalige, n.d.). After gaining independence agriculture production accounted for over 30% of the Gross Domestic Product. At that time industrial activity was in its infancy and was largely confined to the processing of agricultural commodities for exports. With the independence Sri Lanka gave a good example for dual economy. Sri Lanka's resource endowment led the country to specialize in agriculture and emerged as an agriculture economy by the

end of the colonial period. Sri Lanka's agriculture sector consisted of two distinct sectors namely, highly organized plantation sector producing for exports and a peasant sector of relatively low productivity, depending on small scale cultivation of paddy

(https://www.cbsl.gov.lk/sites/default/files/cbslweb_documents/publications/otherpub/40th_anniversary_chapter_1.pdf). In 1948 there were more emphasis on cultivation of crops. First Prime Minister of Ceylon, late Mr. D.S. Senanayake and other leaders took actions to promote paddy cultivation and other food crops in Sri Lanka. Large extents of land were cleared and irrigation schemes such as Galoya were initiated to increase the food production of the country. (https://en.wikipedia.org/wiki/Agriculture_in_Sri_Lanka#cite_note-:0-4).

At the present time, agriculture, including fisheries is a major contributor to economic growth and it is the only source that provides adequate food to prevent hunger and starvation. Sri Lanka agriculture sector mainly comprises a food crop sector and a plantation (tea, rubber and coconut). The food crop sector is mainly consisting of small-scale farmers growing rice, vegetables, fruits and other field crops. These are mainly for domestic consumption. Tea, rubber and coconut are the main export focused products in the country (Oxford Business Group, 2018). Sri Lanka also imports several essential food products including wheat, lentils, sugar, milk and milk products and fruits (International Trade Administration, 2019).

In present, Sri Lanka's agriculture sector contributes about 7% to the Gross Domestic Product (GDP). Even though the contribution of agriculture sector to the GDP declined substantially during the past three decades (from 30% in 1970 to 7.3% in 2020) it is the most important source of employment for the majority of the Sri Lankan labour force. Approximately 25.5% of the total employed population are engaged in agriculture sector including forestry and fishery. Especially, most of the rural population are employed in agriculture sector. Most importantly cultivating paddy is the main economic activity for the majority of rural people (Thanigaseelan, 2021).

Even though the main economic sector of Sri Lanka is agriculture, the United Nations Food and Agriculture Organization (UNFAO) estimates that 4.7 million people of 21 million population of Sri Lanka do not have sufficient food to sustain a healthy life (Institute of Policy Studies, 2017). This means that Sri Lanka is going towards food insecurity.

"Food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life" (World Food Summit, 1996). From this world famous definition, four main dimensions of food security can be identified as physical availability of food, economic and physical access to food, food utilization and stability of the other three dimensions over time (<http://www.fao.org/3/al936e/al936e.pdf>).

Food security in Sri Lanka is mainly rely on food availability, domestic food production, food imports and access to food. Food availability of Sri Lanka is primarily dependent on local production and the import of food crops, livestock and fish products. Sri Lanka is nearly self-sufficient in rice. Local production of the main supplementary food items such as vegetables and green leaves, pulses, root crops, spices and fruits exceed 70% of total availability (South Asia Policy and Research Institute, Institute of Policy Studies, Medical Research Institute, Hector Kobbekaduwa Agrarian Research and Training Institute, Department of Census and Statistics, 2017).

According to Household Food Security Survey (2014), food security can be defined as the ability to have sufficient, safe and nutritious foods to ensure an efficient and healthy life of all people at all time.

National Nutrient and Micro Nutrient Survey in 2012 has identified that the lack food insecurity in Sri Lanka has led to development and growth issues measured in terms of stunting, wasting and weight which are known as the key indicators of a country's nutritional status. Moreover Sri Lanka suffers from high levels of stunting (17.3%) and wasting (15.1%) among children less than 5 years. (Global Hunger Index, 2020).

Sri Lanka as a country, has achieved a notable progress in several areas such as education, reduction in child birth rate and decreasing poverty levels. Though, the food insecurity of the country still remains a constant problem. Sri Lanka ranked poorly on the Global Hunger Index and Global Food Security Index which are known as the main indicators of food security in any country. According to the 2020 Global Hunger Index, Sri Lanka ranked 64th among 107 countries (<https://www.globalhungerindex.org/sri-lanka.html>), and according to the Global Food Security Index, Sri Lanka ranked 75th out of 113 countries in the world (<https://foodsecurityindex.eiu.com/index>).

Achieving food security has become a serious problem mainly due to less agriculture productivity, population growth, natural disaster and climate changes, higher food prices, poverty (Pawlak & Kolodziejczak, 2020). Another significant reason for food insecurity in Sri Lanka is climate change. This can result all aspects of food security including food access, utilization and price stability. These climatic changes severely threaten agricultural production and food security of the country. Steadily increasing temperatures and increased intensity and frequency of extreme weather events such as irregular rainfalls, tropical storms, floods and droughts negatively affect on Sri Lanka's agriculture. As an example, in 2017 Sri Lanka experienced the worst drought faced in 40 years in which the main harvest (known as Maha) was reduced by more than half of the secondary harvest (known as Yala) was also further impacted. Drought period that already started in 2016 was negatively affected the food intake, especially for the poorest families in the country (European Commission, 2018).

Increasing agriculture output is the most significant way to accommodate the growing population. The increase in the agriculture output is expected to come from producing more on existing farmland, and new farmlands will be also needed. Boosting crop yields and closing the gaps between actual and attainable yield can be achieved by implementing numerous practices and technologies as well as fertilizer technologies (Stewart & Roberts, 2012).

Long term food security is highly depend on the agriculture sector. Agricultural development is the key driver to achieve food security of the country (Pawlak et al., 2020). Therefore, the focus of the country should be on developing agriculture

productivity, increasing accessibility for nutritious and healthy food, adopting climate smart agricultural practices and to act as a driver of economic transformation for the rural people who are the most food insecure population in Sri Lanka (Institute of Policy Studies, 2017).

1.1 Research Problem and Research Objectives

Problem of the study is to identify the role of agriculture on ensuring the food security in Sri Lanka. The principal objective of the study is to identify the role of agriculture on ensuring food security of Sri Lanka. Other secondary objectives are to identify the productivity of agriculture, to identify the impact of food imports on food security, to identify the major issues in agriculture sector and finally to identify the solutions and strategies to enhance agriculture sector and food security in Sri Lanka.

2. METHODOLOGY

This research article is mainly based on secondary data which were collected through different annual reports, research articles and websites. Collected data were analyzed using descriptive statistics and presented using Figures and Tables.

3. RESULTS AND DISCUSSION

The main objective of the study was to identify the role of agriculture on ensuring food security in Sri Lanka. There are number of factors that influence the agriculture growth which has a direct impact on the food security of a country. Under this section several aspects of agriculture sector will be concerned.

3.1 Agriculture Land Extent

Land is the most important aspect of production, especially agriculture production. Food production and supply mainly depend on the amount of arable lands in the country. Out of total land area of 6.55 million hectares, 2 million hectares are agricultural lands in Sri Lanka, and 650,000 hectares are irrigated. The total cultivated area including home gardens and plantation is estimated at 2.86 million hectares (Food and Agriculture Organization, 2018).

Figure 1: Agriculture Land Extent in Sri Lanka (Square Kilometers)

According to the above Figure 1, it shows that there is gradual increase in the agriculture lands in Sri Lanka. In 2018 according to the World Bank indicators, agriculture land in Sri Lanka was reported at 28116 sq.km. Agriculture land refers to the share of land area that is arable and includes land defined by the FAO as land under temporary crops, temporary meadows for mowing or for pasture, land under market or kitchen gardens, and land temporarily fallow (<https://tradingeconomics.com/sri-lanka/agricultural-land-sq-km-wb-data.html>). Increase in the arable land is very much important as there is a close link between the land extend and the food security. Land is the main thing that is needed for cultivating food crops. Protecting agricultural lands enables long term food security. It gives more access to fresh, healthy and local food which will directly impact on increasing food production and food security of the country.

3.2 Employment in Agriculture Sector

Agriculture was the mainstay of employment in the world until 2000. Since then employment growth in agriculture has declined (<https://blog.agrivi.com/post/employment-in-agriculture>). To achieve food security it is important to have more workers in agriculture sector as it directly contribute to produce food security. Moreover, the amount they generated from agriculture work determines the amount and quality of food that workers and their family can purchase. Further, more productive and decent employment in the agriculture sector can increase the local food availability by contributing to a sustainable increase in food production (Food and Agriculture Organization, 2012).

Nearly 80% of Sri Lanka's population lives in rural areas and the agriculture sector provides a major source of employment for the country's rural labour market (International Labour Organization, n.d). But in the recent years

number of employees in the agriculture sector is declining in Sri Lanka. The main reason for this matter can be identified as lack of participation of the youth generation in agriculture sector. Apart from this reason low return from agriculture, government's poor agriculture related market policies, land reform policies are also impact the decrease in the employment.

Figure 2: Employees in Agriculture Sector

According to the above figure it shows that from 2011 there is gradual decrease in the number of employees in the agriculture sector. In 2011 there were 2,511,266 employees in agriculture and in 2019 it shows that were only 2,071,940 employees. From this Figure we can predict that in future employees in agriculture sector will decrease further. This will directly affect the food security of Sri Lanka as employees in agriculture sector play a major role in cultivating food crops.

3.3 Fertilizer Usage in Agriculture

Crops need essential minerals and nutrients for strong, healthy growth as human beings. Fertilizer production and fertilizer usage is strongly connected with agricultural productivity and food production. Fertilizer is simply used to provide nutrients not available in the soil, replace nutrients removed at harvest and balance nutrients for better produce equality and higher yield (Yara, 2021). Fertilizer helps plants to become resilient against harmful plant pathogens, pests and weeds. Eliminating these diseases in plants will increases the value in the harvest. In present day synthetic fertilizers incorporate at least one of the three components that are most significant in plant sustenance and those are nitrogen, phosphorous, and potassium. Secondary significance are the elements are sulphur, magnesium and calcium (James Lind Institute, 2019).

Figure 3: Fertilizer usage in Sri Lanka

Fertilizer usage in Sri Lanka was 131.92 kg in 2016. Though Sri Lanka fertilizer usage fluctuate substantially in recent years it tended to decrease through 2009-2016. Highest value over the past 14 years was 311.71 in 2008, while the lowest value was 131.92 in 2016.

Using fertilizer plays and important role in increased crop production. There are several fertilizer subsidy programmes in Sri Lanka. It is widely accepted that the fertilizer subsidy has led to increase the land productivity and encouraged

farmers to expand the land under paddy cultivation (Weerahew, Kodithuwakku, & Ariyawardana, 2010). The first fertilizer subsidy programme in Sri Lanka was initiated in 1962, and its main objective was to induce farmers to adopt high yielding varieties with a view to achieving self-sufficiency in rice as well as to help farmers to defuse their financial liabilities. Another programme named Fertilizer Cash Grant was also introduced in 2016, and its main objectives were to cut down the high usage of inorganic fertilizer, encourage the usage of organic fertilizer and allowing farmers to make effective decisions regarding identifying and application of the most suitable quantities of fertilizer for their fields. Fertilizer subsidy has a positive impact on agriculture productivity and production (Edirisinghe, Amarakoon, & Kuruppu, 2019).

3.4 Imports of Food Products

Sri Lanka imports variety of agricultural products and food items including rice wheat, lentils, sugar, fruits, milk and milk products. The importation of foods and beverages account 7.2% of total imports in 2018 in Sri Lanka. Total agriculture, food and beverage imports were 1.6 billion dollars in 2018. Sri Lanka imported approximately 1.29 million metric tons of wheat in 2018 and annual imports of lentils is estimated at approximately 79 US dollars. Moreover, more than 150,000 metric tons of corn are also imported to country annually to supplement the local production. Further, Sri Lanka is a well-known dairy products importer. The country has imported 349 million dollars milk and mild products in 2018 (export.gov, 2019).

Figure 4: Imports of rice, wheat, cereals and maize

According to the above Figure its shows that there is a fluctuation in imports of different crops. The figure indicates that rice imports have gone down significantly when compared to the previous years. This is a considerable achievement of Sri Lanka since it helped saving a significant amount of foreign exchange earnings that were spent on importing rice.

3.4.1 Import Dependency Ratio (IDR) and Self Sufficient Ratio (SSR)

Table 1: Import Dependency Ratio and Self Sufficient Ration for selected food items from 2013-2017

Food Group	Import Dependency Ratio (IDR)					Self Sufficient Ratio (SSR)				
	2013	2014	2015	2016	2017	2013	2014	2015	2016	2017
Cereals	23	42	32	24	56	80	60	70	78	46
Wheat	111	111	108	109	106	0	0	0	0	0
Rice	1	20	8	1	31	100	80	92	99	69
Starchy roots	18	23	21	32	24	83	78	79	68	78
Potatoes	61	59	60	61	65	39	41	40	39	35
Sugar & sweeteners	79	83	87	83	84	22	17	16	19	19
Pulses	85	96	90	89	89	21	17	15	15	16
Oil Crop	1	1	2	2	3	121	138	120	134	127
Vegetable oil	72	55	58	88	83	29	61	66	20	25
Vegetables	8	7	8	14	10	92	93	92	86	91
Fruits	7	5	7	6	9	96	98	96	96	93
Milk	45	49	52	55	56	56	51	48	45	45
Fish	12	12	18	17	16	91	92	85	85	88

Notes: *SSR <100% production is insufficient to meet utilization, SSR>100% production exceeds utilization. IDR> 100% totally imported.

According to the data shown in the above table, the average IDR for cereals fluctuated between 23 and 56 percent. The SSR ratio of cereal also shows that the local production is not sufficient to meet the local utilization. IDR of wheat indicates that wheat are totally imported over time in Sri Lanka. The above table also reveals that potatoes, sugar and sweeteners, pulses and milk production is not sufficient to meet the local utilization. It means that Sri Lanka has to depend on imports

of those products to feed the people in the country. Some of the food items such as fruits, vegetables, fish, rice and starch roots are relatively self-sufficient.

High dependency on essential food items is a risk for the food security of the country. Therefore, it is crucial to reduce essential food imports and promote local production. The current Government's "Saubhagya" programme is mainly aimed at being self-sufficient in food. For making that aim possible, the Government of Sri Lanka is empowering villagers and small farmers by giving them sufficient technology, knowledge, planting material and seeds to enhance the capacity of the production. Moreover the Government also wishes to use all the arable land available in the country for cultivation. Another goal of the Saubhagya programme is to be self-sufficient in mils and stop imports of powdered milk. Further, this programme is also aim to reduce the dependency on imports and expanding and promoting the cultivation of high priority crops. The home garden programmes was also launched to improve vegetable security in urban and semi-urban households. The main goal of the home garden programme is to improve household food security by providing nutritious and healthy diet. Government also implement programmes to achieve self-sufficiency in locally produced crops to reduce the import dependency. This directly increase the local production and it will impact on securing food security of the country (<https://www.dailynews.lk/2020/11/02/features/232729/drive-prosperity-and-food-security>).

3.5 Major issues in the agricultural sector in Sri Lanka

As discussed earlier, there is no doubt that Sri Lanka is an agricultural country. Most of the domestic requirement of staple food: rice is grown in Sri Lanka. Apart from rice, vegetables, fruits and oilseed crops are also cultivated in the country.

Even though Sri Lanka is a fertile land that is potential for cultivating different crops including rice, issues such as low productivity and low profitability negatively affects the agriculture sector in Sri Lanka. Challenges of the agriculture sector can be divided into four areas namely, the food security needs of the growing population, recovering the growth potential of the export agriculture sub sector, renovation and sustained management of the fragile natural resources and threat of climate change (Institute of Policy Studies, 2017). Even though Sri Lanka is self-sufficient in rice and the import of rice have decreased over time other food import dependency is still significant. They include wheat, milk products and other essential food items. The import amount of Sri Lanka increased by almost 9% in 2017 (Wijesiri, 2018). These issues have serious impacts not only on the profitability of Sri Lanka's agricultural industry, but also on national food security. Depending too much on essential food imports badly affect food security, especially in a situation like COVID-19 pandemic.

Ineffective labour force is one of the main issues of the agriculture sector. Around 25.5% of the population of Sri Lanka is engaged in agriculture sector, but the sector's contribution to GDP is low and it accounts as 7.3%. It says that industrial worker and a service sector worker is four times as productive as someone working in agriculture sector in Sri Lanka (Thanigaseelan, 2021). Lack of interest shown by the youth generation for agriculture sector is another issue that affects the productivity of agriculture. Lack of employees in the agriculture field will create serious problem in future as it will eventually affects the food security (http://static.dailymirror.lk/assets/uploads/image_de3a454179.jpg).

The Ministry of Agriculture in Sri Lanka itself has identified some major issues in Sri Lanka's present agriculture sector. "Low productivity of crop and animal products for which demand is rising, poor match between food commodities that are promoted under agriculture development programs and those important for food security, inadequate attention to agricultural diversification in favour of crops that have better income prospects, heavy post-harvest losses, especially in the perishable products, failure to respond to growing concerns of food safety with appropriate responses through the full value chain, low priority given to processes food products to cater to demand shaped by changing lifestyles and inadequate attention on producing/developing nutrition rich food products" (Chadha, 2021).

Climate change and natural disasters are also serious problems that affect the agriculture sector in Sri Lanka, and the country is in 2nd in the Global Climate Risk Index. The rainfall pattern in recent years have emerged as a risk for the entire agriculture sector. Heavy rains and flood in 2015-2017 have caused adverse impact on agriculture. This problem seriously affects the food security in the country. (http://static.dailymirror.lk/assets/uploads/image_de3a454179.jpg).

Lack of market information is also another issue that agriculture sector face. This prevents farmers from accessing markets efficiently. Weak functioning of agriculture research and development programs also negatively affects the agriculture sector.

Post-harvest losses is another problem in Sri Lanka. Improper and non-scientific post-harvest practices cause losses in agriculture production specially, fruits and vegetable production. The annual loss of fruits and vegetables due to poor post-harvest practices accounted about 270,000 metric tons annually causing a great loss to the Sri Lankan economy of approximately Rs. 20 billion ([http://www.ft.lk/front-page/Post-harvest-losses-cost-SL-Rs-20-b-annually-COPA/44-716201#:~:text=An%20estimated%20270%20metric%20tons,Accounts%20\(COPA\)%20this%20week](http://www.ft.lk/front-page/Post-harvest-losses-cost-SL-Rs-20-b-annually-COPA/44-716201#:~:text=An%20estimated%20270%20metric%20tons,Accounts%20(COPA)%20this%20week)).

3.6 Strategies and solutions to increase agriculture production and food security

The first step should be modernizing the agriculture sector. This means that agriculture of the country should be transformed in to commercial agriculture from the traditional agriculture to face the global challenges, specially the food insecurity problem (Wijesiri, 2018).

Adopting technology to increase labour productivity, improving farm market linkages, investing in value chains and generating off farm employment to absorb excess labour in the rural areas is very much needed to enhance the productivity of agriculture sector. The new technologies can be introduced to enhance the agriculture productivity. Post-harvest handling and processing is essential to enhance the agriculture growth by: reducing post-harvest losses and

assuring food security through innovative technology development, increasing value addition, improving processing, packaging, quality control and value addition (http://nastec.gov.lk/files/nrdf/2_Agriculture.pdf). Reducing post-harvest losses are also important to increase the productivity of agriculture (Thanigaseelan, 2021). Government should implement assistance programs to encourage modern technology for the whole production process from seeding to marketing.

Attracting youth to agriculture sector is very essential to combat the future labour problems in that will directly affect the food security of Sri Lanka. Enhancing youth involvement should be done through promoting scientific agricultural entrepreneurship training, encouraging scientific farming and promoting agro-enterprises (Wijeisri, 2018)

Increasing research and development is a must to enhance the agriculture sector. It will help to increase crop yields, improve productivity, reduce losses due to different diseases and pest attacks, develop high technology equipment, new storage methods, efficient marketing and to increase the food quality which is very much needed to ensure food security. Sri Lankan government has taken necessary actions to improve agriculture production and food security. According to the Sri Lanka Agriculture Policy, government has formed national policies related to improve agriculture production focusing on different sub sectors such as promoting agricultural production, seeds and planting materials, fertilizers, pesticides, agriculture machinery, irrigation and water management, land use, soil conservation, agriculture credit, agriculture insurance, agriculture research, agriculture extension and education, post harvesting technology, marketing, agro based industries, traditional agricultural crops and methodologies, home gardening, investments in agriculture, institutional development, utilization and sharing of plant genetic resources, youth involvement in agriculture and agriculture exports. Implementing these policies will improve the agriculture sector in Sri Lanka and it will impact positively on food security of the country (<http://www.agrimin.gov.lk/web/images/docs/1252389643AgPolicy4.pdf>).

4. CONCLUSION

Sri Lanka has been a rich agricultural country since history. Paddy cultivation was not only just an economic activity but also a life that shaped the society culture, religion and the economy. Agriculture is the most important sector of the Sri Lankan which makes a significant contribution to the national economy, employment and food security. Major changes to agriculture sector occurred during the colonial period starting from Portuguese, Dutch and British.

Sri Lanka as a country, has achieved a notable progress in several areas such as education, reduction in child birth rate and decreasing poverty levels. Though, the food insecurity of the country still remains a constant problem. Achieving food security has become a serious problem mainly due to less agriculture productivity, population growth, natural disaster and climate changes, higher food prices, poverty. Food security is highly depend on the agriculture sector. Therefore, the focus of the country should be on developing agriculture productivity, increasing accessibility for nutritious and healthy food, adopting climate smart agricultural practices and to act as a driver of economic transformation for the rural people who are the most food insecure population in Sri Lanka.

Increasing agriculture productivity is a very much needed to ensure the food security in Sri Lanka. As Sri Lanka is highly depend on food imports, Sri Lanka as a country should focus on increasing local agriculture production which is essential to ensure food security especially in the situations like pandemics.

ACKNOWLEDGEMENT

IMPACT OF SUBSIDY AND CREDIT SUPPORTS ON PRODUCTIVITY OF MARGINAL AND SMALLHOLDER RICE FARMERS: A PROPENSITY SCORE MATCHING APPROACH

Md. Elias Hossain¹, Md. Khairul Islam², Md. Shamsuddin Sarker³

ABSTRACT

In the agriculture of Bangladesh, marginal and smallholder farmers comprise the largest group, whose performance, in terms of productivity, plays crucial role in the growth of this sector. To increase the productivity of marginal and smallholder farmers, government has been providing direct subsidy and credit supports to selected farmers for last several years. While direct subsidy and credit expectedly have positive impacts on farm productivity, there are other factors also, which can affect agricultural productivity. Therefore, this study aims to analyze the impact of subsidy and credit on the productivity of marginal and smallholder rice farmers in Bangladesh. For the study, primary data are collected from 1270 marginal and smallholder farmers from five districts of Bangladesh. Considering the existence of endogeneity and self-selection bias in the covariates that generally occurs in a non-random experiment, the study employs Propensity Score Matching (PSM) approach to observe the net effects of subsidy and credit on productivity of the farms. The results show that after balancing the covariates, subsidy and credit have significant contributions to the productivity of rice farms as the average treatment effect on the treated (ATT) in both cases, *Boro* and *Aman*, are positive and statistically significant. The findings justify the government's decisions to support the farmers through channeling of subsidy and credit. This study came up with the suggestion that both horizontal and vertical expansions of subsidy and credit supports are needed to increase agricultural productivity in Bangladesh.

KEYWORDS

Subsidy and Credit, Propensity Score Matching, Non-random Experiment, Rice Productivity, Bangladesh

1. INTRODUCTION

Agricultural production enhancement has been the major policy thrust in developing countries where cereals are the staple food of the population (Uddin and Dhar, 2018; Shelley *et al.*, 2016). In order to increase rice productivity, governmental and non-governmental organizations of developing countries give some direct supports to farmers (Linh *et al.*, 2019). The most common form of supporting farmers is to provide them with subsidy and credit facilities so that they can afford modern inputs such as chemical fertilizers, pesticides, irrigation and quality seeds in production (Quattara *et al.*, 2020). Many scholars observe that subsidy and credit provisions have an effective role in increasing farm productivity especially in the case of marginal and smallholder farmers (Khandker and Koolwal, 2016; Guirkingner and Boucher, 2008). Impact evaluation of subsidy and credit supports on agricultural productivity has always been one of the important issues of debate in the countries which possess lower resource base (Skreli *et al.*, 2015). Although, agricultural subsidy and credit play encouraging role in improving farm productivity, many economists have expressed doubt regarding the successes of such supports because of inconsistent and indistinguishable objectives of the farmers (Skreli *et al.*, 2015; Baltzer and Hansen, 2011). Mixed experiences are evident about the effectiveness of such incentive-based agricultural programs as some researchers found a positive association, while others revealed negative association of such programs with the productivity of the farms (Skreli *et al.*, 2015; Minviel and Latruffe, 2014). Moreover, agricultural productivity not only depends on subsidy and credit supports but also depends on many others farm specific attributes or covariates which often suffer from self-selection bias. In that case, attributing the increase in farm productivity only to subsidy and credit programs may not be acceptable.

Agriculture is the lifeline of Bangladesh economy and around 40.6% of the people of the country are directly or indirectly dependent on agriculture (BBS, 2019). As a lower middle income developing country, poverty remains widespread in the country and due to less opportunity of non-farm activities, people are increasingly getting dependent on agriculture (Dixon *et al.*, 2001). Therefore, the pledge to end poverty through increasing farm income is a top priority of the government, and subsidy and credit programs for marginal and smallholder farmers appeared to be a strategic policy in this regard. In Bangladesh, more than 65% farmers are marginal and smallholder farmers whose livelihoods are managed from agriculture (BBS, 2018). To increase the income of the people through increasing farm productivity, the government in the past decades has embarked on several schemes of credit and subsidies for the farmers (FAO, 2018).

Bangladesh is geographically a plain land delta, of which around 60% of the total land is arable. However, due to the odd of increasing non-agricultural use of land amid a large population, per capita arable land is only 0.0492 hectares in

Bangladesh (WB, 2016). The contribution of the sector to GDP of the country is 14.1% and the contribution of crop agriculture to GDP is 7.37% (BER, 2019). The agricultural land in the country has been fragmenting continuously over the years. Most of the farms operating in the country are very small in size caused by consistently rising population, and inheriting land ownership and regulations. Maximum of the crop farms in the country are subsistence in nature (BBS, 2018). In spite of having these backdrops, the agricultural sector of the country has been successful to touch a gratified position in the history of world agricultural statistics. The country is now second in jute production, third in rice, vegetable, and inland fish production, fifth in aquaculture production and seventh in mango production in the world (BBS, 2018). The most important matter is that the country is self-sufficient in rice and fish production.

As staple food for around 165 million people, rice is the dominant crop in Bangladesh which is cultivated in about 75 percent of the total agricultural land (UN, 2019; Nasim *et al.*, 2017). The country was the third largest rice producer in the world, and it has become possible as the climatic condition of the country is perfectly congenial to rice farming. The total amount of rice production in the country was only 10.59 million metric tons in 1991 which has increased gradually and reached to 36 million metric tons in 2020 enough to feed 165 million populations. This indicates that self-sufficiency in rice of the country has been achieved as the growth of rice production was much faster than the growth of population. As per Hossain (2019), with a production of 36 million metric tons of rice, Bangladesh places in third position globally in rice production after China and India with rice production of 146 million tons and 116 million tons, respectively. It is to note that rapid increase of rice production benefitted the country in two ways- first, saving of foreign currency for rice import, and second, diversion of resources for development activities which otherwise would have been spent for rice import.

Marginal and smallholder farmers in Bangladesh have the major role in rice production and the growth of rice production can be attributed to their performance during the cropping seasons. As farmers belong to these groups often lack operational capital in terms of money during the cropping seasons, they struggle to purchase inputs like fertilizer, seed, irrigation and pesticides (Linh *et al.*, 2019; Uddin and Dhar, 2018). To cover these costs, they mostly take credit from government and non-government agencies. In addition, the government also allocate agricultural subsidy to selected marginal and smallholder farmers. For last several years the government of Bangladesh gives special allocations for distribution of credit and subsidy for farmers involved in crop and non-crop agriculture towards increasing their productivity. Several studies have observed that credit extension and subsidy programs resulted in significant outcomes of the farmers in terms of increasing productivity of crops (Allotey *et al.*, 2019; Dlamini *et al.*, 2019). However, there are many other factors as well which also can have positive effect on the productivity of farmers, and increase in productivity may be an outcome of the joint influence of many variables including credit and subsidy.

In the empirical studies, endogeneity among the variable can exist and there can be self-selection bias arises among the subjects (Brookhart, 2006; Rosenbaum and Rubin, 1983). In such a situation, conventional quantitative techniques cannot disentangle the separate effect of one or more particular explanatory variables on the outcome variable. Rusenbam and Rubin (1983) suggests that in the presence of endogeneity and self-selection bias Propensity Score Matching (PSM) method can be applied to identify the separate effect of a variable on outcome variable. Thus, this study employs the Propensity Score Matching (PSM) approach to analyze the impact of credit and subsidy supports on rice productivity of marginal and smallholder farmers in the context of Bangladesh.

The paper is organized as follows: after giving a background of the research issue reviewing earlier studies, and setting the research objective in the introductory section, the scenario of subsidy and credit disbursement provided in the agriculture sector of Bangladesh is discussed in Section 2. Methodology and data collection issues are provided in Section 3. Section 4 presents the estimation results and core findings, and finally, Section 5 concludes.

2. AGRICULTURAL CREDIT AND SUBSIDY IN BANGLADESH

Bangladesh government has been continuously emphasizing on increasing agricultural productivity with a view to ensure food security, poverty eradication, increase income and employment generation, and by this way the government has been striving to make the economy more sustainable and stronger. This was manifested in various plans and policy documents of the Government of Bangladesh at different times. The need for agricultural credit and subsidy was felt seriously with the technological breakthrough which was incepted by the GR (Green Revolution) that resulted in increasing productivity of food crops (Mondal, 2010). In Bangladesh, agricultural subsidy and credit disbursements have been mostly targeted to attain higher productivity and yield of rice, the main crop typically produced by marginal and small farmers. The scenario of agricultural credit, subsidy and rice production in Bangladesh is shown in Figures 1, 2, 3, & 4.

Figure 1: Trend in agricultural subsidy

Figure 2: Trend in agricultural credit

Figure 3: Trend in Aman rice production

Figure 4: Trend in Boro rice production

Source: Bangladesh Bureau of Statistics (Several Years).

The graphs above show that both agricultural subsidy and credit disbursement have increased over the last two decades. Figure 1 shows that although subsidies given to the agricultural sector fluctuated markedly in different years, its trend has been increasing. Compared to subsidies, the increase in agricultural credit disbursement has been stable over the years with significantly increasing trend (Figure 2). Figure 3 and 4 show that over the year government's policy of increasing expenditures on subsidy and credit to agriculture sector has resulted in increased volumes of production of Aman rice and Boro rice, although a downtrend is observed in case of Boro rice production due to the occurrence of early floods in the years of 2016 and 2017, in the Haor areas of the north-eastern region. All the four figures give an insight that subsidy and credit have positively contributed to increase agricultural production.

3. RESEARCH METHODOLOGY

Rice farming in Bangladesh has been supported by subsidy and credit programs by the governmental and non-governmental organizations for many years. This study attempts to draw a precise impact assessment of agricultural subsidy and credit programs on rice productivity of marginal and smallholder farmers following a quasi-experimental research design, namely the Propensity Score Matching (PSM) approach, because farmers are not randomly assigned to both the programs. The methodological steps that are followed throughout this study are stated in the following sub-sections.

3.1 Theoretical Framework of PSM

Propensity score matching method is becoming increasingly popular in impact evaluation studies as they afford researchers the ability to account for systematic bias related to self-selection. By controlling for variables related to self-selection into interventions, propensity score matching technique helps to render a more precise estimate of the effects of an intervention (Rosenbom and Rubin, 1984). Austin (2011) asserts that if variables related to participants' self-selected into an intervention are known, then the associated bias can be captured by using the propensity matching methods.

As a quasi-experimental method, PSM involves the conditional probability of getting treatment assuming pre-treatment or exogenous individual characteristics (Rosenbaum and Rubin, 1983). The process of conducting propensity score matching involves several steps. In these steps decisions must be made regarding the choice of covariates, models for creating propensity scores, matching distances and algorithms, the estimation of treatment effects, and diagnosing the quality of matches (Caliendo and Lopeing, 2008; Stuart and Rubin, 2008). In the beginning, propensity scores are created from covariates related to the recipients' self-selection into an intervention (treatment). The probability of treatment (i.e. propensity score) allows the researcher to balance the intervention and comparison group, conditional upon the multivariate distribution of the covariates. After creating the propensity scores, comparison groups are created by

making matches using different approaches and the quality of matches has to be assessed. Finally, treatment effects in terms of ATT and ATE are measured.

3.2 Selection of Target Group

In Bangladesh, marginal and small-scale farmers have been confronting disappointing constraints in case of using appropriate amount of necessary inputs during farming season because of not having enough resources which disheartens them, impedes their production activities, and finally reduces farm productivity (Bagchi *et al.*, 2019; Mondal, 2010). As a result, some of them are provided with credit and subsidy supports to continue their production process (Bangladesh Bank, 2014). Therefore, marginal and smallholder farmers who receive agricultural subsidy and credit from governmental and non-governmental organizations are the target group in this study.

3.3 Study Area

Rice is grown all over Bangladesh throughout the year as the agro-climatic condition is congenial enough to farming rice. This study is carried out in five purposively selected districts (namely, Gaibandha, Rajshahi, Naogoan, Dinajpur, Kushtia) of Bangladesh. The study districts are selected purposively on the basis of their degree of contribution to total rice production of the country. The selected districts are the most rice producing regions in Bangladesh. The survey for collecting required data is conducted between the time from February 2020 to July 2020.

3.4 Sampling and Data Collection

The required data for this study are collected using a structured questionnaire from a total of 1270 marginal and smallholder rice farmers (among them 70 farmers does not grow *Aman* rice) following a face-to-face interview method. Before using for data collection, the questionnaire was trialed through pilot survey and it was adjusted based on the suggestions found in the survey. The farmers of treated group were identified randomly based on the lists of farmers provided by the regional Department of Agriculture (agriculture extension service office) and the farmers of control group were selected following a systematic random (quasi random) sampling technique. Interviews were conducted by well-trained postgraduate students of Rajshahi University, Bangladesh. Their work and whole process of survey was coordinated and monitored by a research team.

3.5 Covariates Selection with Justification

Appropriate covariates selection, their measurement procedures and logical explanation of selecting each covariate in propensity score matching (PSM) analysis are imperative (Rosenbaum and Rubin, 1983). By controlling for all chosen covariates associated with the participants' self-selection into the intervention programs, the PSM technique helps us to sketch more trustworthy estimation of effects of interventions on outcome (Harris and Hosrst, 2016). During propensity score computation applying a suitable regression model, covariates act as predictors of participation into the intervention programs (Harris and Hosrst, 2016; Stuart and Rubin, 2008a). Considering the importance, all necessary covariates for this study have been selected carefully and sincerely. These covariates are chosen based on the conventional wisdom drawn from the studies done by Mottaleb *et al.*, (2016), Mondal (2010), Memon *et al.*, (2016) and Afrin *et al.*, (2017). The unit of measurement and description of covariates and interventions that have been chosen for this study are stated in Table 1:

Table 1: Description of variables their measurement

Variables	Measurement unit	Description
Land	Bigha(33 decimal)	Cultivable land under rice cultivation
Rice productivity	Maund(40 kilogram)	Amount of rice in per <i>bigha</i> land.
Age	Year	Age of farmers
Education	Years of schooling	Education level of farmers
Occupation	Dummy	1 if main occupation is farmer, 0 otherwise
Experience	Year	Years of engagement of farmer in agriculture
Family size	Number	Total family members
Earnar member	Number	Total members of family who earn
Agri. Member	Number	Total family members engaged directly in farm activities
Educated member	Number	Total family members who have formal education
Subsidy	Dummy	1 if farmers receive subsidy; 0 otherwise
Credit	Dummy	1 if farmers receive credit; 0 otherwise
Seed quality	5 point Likert scale	1 if seed quality is very bad, 5 if excellent
Seed amount	Kilogram	Amount of seed used in per <i>bigha</i> rice land
Social organization membership	Dummy	1 if have membership of any social organization, 0 otherwise
Fertilizer	Kilogram	Amount of fertilizers used in per <i>bigha</i> rice land
Rice price	Taka	Price of per <i>maund</i> rice
Durable asset	Thousand Taka	Total value of durable assets
Income	Thousand Taka	Annual income of farm household
Extension contract	Dummy	1, if farmer receive extension services from locally employed agricultural experts; 0, otherwise
Livestock asset	Number	Total livestock possess by farmer
Poultry asset	Number	Total poultry possess by farmer
Soil quality	5 point Likert scale	1 if soil quality is very bad, 5 if excellent

In this study, the single-factor productivity has been used as an outcome variable. We have computed per *bigha* rice productivity as follows:

$$Y_i = \frac{\sum P_i}{\sum L_i}$$

Where Y_i is the rice productivity of land of i^{th} farmer; $\sum P_i$ is the total rice production (in maund) of i^{th} farmer; and $\sum L_i$ is the total land under rice production of i^{th} farmer (in *bigha*).

3.6 Selection of the Model for Creating Propensity Score

Appropriate model selection for propensity score calculation depends on the level of intervention (dependent variable) (Harris and Hosrst, 2016; Rosenbaum and Rubin, 1983). In our study, agricultural subsidy and credit are interventions and both are taken as binary variables with the value of 1 if farmer receives subsidy (credit), and 0 otherwise. The propensity score in this study is the probability of receiving agricultural subsidy (credit) for growing rice given a vector of covariates covering socioeconomic, demographics, and farm related characteristics of farmers. The mostly used technique for computing propensity score is the Logistic regression model (Harris and Madison, 2016; Austin, 2011; Stuart, 2010). The form of the logistic regression model is as follows:

$$L_i = P(I_i = 1|X_{ij}) = \ln\left(\frac{P_i}{1 - P_i}\right) = \beta_0 + \sum_{j=1}^m \beta_j X_{ij} + \mu_i [i = 1 \dots n]$$

Where, L_i is log of odd ratio of i^{th} farmer, I_i is intervention (subsidy or credit) status of i^{th} farmer, P_i represents the probability of receiving subsidy or credit by i^{th} farmers, $(1 - P_i)$ indicates the probability of not receiving the subsidy or credit by i^{th} farmer, X_{ij} represents the j^{th} covariate of i^{th} farmer, β_j stands for regression coefficients, μ_i is stochastic error term.

3.7 Selection of Propensity Score Matching (PSM) Methods

Propensity score matching attempts to trace one (more) individual(s) with similar propensity score in the treatment and control groups (Austin, 2011). In our study, we have filtered out the farmers who have similar propensity score from subsidy (credit) receiving group and non-receiving group (Stuart and Rubin, 2008a) applying the following matching methods.

Nearest neighbor matching (NNM): NNM is the simplest matching technique in which individual from the control group is preferred as a matching associate for treated individual who is closest in terms of propensity score (Stuart, 2010; Smith, 1997; Rosenbaum and Rubin, 1985).

Radius caliper matching: Another matching technique is NN matching with the caliper adjustment. In this method, a specific distance is set to match treated and non-treated farmers. Each treated farmer i is matched with non-treated farmer j that fall within the specified distance.

Kernel matching (KM): In order to construct counterfactual outcome, KM is done on the basis of weighted average of entire entity of control group. As a result of applying this method, lower variance is found as it can capture more individuals from control group compared to other methods. In case of radius matching, all individuals remain within a pre-specified radius receive the same weights. The weight is given considering the distance between the propensity score of an individual of control group and an individual of treated group for which the counterfactual is expected (Caliendo and Kopeinig, 2005).

3.8 Estimation of Treatment Effects of Agricultural Subsidy and Credit on Productivity

In our study, propensity score matching approach is followed to assess the impact of agricultural subsidy and credit on rice productivity in Bangladesh. The method is used to compare the rice productivity of marginal and smallholder farmers who are assigned to agricultural subsidy and credit supports with the productivity of farmers not assigned to the supports. Under this approach, two ways can be applied to estimate the aggregate effects intervention: average treatment effect (ATE) and average treatment effect of treated group (ATT). We can compute ATE and ATT as follows.

$$ATE = E(R_{1i}|T_i = 1,0) - E(R_{0i}|T_i = 1,0)$$

Where $E(.)$ indicates the expectation in population (whole sample). T_i represents the treatment (subsidy or credit) with the value of 1 for the treated group and the value of 0 for the control group, R is the outcome variable (productivity per unit of land). In other words, ATE is the average effect that would be observed if everyone in the treated and control groups receive treatment, compared with if no one in both groups receives treatment (Harder, *et al.*, 2010). On the other hand, ATT means the average effects that would be observed if everyone in the treated group receives treatment compared with if none of the individuals in the treated group received treatment. The formula for ATT is as follows.

$$ATT = E(R_{1i}|T_i = 1) - E(R_{0i}|T_i = 1)$$

4. RESULTS AND DISCUSSION

4.1 Socioeconomic, Demographic and Farm Characteristics of Farmers

The socioeconomic, demographic and farm related characteristics of farmers are assumed to have a correlation with the productivity of farms. For example, a farmer with higher level of education, training, extension contracts, farming experience, subsidy, credit etc. could have more productivity. Therefore, a short description of the features of farmers is

given in this section to have insights about marginal and small holder farmers of Bangladesh. The obtained features are shown in Table 2. From the table it is revealed that there the average cultivable land size of small and marginal is very small. On the average farmers are in middle age of their life with a long farming experience and the have completed only primary education.

An interesting fact is that although farmers are involved in farming on their land, farming is not the main occupation of all the farmers. It is revealed that less than fifty percent farmers grow crops as their as main occupation. It is found that farmers have a moderate family size with more than one earner members and more than two educated members. The average productivity of *Boro* rice is higher compared to *Aman* rice.

Table 2: Basic features of the farms and farmers

Characteristics	Boro			Aman		
	Mean	Stdv.	%	Mean	Stdv.	%
Land	2.65	1.68	-	2.61	1.62	
Age	44.66	13.65	-	44.45	13.66	
Education	5.87	4.29	-	6.52	3.91	
Occupation (1 = Farming as main occupation)	0.47	0.50	47.7	0.47	0.50	47.0

Source: Authors' own calculation based on field survey data.

It is found that 52% *Boro* and 54% *Aman* rice farmers have received credit for agricultural production activity. On the other hand, 46% *Boro* and 52% *Aman* rice marginal and smallholder farmers have received subsidy. The farmers reported that they are to use lower quality seeds. Membership of social organization helps farmers to know about different agriculture related problems and solutions through sharing each other although it is found that only 21% *Boro* and 24% *Aman* rice farmers are associated with social organizations. Agriculture extension services also promote productivity. It is revealed that 70% *Boro* and 68% *Aman* rice farmers received agriculture extension services. The average annual income of farmers is very small and they have lower durable, livestock and poultry resource base.

4.2 Distribution of Propensity Scores and Covariate Balance

In Bangladesh, the aim of giving subsidy and credit supports to rice farmers is to increase rice production. Therefore, outcome variable used in our study is rice productivity (per *bigha* production of *boro* and *aman* rice varieties). As the study is done following PSM approach, first we discuss the distribution of our computed propensity score. Propensity score hold a good balancing property, if the scores of both groups are equally distributed. Figures 5, 6, 7 and 8 show the propensity score distribution of treated and control groups. From the figure it is clear that there is a substantial overlap in the distribution of propensity scores of treated and control groups. This result satisfies the balancing property of our computed propensity score and means that obtained propensity score is reliable enough to make control and treatment groups similar and comparable.

Figure 5: Boro and subsidy model

Figure 6: Boro and credit model

Figure 7: Aman and subsidy model

Figure 8: Aman and credit model

The propensity score balance can also be represented using boxplot of computed scores. From Figure 9, 10, 11 and 12, it is revealed that the medians, 25th percentiles and 75th percentiles of our estimated propensity scores are almost similar for both treatment and control groups after matching. This result indicates the strong balance of covariates selected for our study.

Figure 9: Boro and subsidy model

Figure 10: Boro and credit model

Figure 11: Aman and subsidy model

Figure 12: Aman and credit model

The covariate balance can be tested comparing the mean of all individual covariates of control and treated groups, which is termed as standardized bias. It is another standard test to assess the quality of propensity score matching. According to rule-of thumb, the standardized bias for an individual covariate should be less than 5% after matching (Rosenbaum and Rubin, 1985). From, the covariate balance test results shown in Table 3 & 4, we can see that the standardized biases are less than 5% in case of all covariates in the *Boro* and *Aman* model. It is also revealed that the mean bias is less than 5% in all the four cases. This result implies good covariate balance.

4.3 Impact of Agricultural Subsidy and Credit on Rice Productivity in Bangladesh

The calculated results of ATT are shown in Table 5 and ATE results are reported in Table 6. Both the ATT and ATE results confirm that the average effects of subsidy and credit supports to marginal and smallholder farmers are positive in all the cases. These results mean that both the subsidy and credit supports have positive role in increasing the production of both *Boro* and *Aman* rice in Bangladesh.

5. CONCLUSION AND POLICY IMPLICATIONS

As the economy of Bangladesh and the livelihoods of most of the people are agriculture centric, agricultural productivity is one of the most widely discussed and debated issues. Among the three groups of farmers- marginal, small and large farmers in the country, large farmers with more land asset, equipment, and capital enjoy additional privileges to raise productivity of their farms compared to marginal and smallholder farmers. Capital shortage among marginal and smallholder farmers during crop seasons impedes their production potentials at a considerable rate. Therefore, in order to raise the agricultural productivity, the government of Bangladesh allocates some budget as agricultural subsidy and credit in the national budget each year to be disbursed to the marginal and smallholder farmers. In this study, it is obvious that both agricultural subsidy and credit have positive effects on rice productivity in Bangladesh as the ATT and ATE is found positive and statistically significant in all the cases. As both agricultural subsidy and credit programs increase the productivity of rice of small holders and marginal farmers in Bangladesh, the government should continue and expand the programs horizontally and vertically with careful look over. Government should also ensure the access of all helpless farmers to these programs. To this end, government is urged to increase the share of agricultural budget and to make

strong the *upazila* agriculture office with substantial manpower. In addition, government has to inspect the programs with higher authority to ensure the accountably and transparency of works of all staff associated with the programs.

COMMON GOODS AND TERRITORIAL DEVELOPMENT: REFLECTIONS ON GOVERNANCE ISSUES

[Leila Kebir](#)¹, [Frederic Wallet](#)²

¹University of Lausanne, Switzerland. ²INRA-UPS, Switzerland

ABSTRACT

Today is an upsurge in initiatives based on the concept of 'commons' in regional and urban planning, and territorial development. The use of this concept crystallizes several contemporary cross-cutting issues that mobilize local collectives, such as the energy transition, sustainable urban development, management of natural resources or public places, emergence of a circular economy, urban ecosystems, biodiversity, etc. Moreover, we observe a multitude of commons in contemporary society: more or less inclusive / excluding devices involve forms of pooling and shared management of resources (land, urban infrastructure, knowledge, etc.) that lie beyond the market and public management. They also refer in a more or less pronounced way of ethics and collective interest (cf. Thomas Aquinas) that exceed or add to the individual interest. In a context of shrinking public finances, these devices imply a redistribution of responsibilities structured largely around the user and the producer of the property for managing territorial resources. These emerging phenomena questions the way in which the development of territories is conceived today. The economic and competitiveness dimensions (creation of knowledge, productive resources, etc.) now also combine societal and non-economic aspects (improvement of well-being and quality of life). It tends to become increasingly explicit in development strategies. These phenomena are also signs of an evolution of our society towards more collective and participative modes of exploitation and management of territorial resources in which stakeholders and in particular users are involved. These approaches seem today to reflect an aspiration towards a more localized, inclusive, sustainable and equitable development model, without ignoring the tensions and conflicting dimensions of development. The objective of this paper is to identify what the notion of commons translates in terms of territorial development issues. In particular, it will identify the opportunities and importunities that it reveals in terms of governance. The first part proposes to return to the notion of common good in order to grasp the related conceptual issues. Then we present an analysis of the contributions of this notion to territorial development approaches. More specifically, we grasp the differences and similarities between commons and territorial resources, thus highlighting what the mobilization of this concept indicates in terms of issues. The third part addresses the challenges of territorial governance posed by contemporary forms of management in commons.

CULTURAL AND CREATIVE CITIES AND REGIONAL ECONOMIC EFFICIENCY: CONTEXT CONDITIONS AS CATALYZERS OF CULTURAL VIBRANCY AND CREATIVE ECONOMY

Silvia Cerisola, [Elisa Panzera](#)

Politecnico di Milano, Italy

ABSTRACT

Following the hype that has been given to culture and creativity as triggers and enhancers of local economic performance in the last 20 years, this work aims at assessing the impact of Cultural and Creative Cities (CCCs) on the development of their regions. In this sense, the cultural and creative character of cities is considered as a strategic strength and opportunity that can favor the economic system of the entire regions in which the cities are located.

Exploiting a regional production function and data from the Cultural and Creative Cities Monitor (CCCM) provided by the JRC, the effect of cities' cultural vibrancy and creative economy on the output of the regions they belong to is econometrically explored. The possible role played by the enabling environment in catalyzing the action of cultural vibrancy and creative economy is also considered.

The implications are thoroughly discussed: CCCs are a strategic resource for the sustainable development of their region since they contribute to feed a long-term self-supporting system, interpreted according to a holistic conception that includes economic, social, cultural, and environmental domains.

PROXIMITY ANALYSIS OF LOCAL ACTORS' COORDINATION IN THE CIRCULAR ECONOMIC PROCESS A STUDY CASE ON METHANISATION BASED ON SOCIAL NETWORKS APPROACH

[André Torre](#)^{1,2}, [Amadou Niang](#)^{1,2}, [Sébastien Bourdin](#)³

¹University Paris Saclay, France. ²INRAE, France. ³Normandy Management School, France

ABSTRACT

Our article aims to analyze the dynamics of social and economic interactions and proximity relationships. It is based on a theoretical framework combining the approaches of analysis of social networks and proximities, applied to the mechanism of methanisation of household and assimilated garbage of the Syndicat Mixte du Point Fort (SMPF) of the commune of Cavigny. This case study is symptomatic of the problems of connecting actors at the local level. Stakeholders with diverse functions and from different territorial scales coordinate around issues of waste mobilization, co-product flow, risk management and social acceptability. In our approach the social networks tool is coupled with an analysis of proximities (geographical and organized), in order to provide a better understanding of governance associated with the structuring of productive and social interactions. We first present the SMPF methanization project, then the theoretical framework and methodology used to analyze the territorial governance of this case study. We study, on the basis of our surveys, the technical and innovation trajectories and their evolution at the local level, by representing them in the form of flow networks. We then analyse the dynamics of social networks, which reveal the evolution over time of synergies and cooperative behaviors between the actors of the methanisation of Cavigny. The last part is devoted to the analysis of the importance and the role played by proximity relationships in the productive choices and relationships maintained by the actors of this process.

Special Session: SS18.2 - Urban Future in the Global South

11:00 - 12:15 Tuesday, 25th May, 2021

ASSESSING WATERSHED ENVIRONMENTAL VULNERABILITY IN CLIMATE CHANGE CONTEXT: CASE OF ARID WATERSHED FROM MOROCCAN ANTI-ATLAS

Said Lahssini, Abdellatif Khattabi

Ecole Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

Climate change is global concern. Within Mediterranean region, it will highly affect Morocco with a perspective of higher temperature and variable rainfall patterns. As consequence, it will lead to high extreme events and to environmental hazards affecting food security and social stability. In arid mountainous lands, the scarcity of land resources, the expansion of human consumptive needs, in addition to the high pressure on natural resources and the emerging climate risks, natural capital will be highly threatened. This study focusses on Mountainous watershed located on Atlas Mountains. It aims to assess environmental vulnerability within climate change context. Vulnerability was assessed using Environmental Vulnerability Index (EVI). The index calculation of the EVI is based on the aggregation of indicators related to vulnerability components that includes risk, exposition and adaptation capacities. The indicators, providing information on the magnitudes and trends of several environmental vulnerability components, are then standardized on common scale according to EVI calculation methodology. Our results stress out that the studied area is highly vulnerable with higher EVI values. According to vulnerability components ranking, vulnerable sectors within study area could be classified, according to their priorities, as follow: i- human health, ii- water, iii- biodiversity, iv- agriculture, v- exposure to natural disasters, vi- climate change, and vii- desertification. The results of this work could be shown as a prerequisite for assisting decision- makers to establish an adapted management plan of the watershed and to enhance the contribution of landscape ecosystems to the hydrological functioning of the watershed in the context of climate change. Moreover, if the needs of promoting human capital development seems to be major priority, the degradation of natural resources requires restoration actions in order to maintain the ecological services provided by forest ecosystems. The conclusions obtained will be helpful for public action to strengthen the resilience of the natural environment.

OPERATIONALIZING DISASTER RESILIENCE IN NORTHERN MOROCCO: A COMPARATIVE STUDY OF COMPOSITE INDICATOR EFFECTIVENESS FOR MEASURING FLOOD RESILIENCE

Satour Narjiss, Ilias Kacimi, Nadia Kassou

University Mohamed V, Morocco

ABSTRACT

Serving natural disasters and risk management purposes, resilience approaches aim to understand characteristics contributing to managing the capacity of an urban system to adapt and cope with natural hazards such as floods. The identification of metrics for measuring flood resilience is becoming a robust area of several studies. Many purposes, variables and assessment methodologies were applied. Indices are frequently used as a measurement tool. While getting the same name many index-based approaches for assessing resilience to floods have differences in indicator selection and calculation methodology. Leading therefore for different output scores and different policy implications. These inconsistencies call for more critical reflection on index design and utility. In this regard, discussing and comparing index outputs is an effective approach. Here, the Flood Resilience Index (FRI) is developed and applied at Fnideq, M'diq and Martil coastal municipalities (Northern Morocco) within the same theoretical approach three times. While the Composite Indicator FRI (1) is calculated with a set of indicators and compensatory aggregation technique, the FRI (2) incorporates different indicators and two alternative methods on constructing composite indicators: Principal Components Analysis (PCA) and Self-Organizing Map (SOM), to measure flood resilience. Maps, class rank changes, and correlations are used to realize a visually and quantitatively comparison. Results show that different theoretical frameworks influence highly scores, and the methodology of index calculation used has an even effect on output. The growing trend on resilience assessment could tackle simultaneously the assessment frameworks and validation step of results with transparency and critical presentation of the whole process limitations.

KIGALI AND THE SECONDARY CITIES AS A POLYCENTRIC GREEN STRUCTURE FOR RWANDA

Manlio Michieletto

Department of Architecture, School of Architecture & Built Environment (SABE) University of Rwanda, Kigali, Rwanda, KK 737 St, Kigali, m.manlio@ur.ac.rw

ABSTRACT

The last decades have shown an African rapid urbanization's rate culminated with the appearance of extraordinary growing metropolises, a process that inevitably raises the need of preventing the cities' collapse and implosion re-thinking their urban future. In the East African Region, Kigali, the capital city of Rwanda, first responded to this issue through the adoption of a national and urban sustainable plan primarily directed to the achievement of the 11th Sustainable Development Goals (SDG). In fact, the country is structured according to a system of secondary cities – Musanze, Huye, Muhanga, Rubavu, Rusizi, Nyagatare, revolving around Kigali revealing the adherence to a polycentric planning model scaled at different levels. Starting from the assumption that the city builds and shapes itself over time, Kigali is experiencing an urban rebirth boosted by a series of master plans, 2007, 2013 and 2020, that are tracing its passage to a sustainable satellite city composed of green settlements. After the analysis of the transition to green architecture and an excursus on the adopted policies it is described the geographical and historical background and context. Furthermore, it is studied the use of a well-known urban development plan, the satellite city combined with the needs of “make cities inclusive, safe, resilient and sustainable” where tradition and modernity have to find the way to establish an architectural dialogue. The satellite city model was applied in the development plans of regional cities in adherence to the local environment providing interesting case studies for contemporary projects in the same area. Three settlements in the capital city – Kigali 2020, Kigali Vision and Green City Kigali are explored as urban examples of the green strategy together with the proposed master plans for the secondary cities. Therefore, the research explores both the capital city and national urban development as sustainable steps towards a green future, for a harmony between the natural and artificial environment, demonstrating the need of an adequate political action in order to guide the achievement of the Sustainable Development Goals.

KEYWORDS

Kigali, Rwanda, satellite city, sustainable architecture

1. INTRODUCTION

1.1 The African urban growth

The world in the 21st century is experiencing an unprecedented urban growth and the development prospects of the continent largely depend on how this process will be handled over the next few decades. In fact, the “urban population is expected to rise by 2.5 billion persons, from 4.2 billion to 6.7 billion, while the total world population is projected to grow by somewhat less, 2.1 billion, from 7.6 billion in 2018 to 9.8 billion in 2050!” “United Nations (2018)”. Most of the growth is occurring in developing Regions predicting that seven out of ten urban dwellers will be African or Asian in 2030 “World Health Organization (2010)”. The current global urbanization is not only purely a demographic phenomenon but is also a transformative force that continually shapes societies, their economies, political systems and environments both built and unbuilt.

The new cosmography of the African continent shows a diffuse macrocephaly, with seven megacities – with more than 10 million of inhabitants: Cairo, Kinshasa, Lagos, Accra, Johannesburg, Pretoria, Khartoum e Nairobi. In the next 15 years it is estimated that will be added also Dar El Salaam in Tanzania, currently around the 4.5 million and Luanda in Angola, currently around 2.5 million. Cairo is the most populous city on the continent and with a density that reaches even 1000 inhabitants / km².

Sub-Saharan Africa is usually regarded as the world fastest urbanizing continent's area that will host two of the world largest megacities – over 20 million, in the near future: Kinshasa and Lagos. Kinshasa, the capital city of DR Congo according to the predictions “will count in 2050 a population of around 35 million of inhabitants and Lagos, the Nigerian Capital city around 32 million” “Hoornweg and Pope (2014)”. The development prospects of the Continent largely depend on how the process of rapid and vast growth will be handled over the next few years. In this regard the process has to be based on inclusivity, wide distribution of infrastructures, food and circular economies and nature-based solutions.

1.2 The Rwandan case

Ranked as a rapidly growing city, Kigali accounts for almost 60% of the Rwandan urban population with an annual incremental rate of 9% “Government of Rwanda and GGGI (2015)” and the country's aim is to reach 35% of urbanization

by 2024 “REMA (2017)”. The “Rwandan population is expected to increase from 10.5 million in 2012 to 16.3 million in 2032” and in the same period also Kigali will register a large growth from 1.3 million up to 3.7 million inhabitants as predicted by the “Rwanda National Institute of Statistics (2012)”.

Kigali became the capital city in the early 1960s and is living today a fervent urban rebirth driven by the adoption of a sequence of master plans. The design process began in 2008 by the Singapore-based firm called Surbana with the first Kigali Conceptual Master Plan (KCMP). Thereafter, the municipality approved an integrated and detailed plan for the entire city as part of the Vision 2040, also named the Kigali Master Plan 2013 “City of Kigali (2013)”. Since 2018 the same Singaporean firm has been identified to lead the revision of the present master plan extending its validity under the strategic Vision 2050. Recently the municipality presented to the public the updated Master Plan identified by the motto *Kigali Yacu!* (Our Kigali!) that emphasizes the inclusive nature of the Master Plan approach and intent to work for and with the people thus strengthening the communitarian value of the project. The core characteristic of the developed plans is the construction of a polycentric city to be stretched in all four provinces and at the same time to strength the iconic value of Kigali as modern capital city.

2. RESEARCH METHOD

This study will focus on presenting the state of art regarding the actions adopted and put in place by the Rwandan Government in order to fulfil the engagement of becoming an adequate case study of green vision not only for the region but also for the continent. The Kigali and Rwanda development plans have to be divulgated from the national to a broader audience as well as to all organs and institutions interested to have a real series of projects successfully realized or references according to ad hoc policies and legal framework.

The research is not the ending point of a study but the continuation of a path that has begun in 2019 as result of the third National Urban Forum organized in Kigali in partnership with the School of Architecture and Built Environment (SABE) of the University of Rwanda located in the College of Science and Technology in Kigali. Main topic was the important issue of reshaping the capital city according to the master plan recently revised. Therefore, the study is mostly concentrated on topics related to Rwanda over the time with an historical investigation on case studies in the East Africa Region of satellite cities projects.

3. THE HISTORICAL CONTEXT

Rwanda achieved Independence on the 1st of July 1962. Two different colonizers – the Germans and the Belgian, occupied the territory that previously was under the domination of the local Kingdom.

3.1 The colonial period

The German East Africa (*Deutsch-Ostafrika*) was the German colony located in the African Great Lake Region and composed of the territories today occupied by Tanzania, Burundi and Rwanda. Rwanda formally became a German colony in 1885 first as a district as well as Burundi and later getting an autonomous civil administration upon the arrival of the Belgians in 1916. The Germans appointed in 1907 the Doctor R. Kandt -that already spent 6 years in the region seeking for the Nile sources, as administrator and giving him the task to identify a location for the new capital “Sirven (1984)”. The chosen area is placed about at the centre of the Country on the top of the Nyarugenge hill and surrounded by three mountains: Nyarurema, Jari and Kigali. At the beginning of 1908 R. Kandt realizes the very first building the *Boma* (fortress in Swahili), on the north-west side of the Nyarugenge plateau oriented to the valley of Nyabugogo the only practicable passage for the merchant caravans (Fig. 1).

Figure 1: Boma site layout and view from south side

The 9th of May 1916 the Colonel Molitor leading the Belgian troops occupied Kigali. The new administration placed its offices on the plateau of Nyarugenge close to the residential quartier *de facto* abandoning Boma. The military compound was moved in between the city for the Europeans and for the Indigenous that was extended to Nyamirambo. From 1916 up to the Second World War the urban spatial occupation was multiplied by four – 40 hectares that will become 200 in 1958. Three parallel roads are traced all along the Nyarugenge plateau from north to south guiding the construction of the administrative and dwelling edifices as well as in the lowest of the three hosting the commercial activities. The prison

built in 1930 is one of the few Belgian constructions still standing and visible in the modern Kigali. During the Belgian colonization Rwanda had eleven small cities: Butare, Gisenyi, Ruhengeri, Naybissindu, Cyanguu, Byumba, Kibundo, Rwamagana, Kibuye, Gikongoro. Normally built on the top of a hill they were expanded along the gentle sloped sides.

3.2 The post-colonial period

Kigali became officially the capital city of Rwanda the 1962 after the Independence, counting a population of 5.000 – the smallest Capital City on that époque and dislocated in two distinct areas, the plateau of Nyarugenge and Nyamirambo hill. The first Masterplan was set up in 1964 and in 1971 the city boundaries were extended to Kimihurura Hill within the creation of the very first industrial zone. In 1978, Kigali counted 90.000 people experiencing a regular growth that pushed the Government to adopt in 1982 the so called Schéma Directeur d'Architecture at d'Urbanisme (SDAU) that was set up under the vision of 20 years' urban development, and based on a prevision of reaching half a million inhabitants by 1995. Anyway, the tragic events occurred in 1994 determined a drastic and rapid fall in terms of the population, reduced at the end of the same year at around 50,000 inhabitants, a reduction that affected the entire nation. The Conceptual Master Plan of 2008 marks the definitive urban rebirth orienting the reconstruction along the direction of a polycentric shape.

4. THE POLICIES FRAMEWORK

4.1 Towards a green (tropical) architecture

In 2016, countries across the world adopted the *New Urban Agenda* (NUA) during the UN Conference on Housing and Sustainable Urban Development (Habitat III) in Quito, Ecuador “GGGI (2015a)”. Final text of the NUA has its emphasis “on promoting safe, inclusive, accessible, green and quality public spaces, mentioned in nine paragraphs through the lens of urban sustainability or as stand-alone commitments” “United Nations (2016)”. Rwanda also ratified the New Urban Agenda driving the architecture of Kigali and of the all country in a green framework organizing three National Urban Forums (NUF) in 2008, 2011 and 2019.

The building sector is one of the heaviest contributors to human-related greenhouse gas emissions but at the same time reveals a potential to lower its emissions. Urban areas are characterized by the concentration of built structures and infrastructures therefore, green building has become a major component of urban climate change strategies. Nonetheless, the governments' endeavour to reduce the carbon footprint of buildings and the related uses it's taking into account both the local context and the social dimensions of sustainability such as ideas of liveability and affordability. The process of growth in population density, socio-economic inequalities and infrastructure related problems are stressing the need for sustainable city planning to result in the efficient running of cities “Chrysoulakis, de Castro and Moors (2014)”.

Green building transitions means a long time and radical process supported from the new innovations in the construction sector and also from the adoption of dedicated policies. Objectives of smart growth, sustainable cities, sustainable urbanism and green cities are shaping urban agendas and commonly contribute to core objectives in cities around the world “Joss (2010)”. The motto of the recently approved *National Land Use Development Master Plan* is “Ensuring tomorrow's sustainability today!” that highlights the need of investing in green projects.

The Kigali Master Plan 2050 approved in 2020 provides a set of criteria to define and direct the transition: “Acknowledging the natural landscape of the city; protecting sensitive ecological areas from urban growth; restoring damaged natural elements like water bodies; adopting natural resource management system, green building initiatives; forest protection strategies; steep slope protection strategies and green and blue plan – hierarchy of parks, connectors etc.” “City of Kigali (2020a)”.

4.2 The 11th SDG

The World Green Building Council in 2018 declared that “progress towards sustainable buildings and construction is advancing, but improvements are still not keeping up with a growing buildings sector and rising demand for energy services” “World Green Building Council (2018)”. Unfortunately, the buildings sector remains the prime Greenhouse Gas (GHG) emitter as per Paris Climate Accord ratified in 2016. Hence, urban and building design, construction and operation – as observed by the Global Green Growth Institute in collaboration with the Republic of Rwanda, “have a significant effect on the chances of meeting the 2°C target and pursuing efforts to stay well below 1.5°C” “Republic of Rwanda (2019)”. The definition of green urbanism and green architecture is based on a precise design approach which focuses on increasing the efficiency of exploiting the resources but at the same time targeting a reduced urban and building impact on the human health and the environment during their life cycle.

Therefore, the definition of green embeds a variety of necessary actions: to promote energy & water efficiency; to benefit from the ambient climate; to reduce the use of air-conditioning; to implement the natural cross-ventilation; to maximise the use of local and sustainable construction materials; to provide superior indoor Environmental Quality (IEQ); to protect the natural environment and to promote biodiversity. Green Architecture is also relevant to several targets of the UN Sustainable Development Goals included in the Agenda 2030 for Sustainable Development that forms the Global Development Framework.

The concepts of sustainable development and sustainability are founded on the assumption of securing that there is an improvement in the life's quality, a substantial equity, a conservation of biodiversity as well as a promotion of human survival. In this respect, sustainable urbanization ensures that urbanites have a good standard of living through access to basic services and that there is equity in terms of allocation of services such that social justice is promoted.

4.3 The Rwandan adopted policies

The Government of Rwanda, through the Ministry of Infrastructure and the support of the Rwanda Housing Authority has elaborated and adopted a set of different policies designed to achieve the mentioned goals. The *National Green Growth and Climate Resilience Strategy for Climate Change and Low Carbon Development* adopted in 2011 and designed to support Rwanda's development into "a climate-resilient, low-carbon economy by 2050, the strategy suggests favouring the creation of high-density, walkable cities to avoid excessive sprawl and long commuting times" "GGGI (2019)" has been followed by the *National Urbanization Policy* (2015) that sets the framework for interactions between private and public sectors in the country's urbanisation process supporting as main objective the sustainable development. The *National Roadmap for Green Secondary City Development* (2015) that identifies building and construction as key pillars to achieve green urbanization in Rwanda. Then, the *National Housing Policy* adopted in 2015 based on a vision of enabling all income class people and their location to get adequate housing in sustainably planned and developed settlements. Moreover, it supports privates that want to invest in affordable housing thus, allowing a wide range of population to be appropriately dwelled at a reduced cost. The *Urbanization and Rural Settlement Sector Strategic Plan 2018-2024* is more focused on the achievement of good development management and spatial distribution of growth.

More recently Rwanda has adopted through a Ministerial Order a series of new regulations and policies set up in order to achieve a sustainable and green urbanisation. The *Urban Planning Code* determining the urban planning and building regulations, at the same time it provides a basis for forward planning, development management and plan implementation. The *Building Faults and Sanctions* that lists fines related to faults committed during construction of buildings and/or urban planning and the *Rwanda Green Building Minimum System* also approved in 2019. It is composed of green building indicators that address the basic green aspects the buildings should have: "appropriate orientation, day lighting, natural ventilation, rainwater harvesting, efficient plumbing fixtures, low-impact refrigerants, greenery protection and paints not harmful to the occupants" "GGGI (2015c)". Impressive is also the motto of the recently approved *National Land Use Development Master Plan* - "Ensuring tomorrow's sustainability today!", that highlights the green path paved toward sustainability. The overall objective of the mentioned policies and strategies is to support good urban development that can enhance both local and national economic growth ensuring a good quality of life for all citizens.

4.4 The green council building

"Rwanda guides urbanization and human settlement in a way to efficiently use and manage its natural resources while promoting sustainable development" "Ministry of Infrastructure (2015)". Conceived as a simple, effective and environmental performance-oriented regulation the *Rwanda Green Building Minimum Compliance System* collects a series of indicators that have been identified to foster in particular the energy & water efficiency, the environmental protection, a better IEQ for the inhabitants and green innovation "Republic of Rwanda (2019)". The approved System that is not yet targeting the residential buildings is composed –as said, by five main modules or focus areas. The first one is conceived to improve the energy efficiency with a special regard on the orientation given to the building, on the overall design, on the construction materials used and on the choice of equipment. Afterwards, the building has to optimize the water efficiency that is mostly based on appropriate devices to harvest the rainwater, on the installation of water efficient features and last but not least on the wastewater treatment plant that cuts down the use of potable water. The module named "environmental protection" is much more oriented to the reduction of the building impact to the environment through a contextualized design, the adoption of good practices and an accurate selection of materials to implement the project. Further, the IEQ enhances the fresh outdoor air provision and also the thermal and acoustic comfort. The last module – green innovation, targets the application of green practices and new technologies that are innovative and have potential environmental benefits.

5. THE POLICENTRIC STRUCTURE

5.1 An historical overview

The famous diagram of the *Three Magnets* coined in 1898 by Ebenezer Howard, was proposing a city-exit towards the promise of fresh air and nature, offering sufficient work and a new social life. Built on the idea of a polycentric Social City the Garden City of To-morrow was able to host 32,000 people, living in 1,000 acres of land and surrounded by a vast green belt. Once reached the limit of population another satellite would have been initiated a short distance away nonetheless, remaining all interconnected by a rapid transit system "Hall (2014)". Howard's idea of the satellite city was put into practice for the very first time by Barry Parker and Raymond Unwin in the design of Letchworth and Hampstead. A young German architect, Ernst May, in 1906 was working by Unwin at the translation of *Town Planning in practice*, Unwin's work on urban design theories.

5.2 East African references

The link between May and the development of the Satellite city in the East African Region is based on his decision to move from Europe before the clash of second world war buying a farm in Arusha, Tanzania. Afterwards, Ernst May worked for the Uganda Government in the definition of the Kampala Extension Scheme and in 1945 he signed a contract for the British colonial authorities in order to conceive "a plan for the rapidly growing post-war building market, the plan will stand out for its progressive idea to include large settlements for low and middle-income Africans, one of the first in East Africa to do so" "Gutschow (2009)". The German architect "started to design the plan with the observation that the existing city was a beautiful garden city" "Demessie (2012)". The founding architectural element is the so-called

Zielenbau or row house adapted to the tropical context: main axis facing east-west sides; use of local materials; employ of features to enhance the sun protection and the cross ventilation; a flourishing greenery surrounding the dwellings. In 1952 was offered by the oil company Shell the opportunity to design a settlement in Port Tudor, west of Mombasa in Kenya. Port Tudor was intended as a satellite for workers characterized by a large common green zone around which he located different housing typologies. Analysing these completed projects, the intention of May to introduce some architectural principles typical of the tropics is evident: orientation, wind and ventilation, shading, protection against heat transmission and large use of natural lighting. The climatic problem, connected with the composition of the constituent parts of the buildings, gave birth to an identity that must not forget that “simple life forms are the closest to perfection” “Dequeker and Kanene (1992)”. These features reveal also a sort of green approach or a sustainability before sustainability and around fifty years later in the same African Region the City of Kigali is building its urban future following the past traces. Therefore, the rediscovery of the Tropical Architecture seems to be the fundamental point to achieve the country Renaissance towards making cities inclusive, safe, resilient and sustainable.

6. KIGALI AS A PROJECT

6.1 The Kigali Master Plans

The paper aims to tackle the nature of the Kigali urban future. The starting assumption is to intend the city as an architecture that builds itself over time. In the book the Architecture of the city Aldo Rossi reminds that the city “is to be understood as architecture. By architecture, we do not only mean the visible image of the city and all its architectures. It’s more about architecture as construction. It wants to talk about the construction of the city over time” “Rossi (1982b)”. Therefore, the city built itself over time, a time that is becoming more and more sustainable in the sense of a continuous comparison with its history and its identity towards the future.

The Kigali Master Plan is a comprehensive long-term plan intended to guide growth and development of Kigali City “Republic of Rwanda (2013a)” and at the same time providing a road map for the future expansion. As previously mentioned the first Master Plan was developed by Surbana in 2008 revised in 2013. The Kigali City Masterplan from 2013 underlines the principles of sustainable development and its vision is to make Kigali the Centre of Urban Excellence in Africa. The master plan adopts a structure of a satellite city, with decentralized growth nodes and development meant to intensify along transit corridors mainly directed east and south, and with the Central Business District (CBD) being the centre point of the growth. The adopted satellite structure is meant to be extend to all country with a six secondary cities network revolving around the Rwandan capital (Fig. 7). Therefore, the country and Kigali have to be intended as parts of a unique plan designed to shape the built and unbuilt environment and also as the result of political intention. Architecture has to regain its fundamental role in shaping the city and paving the urban future. In fact, the project of Kigali as a green city begins from a peculiar model of city, the satellite model, composed by architectural projects, the green settlements (Fig. 2).

In 2020, the municipality approved the revision of the 2013 Masterplan. The new Kigali Master Plan 2050 is envisaged to integrate the old plans providing corrective measures to improve and adjust the Kigali urban development strategies to support the economic green growth positioning the country as the centre of excellence for innovative and inclusive urban planning in Africa. The plan aims to achieve eight main goals to direct the urban and economic growth as well as the land and urban management for the next decades.

Figure 2: The satellite development of the City of Kigali

6.2 Satellites and settlements

Kigali builds itself and its green future over time. The 21st century has seen the re-shaping of the capital city directing its development through a very peculiar project: the satellite city. The paper is focusing on the analysis of three settlements, Kigali 2020, Kigali Vision and Green City Kigali that represent the quintessential green urban examples of the Masterplan. All located in the north- east side of the Capital, Kigali 2020 and Kigali vision are part of the Gacuriro area instead, Green City Kigali is a project under realization on the Kinyinya Hill (Fig. 3). In the Satellites the single-cell is articulated in different dwelling types and jointly with the public facilities constitute an entire settlement, and the three *imudugudu*, in Kinyarwanda, shape the whole City design. They seek also to address issues related to urban sprawl, poor connectivity, singular urban functions, poor allocation of social infrastructure, lack of socioeconomic mix and poor connectivity of movement, infrastructure and ecological networks. These principles are designed to ensure that socioeconomic and environmental sustainability is protected and promoted as urban growth occurs through controlled expansion and upgrading/densification of existing and future areas. In addition, the promotion of a sustainable economy via local production, employment and consumption is a key area of development within the Planned City Extension (PCE) principles "UN-Habitat (2015)". All these aspects are strictly connected with the initial assumption of a green urban development.

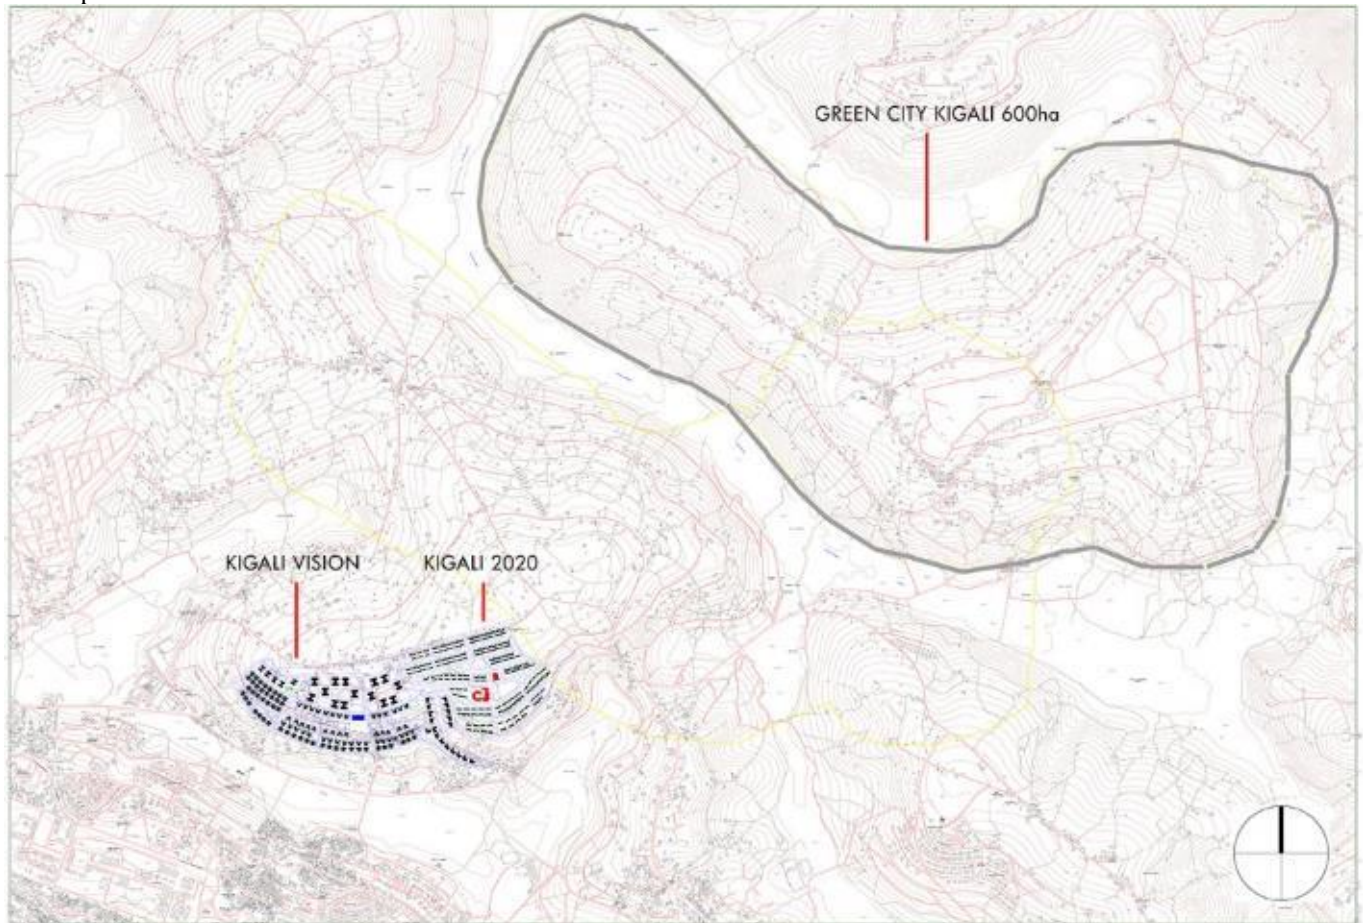

Figure 3: Kigali 2020 and Kigali Vision in Gacuriro satellite; Green City Kigali project in Kinyinya satellite

6.3 Kigali 2020

The Kigali 2020 represents the first compositional element of the satellite city. Located in the Gacuriro hill the settlement is characterized by the aggregation of 4 different semi-detached housing typologies placed along the contour lines in order to protect the existing context from invasive site works. The available public facilities – the church and the Schools, build the central green area that serves as community main space (Fig. 4). All the edifices are realised making use of locally produced materials thus augmenting the environmental protection such as granite stone for the foundations, fired bricks for masonry, tiled/pitched roof, timber ceiling and other details that guarantee high indoor environmental quality comfort. Moreover, the use of clay increases the thermal mass and at the same time decreases energy consumption. The main elevations of the units follow the north-south orientation while the east-west facades present few and small openings due to the more sun exposure during the day. The typical overhanging roof protects from the north side heat but unfortunately is not exploited to harvest rainwater thus reducing the water efficiency. Each unit is provided by a front and back yard, two traditional spaces that enhance the outdoor life and activities and residents should be able to enjoy the social and economic benefits of urbanization while minimizing ecological footprints.

Figure 4: Site layout of Kigali 2020 and exterior view of twin houses

6.4 Kigali Vision

The *umudugudu* (settlement) Kigali Vision completes the second phase of the Gacuriro Satellite. It is made by a variety of dwelling typologies: apartment blocks, townhouses and villas. The 544 units composing the settlement are located in different areas of the hill side with the highest building at the top and the lowest at the bottom between a narrow green strip that physically connects the east and west parts of the project. Unlike the Kigali 2020 project where the common facilities are located in the middle of the settlement are grouped around a main green cluster the ones in Kigali Vision are scattered all along the green common area (Fig. 5). The whole settlement is surrounded by a fence, giving it a protected compound nature and at the same time rejecting the connection with the future urban expansions. The main goal of Kigali Vision is to bid for the modern citizen a modern lifestyle in a safe, quiet and natural environment, but despite these premises its construction reveals some criticality in terms of green innovation. First of all, the design of the houses does not comply with the basic principles of the tropical architecture found in Kigali 2020. The rule of orienting the main facades facing north-south and the shortest east-west dwellings is not always respected as well as following the contour lines of the slope in order to achieve adequate environmental protection. The fact of not orienting the buildings correctly affects the indoor environmental quality with an increase in temperature that required an inevitable increased trend in energy consumption. As seen for Kigali 2020 also the Kigali Vision settlement doesn't adopt a harvesting system for rainwater with the roof not adequately sized to protect the elevations.

Figure 5: Site layout of Kigali Vision and exterior view of villas and apartment buildings

6.5 Kigali Vision

Green City Kigali (GCK) is a 600ha project of sustainable community intended to be occupy the Kinyinya Hill site (Fig. 4) and that will be realized as part of the Vision 2050. The aim of the Green Vision Kigali project is to combine social, economic and environmental targets with strong governance to create a liveable and resilient urban community – a shining example of the future sustainable urban community in the East Africa Region. Residents of the updated Kinyinya Hill should be able to enjoy the social and economic benefits of urbanization while minimizing ecological footprint for environmental protection and optimizing green innovation. It will be mostly composed by affordable housing, that is linked with climate change adaptation and mitigation measures setting standards for sustainable urban development in Rwanda. The new city will assist also in healthy urban growth, maintaining Kigali's low carbon footprint by using local materials and resources both for the indoor environmental quality and for the construction of energy efficient buildings. Another goal is to promote a sustained and inclusive economic growth cycle for an economic wellbeing supported by a non-vehicular internal and external connectivity.

7. RWANDA AS A PROJECT

7.1 Secondary cities structure

Rwanda is one of the most densely populated countries in Africa, with around 400 p/sq.km and “with a current annual growth rate of 2.4% the population in the Country may reach 25.8 Million in 2050, with gross density approaching 1000p/sq.km, one of the highest in Africa” “Republic of Rwanda (2020)”. The Six Secondary Cities Plan guides and orients the future urbanization according to a precise road map to reduce also the urban pressure on the capital city. First, the growth of Kigali will be limited to 3.8M in order to boost the decentralisation process focused on the secondary cities moving from the chronic issue of urban monocephalism. The majority of the population lives in the countryside and engage in agriculture and the Government of Rwanda has embraced urbanisation as a tool to further build the Country. Urbanisation process is supported by a stronger transportation system linking nodes and centres that is at same time also a prerequisite for the economic growth of Rwanda able also to unlock more financial and trade opportunities. The polycentric structure of Rwanda –as previously said, is articulated in six secondary cities (Fig. 6): Musanze (Northern Province), Huye and Muhanga (Southern Province), Rubavu and Rusizi (Western Province), Nyagatare (Eastern Province). Therefore, the government priority has become the development of cities as poles of growth and sites for pilot green projects based on experiences and case studies set in Kigali: “Behind the priority of supporting the development of chosen secondary cities is the idea that proactive development of secondary cities can mitigate the risks and construct a competitive national economy on the basis of sustainable city network, crucial for Green Growth of the Country” “Ministry of Infrastructure (2013)”.

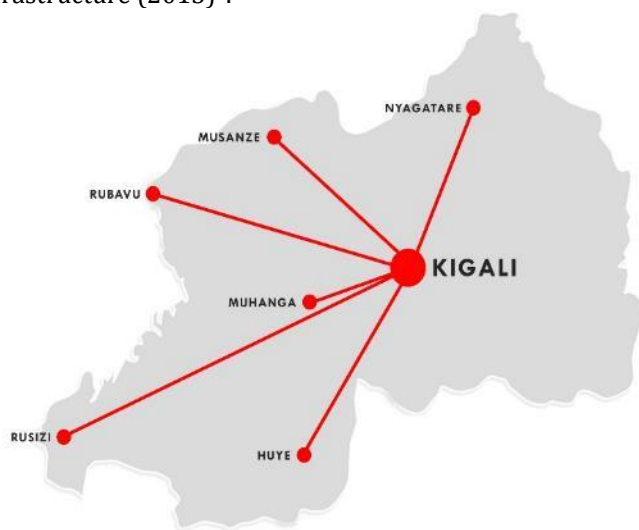

Figure 6: Kigali and the six secondary cities

In the Economic Development and Poverty Reduction Strategy II (EDPRS2) is mentioned the National Green Growth Strategy addressing the urbanization process as a key factor to “transform the economic geography of Rwanda by facilitating and managing urbanisation and promoting secondary cities as poles of economic growth” “Republic of Rwanda (2013b)”. The target was also to get for each of the city an Urban Master Plan and a Land Use Management able to appropriately resettle the population scattered in the rural areas concentrating it around the existing centres. The secondary cities have to be better served with infrastructure and services identified by a peculiar character.

Musanze is the major tourism hub in the country focused on the Gorilla attraction; Huye is the academic hub and the heart of cultural tourism due to the high concentration of historical sites; Muhanga is considered the centre of mining activity for Rwanda; Rubavu and Rusizi are the trade and lake tourism centres; Nyagatare continues to be the main reference for agriculture and processing.

7.2 Towards green Rwandan cities

So far, three out of six master plans have been presented and publicly displayed, the one of Huye, Musanze and Rusizi. Analysing the developed structure plans it’s possible to recognize the features that have inspired the green approach and how they have been applied. The structure plan of Huye (Fig. 8) in which the historical city centre is surrounded by green spaces intended as touristic sites. The administrative boundaries are delimited using areas for urban agriculture in the vision of a full sustainability but at same time limiting the expansion of the city. The plan of Musanze (Fig. 7), reveals the intent of shaping the development according to a renewed relationship with the natural context that to some extent control the urban growth. Buildings scale down from the centre moving to the peripheral areas. The case of Rusizi raises the issue of a green city placed and articulated along the Kivu lake shores. However, it is also identified by a wide green belt on the east side that has to preserve its sprawl (Fig. 8).

Figure 7: Proposed master plans for Huye, Musanze and Rusizi

8. CONCLUSIONS

The research depicted the state of art regarding the rapid rate of urbanization that the African continent is experiencing, a phenomenon that in the case of Rwanda has been tackled following a sustainable and green approach. The achievements envisaged by the 11th SDG and the other related goals focusing on technology, poverty and climate change are engaging the urban agenda and the new Masterplan of Kigali City and the six secondary cities are the foundations for a sustainable, inclusive, resilient, and safe urbanization. The country vision 2050 is built on the Green Growth and Climate Resilience Strategy and is mainly grounded on “a developed climate-resilient, low carbon economy, with a strong services sector, low unemployment and low levels of poverty” (Republic of Rwanda 2015). All these objectives reflect the orientation given to the urban and national development through the adoption of a precise structure: a polycentric regional plan composed by six secondary cities interconnected with the Capital City, Kigali. Kigali is shaped according to a satellite model that has been already applied in the Region and each satellite is made by green settlements. Starting from the assumption that the City builds itself over time it has been demonstrated that the green future began in the past and its proceeding through a series of architectural interventions: Kigali 2020, Kigali Vision and Green City Kigali. Even though Kigali 2020 reveals more sustainable features than Kigali Vision the two artefact represent the Government commitment to reach the targets of the Agenda 2030. New settlements have to focus on affordable housing and on how to integrate housing with climate change adaptation and mitigation measures. Paraphrasing the words of the Congolese writer Sony Labou Tansi, Kigali will never be New York, each city has its own soul, the genius loci that contextualizes the global green model to each specific environment. The green polycentric pattern has been stretched at national level providing a scheme composed by six secondary cities each of them developed though the adoption of single master plans. These master plans, as the ones for Kigali are based on the assumption of realizing a sustainable urban growth.

SPACE, LAND RENT AND INCOME DISTRIBUTION

Roberto Camagni

Politecnico di Milano, Italy

ABSTRACT

The paper addresses an evident bias in the theoretical scientific trajectory of regional science: a bias towards a functional-geographic dimension, addressing mainly the production and demographic side of the economy, as opposed to a hierarchical distributive dimension, addressing the power and income distribution side. This neglect has generated in recent times the inability to foresee and even perceive the phenomenon of growing «uncertainty» and «discontent» in wide parts of the society. The geography of physical assets should merge with a geography of control through networks of power élites and the selective and cumulative learning role of places. The use of GDP statistics at constant prices should be replaced by current prices, pointing out disparities in monopoly pricing and unbalanced terms-of-trade between the large cities and the rest of territory. Income distribution should be intended in three senses: personal, functional (wages, profits and rents) and «territorial». Early results on these fields are shown, pointing out the difficulties of a part of the middle class, threatened by the automation of their occupations, and the command role of large cities. Evidence are shown concerning the increasingly unbalanced situation of Italian cities (with a widespread effect on entire macroregions as the Mezzogiorno: again!) and of European cities.

OPENNESS AND REGIONAL GROWTH

[Laura Resmini](#)

Università di Milano-Bicocca, Italy

ABSTRACT

The openness-growth nexus is an issue that has intrigued many scholars from different disciplines, like international economics, economic geography, regional economics, international business, for a very long time, difficult to date. While theoretical implications are quite clear, the empirical evidence is mixed and scarce, especially at sub-national level. Indeed, openness is not observable at regional level; therefore, it is difficult to identify a comprehensive and reliable set of quantitative variables measuring the different dimensions of the phenomenon. Despite this objective difficulty, much has been done and today we have a more comprehensive view of the nature of the phenomenon, as well as its trends and territorial impacts. This paper summarizes the theoretical milestones, i.e. the principles universally accepted by the literature, and the most recent empirical trends at territorial level, with special emphasis on the contribution of Italian Regional Scientists.

**EVALUATION OF THE EFFECTIVENESS OF FIRM SUBSIDIES IN
LAGGING-BEHIND AREAS: THE ITALIAN JOB**

Augusto Cerqua, Guido Pellegrini

Department of Social Sciences and Economics, Sapienza University of Rome, Italy

ABSTRACT

Since the late 1990s, Italian scholars have produced numerous studies in the field of regional policy evaluation, especially ones that have investigated the impact of financial incentives aimed at supporting the accumulation of private capital in underdeveloped areas. The number and innovativeness of these studies make it possible to define the presence of an Italian school for evaluating regional policies. This paper testifies to the importance and methodological advances of this school, putting it at the frontier of policy evaluation analyses. The presentation of the studies moves in two directions, historical and methodological, identifying the main themes and techniques addressed in recent years: the evaluation of Law 488 and negotiated programming policies, on the one hand, the advance in policy evaluation techniques in the presence of interactions and continuous treatment, on the other. The paper does not claim to be an exhaustive review; rather, it should be considered an overview of the historical path and the future prospects of what we call «the Italian school of regional policy evaluation».

RESILIENCE AND CONVERGENCE: SHORT VS. LONG-RUN. REGIONAL EFFECTS OF ECONOMIC CRISES AND MACROECONOMIC POLICIES

Fabio Mazzola, Pietro Pizzuto

University of Palermo, Italy

ABSTRACT

Within-country disparities in advanced economies have increased substantially during the past decades. They have become a major concern for policymakers since, beyond the direct social welfare and equity consequences of this rising trend, there is growing evidence that regional disparities may have important implications for economic outcomes.

Before the outbreak of the Great Recession, considerable attention was devoted to what makes a region successful, and why some regions grow faster than others, but researchers often overlooked how regions react to shocks and why this happens in a heterogeneous way. Furthermore, the classic literature on regional inequalities has mainly focused on the long-term relationship between economic growth and regional disparities and on the role of labor mobility, sometimes also as a mechanism of adjustment to labor demand idiosyncratic shocks. This literature trend has reversed since 2008, when investigation of the heterogeneous impact of shocks across areas became prominent in regional studies through the analysis of regional resilience. Moreover, the discussion on the asymmetric effects of macroeconomic policies, which was not a major concern in recent decades, has suddenly reemerged.

This paper surveys the recent approaches adopted to study regional disparities as related not only to the process of economic growth but also to economic downturns. The investigation focuses initially on the relationship between national business cycles and idiosyncratic regional shocks and then moves on considering explicitly the role of macroeconomic policies and dynamics in affecting, through the impact on specific local assets, the process of (unequal) long-run regional growth as well as short-run resilience to economic shocks.

GEOSPATIAL TECHNOLOGIES FOR MONITORING THE SUSTAINABLE DEVELOPMENT GOALS

Jozsef Benedek¹, Kinga Ivan¹, Ibolya Török¹, Arnold Temerde², Iulian-Horia Holobacă¹

¹Research Centre for Sustainable Development, Babes-Bolyai University, Romania. ²AROBS Transilvania Software, Romania

ABSTRACT

In order to measure progress in achieving the Sustainable Development Goals by 2030, 169 targets have been approved globally. Even though interest in implementing these goals is high, many states have not yet established a set of subnational indicators to measure the implementation of the SDGs and have not completed their own assessment of progress in achieving these Global Goals. This study aims to measure the progress towards achieving the SDG at local and regional level in Romania by calculating the SDG Index. For the calculation of the SDG Index at subnational level we propose an integrated approach based on 90 indicators, stored and processed in a PostgreSQL object-relational database. This approach offers three novelties: the generation of a territorial database on local level, which includes both rural and urban areas; the large employment of earth observations methods in the measurement of the SDG indicators; and the development of a new data model for the measurement of the SDG index.

The results show the concentration of the highest performances of sustainable development in some specific geographical areas. The rural areas and the extended peripheral regions in the eastern and southern part of the country are the poorest performers.

We outline that the our model is an attempt to quantify the performance of each LAU (Local Administrative Units) on the SDGs, contributing in this way to calls for more progress in the operationalization of SDGs and in the evaluation of indicators' relevance. It will provide a policy-relevant assessment tool for the LAUs in establishing their position within each SDG, which in turn will help them to set up empirically sound and politically relevant Local Development Strategies. Moreover, understanding the differences in sustainable development across multiple scales and resources will enhance the ability of central authorities to balance sustainable development between national and various sub-national levels.

INEQUALITIES AND SUSTAINABLE DEVELOPMENT: TOWARDS THE IDENTIFICATION OF A NEW INTERPRETATIVE MODEL?

[Andrea Salustri](#)

Sapienza University of Rome, Italy

ABSTRACT

The ongoing COVID-19 Crisis is making manifest how the current development model driven by technological progress and market interactions may be structurally mis-specified with respect to the existence of societal needs that may trigger non-linear dynamics. Starting from these premises, this research deepens previous analyses framed within the broader international literature on the SSE, and on its interaction with private and public actors, particularly in the context of the implementation of the 2030 Agenda and of the activation of local development of marginalized groups in peripheral territories. However, contrary to a generalized tendency to prefer qualitative over quantitative approaches, qualitative issues are reframed within a quantitative framework of analysis. The research lacks empirical support as it is mostly the result of a theoretical investigation into the neglected structural fallacies of economic models (i.e., the omission of distance costs and the related lack of concerns for proximity, the adoption of the coeteris paribus assumption and lack of interest for the “unobservables”, and the absence of qualitative considerations). It is worth noting how the critique to the mainstream approach is functional to the identification of a more complex (and flexible) theoretical model. Results may lead to develop an epistemologically unbiased theoretical construct able to foster a more articulated interpretation of the SDGs and of their targets. A more in-depth analysis of the structural properties of the model may suggest new ways of tackling the COVID-19 crisis.

SUSTAINABLE MEASURES IN HOTELS ANALYSED FROM THE DEMAND SIDE

Éva Happ, Júlia Nagy-Keglovich

Széchenyi István University, Egyetem tér 1. Győr, Hungary, happ.eva@sze.hu, nagy-keglovich.julia@sze.hu

ABSTRACT

Tourism, and especially the hotel industry has a huge impact on the environment. While revenues and the number of jobs in tourism are significantly increasing yearly, the negative impact on the environment is growing as well. Hotels have become more conscious over the last two decades, due to the legal obligations. In the point of view of marketing, it is very useful to introduce the guests to technological processes which a hotel operates. However, developing an environmentally conscious approach is a long-term process that must also function as an element of organizational culture. We can say that all tourism businesses have activities and impacts which are harmful to the environment. There are number of papers which investigated how, with which methods and tools the hotel industry could reduce its environmental footprint. The purpose of this study is to investigate the “green” hotel experience from a guest perspective, from the demand side of tourism. The aim of the research is to find out how much the guests are eco-conscious and responsible, if they take into account the negative environmental impacts of their travel. The research examines the extent of the guest experiences’ decline while using different eco-conscious tools in hotels and whether guests are supporting green solutions at the expense of the decreasing of guest experiences. A survey was conducted among the guests of a four-star city hotel to find out the importance and disturbance of sustainable measures at a hotel. Based on the responses of the questionnaire, it is clear that guests are rather eco-conscious and they also consider what green activities and actions the hotel is pursuing. Based on the research the following conclusions can be drawn: hotels have a great responsibility for the “green” hotel issue. The guests will always be more eco-conscious at home than at the hotel, but this can be changed on purpose. The first mission is to make “green” the hotel’s long-term strategy, which requires the commitment to the environment from the particular manager/owner.

KEYWORDS

consumer profile, green hotel, responsibility, sustainability

1. INTRODUCTION

Tourism is the second fastest growing industry in the world economy. According to a February 2019 report by the World Travel and Tourism Council²⁵, the GDP contribution of the travel and tourism sector to the total world GDP increased by 3.9% in 2018, while the total GDP grew by 3.2%. Today, one in five new jobs in the world is generated in this sector, resulting in 319 million people currently working worldwide in this industry and an additional 100 million jobs will be created over the next 10 years. On one hand, tourism makes a large use of resources and, on the other hand, its emissions are released into the environment. According to a 2018 survey, the tourism sector is responsible for 8% of greenhouse gas emissions. Between 2009 and 2013, CO₂ emissions increased by 15% worldwide in tourism, showing much higher growth than expected (Lenzen et al. 2018).

These figures show that tourism, and within that the hotel industry, has a huge impact on the environment. The parallel is visible: while the number of revenues and jobs is growing significantly from year to year, the negative impact of tourism on the environment is also growing significantly. This is why hotels have a great responsibility, as sustainability is an important area for everyone. Hotels have become more and more environmentally aware in the last decades, which is partly due to the obligations of the law, but from a marketing point of view, it is also useful to introduce the technological processes the particular hotel use to the guests. However, developing an environmentally conscious approach is a long-term process that should also function as an element of organisational culture. Happ (2014: 92) writes about responsible tourism, which is an “emerging approach to how the market players of tourism can take their share of responsibility”. More and more people are starting to live eco-consciously and pay attention to their environment, which also affects their travels. Hotels should therefore place as much emphasis as possible on the use of green activities.

According to the American Green Hotels Association, the concept of a green hotel is the following: green hotels are environmentally friendly facilities whose management is committed to programs that reduce water and energy use as well as the quantity of solid waste to protect the Earth while they also save money. (www.greenhotels.com)

The Association of Hungarian Hotels and Restaurants (MSZÉSZ) also pays special attention to changing Hungarian hotels “green.” The work on this issue has been ongoing since 1993, and since 1994 hotels have been able to apply for a “Green Hotel” tender as well. It includes the following aspects: disclosure of information, energy, water, wastewater, waste management, ozone layer protection, green procurement and green office (www.hah.hu).

²⁵ World Travel and Tourism Council, wtcc.org.

The aim of the study is to examine the extent to which guests in hotels tolerate the use of various "green", environmentally conscious devices and the extent to which the guest experience is harmed during the use of these eco-friendly solutions. The research also examines whether guests are supportive when the the guest experience is damaged due to the processes to achieve sustainable development goals. The sample is not representative, but in the light of the results we can get a comprehensive knowledge of what the attitudes of guests are towards the use of green hotel facilities.

2. ENVIRONMENTALLY CONSCIOUS BEHAVIOURS BASED ON THE RESULTS OF FOREIGN RESEARCH

Consumer behaviour is also a key indicator of the quality and efficiency of work done in any industry, including tourism. Therefore, it is important for a given hotel to get to know the environmentally conscious behavioural attitudes of its guests as much as possible.

Individuals, including hotel guests, are becoming increasingly aware of the environmental impacts of hotel activities. An environmentally conscious consumer will exhibit environmental behaviour sooner than a guest whose motivational medium does not include eco-consciousness.

The 4 levels of environmentally friendly attitude are the following (Laroche et al. 2001):

- Who merely perceives environmental problems and gets stuck at the level of concepts such as declining drinking water supplies, limited energy, and shrinking forests.
- Those who feel uncomfortable due to the perceived problems are already able to perform basic green activities.
- Anyone who cares about environmentally friendly behaviour, recognises that green activities can reduce pollution.
- The last dimension is the level of corporate responsibility. Anyone who gets this far is confronted with the fact that companies are the ones who are really involved in the environmental impact.

Environmental awareness is usually associated with a positive attitude, which promotes environmentally friendly activities. This is based on cognitive consistency (Festinger 1957), according to which if an individual is involved in ecological issues, he or she will most likely be motivated to address and solve them as well. An environmentally friendly attitude and commitment to environmental protection help an individual to buy a green product or use a green service, which implies that they also seek the services of green hotels (Baker et al. 2014). According to the research of Lee et al., although an individual may be environmentally conscious, but if there is no immediate benefit from their purchase, the environmentally friendly attitude will not always prevail (Lee et al. 2010). Further research has demonstrated that an individual with an environmentally friendly attitude is willing to pay more for a green product or service (Han et al. 2009). According to social identity theory (Tajfel 1978), there is a positive correlation between the level of environmental awareness and how much an individual is willing to pay.

It is also a challenge for hotels to better understand guests' attitudes towards green consumption. While hotels are forced to take part in green activities under legal and social pressures, guests do not always accept this. There are three barriers to adoption:

- if the guest's sense of comfort is compromised, they immediately become dismissive of green initiatives.
- the guest is reluctant to give up their "right to luxury"
- if the cost reduction is to the detriment of the guest (Tzschentke et al. 2008)

Tzschentke-Kirk-Lynch's findings are supported by Tsai-Tsai's 2008 research, which concludes that there is a less positive correlation between environmental ethics and environmentally friendly consumer behaviour due to hotels' emphasis on promoting their luxury services (Tsai-Tsai 2008).

Further research has focused on whether there is a difference between environmentally conscious behaviour in hotels and at home. Dolnicar and Leisch sought an answer to this in their 2008 study. 92% of the respondents stated that they were environmentally conscious at home, while only 25% behaved in an environmentally friendly way during their stay at the hotel.

Thanks to TripAdvisor's GreenLeaders Program²⁶, the correlation between the green activity of hotels and consumer behaviour were analysed based on 572 guest comments. The key findings are: eco-conscious nations behave in an environmentally conscious manner during their travels and this is reflected in their comments as well; environmentally conscious cities receive more guest reviews on this topic; and there is a deep gap between the green activity of hotels and guest information (Londono-Hernandez-Maskivker 2016).

Research from the University of Arkansas (Ogbeide 2012) sought answers to the following questions: the importance of the green hotel concept for guests; what guests would do to support the green hotel; what are the green practices that guests are still willing to endure. The result showed that, in theory, most respondents rather group the measures to the 'more important' category, but would not be willing to pay more for them. Half of the respondents would even expect to be rewarded with loyalty points (Ogbeide 2012).

In a 2014 research, Baker-Davis-Weaver looked for the answer, which group of people with different environmentally conscious attitudes are the ones who prefer to stay in a green hotel and are willing to pay more for green services; what are the barriers, such as the desire for comfort and luxury, and how much they influence guests in their decision making; and whether guests behave as environmentally conscious in hotels as at home. The most important results of the research are:

²⁶ <https://www.tripadvisor.com/hc/en-us/articles/200614147-What-is-the-TripAdvisor-GreenLeaders-Program>

- those who care about eco-friendly behaviour prefer to stay in a green hotel
- who is only at the level of perception in environmental awareness, prefers not to choose a green hotel
- who is only at the level of perception will not pay more for a green hotel
- comfort expectations negatively affect greater willingness to spend
- luxury expectations negatively affect the choice of a green hotel
- green cost-cutting measures have a significant impact on willingness to pay
- cost-cutting measures have a significant impact on green hotel choices
- individuals theoretically expect green activity from the hotel, but do not take it into account during the decision making process
- individuals are much more environmentally conscious in their homes than in hotels (Baker et al. 2014).

In 2015, Kubickova-Parsa-Nusair-Hu conducted a survey among Generation Y, which found that the millennial age group pays attention to green activities and is willing to pay more for the services of an environmentally friendly hotel (Kubickova et al. 2015).

Also in 2015, Deraman-Kassim-Ismail-Arifin-Zaini conducted a survey in Malaysia on how committed guests are to green activities. Results showed that there is a positive relationship between environmental awareness and acceptance of and participation in green activities, but hotels have a very high responsibility for education as well, which still lags behind (Deraman et al. 2015).

It is also clear from the short summary table of foreign research presented by the authors (*Table 1*) that geographical differences are less significant, rather the individual consumer behaviour of people is decisive in adopting green activities.

Table 1: Summary of the results of foreign research

<i>Researchers</i>	<i>Year of research</i>	<i>Topic of research</i>	<i>Short summary</i>
Tzschentke-Kirk-Lynch	2008	acceptance of green activities among guests	3 barriers of acceptance: loss of comfort, violation of the right to luxury, extra costs
Tsai-Tsai	2008	acceptance of green activities among guests	luxury and environmental awareness are mutually exclusive
Dolnicar-Leisch	2008	differences in home and hotel behavior	people behave in a more environmentally conscious way at home than in hotels
Ogbeide	2012	acceptance of green activities among guests	guests prefer green activity until they have to pay more for them
Baker-Davies-Weaver	2014	acceptance of green activities among guests	confirmation of the above 4 research
Londono-Hernandez-Maskivker	2016	relationship between green activities and consumer behaviour	environmentally conscious nations behave in an environmentally conscious manner in their travels
Kubickova-Parsa-Nusair-Hu	2015	consumer behaviour of generation Y	environmentally conscious and willing to pay more for it
Deraman-Kassim-Ismail-Arifin-Zaini	2015	acceptance of green activities among guests	positive correlation between environmental awareness and acceptance of green hotel activities, but the role of the hotel in education is huge

Source: Own editing.

After studying the above research, the authors have come to the conclusion that they should conduct an own research that does not focus on generally accepted green activities, but rather on those which may be detrimental to the customer experience.

3. RESEARCH METHODOLOGY

The aim of the research was to examine guests' environmentally consciousness through the "green" services of hotels. The research questions are the following:

- How "environmentally conscious" hotel guests are?
- What is the consumer profile in terms of environmental awareness?
- What "green" measures do guests consider important in a hotel, and how much these measures bother them.

In order to examine environmentally conscious behaviour, the questionnaire was compiled by the authors by excluding the types of green programs that guests do not notice and green services that do not affect the experience in either direction. Some of the studied areas (green plants, electric charging station, information disclosure) were surveyed using an importance scale. With other hotel activities (local products, digital devices, water consumption, selective waste collection, energy saving), the authors surveyed how disturbing these were for guests and how willing they would be to comply with the measures. Respondents could choose answers from values 1-6 for the questions. The guest profile based on environmental awareness was created using the Osgood scale. Consistent with previous research findings presented

in the previous chapter, the authors focused in their own research the plethora of green activities, which may reduce guests' comfort.

An additional aspect during the compilation of the questionnaire was the easy and quick completion. During the survey between September 2019 and January 2020, 204 evaluable questionnaires were created.

The sample elements were not selected in a random sampling procedure, so the sample is not representative. Thus, the results of the research can only be formulated for the respondents and it is not possible to generalise on the basis of the answers received. However, the results obtained can form the basis of further studies.

Table 2: Distribution of respondents included in the study based on demographic variables

Background variable	Number	%
Gender		
Male	43	21,1%
Female	161	78,9%
Age		
18-34	64	31,4%
35-55	114	55,9%
56-	26	12,7%
Total	204	100%

Source: own editing based on research questionnaire.

In the sample, women are clearly overrepresented, and members of the 35-55 age group account for more than 50% of respondents (Table 2).

4. RESULTS OF THE RESEARCH

The aim was to create a guest profile in order to create two separate groups in terms of environmental awareness (the cluster analysis did not have appropriate results because the two groups cannot be significantly separated). The two groups were created based on responses to the semantic differential scale, which included attitudes about environmentally conscious measures. These are pairs of contrasts shown in Figure 1.

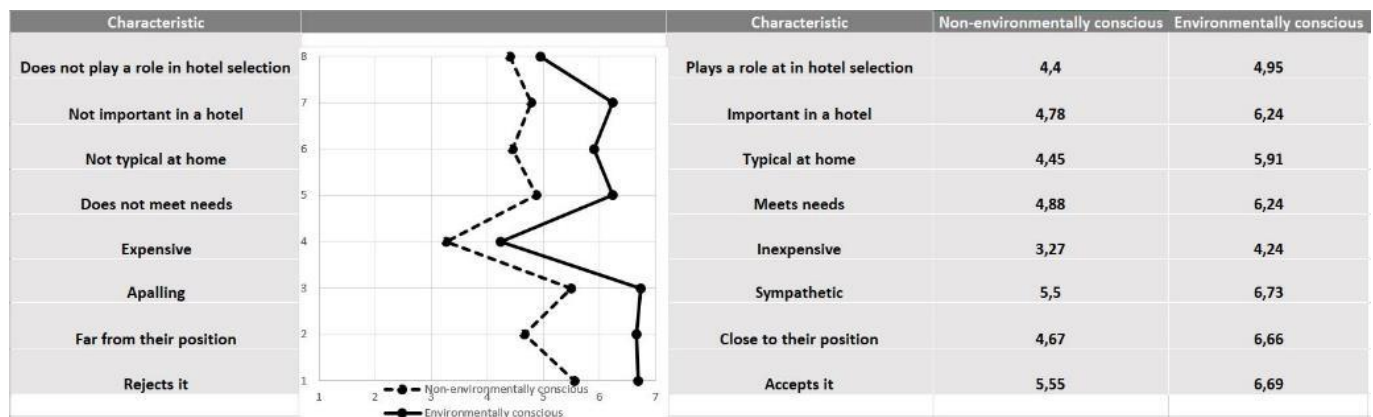

Figure 1: Consumer profile on environmental awareness

Source: own editing based on research questionnaire.

Consumer profiles created on the basis of the Osgood scale (Figure 1) show well-distinguishable characteristics based on environmental awareness. When applying the Osgood scale, the respondent should determine the extent to which the indicated pairs of opposites characterise the attitude object (Forgács 2017). There is a strong positive correlation between the values of the scale, so the movement of the answers to the questions allowed us to use it as a group-forming variable treated as a factor.

The “non-environmentally conscious” part of the arbitrarily created groups consisted of those who indicated lower values for scalar questions (1-5), while members of the “environmentally conscious” group were closer to green measures (value 6-7).

Table 3: Distribution of groups divided on the basis of environmental awareness

Variable	Capita	%
Non-environmentally conscious	60	29,4%
Environmentally conscious	144	70,6%

Source: own editing based on research questionnaire.

Table 3 shows that the majority of the sample agrees with environmentally conscious measures and for more than 70% of them, this behaviour also plays a decisive role in their home and accommodation choice.

Examining the two groups further, we also looked at the willingness to adhere to each environmentally conscious activity. The difference between the members of the two groups in terms of their willingness to give up certain comfort aspects during their trip in the spirit of environmental awareness was measured on the basis of responses to several compelling scales. This comparison was performed by discriminant analysis.

Table 4: Distribution of mean values for the two groups

<i>Variable / Determination</i>	<i>Non-environmentally conscious</i>	<i>Environmentally conscious</i>
Selective waste collection in the room	4,83	5,61
Multiple use of towels for multiple nights	4,83	5,54
Minimal use of air conditioning in heat	3,30	4,11
Use only the necessary lighting	4,62	5,29
Shower for minimum duration	3,67	4,56
Eating with minimal leftovers	4,92	5,59

Source: own editing based on research questionnaire.

The results show that members of the environmentally conscious group show a greater willingness to minimise the environmental impact during their stay at the hotel (Table 4). However, the use of air conditioning and the reduction of shower time are extremely low for both groups (the standard deviations do not provide more relevant information). Because the variables are not evenly distributed, we performed the Mann-Whitney test as a nonparametric test as well (Table 5), which shows that there is a significant difference between the two groups for each question.

Table 5: Significance test result

	<i>Willing [Selective waste collection in the room]</i>	<i>Willing [Multiple use of towels for multiple nights]</i>	<i>Willing [Minimal use of air conditioning in heat]</i>	<i>Willing [Use only the necessary lighting]</i>	<i>Willing [Shower for minimum duration]</i>	<i>Willing [Eat with minimal leftovers (eg. eat less for more turns at buffet)]</i>
Mann-Whitney U	3169,500	3245,500	3089,000	3192,000	2942,000	3438,500
Wilcoxon W	4999,500	5075,500	4919,000	5022,000	4772,000	5268,500
Z	-4,032	-3,608	-3,260	-3,304	-3,683	-3,089
Asymp. Sig. (2-tailed)	,000	,000	,001	,001	,000	,002

Note: a. Grouping Variable: Environmental awareness.
Source: own editing based on research questionnaire.

No significant differences can be detected in the gender distribution of the individuals in the sample, so it can be said that the gender variable has no effect on environmental awareness.

In contrast, age proved to be a much more determining factor for eco-consciousness during a hotel stay. The data in the cross-tabulation (Table 6) show that 76.9% of the over-56 age group were in the non-environmentally conscious group, while this value decreases consistently with age.

Table 6: Cross-tabulation of the age distribution of environmental awareness

<i>Age</i>	<i>Non-environmentally conscious</i>	<i>Environmentally conscious</i>
18-34	48,8%	51,6%
35-55	58,8%	41,2%
56-	76,9%	23,1%

Source: own editing based on research questionnaire.

In order to find the reason for such a high proportion of the over-56 age group in the non-environmentally conscious group, we asked the respondents about the various eco-friendly measures they find disturbing during their stay at a hotel. The answers to the questions were examined one by one. As a result of the Kruskal Wallis test, we found a significant correlation for 3 aspects in the distribution of age groups (Table 7).

Table 7: Significance test based on age group

	<i>Selective waste collection</i>	<i>Tap water instead of mineral water</i>	<i>Domestic products</i>	<i>Water saving toilet tank</i>	<i>No printed guest information material</i>	<i>Only electronic invoice</i>	<i>Online registration form</i>	<i>More expensive non-genetically modified food</i>	<i>Hand towels and toilet paper made of recycled paper</i>
Chi-Square	,887	12,869	4,598	2,373	11,291	9,415	10,645	2,608	5,436
df	2	2	2	2	2	2	2	2	2
Asymp. Sig.	,642	,022	,100	,305	,004	,009	,005	,271	,066

Note: a. Kruskal Wallis Test, b. Grouping Variable: Age.
Source: own editing based on research questionnaire.

As a result, the following environmentally conscious measures would be most disturbing for the over-56 age group:

- If there were no printed guest information material in the rooms
- If they would only received their invoice electronically
- If they had to fill out an online registration form before arrival

Based on the obtained results, we believe that it is not environmental awareness that plays a great role in the breakdown of age groups, but rather the fear of digitisation. The responses show that there is no significant difference in the alignment with environmentally conscious measures as long as they do not constitute e-administration outside the comfort zone of the respondents, and the perceived risk associated with it remains low.

It is also important to point out that regardless of age and the level of environmental awareness (i.e. for the whole sample), guests would be most disturbed by the group of eco-measures that come at an additional cost.

5. CONCLUSION

In our study, we focused on examining the attitudes of hotel guests towards the issue of green hotels. The results of foreign examples show a broadly uniform picture of consumer behaviour. The authors' questionnaire survey was a much shorter, more detail-focused research. Nevertheless, it can be concluded from the questionnaire as a whole that the environmental awareness of individuals also improved during the time between different research. The study also provides practical advice to hoteliers on how to pursue green activities. In the 21st century, this is almost a mandatory element for hotels, so the task should focus on which is the most effective way to implement the green solutions into the life of a hotel with the least harm to guests' sense of comfort.

Based on the research results, we believe that the responsibility of hotels has a huge impact on the green hotel issue. The guest will always be more environmentally conscious at home than in the hotel, but this can be changed consciously. With this in mind, the hotel is responsible for:

- searching for and finding guests who also follow environmentally conscious behaviour at the hotel
- informing guests about the hotel's green activities
- educating guests in an understandable and clear way on how to be more environmentally conscious
- communicating the sense of the term green hotel to prospective guests in a way that positively facilitates the booking decision
- phrasing green hotel activities in plain language
- using the term green hotel as a marketing tool only if there is specificity behind it
- introducing as many green activities as possible
- strategic thinking when introducing green activities

An eco-friendly attitude should be reflected in the strategy of the particular hotel, as these green activities involve increased costs on the part of the hotel.

COVID-19 AND GUESTS' PREFERENCES IN SHORT-TERM RENTALS: EVIDENCE FROM MADRID

[Alberto Hidalgo](#)¹, [Massimo Riccaboni](#)¹, [Armando Rungi](#)¹, [Francisco J. Velázquez](#)²

¹IMT School for Advanced Studies Lucca, Italy. ²Complutense University of Madrid, Spain

ABSTRACT

This paper aims to test whether and how guests' preferences shifted towards social distancing attributes when they chose short-term rentals (Airbnb) in the first COVID-19 summer season. For our purpose, we make use of a semi-parametric hedonic modeling framework to check whether the implicit prices of what we identify as social distancing attributes changed between August 2019 and August 2020 in the city of Madrid. Our main variables of interest are accommodation size, the presence of a fully equipped kitchen, and room type (shared/private room vs entire apartment) as proxies of the capacity of the listing to allow social distancing. As for size, we expect that a reduction in the size of travel groups may lead to a shift in guests' preferences towards smaller listings. Besides, the availability of kitchen amenities may help to make for a more pleasant stay without the risk of eating out.

We find that guests preferred smaller, well-equipped listings to preserve social distancing during this time. Listings that have kitchen amenities had a premium price of around 20.4% in August 2020, up 15.2 percentage points compared with August 2019. Moreover, the implicit price for size-related variables decreased 2.7 percentage points, which indicates a preference for smaller accommodations. However, we do not have statistical evidence that guests are less willing to pay for shared and private rooms after COVID-19. Ultimately, we consider that Madrid is a suitable setting to study the effect of COVID-19 on the change of guests' preferences, since it is a major tourist destination that has been severely affected by the COVID-19 outbreak.

To answer our research question, we adopt a Generalized Additive Model (GAM) that allows controlling for non-linearities in both price determinants and spatial dependence of the error term. GAMs are suitable for detecting the non-linear relationship between prices and the urban environment, as the latter strongly influences accommodation prices. Our results are robust under different model specifications, including simple OLS. Additionally, we rule out the possibility that results depend on time and geography by performing several robustness checks. First, we reproduce our analysis on a different time frame, comparing August 2019 and August 2018, and we do not find any specific change in how social distancing attributes had been priced. Then, we show that results are similar if we choose a different case study by replicating the analysis for Barcelona, a city that, like Madrid, is of touristic interest and was an epicenter of the outbreak. To the best of our knowledge, this is the first contribution that provides evidence of a shift in guests' tastes for attributes that help preserve social distancing in the aftermath of the COVID-19 crisis. We argue that our findings are relevant well beyond the evolution of the ongoing pandemic, since we may reasonably expect long-lasting effects after a reorganization of travel patterns to better cope with future pandemics.

THE EFFECTS OF SECTORAL SHUTDOWN ON THE WESTERN MEDITERRANEAN REGION ECONOMY OF TURKEY

Selim Çağatay¹, Zafer Barış Gül¹, Mehmet Kula², M. Şükrü Erdem¹, Şebnem Arık²

¹Akdeniz University, Turkey. ²-, Turkey

ABSTRACT

Antalya, a province in the Western Mediterranean Region (TR61) in Turkey, has great importance in Turkey's tourism and agriculture industries in terms of production value and creating income. The output value of the tourism industry in the region approaches 40% of Turkey's tourism. Fisheries and agriculture are the other prominent industries in the regional economy, with shares of approximately 11% and 8% respectively in the regional GDP. In addition, the tourism industry triggers the demand in many service industries including accommodation and catering services, travel agencies, creative arts, performing arts and entertainment services, sports services and entertainment and leisure services, and air transport. Thus, it can be said that the importance of the tourism industry increases even more when its direct and indirect effects on income and employment are considered.

The negative effects of the Covid-19 pandemic started to be felt as of March 2020 and continued to intensify. The measures taken against the pandemic have been implemented as partial and/or complete shutdown, especially in the service industries. The shutdown indicates the emergence of a simultaneous contraction in both supply and demand sides in the economy.

From this perspective, this study focuses on the effects of the Covid-19 pandemic on TR61's economy and the reflection of the regional economic contraction on the Turkish economy.

The 2017 TR61 Regional 74-industry Input-Output matrix is used in the analyses. Demand-side scenarios are run to see the impacts of contraction in final demand components and the hypothetical extraction method is used to see impacts of the shutdown. The latter allowed observing the relative importance of each industry.

The contribution of the study is twofold. Firstly, the "real" value of the industries in the regional economy in terms of the total impact on other industries is derived by using the hypothetical extraction method. Secondly, the overall economic damage in the region and in the rest of Turkey that occurs through the tourism industry is revealed. Various multipliers and linkage coefficients derived from the I-O matrix are also used to further interpret the effects of the pandemic.

According to the findings, with a complete shutdown of the tourism sector, the production loss in the whole economy is 31.47%. The fisheries industry ranked first with a contraction of 48.81% among the others negatively affected by the tourism's shutdown. The fishing industry is followed by transportation and logistics with 22.26%, manufacturing of rubber and plastic products with 21.92%, and trade with 21.31%. The average contraction experienced in the industries corresponds to 16.37% with the complete shutdown of the tourism industry.

**DETERMINANTS OF ATTENDEES' EXPENDITURE: AN ANALYSIS FROM
A LOCAL ECONOMY POINT OF VIEW**

António Almeida, Luiz Machado

Faculty of Social Sciences-University of Madeira, Portugal

ABSTRACT

This study aims at investigating the determinants of expenditure participating in a number of well-known events staged in Madeira. In order to identify the most important variables we run a number traditional of econometric approaches, based on a database containing information on 3200 attendants to a portfolio of events. The results suggest that the benefits accruing to the local community will be enhanced by promoting in a synergistic way a number of initiatives and resources aiming at a specific market niches, namely the senior market. The events under analysis share to a certain extent a number of commonalities and similarities such as being rooted in the cultural traditions of the island and a similar average background in terms of visitors' profile. Events are expected to contribute to urban regeneration, commercial development, generation of income and creation of employment. Therefore, besides taking a prominent role in the overall tourism development strategy, events must also take a noticeable place the overall economic development strategy. Therefore, in this study we discuss in a tentatively manner a number of steps aiming at linking the tourism development strategy with initiatives aiming at developing the local economy.

Regular Session: RS18.1 - Resilience and Risk Management

BIG REMOTELY SENSED DATA APPLICATION FOR FIRE SEVERITY AND POST-FIRE MONITORING

Hicham MHARZI ALAOUI¹, Assali Fouad¹, Said Lahssini², Said Moukrim³, Hicham Hajji⁴

¹Climatic and Forest Risk Management Center, Morocco. ²National Forestry School of Engineers, Morocco. ³Mohammed V University, Morocco. ⁴IAV, Morocco

ABSTRACT

The importance of wildfires as a natural or a human-induced phenomenon has gained importance at regional and global levels in the last years. Improved remote sensing and computational capabilities enable the fast processing of large image datasets in real time. resulting in an increased need to evaluate fire impacts at a landscape scale, burn severity has become an important indicator of fire impact on the ecosystem. The main aim of this study is to propose a model to assess burn severity and post-fire recovery in the north of morocco. A sample of 50 fires that occurred in the morocco from 1997 until 2016 was selected, and then fire severity for each sample fire has been estimated using the pre- and post-fire landsat imagery on the Google Earth Engine (GEE) platform to estimate the degree of fire-induced ecological change. The rate of post fire regeneration has been estimated using the Normalized Regeneration Index (NRI).

RISK ASSESSMENT OF GULLY EROSION BY MULTICRITERIA ANALYSIS (RHÉRAYA WATERSHED - WESTERN HIGH ATLAS)

Farid El Wahidi, Aïcha Fadil

UCA, Morocco

ABSTRACT

The Moroccan territory is 93% dry and where land degradation is fundamentally an environmental risk. It happens particularly in the mountainous regions of the High Atlas which are on the fringes of development and economic growth. This could take on disproportionate magnitudes under the combined effect of natural and anthropogenic drivers; the consequences are often exacerbated by inadequate management and exploitation systems of available natural resources. Gully erosion is the most active and harmful to the soil and the population's assets in mountainous areas (e.g., Rhéraya watershed in Western High Atlas). Preventing this degradation dynamic and correcting its symptoms would help mitigate the vulnerability of the local population and strengthen the resilience of socio-ecological systems. Reducing the risk of soil gullying requires the use of decision support tools to make a complete diagnosis and identify priority action areas according to their severity level. The present study aims to systematically classify on an ordinal scale the risk of gullying in the Rhéraya watershed. Risk is estimated as a combination of hazard and vulnerability. These two components have been estimated using aggregative indicators using multi-criteria analysis (MCA) of various biophysical (precipitation, land cover, lithofacies, slopes, aspect) and social factors (human issues, infrastructure issues, economic issues) related to land degradation risk. The approach is inspired from the SCALES model (Spatialisation d'échelle fine de l'ALéa Erosion des Sols/large-scale assessment and mapping model of soil erosion hazard), the multi-criteria analysis AHP (Analytic Hierarchy Process) and spatial modeling techniques (GIS). The main results lead to a systematic classification of the territory with a focus on ravines as regards of the risk that they constitute for the environment and the local population assets. The developed model could be used as a spatially explicit information system and as a catalogue (Atlas) of dangerous ravines for sizing torrential correction thresholds and identifying their localization. It also serves as a tool to build defense and soil restoration strategies to protect the environmental goods and services and enhance the resilience of hydro-ecological system.

MANAGEMENT OF RISK IN TOURISM**Zakaria Adidi**

Fsjes Souissi, Morocco

ABSTRACT

The tourism industry in Morocco is a fairly important economic sector; good year bad year he represents 8% to 10% of the country's GDP. The Moroccan state has always relied on tourism as a lever development producer of wealth and creators of jobs. In terms of tourism, Morocco has remarkable assets: its climate, its specific culture, its imperial cities and its geographic position. We should also underline the strong dependence of Moroccan tourism on five major European countries. Certainly, there seems to be some mitigation of the political risk associated with the Moroccan destination for French, English and Spanish tourists; tourists from Germany and Italy remain sensitive to this phenomenon. However, the Moroccan tourism sector remains highly vulnerable and dependent on demand foreign, mainly European. It is a sector at risk par excellence, because its evolution depends of the economic, political, security, climatic and health situation both at the national level internationally. The Effects of the Two Golf Wars, the "Arab Spring" and the Terrorist Attacks perpetrated in Europe or in the Maghreb countries are widely felt by Moroccan tourism. Added to this are the effects of climate change, which is hitting the territory hard. National; floods, floods, landslides, collapse of old buildings, more and more recurrent drought, without forgetting the seismic risks to which are exposed many regions of the country are all factors that can disrupt at any time, even deconstruct tourism which constitutes the main economic base of many Moroccan cities. However, the various economic development plans that Morocco had known since its Independence, as well as tourism sector strategies (Plan Azur for example) have not attached great importance to the tourist hazard which can occur at any time. Hence the need to adopt a new approach based on knowledge, forecasting, anticipating and managing tourism risk. It's Tourism Risk Management (or management of tourist risk). At a time of advanced regionalization, the Regions, each in relation to its natural and cultural specificities, its strengths and its structural weaknesses and through documents of territorial planning such as SRAT and PDR, but also tourism companies present in the territory are obliged to anticipate and prevent all kinds of risk: natural, technological, economic and financial, socio-political and security. Research objective: The objective of the thesis is to understand the management processes of the management planning of risks in a vulnerable economic sector such as tourism, their identification, their analysis, the planning responses to risks, as well as monitoring and controlling them as part of a territorial and regional development project. PROBLEM: The strong dependence of Moroccan tourism on the international market has made it a vulnerable sector subject to economic, financial, political, security and now economic fluctuations climate. The central problem that will guide this research will consist in answering the following question: What approach and what device to put in place in a tourist region in order to know, anticipate and manage risks?

**THE ROLE OF THE COHESION POLICY FOR SUSTAINING THE
RESILIENCE OF EUROPEAN REGIONAL LABOUR MARKETS DURING
DIFFERENT CRISES**

Paolo Di Caro¹, Ugo Fratesi²

¹Department of Law-University of Catania, Italy. ²Politecnico di Milano, Italy

ABSTRACT

For this paper we assembled a novel panel-time series dataset to study the resilience of the European regional labour markets during the major economic shocks registered over the past three decades. Our analysis suggests that employment resistance varies across regions and economic crises. We also study the role of European cohesion policy for sustaining employment resilience during shocks in the European regions at Nuts2 level, by applying a heterogeneous coefficient modelling framework to new time series data on the EU funds. We find the presence of region- and crisis-specific patterns when looking at the impact of the cohesion policy in the short-run, even if there is a prevalence of cases with a positive impact of cohesion policy in crisis resistance. We finally discuss the policy implications of our study, which are of relevance for the current discussion on the recalibration of the cohesion policy after Covid-19 crisis.

REGIONAL INEQUALITIES AND DECENTRALIZATION IN THE CENTRAL AND EASTERN EUROPEAN COUNTRIES

Tomasz Kossowski, Pawel Motek

Adam Mickiewicz University, Poland

ABSTRACT

The purpose of the study is to determine the relationship between decentralization and regional inequalities in the Central and Eastern European countries. Results of the research presented in many papers, mainly done since the beginning of the 21st century, do not lead to clear conclusions. Depending on the approaches used by researchers, the number of countries, the level of their socio-economic development, we can observe that decentralization leads to an increase in regional inequalities, as well as to their reduction in some situations. Studies also emphasized that this relationship may take the form of an inverted U. In the case of the Central and Eastern European countries, results of previous research are usually very general, ignoring diversity of these countries and treating them as one homogenous group. However, the political and socio-economic transformations in these countries followed different models. As a consequence of this fact, decentralization reforms were different among CEE countries, economic growth was different, and it resulted in various size of regional inequalities. In this research, we try to verify hypothesis that the relationship between decentralization and inequality will be best explained by the Kuznets curve in Central and Eastern European countries. To do this, we have created a panel database covering the countries of Central and Eastern Europe in the years 1990-2016. According to many previous studies, this database contains four groups of measures. The first of these groups has only one measure for assessing regional inequalities. It is calculated in a classic way based on regional GDP per capita. The second group of measures refers to fiscal decentralization and includes, for example, the share of regional authorities' expenditures in total state expenditure and, the measure of degree of tax decentralization. Political decentralization is measured by variables such as: the number of levels of regional authorities and the place of local government in state constitutional law. The measure of administrative decentralization is calculated as the degree of freedom in decision making at the regional level. We have run a model describing the impact of decentralization on the level of regional inequalities on this database. Due to the presence of spatial effects, the model has been estimated in several variants. For this purpose, classical and spatial econometrics methods were employed. The model approach was also used to verify the hypotheses about the change in inequality over time according to the Kuzniec curve and, the impact of economic growth on these changes.

EUROPEAN METROPOLISES AND ITS DEMOGRAPHIC PROBLEMS: A SPATIAL APPROACH

Tomasz Kossowski, Justyna Wilk

Adam Mickiewicz University, Poland

ABSTRACT

European metropolises are centers of life and socio-economic development of regions and countries. Despite of their privileged position in urban and economic system, they also try to overcome demographic challenges as other centers. Among them, the most important are aging processes that may strengthen or weaken metropolitan development. As a consequence, current activities in the field of the spatial planning and the spatial policy, as well as strategic plans, should take into account demographic processes taking place. The aim of the paper is to determine the demographic problems of European metropolises, such as disparities between the number of women and men, inadequate reproduction, shortage of people of working age, the growing share of older people, as well as to identify the spatial development of demographic processes and the role of metropolises in this respect. Another problem solved in the paper is classification of metropolises based on their population and age pyramids using symbolic data analysis methods and cluster analysis. It is a part of the larger study of demography in 1397 NUTS-3 units from 37 European countries in 2015., and these results will be also delivered as a background for the main problem of the study.

THE UNINTENDED EFFECTS OF COHESION POLICY: THE WEALTHIEST REGIONS WILL FURTHER FLOURISH IN ROMANIA

Réka Horváth, Tünde Petra Szabó

Babes-Bolyai University, Faculty of Economic Sciences and Business Administration, Romania

ABSTRACT

In this study, we explore a new research direction on the European Union (EU) cohesion policy. We identified a gap in the scientific literature and tested our assumption in Romania. According to our hypothesis, more economically advantaged regions attract more EU funds. We constructed several multiple regressions to determine whether GDP per capita and other economic variables can explain the total amount of structural and cohesion funds received by the different beneficiaries in certain regions. The results are mixed and support the hypothesis that wealthier regions attract more EU funds, which is not the intended purpose of the cohesion policy.

IMPACTS OF THE BUILT ENVIRONMENT AND TRAVEL BEHAVIOUR ON ATTITUDES: THEORIES UNDERPINNING THE REVERSE CAUSALITY HYPOTHESIS

[Bert Wee](#)¹, [Jonas de Vos](#)², [Kees Maat](#)¹

¹Delft University of Technology, Netherlands. ²Bartlett School of Planning, University College London, United Kingdom

ABSTRACT

The importance of attitudes in the relationship between travel behaviour (TB) and the built environment (BE) has been the subject of debate in the literature for about two decades. In line with the Theory of Planned Behaviour, attitudes – which affect behaviour – are generally assumed to be constant. However, it is plausible that attitudes can change, both directly, and indirectly, through the impact of the built environment on travel behaviour, a process which is referred to as reverse causality (RC). Based on literature from social psychology, this paper provides a conceptual model for the explanation of attitude changes. It also reviews the literature in the area of BE and TB concluding that two explanations dominate: a change in attitudes due to new experiences which can be underpinned by learning theories, and a change in attitudes due to mismatches between attitudes and behaviour which can be explained by cognitive dissonance theories. The literature also suggests a few additional explanations, while we also suggest explanations not provided in travel behaviour literature. Finally, we present an agenda for future research.

HIGH SPEED RAIL AND SPATIAL EQUITY IN DEVELOPING COUNTRIES: THE CASE OF TURKISH HIGH-SPEED RAILWAYS

[Ahmet Bas](#)¹, [Marie Delaplace](#)²

¹Abdullah Gul University, Turkey. ²University Paris Est, Lab'Urba, France

ABSTRACT

The twenty first century is characterized by the current and future extension of the high-speed rail (HSR) network in developing countries. According to the UIC (International Union of Railways) data there are 47,560 km of high-speed lines (HSL) in the world, 12,892 km were under construction as the date of 1st October 2019. More than 40,000 km were planned worldwide for completion by 2050. The twenty first century is characterized by the network extension in developing or emerging countries (China, Turkey, Morocco) and by projects in many others (India, Brasilia, Malaysia, Egypt, etc.). If lines are already in operation in China, Turkey, Morocco and others are built (Iran) and projects exist in numerous countries (Brasilia, Malaysia, Egypt, etc.) that is, in very different socio-economical contexts. High Speed Railway systems (HSRs) are an alternative way to the aviation sector and road transportations from the point of time reduce, cost and accessibility over distance of 250-1000 km. As it commonly known that HSR improves intra/inter-regional accessibility, enhance the mobility and can induce different travel purposes. When a new High-speed line (HSL) line is constructed, the cities which are located and have stations on the line are therefore gained advantages from these opportunities, because of accessibility improvements. However, can the issue of the potential increase in accessibility and in mobility be addressed in the same way in developing countries which are characterized by larger inequalities than in developed ones? The issue is to know for whom and for what use they are built. Has everybody access to high-speed rail in developing countries? Who can use HSR? Do low income and greater inequalities which characterize the developing countries influence the use of the transport infrastructure? The main issue is linked to the price policy, to the income level and also to the alternative mode of transportation. The aim of this communication is to analyze the link between high-speed line and spatial and social inequalities. After presenting the Turkish' case, we will analyze the HSR from the point of passengers' income, trip purpose and regional accessibility. We will show that the price policy in Turkey and the willingness to serve numerous cities all over the country makes High Speed rail a tool for a better equity.

TRUCK PLATOONING TECHNOLOGY DIFFUSION: A MICRO-FOUNDED MACROECONOMIC MODEL WITH PROFITABILITY CONDITION AND CLUB EFFECT

[El Mehdi Aboukacem](#)

Université Gustave Eiffel, France

ABSTRACT

Truck platooning refers to the technology allowing Heavy Duty Vehicles (HDV) to travel in convoy formation using wireless communications and advanced driver assistance systems. Such convoys are called platoons. The lead truck is fully controlled by a human driver. In the followers, humans are still needed. However, in the “platoonable” sections of the roads, the followers react to the changes in the leader's movements automatically.

Platooning is expected to increase road safety and capacity, and to decrease fuel consumption and GHG emissions. However, despite the promises of profitability platooning suggests, the literature dealing with it lacks economic studies. Two important reasons may explain this situation. Firstly, the doubts concerning platooning technical functioning and its practical use are still numerous. Secondly, the literature dealing with the “engineering” aspects of platooning presents contrasting results concerning the benefits this technology can bring.

We explore here the mechanisms underlying the potential future spread of platooning. To the best of our knowledge, there are only two papers where the spread of a driverless technology dedicated to HDVs is addressed : Raj et al (2020) and Jesse (2019).

Despite they present very interesting insights, these papers can hardly be considered as falling within the scope of economics. In both, the adoption rates evolutions depend on time and on some other non economic criteria. Also, the two papers neglect an essential criterion for the commercial success of any driverless technology dedicated to HDVs: its profitability from the perspective of trucking companies. Yet, the individual decisions these companies make regarding these technologies is the cornerstone of their diffusion at a macroeconomic scale. To put it at its most basic, trucking companies' main objective is to make profit. Thus, they would adopt trucks equipped with new driverless technologies only if the profits generated thanks to them are higher than those generated by using the conventional trucks. As such, the issue of the “technological” trucks purchase and usage costs is central. However, to the best of our knowledge, this issue is never addressed in the literature.

Furthermore, when addressing platooning, it should be borne in mind that a truck equipped with this technology brings value only when it travels within platoons. Thus, from trucking companies' point of view, investing in such a truck can be profitable only if there are on the roads enough trucks with whom it is possible to form platoons. To the best of our knowledge, such a club effect has never been explored.

In the present paper, we build a micro-founded macroeconomic theoretical framework, dedicated to understanding some of the economic mechanisms underlying a potential diffusion of platooning. The model considers geography, expresses finely the costs of transport operations, and takes explicitly account of platooning costs. Furthermore, it formalizes mathematically the club effect inherent to the functioning and the commercial success of this technology. We simulate then many diffusion scenarios. In each one, we make different assumptions concerning the technology characteristics and the geographical environment. The calibration is conducted using different data sources.

THE 'GOOD NIGHT' PROGRAM: AN INNOVATIVE MODEL FOR THE SOLUTION OF TRUCK CONGESTION IN ISRAEL

David Bentolila

Ruppin Academic Center, Israel

ABSTRACT

Avoiding truck congestion and peaks in landside activity is one of the challenges to all transportation problems as well as container terminals. This paper presents an innovative model of economic incentives combined with state regulation that motivated 7.9% of the customers of Haifa sea port to shift to night hours for transportation to the port instead of peak hours during the day.

Efficient terminals seek a balance between ship-to-shore, yard and landside operations in order to create an integrated system without bottlenecks (Notteboom, 2006; Vernimmen et al., 2007, Bentolila et al 2016) and peaks in landside activity, particularly at the level of trucks arriving at the terminal to pick-up or drop containers.

We started analyzing the congestion problems in Haifa port a decade ago. The first step was to elaborate a pilot program called " Good Night" that overcame some of the night issues, by opening empty containers terminals during night. The program included a state resolution to pay monetary incentives to customers shifting to night hours. A deeper field study of the Good Night pilot project has been conducted in 2013, including 14,149 trucks, in order to face three critical issues of the program: what are the constraints of the customers during the night that we have to overcome in order to motivate them to shift to night hours, what is the level of the monetary incentive that is cost effective to pay for every truck or container and what are the effective hours to pay this incentive.

An economic transportation congestion model has been developed in order to define the market utility depending of different hours. The incentives hours of night went from 20:00 until 06:00 and the incentive payment varies from 80 to 100 IS (about \$28) for one full container arriving or leaving the port.

In Israel, as in many other countries, the problem of traffic congestion is becoming more and more crucial over the years. So, a further pilot program has been launched in 2019, in which the night incentives hours have been enlarged to 12 hours daily, starting at 18:00 until 06:00 and then reduced gradually again to eight hours daily.

The idea is to follow carefully the actual pilot and suggest further steps that will elevate the level of night transportation to 20% and even 25%.

Further research will be directed to the examination of the impact of night transportation on decongestion of traffic problems.

Special Session: SS12.1 - SMEs/Family Businesses and Regional Development

FAMILY FIRMS, REGIONAL COMPETITIVENESS AND PRODUCTIVITY: A MULTILEVEL APPROACH

Stefano Amato

IMT School for Advanced Studies Lucca, Italy

ABSTRACT

In this paper we adopt multilevel design to investigate how much of the labour productivity of a sample of Spanish manufacturing is explained by firm-level versus regional characteristics. To account for differences across regions in terms of human capital, knowledge intensity, innovation, and physical endowment, we calculated by applying the principal component analysis (PCA) a synthetic indicator of regional competitiveness for the period 2002-2015. Our findings reveal as most of the variability of firms' productivity is attributed to firm-specific characteristics. However, the regional context matters with firm's performance that is strongly influenced by the overall quality of the regional environment in which are located. When firms are differentiated according to the family status, that is in family and non-family firms, cross-level interactions show as family firms are particularly sensitive to spatial advantages offered by location in well-endowed and prosperous regions. Theoretical implications at the crossroads between family business and regional studies together with policy implications are discussed.

SMALL BUSINESS CLINIC: A DATA-DRIVEN DIAGNOSTIC AND ADVISORY TOOL FOR SMES IN LAGGING REGIONS

George Petrakos, George Anastasiou, Alexandra Sotiriou, Dimitris Kallioras

University of Thessaly, Department of Planning and Regional Development, Greece

ABSTRACT

In Europe and in Greece, Small Business are a vital part of the economy and the challenges they encounter in their post crisis environment need to be addressed as a matter of urgency. Their size, in most cases, does not allow them to have real access to financial advice, guidance and support in planning, restructuring and developing their business, because of the lack of sufficient resources. In addition, such services are not always available outside large urban centers and the periphery. In contrast, larger firms typically receive these services from major consulting firms that are mainly based in the capital or large cities and have the expertise, access to big data and business analytics tools. Lack of access to advisory services is partly responsible for the high mortality rates of SMEs and especially the mortality of new businesses. Adapting to changes in a successful way requires addressing critical operation problems and improving effectiveness in decision-making.

This paper is based on research work conducted in the framework of a project aiming to create a web-based online 'big data hybrid business analytics advisory service model' for SMEs, that incorporates business analytics tools utilizing big data and supported by experts, called "Small Business Clinic" (SBC). Our approach combines economic and business information available with survey data depicting also the perceptions, attitudes and choices of the entrepreneurs. Databases of structured and unstructured information, alongside with input data from the surveyed enterprises, are linked, correlated and analyzed within an integrated business model in order to produce a set of indicators and algorithms. The tool delivers individualized diagnosis, benchmarking and advisory to small businesses in order to take advantage of "data-driven decision-making" and to achieve significant improvement in their productivity and profitability. Furthermore, the paper analyzes the adjustment and prospects of the productive system of SME's of Greece. The analysis focuses on the role of the internal and external environment, specialization, human resources and inter-firm relations, as well as their ability to compete in the post crisis demanding environment. The analysis is supported by a pilot survey conducted in the region of Thessaly, inquiring the patterns of decision making, the drivers of change, as well as the perceptions and attitudes of small firms in a number of critical domains. The results of the survey are used to control and fine-tune the indicators and algorithms used to produce the diagnostic and advisory services to SMEs irrespective of sector and location.

SUSTAINABLE STRATEGIC DESIGN IN FURNITURE MSEs IN UBERLÂNDIA, BRAZIL

[Fernando Moreira da Silva](#), [Juliana Cardoso Braga](#)

Lisbon School of Architecture, Rua Sá Nogueira, Portugal, fms.fautl@gmail.com, cardosodesign@yahoo.com.br

ABSTRACT

In the city of Uberlândia, Brazil, there are 800 formal and informal SME's furniture companies. The majority of these companies are micro, between 6 and 12 workers, of familiar nature. The dispersion of SMEs in the sector over a very large territory and the small size of these productive structures have made it difficult to change the productive paradigm. The production of furniture in Brazil generates a large volume of wood residues and their by-products due to the cutting process itself and, mainly, by manufacturing waste. Each of these companies generates, on average, 300 tons of waste per month composed mainly of MDF chips and powder, i.e. about 7.2 tons per year, per company. Due to the environmental and legal restrictions to obtain solid wood, most of the manufactures use reconstituted wood panels, mainly of MDF produced from the reforestation wood. The manufacturing processes used by these furniture companies are therefore not sustainable, which configures approximately 22,000 m³ of waste discarded per year on vacant lots in the city's peripheral areas. These residues are mainly composed of pieces of reconstituted wood (sawdust, chipboard and MDF scraps): most of the furniture industries still use waste in an irregular way. Residues resulting from the processing of reconstituted wood sheets may present some danger when they are not adequately disposed because of the presence of urea-formaldehyde in the composition and the high flammability of the material. The inspection and penalization actions have been ineffective, so it is necessary to rethink the problem involving the generation and disposal of waste from these companies. Most of these small organizations are too concerned with their livelihood, which is why they have not incorporated changes in their production that could lead to a general improvement in the processes, manufacturing methods and diversity of products. This paper presents a sustainable strategic design model for SMEs in Uberlândia which is part of the results of a research project, aiming not only to minimize the waste generated by these companies, but also to implement sustainability and design practices as strategies to incorporate added value to the developed products, which can generate visible economic gains for the companies and employment for the local community. The research was based on active research methodology to support project development, with a strong intervention component at the level of participatory design of the different stakeholders and the evaluation process using a focus group.

KEYWORDS

Furniture products, Manufacturing Waste, Strategic Design, Sustainable Design.

1. INTRODUCTION

About 97% of the furniture companies in Brazil are made up of Small and Micro Companies (SMEs). The production is essentially made to order and made-to-measure furniture and employs semi-handcrafted manufacturing processes. The production processes are not sustainable, which means waste and a large volume of waste. Waste composed mainly of remains of reconstituted wood (mainly MDF) is often irregularly disposed of in public space, burned in the open or in bakery ovens. The irregular disposal of waste constitutes a threat to public health and the environment, degrades the image of the peripheries and accentuates social asymmetries. Inspection and penalization actions have been ineffective, which led to the present study, leading to a rethinking of the problem that, above all, involves the generation and disposal of waste from these companies. The "spraying" of SMEs in the sector over a very wide territory, as well as the small size of these productive structures, have made it difficult to raise awareness of a change in the productive paradigm, given that these companies are, for the most part, too concerned with their livelihood.

The present investigation aimed to identify and minimize waste and irregular waste disposal by furniture MSEs, reducing the environmental, economic and social impacts resulting from the production of personalized furniture through sustainable strategic design.

From the diagnosis carried out in five MSEs of personalized furniture in the city of Uberlândia, State of Minas Gerais, Brazil, a model was developed, the CACO model, which proposes the continuous improvement of products, services and production processes through a set of sustainable strategic design strategies, guidelines and tools that can be progressively implemented.

The model was evaluated by a panel of experts and an action plan was determined with a view to its implementation in a pilot company, a furniture SME. As a partial result of the investigation, it was found that as a result of the strategy of negotiation and articulation of public and private interests promoted by the Caco Project, 60 carpenters in the region started to dispose of waste in an environmentally correct way in a licensed industrial landfill.

The results showed that the model is a resource to reduce waste and the social, environmental and economic impacts of furniture MSEs, to encourage the correct disposal of waste, to reduce the degradation of public space, to generate savings for municipalities and to reduce the impacts for the community. society affected by irregular waste disposal.

2. FURNITURE INDUSTRY IN BRAZIL

The productive chain of the furniture industry in Brazil is historically specialized in the production of articles made with wood, because of the abundance of raw materials of forest origin (Galinari et al., 2013). However, due to environmental and legal restrictions for obtaining solid wood, the manufacture of wood panels produced with reforested pine and eucalyptus expanded in Brazil. According to information from the Brazilian Tree Industry (IBÁ), in 2016 the production of reconstituted wood panels (MDF, MDP, etc.) in Brazil was 7.3 million m³, of which 86% were destined for the domestic market. There are 18 panels producing factories in Brazil and the country occupies the 8th place in the world ranking of the largest producers of reconstituted wood panels (IBÁ, 2017). Effectively, there is a predominance use of MDF coated with laminate. Panel manufacturers offer products with a single dimension, which makes it difficult to use the boards, and consequently, results in greater material losses in joiners.

Due to the “pulverization” of companies across the national territory and the large number of informal micro-enterprises, in 2016 the Minas Gerais State estimates the existence of more than 17,500 furniture industries made up predominantly of micro and small companies with verticalized and unskilled production processes, many of which are joinery that execute customized furniture (Galinari et al., 2013; IEMI, 2016). These companies have gradually introduced high technology, but most of them still use outdated equipment and production systems. Large companies are basically serving the domestic market, in part, because of the high prices of wood panels in the national market (Leão, 2009); the low technology employed; and the lack of product differentiation due to low investment in design - with a predominance of product imitation (Castro & Cardoso, 2010; Crocco & Horácio, 2010; Galinari et al., 2013; IEL, 2018). One of the main obstacles to the development of Brazilian companies concerns the lack of insertion of design to support the conquest of new markets and the creation of Brazilian design (SEBRAE, 2002: 43). However, even with the drop in the number of personnel employed, the furniture sector is still relevant to the generation of jobs in the country. According to Galinari et al. (2013), the expressive participation of the furniture industry in employment levels and the dissemination of the furniture production chain throughout the national territory evidenced its importance for the Brazilian economy.

2.1 Triângulo Mineiro and Alto Paranaíba Region

A significant number of Micro and Small Companies (MPEs) in furniture is located in Minas Gerais State, in the mesoregion of Triângulo Mineiro and Alto Paranaíba. This mesoregion consists of sixty-six municipalities, seven of which are considered micro-regions, due to their differentiated production, distribution, exchange and consumption structures. Adding its 66 municipalities, the region has an estimated population of two million inhabitants, and has an area equivalent to 54 thousand km² (IBGE, 2015).

According to the Brazilian Institute of Geography and Statistics (IBGE), Uberlândia is the largest municipality in the region (683 thousand inhabitants - estimated population in 2018) and the second largest in the state of Minas Gerais, it has the third largest HDI (0.789) in the State and is the most influential city in the region (IBGE, 2018), mainly for its strategic geographical position in the regional and national context (SEPLAN, 2017), for its relevant economic and social performance in the national, state and regional scenario.

The Union of Woodworking and Furniture Industries of Vale do Paranaíba (Sindmob) established in the city of Uberlândia, Minas Gerais, Brazil, has 80 member companies and seeks to promote, mainly, lectures, exhibitions and trips for companies in the sector. In 2006 Sindmob in partnership with SENAI and SEBRAE carried out a diagnosis of the furniture industries in the region. According to the results, there are approximately 200 formal furniture MSEs. However, it is estimated that the number of furniture companies in the region is much higher, around 800 MSEs, due to the informality of most industries. Micro and Small Enterprises predominate in the region, 96% are Micro Enterprises (up to 19 employees) and 4% are Small Enterprises (from 20 to 99 employees) who have a small number of employees: an average of 6.2 employees per company. The production of companies in the region is essentially made-to-order and bespoke furniture, around 94% (SENAI, 2006).

The production process is semi-handcrafted, due in part to the local culture of handcrafted know-how and the appreciation of users for personalized products that suit defined functions and spaces. In most companies, furniture is made by woodworkers who have the knowledge and practice to make all the furniture. For this reason, production processes require qualified labor. The results are generally quality furniture and, consequently, have high cost, but which still compete with high-tech companies that produce modular furniture (Dal Piva, 2006).

It is important to consider that the production systems have a low degree of specialization, production with a low technological level and occur in a vertical manner, that is, different production processes are carried out by the same company. This process requires a series of steps: the analysis of the project, which is prepared by a professional (usually a designer or architect) or by the carpentry itself; cost calculations are performed; individual negotiation of each piece of furniture; visit at the client's home to survey measures; calculation and purchase of raw material; monitoring of all production until transportation and assembly, which is often completed at the customer's residence. Generally, this entire process is carried out by the joinery owner who participates in the entire production chain.

Generally, for the production of bespoke furniture, the basic raw materials used are panels derived from solid wood (plywood covered with natural wood veneer) and reconstituted wood panels (MDF, MDP, OSB and agglomerate). As

components, mainly used are wood veneers, edge strips, screws, dowels, glues, metallic hardware (handles, hinges, slides), among others. Solid wood is more used for the manufacture of pieces of small width and thickness. Most of the joineries in the region, 86%, produce residential furniture, being these products mainly destined for the local market, in a fierce competition based on prices (SENAI, 2006).

During the research implemented by SENAI, it was not evident how these companies employ design. However, what is observed as a common practice in the region is: (i) the development of personalized projects by the designers and later indication of the joinery services; (ii) joiners that outsource projects to serve customers who are directly looking for joinery; (iii) joiners who develop their own projects, through an intern with a degree in design; (iv) joineries that develop projects through a designer without training in design (SENAI, 2006).

2.2 Furniture waste: environmental, social and economic impacts

If, on the one hand, the furniture sector generates a large number of jobs, on the other hand, it is also considered a major consumer of raw materials and waste generator. The sector carries out the integrated use of materials, which, because of its distinct nature and the “lack of an adequate management plan, ends up hampering reuse, recycling and other modes of proper final disposal” (Kozak, et al., 2008: 205).

In addition to the diversity of materials, the production of customized furniture requires a series of production processes such as machining (cutting, drilling, milling,); sanding; assembly (fixing and gluing); transport; and cleanliness. All of these processes generate a large volume of various types of waste (sawdust, dust, panel scraps, edge tapes, packaging scraps, screws, glues and tow).

The estimated annual volume of residues from the furniture sector in Uberlândia in 2012 corresponded to 22 thousand m³, of which a significant part is composed of reconstituted wood residues (Nunes, 2013). The presence of additives urea-formaldehyde or phenol-formaldehyde used in the composition of reconstituted wood panels, requires special attention because this resin is part of the list of cancer products of the International Agency for Research on Cancer (IARC). For all these reasons, the joineries in the Triângulo Mineiro and Alto Paranaíba have an expressive environmental liability, mainly because of the irregular disposal of waste on land on the periphery of the cities in the region. This practice stems from factors such as: municipal policy, which is not very sensitive to environmental issues; the lack of municipal management aimed at the proper destination of this type of waste; the resignation of the needy populations, who live in the vicinity of these sewers; the low or no interest in assuming the share of environmental responsibility by the entrepreneurs of the MSEs in the region and the weak (social and environmental) awareness of the designers about the environmental impacts of their projects (Nunes, 2013). According to the diagnosis of SENAI (2006), 90.8% of the furniture manufacturers' SMEs in the region discard industrial waste, 3.7% sell it and 5.5% usually carry out recycling. Figure 1 presents the way in which, usually, the remains of production from a small joinery are collected, making provision for their disposal in the public space.

Figure 1: Waste generated in five working days in a carpentry shop located in the city of Uberlândia. (Braga et al., 2017: 7)

To dispose of the generated waste in an environmentally adequate way is insufficient to solve the problems dealt with. It is essential that there is a reduction in the consumption of resources, aiming, fundamentally, to minimize waste and, consequently, to reduce the impact on the environment (Pereira et al., 2010). PNRS recommends reducing the consumption source. According to Art. 9 of this Law, “in the management and management of solid waste, the following order of priority must be observed: non-generation, reduction, reuse, recycling, treatment of solid waste and environmentally appropriate final disposal of waste.” (Brazil, 2012: 15). The problem is the lack of recognition of the importance of these principles by all stakeholders and, consequently, and the innocuous change in behavior and practices.

According to Vicente (2012), the custom furniture sector has great potential to minimize its impacts, but for that it should deepen the knowledge about the life cycle involving its products and should be more open to contributions from other areas. In this context, the important role that design can play in generating value and minimizing impacts on the sector is highlighted. The problems caused by the abandonment of debris without any treatment and outside places previously prepared to receive it are not limited to its volume. The poor joinery waste management also causes social and economic impacts as described above. With regard to social impacts, it is important to add risks to public health from the toxicity of substances used in the production of reconstituted wooden boards. Formaldehyde, for example, is a carcinogenic solution used as an adhesive resin in the production process of this type of material (Pereira, 2013). Because of the use of resins containing formaldehyde, formaldehyde emission occurs both through the manufacturing environment and through the plates produced with these resins (Maloney, 1993).

3. STRATEGIES FOR THE DEVELOPMENT OF SUSTAINABLE PRODUCTS

The insertion of sustainable design strategies in local contexts and non-industrial production scales is very relevant for companies and indispensable to reduce the generation of solid waste, waste of materials, pollution and environmental damage caused by the production of personalized furniture. According to Fiksel (2009), sustainable design practices represent ethical behavior and good citizenship and, above all, a value strategy for companies' businesses. This principle of generating value and economic benefits for companies is known as eco-efficiency – i.e., doing more with less. This perspective is part of reducing the consumption of resources (energy, materials); reduce the environmental impact (reduce emissions, waste and the use of renewable resources); and creating value (providing better products, additional services, offering benefits to customers) (Bhamra, 2007).

Several corporations around the world already recognize sustainability as a strategy for business development, growth and survival and their ability to stimulate new business opportunities, improve competitiveness, increase customer confidence, and motivate employees, local communities, partners, etc. (Bhamra 2007; Fiksel 2009). Organizational changes for the insertion of eco-efficient design strategies also favor innovation and may offer a greater capacity to attract customers, as they improve the image of the organization and provide greater profitability through the reduction of environmental impacts, among other issues. All of these benefits obtained by adopting the principles of design and sustainability need to be integrated at a strategic level so that they can act effectively.

Strategies for the development of sustainable products are characterized by a systemic analysis of the product that also involves the search for alternative production technologies and strategies. Because sustainable design strategies are able to predict the desired result in all aspects of product development, determining the type of use, the market it will be used for, costs and possibilities of execution, generating flexible, durable, modular products or multifunctional, adaptable or recyclable (Barbero & Cozzo 2009).

Strategies aimed at a systemic approach involving all stages of product life should be considered when designing products. In this sense, whenever possible, designers should apply a set of eco-design strategies involving the entire product life cycle, that is, considering the stages of pre-production, production, distribution, use and disposal. They mainly involve: (a) the choice of low impact materials; (b) the reduction in the consumption of materials (raw materials and energy); (c) production optimization; (d) optimization of distribution; (e) optimization during use; (f) the extension of the product's useful life; (g) the optimization of the end-of-life of the product.

The establishment of efficient systems for the collection of materials, separation at the source and the environmentally appropriate final destination must encompass responsibilities shared by the products' life cycle. These initiatives require collective participation involving all generators - the community, manufacturers, importers, distributors, traders and the government - and the latter should stimulate the others, both through tax incentives, the valorization of recycled raw materials, educational campaigns, as well as through stricter legislation, inspection or even penalties. It becomes necessary to avoid disposal as much as possible, developing products that use less resources for production, that are durable, light, foldable, stackable, that use materials from renewable sources, that can be reconfigurable, adaptable, that can be standardized, demountable, upgradeable, refurbished, repaired, reused, which have greater efficiency in the consumption of energy, water and materials, which have more compact, reusable or biodegradable packaging. Most of the time it is impossible to adopt all these strategies for the same product, because these characteristics will be determined according to the performance and due to the context of use for which the object is intended.

3.1 Innovation and sustainable design strategies

It is understood that sustainability strategies can be a key element for innovation, as they require prior understanding of the processes involving the entire product life cycle and also demand continuous improvements through the integration of environmental and social criteria in different stages of the product. process. According to Manzini and Vezzoli (2008: 22), sustainable design strategies should aim at creating “new scenarios that match sustainable lifestyles.” These authors also state that this scenario change can only emerge from the search for innovation through interpretation, environmental redesign, new product-services and the encouragement of new productive ideas that are intrinsically more sustainable for the environment, socially just and culturally attractive. So, sustainable design strategies have significant potential for generating social innovation.

Innovation is directly linked to sustainability, as both generally seek for a change, generally in the sense of improvement. With regard to sustainability, global environmental pressures and the urgent need to minimize environmental impacts with future generations in mind induces modifications and improvements in production processes, products and systems (Crul & Diehl, 2005) with the potential to reframe ways of life, while innovation (incremental or radical) allows the

introduction of novelty in products, processes and services, or allows its improvement, promoting differentiation and, consequently, the creation of value.

4. DIAGNOSIS OF FURNITURE MPES OF THE MINAS GERAIS TRIANGLE

Different procedures and methods were used to collect qualitative data on the activities, operations and environment inherent to the production of personalized furniture and quantitative data on the general volume of waste produced. The diagnosis identified and analyzed the possible correlations between furniture production operations and the generation of tailings, that is, it identified the situations of waste, its causes and the opportunities for its reduction. Once the companies were defined, an active investigation led to the construction of knowledge about the investigated MSEs and to the identification of problems. Several data collection instruments contributed to the diagnosis of MSEs, namely: (i) semi-structured interviews; (ii) direct observation with mechanical support; (iii) documentary research; (iv) meetings with stakeholders; (v) bibliographic survey; (vi) quantitative survey on the volume of waste generated by joiners; (vii) and quantitative survey on the volume of waste sent for final destination. A toolkit was developed to support the diagnostic phase, which aimed to measure the amount of material (MDF) used in each project by joiners (material input and output). The toolkit was completed by the carpenters during the production process of the analyzed furniture. The completion of the toolkit is of low complexity and allowed: (i) to register and, later, to analyze the way in which the cutting of plates is usually planned; (ii) register and, subsequently, identify the quantity of MDF boards (new and reused) used in each project. The toolkit was made available to employees who also received guidance on how to use the tool (Braga, 2019). In addition, during the furniture production process, the waste materials were separated, identified, quantified (weighed and measured) in order to identify the percentage of material loss during the production process (waste output) (fig. 2).

Figure 2: Process of separation and quantification of waste generated during the diagnosis. (Author, 2017)

The data collected on the amount of MDF used for the production of the analyzed furniture were compiled using tables. The five joineries taking part in this research are scattered in different regions of Uberlândia. All SMEs are formal, family-owned and produce customized furniture, to order. The main products marketed by the companies are residential furniture (bedroom and kitchen furniture) aimed exclusively at the domestic market.

The main raw material used by carpenters is reconstituted wood panels (MDF). The finding is that there is a predominance in the use of laminated MDF panels (coated), and as components are used mainly, edge tapes, screws, adhesives, metallic hardware (handles, hinges, slides, aluminum profiles), among others.

In accordance with the statement by FIEMG (2002), it was found that companies have gradually been implementing technology. However, only one company investigated has a Computer Numeric Control (CNC) machine, which manufactures computer-controlled parts. The companies have a mix of semiautomatic equipment such as disconnect switches and edge glues and outdated equipment. The organizational structure of most MSEs is vertical (decision-making and supervision of people and tasks is centralized). The tasks to be performed are characterized by low horizontal specialization, as both owners and joiners are responsible for carrying out different activities (Wagner & Hollenbeck, 2012). The only exception is the finishing services that are usually outsourced. Each joiner is responsible for executing the complete furniture and the same activities are performed by several employees, which can cause communication failures.

4.1 Productive process: description and identification of waste

The process of producing bespoke furniture, in general, involves a set of steps and operations that occur in a non-linear way. The production process by project, is adopted by all investigated carpenters, aiming to meet specific needs, with a fixed deadline to be completed. Once the project is completed, with the final assembly of the furniture, the joiner turns to a new project.

Although this type of production causes a low production volume, waste was detected throughout the process. According to Rampersad and Hubert (2007), waste is usually hidden because it is considered a normal symptom in the workplace. For waste is defined as any activity that does not add value to work or to the client and can be camouflaged in all operations. In this sense, the diagnosis analyzed the production process of personalized furniture and classified the main types of waste and its potential causes: waste of raw material; waste of time; fuel waste; waste of energy; waste of space (Slack, 2016).

It was found that there is an over-dimensioning in the calculation, mainly of MDF and edge tapes elaborated by the carpenters under the justification of avoiding probable interruptions in production caused by the lack of material. Therefore, the inaccuracy of the calculation of materials deserves due attention, as the abundance of materials generates uncontrolled and waste of raw materials on the part of carpenters. The cutting plan is carried out by the carpenters through manual annotations that describe the size of the parts to be sectioned. However, the annotations are only descriptive, referring only to the cutting dimensions, and do not constitute a plan for the optimization of the cutting of plates.

The diagnosis revealed that the lack of optimization of the cut has caused significant losses of material, because the joiners cut the MDF without planning the good use of the board. In these cases, it is valid to assume that: (i) the waste of raw materials is caused by the lack of planning and the large volume of waste generated; (ii) waste of energy is caused by the inefficiency in the use of the cutting machine (unnecessary cuts); (iii) space is wasted as a result of the accumulation of significant amounts of MDF leftovers.

The data triangulation of the three production stages (planning, production and distribution stage) makes it possible to conclude that all the processes characterized as generators of waste cause a certain type of socio-environmental and / or economic impact. However, some production processes have a higher level of correlation with waste (strong and moderate level) and, therefore, need to be prioritized during the development of sustainable strategies. They are: (i) planning stage: project design; verification of measures; analysis of the project and cutting plan; (ii) production stage: cutting; (iii) distribution stage: transport.

When considering the volume of raw material used and the amount of material insufficiently used by companies (24%), it was found that it is necessary to pay special attention to all processes that generate MDF waste. The quantitative analysis shows that a large part of the MDF leftovers made up of pieces (15%) is liable to be reused within the carpentry's own production process. The data reveals the importance of establishing strategies aimed at maximizing the use of MDF, its reuse and the environmentally correct destination. Therefore, we can conclude that sustainable strategic design proposals, as a result, can decrease: the consumption of natural resources (materials and energy); the generation of waste; the need to extract virgin raw materials; negative impacts on the environment; and reduce the production costs of MSEs.

The diagnosis showed that, on average, 24% of the wooden sheets are not sufficiently used. The significant loss of raw material is mainly due to the lack of planning to optimize the cutting of slabs, to design errors, production errors or due to excessive material acquisition. In 2017, the average amount of waste produced in Uberlândia by a universe of 50 furniture industries was 7.2 tons. per year, per company.

5. CACO: SUSTAINABLE STRATEGIC DESIGN MODEL

The compilation of bibliographic and empirical data has allowed us to recognize six main sustainable design strategies, applicable to the joinery sector and which will contribute to the reduction of companies' socio-environmental and economic impacts (Braga, 2019): (a) select materials, equipment and resources with less impact; (b) minimize the consumption of materials and resources; (c) optimize production systems; (d) optimize transport systems; (e) extend the useful life of the furniture; (f) optimize the end of life of the furniture and make the correct disposal of waste. The preliminary model, in addition to the six selected sustainable design strategies, also presented a set of guidelines that aim to minimize the environmental, social and economic impacts of joiners.

CACO model development was based on: (i) preserve semi-handcrafted know-how; (ii) not compromising the furniture's durability characteristic; (iii) improving the work environment and preserving the health of workers; (iv) reduce the impacts on the population on the outskirts of the city caused by irregular waste disposal; and, simultaneously, (vi) promoting the sharing of a commitment of responsibility (social, environmental, cultural) by the stakeholders.

5.1 Support instruments for the insertion of the Caco Model

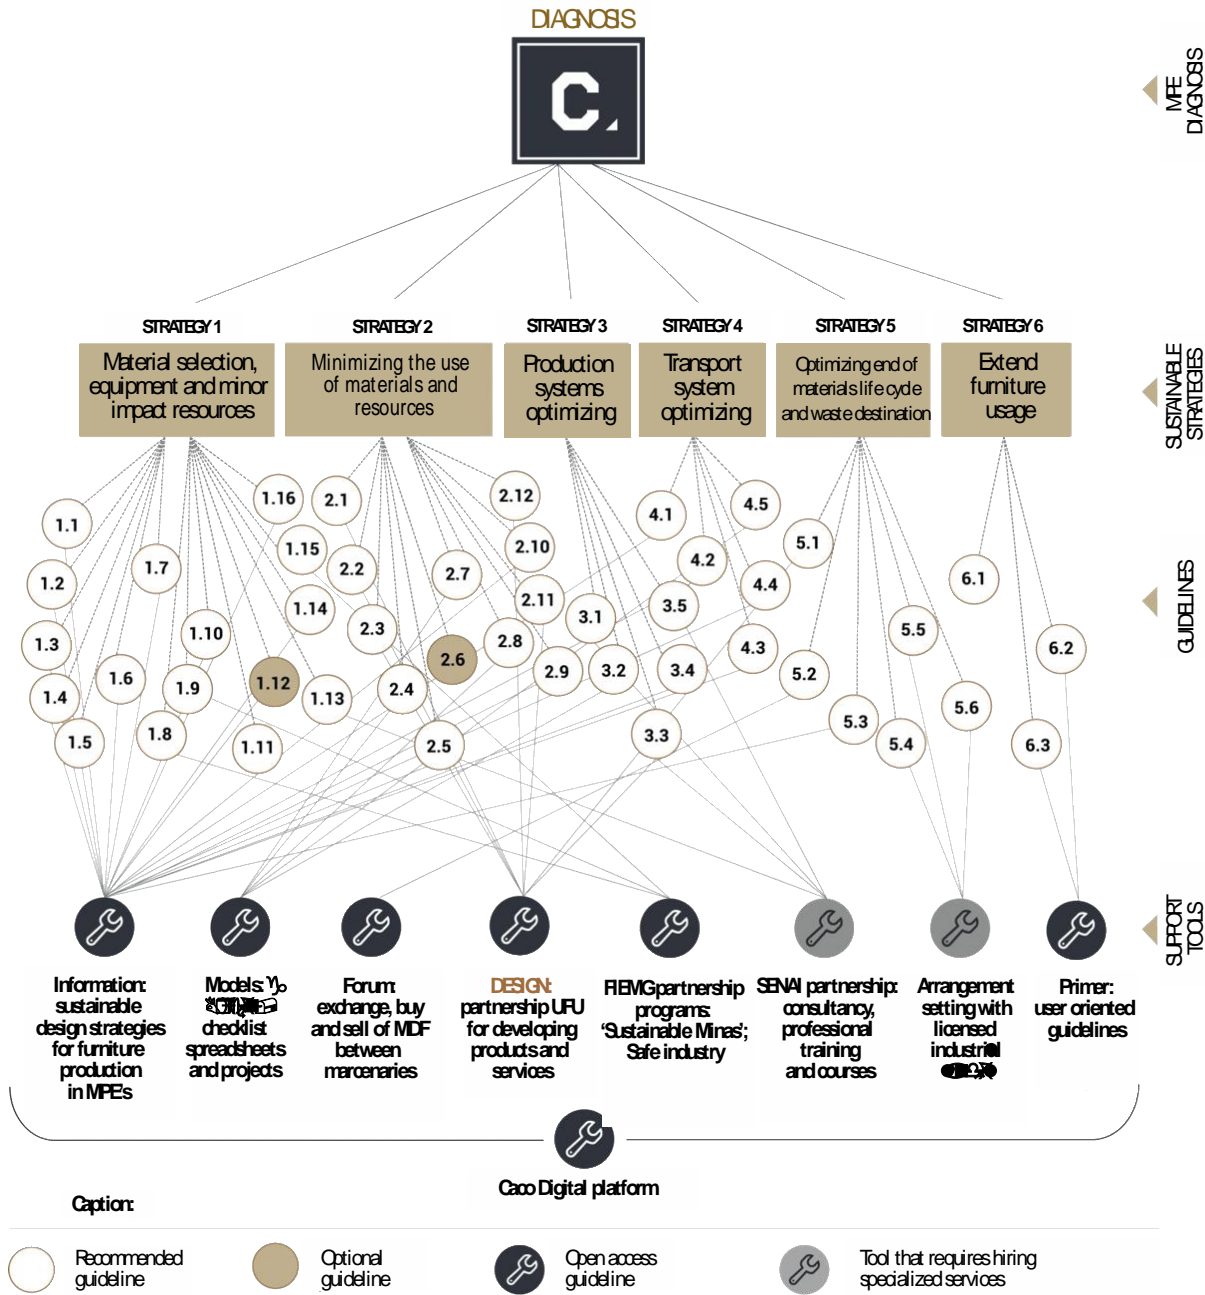

A set of support tools were also developed or negotiated by the Caco Project, targeting its model. These tools aim to disseminate knowledge about the sustainable strategic design model for custom furniture MSEs, assist in the insertion of the model and establish a direct communication process between the companies and the Caco Project.

All information about the sustainable strategic design model and the support tools are available to joiners free of charge through a digital platform, which is being developed by the Caco Project. The digital platform will consist of: (a) data on the furniture sector; (b) information on sustainable design strategies and guidelines applicable to the sector; (c) briefing

templates, spreadsheets, checklist, organization chart; (d) projects to optimize production systems; (e) forum for exchanging, buying and selling MDF between joiners; (f) information on the partnerships established by the Project with the UFU Design course, with FIEMG and SENAI to apply the model; (g) information on the agreement established with a licensed industrial landfill for the correct disposal of waste; (h) booklet aimed at furniture users on the correct maintenance of furniture and correct destination after use (Braga, 2019).

The final sustainable strategic design model proposes the continuous improvement of products, services and production processes of furniture MSEs through its progressive implementation. The insertion of the model is an important resource to reduce the environmental, social and economic impacts of the furniture industries, and to decrease the amount of waste sent to the final disposal.

The Caco Model consists of: (i) the company's diagnosis; (ii) a set of six strategies; (iii) 47 sustainable design guidelines; (iv) and nine support tools that aim to assist in the process of inserting strategies in MSEs. The model (fig. 3) aims to minimize waste, promote the management and correct disposal of waste and minimize the environmental, economic and social impacts of joiners (Braga, 2019).

Figure 3: CACO: sustainable strategic design model (Braga, 2019)

A plan for inserting the strategies and guidelines was developed and the model was partially implemented in a pilot company selected from the furniture MSEs that participated in the diagnosis phase. In addition, as a partial result of the

Caco Project, 60 furniture MSEs from the Triângulo Mineiro region are already disposing their waste correctly in a licensed industrial landfill after the sectoral agreement articulated by the Caco Project.

5.2 Model evaluation by an experts focus group

Aiming at the qualitative approach, the preliminary strategic design model was evaluated by a group of experts according to the methodology presented by the authors Gatti (2012) and Morgan (1996). The selection criteria of the group considered the affinity and experience of the participants with the scope of the investigation (personalized furniture industry) and prioritized professionals recognized in the academic and professional environment as specialists in related areas such as sustainable strategic design, furniture and environmental management. The focus group made up of a total of 10 experts provided a valid judgment on the proposed sustainable strategic design proposal; collectively evaluated concepts, offered feedback on the model and contributed to the organization, selection and introduction of new guidelines.

The specialists considered that the diagnosis is a fundamental part of the sustainable strategic design model, as each company has a different reality and, therefore, the diagnosis is essential to understand the context and to guide the action plan aiming to implement the appropriate guidelines and strategies. The diagnosis allows to determine which strategies and guidelines should be prioritized during the implementation of the model in each company.

In general, the experts considered the sustainable strategic design model suitable for the context of furniture MSEs and to minimize waste, promote the correct disposal of waste and, consequently, minimize the socio-environmental and economic impacts of companies.

The focus group proposed the incorporation of some guidelines and tools in order to ameliorate the sustainable strategic design model. Based on the evaluation carried out by the focus group and the analysis of the contributions of several stakeholders (businessmen, carpenters, class representatives and technical consultants), the model of sustainable strategic design was revised and complemented. If the preliminary model contained 35 guidelines and seven support tools, its final version includes 47 sustainable design guidelines and nine support tools.

6. CONCLUSIONS

The achieved results allow us to prove that the environmental, social and economic impacts resulting from factory waste are of great importance, given the large volume of waste generated and the lack of proper waste management.

The theory that supports this study allowed to underline the importance of combining sustainable interrelated design strategies to achieve the target. Therefore, a set of strategies, guidelines and tools were selected and developed for the development of the sustainable strategic design model, already evaluated by a panel of experts - the CACO model. The insertion of strategies and guidelines on the part of furniture MSEs stimulates innovation, through the introduction of constant improvements in production processes, products and services through a model that bets on an environmentally correct, socially fair, culturally appropriate and economically viable system. From an environmental point of view, CACO is an important resource for furniture MSEs to reduce socio-environmental impacts related to the use of toxic and dangerous materials; reduce the consumption of virgin raw materials; minimize factory waste; reduce the volume of waste sent to final destination; reduce energy and fuel consumption; reduce emissions of particulate matter (dust and VOCs); contribute to increasing the useful life of the furniture; and to reduce the socio-environmental impacts related to the irregular destination of residues. The correct application of the model can contribute to the improvement of the living conditions of the population affected by irregular waste disposal, by burning waste in the open or in bakery ovens, as the model prioritizes the minimization of waste and promotes its proper management, in addition to benefiting the working environment, safety and health of workers in the furniture industries. The platform for waste exchange proposed by the model allows to stimulate the interaction between joiners and cooperation between companies in the sector. Culturally, the model favors the differentiation of furniture MSEs that produce furniture on non-industrial production scales and preserves the culture of semi-handcrafted know-how and local identity. From an economic point of view, the implementation of the model is an important strategy for positioning and differentiating itself from the competition, as the insertion of a set of strategies enhances the image of the company, which now offers an exclusive mix of socio-environmental values to customers. The positioning of the industry in the market for sustainable products and services generates new business prospects and advantages for companies, reducing competition based on price and making the imitation process more difficult. In addition, the implementation of strategies to reduce waste and improve production processes are important for the survival of furniture MSEs in times of crisis, allowing to reduce production and waste disposal costs, reduce energy consumption, reduce delivery time, increase production capacity and profitability.

As main result of the investigation, it was possible to verify that the five furniture MSEs participating in the investigation added to another 55 SMEs in the region started to correctly dispose of the waste in the licensed industrial landfill after the participatory negotiation strategy promoted by the CACO Project. The challenges inherent to the insertion of the CACO model must be overcome with the continuity in the active participation of stakeholders, with the strengthening of the relationship with the sector, with the collaborative work of specialists directly on the shop floor and with the dissemination of knowledge about the practices of sustainable strategic design applicable to the sector.

It was found, therefore, that the insertion of a sustainable strategic design model especially oriented to furniture MSEs, CACO model, encourages the correct disposal of waste, minimizes waste and environmental, economic and social impacts arising from the production of personalized furniture. The CACO model, supported by the strategies, guidelines and tools that characterize it, should continue to be constantly improved and tested, aiming its validation.

THE ROLE OF MEDIUM-SIZED FIRMS AND BUSINESS SIZE EVOLUTION IN REGIONAL RESILIENCE

Adrian Healy¹, Nikos Kapitsinis², Max Munday², Annette Roberts²

¹Cardiff School of Geography and Planning, United Kingdom. ²Cardiff Business School, United Kingdom

ABSTRACT

Scholars have highlighted the role of regional features in the process of building resilience including the role of the dynamism in services sectors and innovation. However, the role of business size diversity and its dynamics in building resilient (and indeed resistant) economies has been largely overlooked in academic discourse. Moreover, economic development policy has focused on the two sides of business size spectrum, either on micro firms or on attracting larger projects through inward investments. In this context consideration of a 'missing middle' may exist in terms of policy development.

This paper focuses on the role of medium-sized firms in supporting regional resilience. Understanding connections between firm size distribution, business size growth dynamics and regional development provides insights for the regional resilience (and resistance) debate. This paper contributes by highlighting the importance of medium-sized firms as a consideration factor in determining the resistant or resilient nature of economies. We argue that locally-owned and highly productive medium-sized companies can offer a relative stability and facilitate the transformation of a regional developmental path, while a poorer performing sector can lead to regional resistance. The issue of medium-sized firms is organically related to business size evolution, the process of firms evolving from micro to small and medium-sized companies. We claim that a dynamic business population, with firms progressing relatively quickly from small to medium, contributes to the transformation and renewal of a regional economic growth path.

We examine these issues through the lens of the region of Wales. A framework linking regional economic resilience to firm size structure, evolution and heterogeneity is developed, before providing evidence of the significance of medium-sized companies in the Welsh economy and considering the implications for processes of regional resilience and resistance.

YOUTH PRECARIETY AND RESILIENCE IN ANGOLA'S SUB-URBAN SETTINGS

Jose Katito, Josefina Castellero

Universidade Óscar Ribas, Angola

ABSTRACT

Based on literature, this text summarizes a research project on youth precarity and resilience in Angola's sub-urban settings, with a special attention on macro structural factors of poverty that underpin precarity. The research adopts a critical-normative stance and intends to produce use-inspired knowledge, targeting policy makers and civil society organizations.

Following Peter Hall with Michèle Lamont (2009) and Jon Schubert (2017), an institutional-cultural approach is utilized in order to understand the way in which institutional practices and cultural repertoires combine to produce young youth precarity. This implies looking, interrelatedly, at the ineffectiveness or lack of state policies and deep-rooted cultural practices that are detrimental to progress. Cultural practices include immediatism and the high symbolic value placed on generating children regardless of material conditions. By its side, the institutional-cultural approach transcends both institutional accounts, which focus exclusively on the public policy, and those that concentrate on the role of culture in development process.

Angola has made significant progress over the last two decades since the end of the civil war in 2002, which virtually destroyed the country since its outbreak in the aftermath of independence in 1975. Peace and security have been largely established and the country is becoming an important global player, while emerging as a regional power in Africa, thanks to a booming oil economy (Oliveira, 2015; Veins & Weimer, 2011; Carvalho et al., 2011; Rodríguez et al. 2013; Power & Alves, 2012; Chabal, 2007).

Moving from these premises, the research project seeks to understand the strategies that sub-urban youth in Angola implement in the search for better material and symbolic resources, the manner in which such strategies unintentionally end up perpetuating their precarity in a context of poor public policies and traditional cultures that basically lack an orientation toward progress for sub-urban life.

The historicity of these processes will also be stressed, by taking into account the impact of pre-colonial, colonial and post-colonial social order, as well as that of the civil war, on sub-urban youth precarity (Soares, 2015). This last point is important inasmuch it complements the focus on institutional-cultural factors, as most sub-urban youth were pushed from the war-affected countryside to sub-urban areas — the former being more secure — or were born in sub-urban areas from families who fled rural areas to seek safety. This means that the civil war marked most young people's lives. Furthermore, peace and political stability, along with scarce state investments in rural areas, have together stimulated youth exodus from rural to sub-urban settings over the last two decades. As a consequence, the living conditions of urban youth have worsened and their expectations for a prosperous sub-urban life frustrated, caught between their expectations with regard to the impact of economic growth and political stability, on the one hand, and the burdens stemming from a combination of institutional practices and cultural repertoires, on the other.

TYOLOGIES OF AGRICULTURE AND THE DECISION TO INVEST IN FAMILY FARMS. A CHI-SQUARE ANALYSIS

Hélder Marcelino

Associação de Ciência Regional de Angola, Angola

ABSTRACT

This research aims to analyze the possible connection between the types of agriculture and the decision of investing in family farms. Specifically, it is intended to estimate the significance level of the types of agriculture influence on investment decisions making on family farms in the commune of Lepi, municipality of Longonjo, province of Huambo, Angola, based on the typification that suggest the criteria of market linking, type of labor and sources of income. For this purpose, an economic analysis was carried out, based on an empirical data obtained through a survey on 361 households in the mentioned location, testing three hypothesis with application of Chi-square analysis, desiring to measure an eventual connection between the variables, assuming that the greater the value, the greater the chance of connection between them. However, the chi-square does not refer to the strength of such connection. If its value is zero, there is no association among the variables. The variables are presented in contingency tables and in graphs. The null hypothesis was tested with a significance level of 0,05. The results indicates that there is no significant connection between the types of agriculture and the decision to invest in family farms, regardless of the relationship they establish with the market, the used type of labor and sources of income.

POOR PEOPLE ON THE OUTSKIRTS OF LUANDA CITY IN TIMES OF PANDEMIC: SOCIAL PRACTICES, HITS AND MISSES

Joaquim Calundungo

Universidade Agostinho Neto, Angola. Associação de Ciência Regional de Angola, Angola

ABSTRACT

This paper focuses on the social practices of peripheral populations of the city of Luanda.

The aim of this paper is to discuss the practices of subaltern populations and its initiatives, actions, and effects in the context of the global pandemic of Covid-19. Also, address a set of government strategies and measures that have been used as a reference for many of the social practices and, at the same time questions several other practices.

Henceforth, based on the approaches made by other authors, particularly in the social sciences, immersed in the treatment of the subject of the global pandemic, it was carried out a preliminary analysis of social practices and, qualitative approach, using various research techniques, such as observation, semi-structured interviews, observation, and focused interviews, as well as documentary analysis.

During the critical situation of the global pandemic, many governments, including the Angolan government started to integrate external models and references to deal with pandemic of Covid-19. At the national level, the efforts undertaken have mainly aimed to the population compliance with the guidelines and initiatives that advocate the defence of life and the minimization of the number of victims of covid-19.

The empirical studies have suggested that a set of practices related to the context of the pandemic of Covid-19 and the need for protection of its subjects and communities sometimes they align with (government) guidelines, some distance themselves or even ignore the guideline measures that can potentially protect the population of Angola.

It is concluded that, despite the fulfilment of some institutional measures by the population, there have also been a number of problematic effects that directly affect subaltern populations. It is also concluded that impoverished populations have shown immense difficulties in following and understanding many of the government guidelines and strategies, which has raised important aspects of the dialogue between leaders and governed and public policies in general.

CULTURAL TOURISM IN ANGOLA AND LOCAL DEVELOPMENT: A REALITY OR STILL A CHALLENGE?

Ziva Domingos

School of Hospitality Management and Tourism of Agostinho Neto University, Angola

ABSTRACT

The socio-economic and cultural changes and the challenges of globalization that are taking place today, across the world, accentuated by the pandemic crisis of Covid-19, call on the public authorities, agents of change and civil society to rethink development models, looking for placing "man" at the centre of their policies and strategies and rationally exploiting all resources in order to contribute to the improvement of the quality of life of local communities, through the eradication of poverty, which is one of the main objectives of sustainable development.

Angola is recognized as a country, not only with a rich economic potential, but also with a rich diversity of its tangible and intangible cultural heritage, constituting the true "substance" for the promotion of cultural tourism at the local and international level, and consequently, one of the means to achieve sustainable development in Angola, aiming at social justice, through the elimination of asymmetries and the promotion of equal opportunities, especially for the most vulnerable populations.

In the Angolan context, the real questioning of the "Tourism and Development" relationship lies in knowing what the impact of tourism has been, in this case, cultural tourism on local development; how cultural tourism has contributed to development aimed at local communities, at this time that Angola is taking on the challenge of deconcentration and decentralization of public power and governance and, at the same time, facing the global health crisis of Covid-19? Considering the current local realities and specificities and moments of crisis, could this binomial "Tourism and Development" in Angola, be already a fact or is it still a challenge? Such is the problem to which we intend to respond. If, on the one hand, the promotion of cultural tourism in Angola starts to take shape, even timidly, its impact on local development seems to be still negligible.

National Session: SS56.1 - The Colombian Economy and its Regional Structural Challenges

ELASTICITIES OF REGIONAL TOTAL FACTOR PRODUCTIVITY IN THE COLOMBIAN ECONOMY

[Carlos Espinel](#)¹, [Eduardo Haddad](#)²

¹Federal University of São Carlos, Brazil. ²University of Sao Paulo, Brazil

ABSTRACT

The principal aim of this paper is to evaluate the implicit total factor productivity (TFP) elasticity of each sector in the model by taking into consideration the Colombian regional structure with regard to national and regional output growth, in the long run. In order to reach this goal, a computable general equilibrium model (CGE) was specified: B-MCOL. The database that enables the use of the CGE model is the interregional input-output system for 2015 in Colombia estimated by The University of São Paulo Regional and Urban Economics Lab (NEREUS). The model is formed by productive sector, investors, household, federal government and regional government. There are 54 sectors responsible for production of goods in the 33 departments of Colombia. This simulation can be understood as the calculation of impacts on output growth given an increase in productivity in each of the sectors of the Colombian economy and this exercise will allow to identify from a new perspective the strengths and weaknesses of the Colombian economy that could be used to promote economic policies or restructure ongoing economic policies that no longer have significant effects. Empirical evidence over the years has strengthened the idea that differences in the stock of physical and human capital alone are not capable of explaining most of the differences in income among countries. In this case, the total factor productivity is a crucial element in explaining economic growth. The main objective of this research is to calculate the impacts of increased productivity in Colombia (by taking into consideration the Colombian regional structure) on output growth by estimating the set of implicit TFP elasticities in the context of the model, defining 1% shocks in TFP in each sector in each Colombian department. The sector that most affect national Gross Domestic Product (GDP) is the other services sector, followed by the industry sector. Bogotá is the region where increased productivity has the greatest impact on national GDP. Also, it has the greatest impact in the other regions as well. Almost 50% of the total growth after an increase in productivity is concentrated in three areas. The results of total factor productivity shocks showed that Colombia has a very concentrated economy, both regionally (Bogotá, as capital of the country and city that concentrates the largest portion of the national population, plays a starring role) as sectorally (other services and industry sectors with a significant share of the gross domestic product).

REVISITING THE STRUCTURAL INTERDEPENDENCE: A COMPARATIVE ANALYSIS FOR BRAZIL, COLOMBIA, AND MEXICO

[Fernando Perobelli](#)¹, [Geoffrey Hewings](#)²

¹Federal University of Juiz de Fora, Brazil. ²University of Illinois at Urbana Champaign, USA

ABSTRACT

The regional interdependence can be measured by different indicators. At this chapter we will address this issue analyzing the interdependence from the intermediate inputs side and from final demand side among Brazilian, Colombian, and Mexican regions using input-output database from 2013-2015. Which is the relevance in this kind of analysis? The analysis of the structure of regional interdependence plays an important role contributing to a better design of regional policy. According to Williamson (1965) regional inequality is an issue related to development. For the author, the inequalities are generated at the early stage of development and as far as an economy became mature there will be a process of regional convergence or at least, a decrease on it. To reach this aim we will use the final demand decomposition and the hypothetical extraction. We depart from the ideas of growth poles and central places (Perroux, 1955 and Christaller, 1933) to implement the regional hypothetical extraction and observe the impact of those regions upon the regional economies. On the other hand, this exercise enables us to measure the relative importance of the most important regions in each country upon the rest of the economies.

REGIONAL DIFFERENCES IN THE ECONOMIC IMPACT OF LOCKDOWN MEASURES TO PREVENT THE SPREAD OF COVID-19

Jaime Bonet¹, [Diana Ricciulli](#)¹, Javier Pérez¹, Eduardo Haddad², Inacio Araujo², Fernando Perobelli³

¹Banco de la República, Colombia. ²Sao Paulo University, Brazil. ³Universidade Federal de Juiz de Fora, Brazil

ABSTRACT

This paper analyzes the regional economic differences in the impact of lockdown measures ordered by Colombia's national government to prevent the spread of COVID-19. Using an input-output model, we estimate the regional economic losses of extracting a group of formal and informal workers from different sectors of the economy. Results show regional differences in the impact of lockdown measures on labor markets, local economies, and their productive sectors. We also find that peripheral regions concentrate a higher number of informal workers in isolation than the inner regions. Regarding the economic impact, regional losses range between 5,4% of GDP (Amazonia) and 6,3% (Coffee Area and Antioquia). Finally, we compare the Colombian case with other developing economies, articulating what the Colombian case can tell us that informs about other countries' experiences in fighting the COVID-19 pandemic.

SMART CITIES AND THE URBAN DIGITAL DIVIDE

[Andrea Caragliu](#)¹, [Chiara Del Bo](#)²

¹Politecnico di Milano, Italy. ²Università degli Studi di Milano, Italy

ABSTRACT

The debate on urban smartness as an instrument for planning and managing more efficient cities has been recently positing that smart cities could be raising inequalities. Several theoretical arguments have been presented in support of this claim, most revolving around the idea that the smart city movement would be driven by MNCs, which would persuade city managers of the need of investing in their devices, at the expense of segments of the population not ready to reap their benefits (Vanolo, 2014; Shelton et al., 2013). Following up on our own research carried out on the impacts of urban smartness (Caragliu et al., 2011; Caragliu and Del Bo, 2012) and Smart City policies (Caragliu and Del Bo, 2018 and 2019a), in Caragliu and Del Bo (2019b) we found that a negative relationship exists between urban smartness and the intensity of urban income inequalities, suggesting that Smart City features, if anything, help reduce income inequalities. In this work we instead empirically verify whether smart urban characteristics are associated to an increase in urban inequalities along the digital divide dimension among urban dwellers. In order to provide an empirical test of this hypothesis we exploit a large data base of 309 European cities, with data on smart urban characteristics, along with the measures of digital divide obtained with the use of survey data carried out at the EU level.

A POLITICAL-ECONOMY PERSPECTIVE ON MAYORAL ELECTIONS AND URBAN CRIME²⁷

[Amitrajeet A. Batabyal](#)¹, [Hamid Beladi](#)²

¹Department of Economics, Rochester Institute of Technology, 92 Lomb Memorial Drive, Rochester, NY 14623-5604, USA. Internet aabgsh@rit.edu, ²Department of Economics, University of Texas at San Antonio, One UTSA Circle, San Antonio, TX 78249-0631, USA. Internet Hamid.Beladi@utsa.edu

ABSTRACT

We provide a political-economy analysis of crime prevention in an arbitrary city in the United States. City residents (voters) elect mayors (politicians) and elected mayors determine the resources to be allocated to crime prevention. Between the two time periods, there is an election. Politicians are either honest or dishonest. The marginal cost of public monies ψ measures how efficiently an elected mayor converts tax receipts into crime prevention. Voters have identical per period utility functions. We ascertain the equilibrium outcome and per period voter well-being. Second, we show that an increase in ψ reduces the equilibrium allocation of resources to crime prevention and voter well-being. Third, a dishonest politician can delay the revelation of his dishonesty. A critical value of ψ , ψ^* , exists such that a dishonest incumbent separates and loses the election if and only if $\psi > \psi^*$ and he pools and is re-elected otherwise. Finally, we note that an increase in ψ can raise voter well-being when politicians are more likely to be dishonest.

1. INTRODUCTION

1.1. Preliminaries

The work of researchers such as Witte (1996) tells us that urban crime is a major issue for Americans. Complementing this point, Rainwater (2019) reminds us that in 2019, “public safety” was one of the top ten worries of mayors in cities throughout the United States (US). Because urban crime is a serious public policy problem, we can now find a large empirical and case-study based literature on this subject. Criminologists in particular and social scientists more generally have examined the ways in which a lack of economic opportunities, social disorganization, poverty, and the presence of unsupervised youth contribute to the presence and prevalence of urban crime.²⁸

Politics and politicians in the form of mayors clearly affect the ways in which the problem of city crime is understood and dealt with (Dunn, 2020). This notwithstanding, Marion and Oliver (2013) rightly point out that it simply does not make sense to only blame mayors for the prevalence of urban crime. What actually matters for crime prevention, says Asher (2020), are the policies adopted by a mayor and not his or her party affiliation. Given the clear connection between politics, politicians, i.e., mayors, and the efficacy of alternate crime prevention policies, it is pertinent to ask what economists and regional scientists have written about the nexuses between the behavior of city residents who vote to select their mayor and the urban crime fighting policies that are put in place by the elected mayor. Therefore, we now briefly discuss this literature and then proceed to the main questions that we study in our paper.

1.2. Literature review

Sharp (2006) examines the reasons for the disparity in the size of contemporary police forces in large cities in the US. Her detailed empirical analysis shows that the size differences in question can be explained by the legacy of the racial unrest during 1960-1970, racial disorders in the 1980s and 1990s, and by the prevalence of racial minorities in the current population. Does a mayor’s party affiliation influence urban crime rates? Using regression discontinuity design analysis, Ferreira and Gyourko (2009) demonstrate that whether a mayor is a Democrat or a Republican has no bearing on either crime rates or on the allocation of local public spending in large US cities.

Does a mayor’s gender have an impact on crime rates in a city? In their study of this question, Ferreira and Gyourko (2014) first point out that women’s participation in mayoral elections in the US increased from negligible numbers in 1970 to approximately one-third in the 2000s. Then, employing a regression discontinuity design, they point out that a

²⁸ See Ward (1976), Lynch (1981), Kohfeld and Sprague (1988), Hale (1996), White (1996), Gibbons (2004), Kourtit (2019), Lehmann (2019), and the many references cited in these sources for more on this and related issues.

mayor's gender has no bearing on city crime rates. Interestingly, this negative result holds in the short and in the long run. Thompson (2017) analyzes how two different fiscal stress labeling systems for municipal governments affect their functioning in Ohio. His econometric analysis shows that the actual label used to delineate a municipality has a minimal impact on both crime rates and on the employment of police.

Heberlig *et al.* (2017) utilize data for 104 cities during 1992 to 2012 and show that a reduction in the crime rate increases the likelihood that an incumbent mayor will seek another term in office. In addition and in contrast with the other mayoral accomplishments they study, a reduction in the crime rate seems to help mayors win re-election. Wiig (2018) describes how a citywide, multi-instrument surveillance network was used to complement the technologically mediated community policing in Camden, New Jersey. He points out that even though the success of this surveillance-driven community policing strategy in reducing crime was mixed, the strategy did succeed in providing Camden with a positive "ready for business" image.

Concentrating on Brazil, Ingram and da Costa (2019) study how the party identification of mayors, the partisan alignment of mayors and governors, electoral competition, and voter participation affect homicide rates. Geographically weighted regression analysis shows that the above four explanatory variables have dissimilar impacts on homicide rates across Brazil's 5562 municipalities. Finally, Batabyal *et al.* (2020) study the centralized versus decentralized provision of a controversial crime-fighting technology such as facial recognition software to the police in American cities. They show that there are circumstances in which the technology is provided with majority voting in a city even though it is inefficient to do so and that it is efficient to provide the technology in a city but majority voting will lead to this technology not being provided.

Our review of the literature leads to the following noteworthy conclusion. To the best of our knowledge, there are *no theoretical political-economy* studies that have analyzed the connections between the voting behavior of the residents of a particular city, the election of a mayor in this city, and the prevalence of crime in this same city.

1.3. Objectives

Given this lacuna in the literature, we adapt the analysis in Batabyal and Beladi (2020) and provide the *first* formal, political-economy analysis of urban crime that arises from the interaction between city residents (voters) and mayors (politicians) who promise to devote resources to the prevention of crime. The remainder of this paper is organized as follows.

Section 2 describes the two-period, political-economy model of crime prevention in an arbitrary city in the United States. In this model, city residents or voters elect mayors or politicians to office in each time period and elected mayors decide the extent of the resources to devote to crime prevention. Between the two time periods, there is an election. Politicians are either *honest* which means that they are genuinely interested and hence efficient in disbursing resources to fight crime or *dishonest* which means that they are less interested and thus inefficient in disbursing resources to combat crime. The marginal cost of public monies $\psi \geq 1$ measures how *efficiently* elected mayors convert tax receipts into crime prevention. All voters have identical per period utility functions. Section 3 computes the equilibrium outcome and per period voter well-being. Section 4 demonstrates that an increase in ψ reduces the equilibrium prevention of crime and voter well-being. Section 5 permits a dishonest politician to borrow money and thereby delay the revelation of his inefficiency. In this setting, a dishonest politician may seem to be honest and this influences his chance of getting elected mayor. This section solves for the equilibrium outcome and then demonstrates that there exists a critical value of ψ , ψ^* , with the property that the dishonest incumbent separates and loses the election if and only if $\psi > \psi^*$ and that he pools and is re-elected mayor otherwise. Section 6 points out that an increase in ψ can raise voter well-being when politicians are more likely to be dishonest. Section 7 concludes and then suggests two ways in which the research described in this paper might be extended.

2. THE THEORETICAL FRAMEWORK

Consider the interaction between residents and politicians seeking to be the mayor of an arbitrary city in the United States. There are two time periods in our model. Between the first and the second time period, there is an election to determine which politician will be elected mayor in the second period. Politicians differ in terms of how *honest* they are in genuinely wanting to reduce crime in the city under study. These politicians also differ in terms of the *efficiency* with which they are able to convert tax revenues into actual crime prevention. Voters are uncertain about the honesty of the politicians seeking to be elected mayor. Put differently, they are uncertain about how efficient politicians are in reducing crime in the city under study.

We suppose that politicians are honest with probability $p > 0$ and that they are dishonest with complementary probability $(1 - p) > 0$. We assume that an honest politician is also efficient in disbursing resources to fight crime and that a dishonest politician is relatively inefficient in disbursing resources to combat crime in the city under consideration.²⁹ We model this efficiency aspect of the story by supposing that an honest or efficient politician disburses resources to fight and thereby reduce crime at *low* cost. Similarly, a dishonest or inefficient politician distributes resources to combat and therefore lower crime at *high* cost. In symbols, an honest politician disburses resources for

²⁹ Following Sharp (2006) and for concreteness, we shall think of "disbursing resources" as being akin to contributing to the size of the city police force. So, in this way of looking at the issue, increasing (decreasing) the disbursement of resources is equivalent to raising (lowering) the size of the city police force. It is understood that all else being equal, a larger police force is likely to reduce crime by more than a smaller police force.

crime reduction at unit cost $\delta_L > 0$, a dishonest politician distributes resources for lowering crime at unit cost δ_H , and we have $\delta_H > \delta_L$.

All residents (voters) of the city under study have an identical per period quasi-linear utility function and this function is given by

$$U(R, T) = H(R) - \psi T, \tag{1}$$

where the function $H(\cdot)$ is differentiable, increasing, and concave, R denotes a crime index, T denotes taxes, and $\psi \geq 1$ represents the marginal cost of public monies. The reader should think of R as a crime index such as the NeighborhoodScout's crime index which ranks crime on a 0-100 scale and where 0 (100) is the least (most) safe that a city can be. The specific point to grasp here is that an increase (decrease) in R raises (lowers) a city resident's utility and is therefore desirable (undesirable).³⁰ Because the parameter ψ can be thought of as a measure of the scarcity of public resources in our city, an increase in ψ means that it is now *more* difficult for politicians to raise tax revenues to increase the size of the police force in our city. Without loss of generality and to keep the subsequent mathematical analysis transparent, we suppose that there is no discounting between the two time periods. Finally, $G > 0$ denotes the private gain to politicians from being elected mayor in the city under study.

With this description of the theoretical model out of the way, we are now in a position to solve for the equilibrium result that arises from the interaction between residents (voters) on the one hand and politicians on the other in our city and to then determine the per period well-being of the voters.

3. THE EQUILIBRIUM RESULT AND VOTER WELL-BEING

Let i denote the type of the incumbent mayor in office in our city in time period 1. Then, the value of the crime index that arises in this time period is given by the solution to the maximization problem

$$\max_{\{R\}} H(R) - \psi \delta_i R. \tag{2}$$

The first-order necessary condition for an interior solution to the above problem is given by the equation

$$H'(R^*) = \psi \delta_i, \tag{3}$$

where R^* is the optimal value of the crime index.³¹ We know that the $H(R)$ function is increasing and concave. From this it follows that the derivative $H'(R)$ is positive and decreasing in R . Using this last point, we deduce that

$$R_L^* \equiv R^*(\delta_L) > R^*(\delta_H) \equiv R_H^*. \tag{4}$$

The inequality in (4) tells us that the value of the crime index when the honest or low cost incumbent fights crime by raising the size of the city police force is *greater* than the value when a dishonest or high cost incumbent combats crime by increasing the size of the city police force. Our city voters observe the value of the crime index that emerges in the first time period and then they re-elect the honest incumbent and get rid of the dishonest incumbent in which case a new incumbent is elected to replace the dishonest incumbent as mayor.

If a dishonest politician is removed from office then the new incumbent will be honest and efficient with probability $p > 0$ and dishonest and inefficient with probability $(1 - p) > 0$. As such, suppose that in the first time period, the incumbent mayor in office is honest. Then, after observing the value of the crime index in our city, residents will re-elect this incumbent. In this case, an arbitrary city voter's per period well-being is

$$U = H(R_L^*) - \psi \delta_L R_L^*, \tag{5}$$

and therefore this person's total well-being is simply the sum of the two per period expressions given in equation (5) or $2U$.

On the other hand, if the incumbent mayor in the first time period is dishonest and inefficient then this incumbent will be removed from office. In this case, an arbitrary city voter's well-being in the first time period is

$$U_1 = H(R_H^*) - \psi \delta_H R_H^*. \tag{6}$$

This same voter's well-being in the second time period depends on whether the elected mayor turns out to be honest (this happens with probability p) or dishonest (this happens with probability $(1 - p)$). Consequently, this arbitrary city voter's second period well-being can be expressed as a weighted sum and that sum is

$$U_2 = p\{H(R_L^*) - \psi \delta_L R_L^*\} + (1 - p)\{H(R_H^*) - \psi \delta_H R_H^*\}. \tag{7}$$

Hence, in this second case, an arbitrary city voter's total well-being is given by the sum of the two expressions given in equations (6) and (7) or $U_1 + U_2$. We now proceed to show that a rise in the marginal cost of public monies or ψ reduces both the equilibrium value of the crime index and the well-being of voters in the city under study.

4. A RISE IN THE MARGINAL COST OF PUBLIC MONIES

Let us begin by totally differentiating the first-order necessary condition for an optimum given in equation (3). This gives us

$$H''(R^*)dR^* = \delta_i d\psi. \tag{8}$$

We now use the concavity of the $H(\cdot)$ function, which means that the second derivative of this function is negative, to obtain an expression that can be signed. That expression is

$$\frac{dR^*}{d\psi} = \frac{\delta_i}{H''(R^*)} < 0. \tag{9}$$

30 Go to <https://help.neighborhoodscout.com/support/solutions/articles/25000001997-what-is-the-crime-index-> for additional details about this index. Accessed on 3 December 2020.

31 Note that because the $H(\cdot)$ function is concave, the second-order sufficiency condition $H''(\cdot) \leq 0$ is satisfied.

Equation (9) shows that when the marginal cost of public monies or ψ increases, the equilibrium value of the crime index *falls*. This result arises because an increase in ψ means that it is now *more* difficult to raise the tax revenues that will be used to increase the size of the city police force and thereby reduce crime.

To demonstrate the validity of a similar claim for the well-being of voters in the city under study, we use a well-known result in microeconomic theory, namely, the envelope theorem.³² Now, recalling equation (1) and then using the envelope theorem, we get

$$\frac{dU(R_i^*)}{d\psi} = \frac{\partial U(R_i^*)}{\partial \psi} = -\delta_i R_i^* < 0. \tag{10}$$

The right-hand-side (RHS) of equation (10) clearly tells us that an increase in the marginal cost of public monies or ψ *lowers* the well-being of voters in our city in *both* time periods and for *both* possible types of incumbent politicians (honest or dishonest). This negative finding strengthens the previous finding in equation (9) that an increase in ψ lowers the equilibrium value of the crime index R^* . Specifically, since the RHS of equation (10) depends on R^* which is lower, it follows that the well-being of voters in our city is also lower. We now proceed to analyze the case in which a dishonest politician is able to hide the fact that he is dishonest by borrowing monies and thereby delaying the revelation of his inefficiency to our city voters.

5. A DISHONEST POLITICIAN SEEMING TO BE HONEST

The modeling framework now is basically the same as the framework described in section 2 but there is one salient difference. Specifically, a dishonest incumbent can *delay* the revelation of his dishonesty and inefficiency by borrowing money denoted by $M > 0$. This borrowing is observable to our city voters only after the election at the end of the first time period. In addition, this borrowing by a dishonest incumbent permits him to appear honest because he can act as if the unit cost of raising the crime index or lowering crime is low when it is, in fact, high. The reader should note that this course of action also results in the creation of a budget deficit in an election year.

In the first time period, the incumbent mayor observes the unit cost $\delta \in \{\delta_L, \delta_H\}$. He then selects the value of the crime index or the amount by which crime is to be reduced R and the amount of money M that he would like to borrow. These two actions lead to a total tax bill given by $T = \delta R - M$. Next, our city voters observe the choices of R and T before the election. On the basis of these two observations, voters draw a conclusion about the incumbent mayor's type. The incumbent is re-elected if he is at least as likely to be honest as a rival who is honest with prior probability $p > 0$ and dishonest with prior probability $(1 - p) > 0$. In the second time period, the politician then in office again selects R given δ and he repays the money M he borrowed in the first time period. These two actions give rise to a tax bill denoted by $T = \delta R_\delta + M$. No additional elections take place in our model.

There are now two tasks to complete. First, we would like to compute the equilibrium outcome that arises in the interaction between our city voters and politicians. Second, we want to establish that there exists a critical value of ψ, ψ^* , with the property that the dishonest incumbent *separates* and loses the election if and only if $\psi > \psi^*$ and that he *pools* and is re-elected otherwise.³³

We begin by pointing out that voters do *not* observe either the incumbent's type δ or the money M that he has borrowed before the election. Therefore, in a pooling equilibrium, the following equality

$$\delta_H R_L^* - M = \delta_L R_L^* \tag{11}$$

must hold. An implication of equation (11) is that in order to bewilder voters into thinking that he is honest, a dishonest incumbent mayor will borrow

$$M = (\delta_H - \delta_L) R_L^* \tag{12}$$

in the first time period. Since this borrowed money must be paid back in the second time period, a dishonest incumbent will choose to pool and be re-elected mayor if and only if the borrowed quantity M is no larger than $2G$ which is his private gain from being mayor for two time periods. In symbols, the inequality that must hold is

$$2G \geq (\delta_H - \delta_L) R_L^*. \tag{13}$$

Now, supposing that the expression in (13) holds as an equality, we get

$$R_L^*(\psi^*) = \frac{2G}{\delta_H - \delta_L}. \tag{14}$$

Using equation (3), we can simplify the expression in equation (14) and, simultaneously, infer the critical value of ψ, ψ^* that we are looking for. We get

$$\psi^* = \frac{1}{\delta_L} H' \left(\frac{2G}{\delta_H - \delta_L} \right). \tag{15}$$

We have already demonstrated in section 4 that the optimal value of the crime index R_L^* is a *decreasing* function of the marginal cost of public monies ψ . This last result tells us that when ψ increases, the left-hand-side (LHS) of (13) decreases. This allows us to conclude that for all $\psi > \psi^*$, (13) holds as a strict inequality and hence we get a separating equilibrium. In this equilibrium, a dishonest incumbent mayor will choose to separate and lose the election at the end of

32 See Varian (1992, pp. 490-492) for a textbook description of the envelope theorem.

33 The game we are analyzing here is a "signaling game" which is one kind of dynamic game of incomplete information. Standard equilibria to analyze in signaling games are the "pooling" and "separating" equilibria. Now, as in our present analysis, consider a signaling game with two kinds of players, i.e., politicians and voters. In a pooling equilibrium, all *types* (honest or dishonest) of a specific kind of player (in our case politicians) send the *same* message or signal to the other kind of player (in our case voters). This interaction between politicians and voters leads to a pooling equilibrium. In contrast, when the different types of politicians (honest or dishonest) send *different* messages or signals to the voters, the ensuing interaction between politicians and voters leads to a separating equilibrium. For more on these ideas, the reader ought to consult a standard game theory text such as Fudenberg and Tirole (1991).

the first time period. In contrast, when $\psi \leq \psi^*$, this incumbent mayor will effectively pool and be re-elected mayor in the second time period.

Before continuing further, let us stress three points about our analysis thus far. First, an inefficient incumbent politician's ability to borrow money M does not ensure that he will be re-elected mayor in the election after the first time period. The purpose of borrowing M is to bewilder voters into thinking that an inefficient mayor is efficient. If voters believe this attempt to bewilder them then this makes re-election more likely but not certain for the inefficient incumbent mayor. Second, the $2G$ term on the LHS of (13) makes sense because the per period private gain from being elected mayor is the constant G and we are accounting for this private gain over two time periods in (13). Finally, in general, there is nothing necessarily untoward about an elected politician borrowing money, promising to pay it back in an ensuing time period, and thereby creating a budget deficit. This happens and hence we now have a literature on the "political budget cycle."³⁴ That said, our final task in this paper is to demonstrate that a rise in ψ can increase voter well-being when politicians are more likely to be dishonest.

6. A SECOND RISE IN THE MARGINAL COST OF PUBLIC MONIES

Upon reflection, it is easy to confirm that in the pooling equilibrium that we have been discussing, the well-being of voters differs only in the second time period. Hence, before the resolution of uncertainty about δ and M , voter welfare in the two time periods under study is given by

$$U_1 = H(R_L^*) - \psi \delta_L R_L^* \tag{16}$$

and

$$E[U_2] = p\{H(R_L^*) - \psi \delta_L R_L^*\} + (1-p)\{H(R_H^*) - \psi(\delta_H R_H^* + M)\}, \tag{17}$$

where $E[\cdot]$ is the expectation operator.

To figure out the effect of the marginal cost of public monies ψ on voter well-being over the two time periods in our city, we differentiate the sum $U_1 + E[U_2]$ with respect to ψ . This gives us

$$\frac{d(U_1 + E[U_2])}{d\psi} = -(1+p)\delta_L \delta R_L^* - (1-p)(\delta_H R_H^* + M) - (1-p)\psi \frac{dM}{d\psi}. \tag{18}$$

In order to sign the expression on the RHS of equation (18), we need to first sign the derivative $dM/d\psi$. To do so, we differentiate equation (12), keeping in mind the dependence of R_L^* on ψ . This gives us

$$\frac{dM}{d\psi} = (\delta_H - \delta_L) \frac{dR_L^*}{d\psi} < 0 \tag{19}$$

and the sign of the expression on the RHS of equation (19) follows from the fact that R_L^* is a decreasing function of ψ .

Let us now use the result in equation (19) to ascertain the sign of the derivative in equation (18). After several algebraic steps, we infer that the well-being of voters in our city *might* increase with a rise in ψ as long as the inequality below

$$-\psi \frac{dM}{d\psi} > \frac{1+p}{1-p} \delta_L R_L^* + \delta_H R_H^* + M \tag{20}$$

holds. A careful review shows that the RHS of the inequality in (20) is *increasing* in the probability p . Therefore, the likelihood that the condition in (20) will hold is higher when p is *small*. In turn, this last inference suggests that the condition in (20) will hold more often than not when $(1-p)$ is large and this means that the politician under consideration is more likely to be dishonest.

Why does this counterintuitive result hold? To answer this question, observe that in comparison with dishonest politicians, we generally expect honest politicians to make our city safer by raising the crime index to a higher value. All else being equal, this increased value of the crime index makes the residents of our city better off. However, in order to fund the increase in the size of the city police force that makes the city safer and hence voters better off, politicians need to raise tax revenues and this taxation influences the well-being of voters negatively.

Now remember that the marginal cost of public monies or ψ measures how hard it is for politicians to raise tax revenues. In our setting, when we allow dishonest politicians to appear honest, there is a range of values for ψ ($\psi \leq \psi^*$) where dishonest politicians effectively appear to be honest. The interaction of this "range of values for ψ " with the magnitude of the probability p gives rise to scenarios in which the activities of dishonest politicians *may* raise the well-being of voters in our city. This completes our political-economy perspective on mayoral elections and urban crime.

7. CONCLUSIONS

In this paper, we provided a political-economy analysis of crime prevention in an arbitrary city in the United States. City residents (voters) elected mayors (politicians) and elected mayors determined the resources to be allocated to crime prevention. Between the two time periods, there was an election. Politicians were either honest or dishonest. The marginal cost of public monies ψ measured how efficiently an elected mayor converted tax receipts into crime prevention. Voters had identical per period utility functions. We ascertained the equilibrium outcome and the per period well-being of the voters. Second, we showed that an increase in ψ reduced the equilibrium allocation of resources to crime prevention and voter well-being. Third, a dishonest politician could delay the revelation of his dishonesty. We showed that a critical value of ψ , ψ^* , existed such that the dishonest incumbent separated and lost the election if and only if $\psi > \psi^*$ and that he pooled and was re-elected otherwise. Finally, we noted that an increase in ψ could raise voter well-being when politicians were more likely to be dishonest.

The analysis in this paper can be extended in a number of different directions. Here are two potential extensions. First, it would be useful to distinguish between *different kinds* of criminal activity in a city and to then see what impact different

³⁴ See Waknis (2014), Bohn (2019), Ferris and Dash (2019), and the references cited in these papers for additional details about this literature.

kinds of crime reducing activities undertaken by the police in one time period have on the electability of mayors and on the well-being of residents in subsequent time periods. Second, it would also be helpful to study criminal activity in a set of cities where the actions of a “tough-on-crime” mayor in one city drives criminals to other cities and hence gives rise to crime related *spatial spillovers*. Studies of crime prevention in cities that incorporate these aspects of the problem into the analysis will provide further insights into how the interactions between politicians (mayors) and voters (residents) can lead to lower crime and hence to higher well-being for all involved parties.

THE SILVER ECONOMY IN EUROPEAN CITIES

Carolina Foglia, Maria Laura Parisi, [Nicola Pontarollo](#)

University of Brescia, Italy

ABSTRACT

In 2018, 101.1 million of EU citizens were over 65, nearly 20% of the total population that will become 28.5% in 2050. The ageing population poses challenges not only for welfare systems sustainability, but also in terms of suitability of goods and services, that should be adapted to the needs of older people, the so-called Silver Economy. This paper concerns the opportunities of the Silver Economy in European cities, investigating their readiness to host an increasing number of senior citizens with their needs, and the vast range of challenges and opportunities that the ageing population represents for European policy makers.

Using representative microdata coming from a recent “Perception Survey on the Quality of Life (QoL) in European Cities, 2019” by the Directorate-General for Regional and Urban Policy for 83 European cities, we assess their suitability for the elderly and which of the factors identified by mainstream literature contribute more to it. To achieve this aim, on the subset of over 65, we correlate to a dichotomous dependent variable identifying if a city is (or is not) a good place to live for elderly people a set of covariates falling into the following macro areas: i) development of an age-friendly built environment; ii) knowledge for an active and healthy lifestyle; iii) integrated care services and improved connectivity; iv) olderpreneurship. Finally, we assess the relative contribution of each regressor to the explained variance.

Our results have various policy implications. First, ranking cities according to their suitability to old people we can identify relevant patterns in Europe. Second, the recognition of the relative importance of each regressor, together with its significance and sign, provides a powerful tool to assess the relevance of each macro area, and of each component, allowing to identify the most appropriate policy interventions and the place to intervene.

Regular Session: RS14.1 - The spatial dimension of sustainable development

DOES PRIOR PERFORMANCE ACROSS SDGS RELATE TO THE SUCCESS AGAINST COVID-19? A COUNTRY-LEVEL ANALYSIS

Damla Benli, Arzu Ece Cetin, Gokcen Arkali Olcay

Department of Management, Gebze Technical University, 41400, Gebze, Turkey, dbenli@gtu.edu.tr, aecetin@gtu.edu.tr, gaolcay@gtu.edu.tr

ABSTRACT

The COVID-19 captured the whole world dragging into a crisis with major health, economic, and social dimensions since it is officially characterized as a pandemic by the World Health Organization. Not only do the countries of all suffer from COVID-19 related infections and deaths, but also they face a severe economic slowdown, unemployment, job losses, and food insecurity, among many other devastating effects of the pandemic. Besides, there is a great amount of uncertainty that makes the decision-making even harder for governments despite living with pandemic for more than a year. The 2020 sustainable development report by the United Nations points to the uneven effects of the COVID-19 for countries on achieving the sustainable development goals (SDGs) for 2030. Developing countries have already suffered severely from the pandemic, which is more unlikely for them to achieve sustainable development goals, and this may even worsen their positions across many individual SDGs. However, some developed countries with strong economies and high sustainability indices also do not appear to control the pandemics more effectively than others. Other characteristics such as the demographical structure, policy approaches, and the regional and contextual factors are likely to play a role in the battle towards the pandemic. Thus, we explore how the country's prior sustainability index might mitigate or facilitate its COVID-19 performance. We choose the members of G-20 due to their wide spatial distribution across all continents of the earth, the large share of the world population, and high representation of the overall GDP. We analyze the two-way relations between the sustainability index and various metrics of COVID-19 in four different quadrants. When countries with high sustainability index put high efforts towards combatting COVID-19, some get better outputs, such as lower deaths related to COVID-19 while others do not. Our initial analyses result in clusters of G-20 countries that differ by their sustainability levels and various performance and effort measures of COVID-19. The interpretation of the clusters of countries will shed light on the regional, demographic, and country-specific characteristics that make their battle against the pandemic a success or failure. Moreover, the real test with a pandemic reveals the susceptibility of the existing sustainable development goals, resulting in more unmet SDGs for 2030 than expected. Policymakers, governments, international and local organizations, and other stakeholders can benefit from this study in revising and building policies in sustainable development.

KEYWORDS

COVID-19, G-20 countries, regional factors, sustainability index, sustainable development goals (SDGs)

1. INTRODUCTION

The emergence of COVID-19 has resulted in millions of lost lives with severe economic and social damage. The human race has shown enormous effort in the battle with the pandemic since its emergence, already with several vaccines developed and used worldwide. Despite the scientific and technological success, the COVID-19 pandemic demonstrated how vulnerable the economic and social systems we built and the resources we rely on. We have seen many wealthy countries suffered in a great deal in terms of lost lives and the inability to provide the proper medical treatment to the COVID-19 patients. At the same time, some countries have handled the pandemic much better, managing to control the spread of the disease by developing timely strategies and policies. The great variability amongst the countries makes us question their sustainability. Is it because they have built more sustainable and resilient systems? Or how does the prior progress across sustainable development goals relate to the performance in dealing with such a rapidly spreading pandemic?

The latest report on sustainable development goals by the United Nations (Sachs et al., 2020) points out how the impacts of COVID-19 have increased the inequality between countries. Many developing countries were already facing difficulties in achieving the 2030 targets for the SDGs before the outbreak of the COVID-19. On the other hand, countries with high SDGs were expected to manage this process better since they have better health infrastructure and well-established institutions. Although there are indications of these, some countries do not fully conform to this classification. The difference in managing performance of COVID-19 could also be attributed to the different policies such as closing schools, restricting transportation, and directing businesses to work from home that they implement.

All these issues point out that sustainable development goals should be examined and re-evaluated in the light of changing circumstances with the effects of the COVID-19. Besides, it should be taken into account that each country handles this pandemic in different ways and reacts with different policies to prevent it. We perform country-level descriptive analyses to explore the nexus between performance across sustainable development goals and the COVID-19

measures. We choose G-20 countries for their broad representation in terms of both the world economy and population. In order to simplify the analyses and to be able to see the effects of different variables at the same time, we classify the countries into four quadrants using a two-way matrix. The quadrants are formed according to two factors: sustainability index showing the country's progress across seventeen SDGs and total tests per one thousand population.

Our analyses reveal different characteristics of the countries in different quadrants. Not all countries were affected to the same degree. The cumulative cases and deaths appear to be higher for countries in quadrants with higher sustainability indices. Such countries are also inclined to perform more tests than the overall median number of tests conducted in our sample. There are also exceptions, such as Canada and Germany deviating from their peers in the same quadrant with fewer deaths and cases. Among the countries in quadrants with relatively low sustainability indices, Mexico has much higher death rates than its peers in the same quadrant. Regarding the effects of the policies that countries adopt during the pandemic, a higher stringency index does not appear to affect the country's response measures such as cumulative deaths and cases nor the effort measured in the total number of tests.

The remainder of this study is organized as follows. Section 2 discusses the relationship between COVID-19 and sustainable development goals in a comprehensive manner. We explain the data and methodology in section 3. Finally, Section 4 provides conclusions and discussions for possible future research directions.

2. THE NEXUS BETWEEN COVID-19 AND SUSTAINABLE DEVELOPMENT GOALS

2.1. Confronting the COVID-19 pandemic while tackling 2030 Agenda for SDGs

When the United Nations (UN) declared the 2030 Agenda for Sustainable Development in 2015, they described the challenges to sustainable development that our world faces at that time. According to the declaration, there are huge disparities within and among the countries in terms of power, opportunities, wealth, and gender (United Nations, 2015). Besides, there are other major problems such as gender inequality, unemployment, depletion of natural resources, global health threats, and natural disasters. The 2030 Agenda acknowledges the risk associated with the immense issues and the opportunities that arise with them as follows, "*The survival of many societies, and of the biological support systems of the planet, is at risk. It is also, however, a time of immense opportunity. Significant progress has been made in meeting many development challenges.*"

The latest report for the Sustainable Development Goals by the UN before the outbreak of the pandemic was released in 2019, revealing the progress against the targets of the 2030 Agenda. While the progress in critical areas was valuable, it is not sufficient to achieve the 2030 Agenda since poverty, hunger, and disease continue to be a problem for low and middle-income countries (United Nations, 2019). The progress towards the 2030 goals has been limited, which turned upside down with the pandemic outbreak. World Health Organization (WHO) declared the COVID-19 as a pandemic on March 11, 2020, which had resulted in more than 118,000 cases and 4,291 lost lives in 114 countries within a few months of its appearance (WHO, 2020). After a year, total cases have exceeded 125 million, with more than 2.5 million deaths (Worldmeter, 2021) along with devastating effects in the world economies, health systems, and social lives. Vaccinations that have started in the mid of December 2020 have been the hope to exit the tunnel for going back to normal; however, only 4% of the world population were vaccinated one year after the outbreak (Worldmeter, 2021).

The COVID-19 pandemic's effects have already been substantial in all aspects of individual lives all over the world. Evaluating sustainable development goals will be pointless without considering the impact of the ongoing outbreak of COVID. Naidoo and Fisher (2020) identify sustainable economic growth and globalization as the two conditions required for the success of SDGs where the pandemic COVID-19 has broken up both resulting in greater uncertainties for the future. The 2020 Sustainable Development Report by the United Nations draws attention to the pandemic's uneven effects on countries with vulnerable population groups, low-quality public health systems, or poor leadership (Sachs et al., 2020). While developing and underdeveloped countries are more likely to suffer more from the pandemic's negative impact, the number of cases and deaths due to the COVID-19 has surpassed others among many wealthy nations.

2.3. Is COVID a Threat for SDGs?

Due to its scope and economic impact, Filho et al. (2020) consider COVID-19 a major threat to achieving the UN sustainable development goals. The authors anticipate the most obvious effects to occur in SDGs 1 (No poverty), 2 (Zero hunger), 3 (Good health and well-being), 4 (Quality education), 5 (Gender equality), 8 (Decent work and economic growth), 10 (Reduced inequalities), and 16 (Peace, justice and strong institutions). Within a short time frame since the pandemic outbreak, several other studies highlight similar issues that are likely to be major obstacles to achieving sustainable development worldwide. Sumner et al. (2020) estimate the increase in poverty to be more than 80 million for the US \$ 1.9/day critical line relative to the 2018 numbers assuming a 5% contraction in per capita incomes. This number would be 180 million and 420 million if the contraction in per capita incomes is assumed to be 10% and 20%, respectively.

Mukarram (2020) anticipates the effects of COVID-19 on sustainable development goals to be two-folded. First, the prior achievements on some of the SDGs will be lost due to the direct effects of COVID-19 on these goals. Secondly, countries face the necessity to shift the priorities among SDGs, affecting the progress of the goals that are shifted down in the priority lists. Considering these effects on SDGs, Mukarram (2020) suggests reformulating sustainable development strategies during and after the post-pandemic period, focusing on SDG 17 (Partnerships to achieve the goals).

On the other hand, there are opinions anticipating the COVID-19 might indeed stimulate the efforts to realize the UN's 2030 goals working as a catalyst (Ottersen & Engbretsen, 2020). While the pandemic delayed the working progress for

all countries, there are many other ways to mitigate the adverse effects on sustainable development goals, such as developing and practicing digital sustainability (Pan & Zhang, 2020).

3. METHODOLOGY AND EMPIRICAL ANALYSES

3.1. Data and Variables

In understanding how prior performance across SDGs relate to the success against COVID-19, we have conducted descriptive analyses of the COVID-19 related variables and the Sustainability Index (SI) for the sample of countries that we consider. We have chosen three different variables to associate with the COVID-19 pandemic: total cases, total deaths, and total tests. Because of the different population sizes of the countries in our sample, we used the normalized versions of these variables to get a more accurate depiction of the comparison among these countries. While total cases and total deaths are scaled by one million, the total tests are normalized by one thousand as calculated and revealed by the data generated at ourworldindata.org (Ritchie et al., 2021). Total cases represent the cumulative number of confirmed cases whose infection status has been verified by the laboratory tests. The number of confirmed cases comes out of another source of data which is the total tests. The number of tests allows us to see countries' performance, which acts as a critical indicator of how much effort countries are making in handling the pandemic process.

In addition to the three variables, we also used the country's stringency index, which is an indicator of how strict the policies implemented by the government during the pandemic. This index, a composite measure of nine response metrics (school closures, workplace closures, cancellation of public events, restrictions on public gatherings, closures of public transport, stay-at-home requirements, public information campaigns, restrictions on internal movements, and international travel controls), is developed by the Oxford Coronavirus Government Response Tracker (OxCGRT) project. The data on Covid-19 variables, which are utilized in the descriptive analyses, have been obtained from the website of ourworldindata.org (Ritchie et al., 2021).

To reflect on the sustainability performance of countries, we have used the sustainability index developed by the United Nations. The sustainability index monitors the countries' progress and assesses their relative positions in achieving the 2030 targets in which all 17 goals are equally weighed (Sachs et al., 2020). The 17 goals and descriptions of them are presented in Table 1. We have used the most recent scores of countries calculated via SI in 2019 in our analyses.

Table 1. Sustainability Development Goals (SDG) and descriptions*

SDG	Description
Goal 1.	End poverty in all its forms everywhere
Goal 2.	End hunger, achieve food security and improved nutrition, and promote sustainable agriculture
Goal 3.	Ensure healthy lives and promote well-being for all at all ages
Goal 4.	Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all
Goal 5.	Achieve gender equality and empower all women and girls
Goal 6.	Ensure availability and sustainable management of water and sanitation for all
Goal 7.	Ensure access to affordable, reliable, sustainable, and modern energy for all
Goal 8.	Promote sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all
Goal 9.	Build resilient infrastructure, promote inclusive and sustainable industrialization, and foster innovation
Goal 10.	Reduce inequality within and among countries
Goal 11.	Make cities and human settlements inclusive, safe, resilient, and sustainable
Goal 12.	Ensure sustainable consumption and production patterns
Goal 13.	Take urgent action to combat climate change and its impacts
Goal 14.	Conserve and sustainably use the oceans, seas and marine resources for sustainable development
Goal 15.	Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss
Goal 16.	Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels
Goal 17.	Strengthen the means of implementation and revitalize the Global Partnership for Sustainable Development

*Source: <https://sdgs.un.org/goals>

In this study, we have chosen G20 countries to form the sample of countries for our analyses. G20 countries include *Argentina, Austria, Brazil, Canada, China, France, Germany, India, Indonesia, Italy, Japan, Mexico, Russia, Saudi Arabia, South Africa, South Korea, Turkey, UK, the USA, and the European Union*. The reason we choose these countries is that they account for two-thirds of the world's population, 85% of global gross domestic product, more than 75% of global trade, and about 80% of global energy-related carbon dioxide emissions. While 19 members of G20 are individual countries, the European Union represents the 27 countries that could not be analyzed as a whole due to the design of our study. Because the efforts countries make towards handling the pandemic vary greatly, the assessment needs to be made at the country level. Besides, the sustainability index is a country-based measure that simply cannot be accumulated over a region. Thus, we have included the European Union countries as separate countries in our sample. However, in order not to overcrowd the sample, we have included the member countries within the EU with a total population of over ten million. Overall, nine countries were added to the sample, which account for approximately 80% of the European Union population.

3.2. Quadrant Analyses of the Sample Countries

To analyze the two constructs together (i.e., COVID-19 and sustainability), we have created a matrix of one designated variable for COVID-19 and another one for the performance of sustainable development goals. The variable *total tests* was chosen as the designated variable for COVID-19 since it represents the country's efforts to deal with the pandemic. The other variable in the matrix is the sustainability index we use to evaluate the progress towards achieving the SDGs. Considering the matrix of the two variables, we come up with four quadrants, as shown in Figure 1. Each of the countries in our sample is positioned in a quadrant according to the values it assumes for the two variables relative to the overall median values for all countries. The circumstances of the countries in these quadrants can be explained as follows:

- **Quadrant 1 (Q1):** Countries with a high sustainability index and carrying out a high number of tests
- **Quadrant 2 (Q2):** Countries with a low sustainability index and carrying out a high number of tests
- **Quadrant 3 (Q3):** Countries with a low sustainability index and carrying out a low number of tests
- **Quadrant 4 (Q4):** Countries with a high sustainability index and carrying out a low number of tests

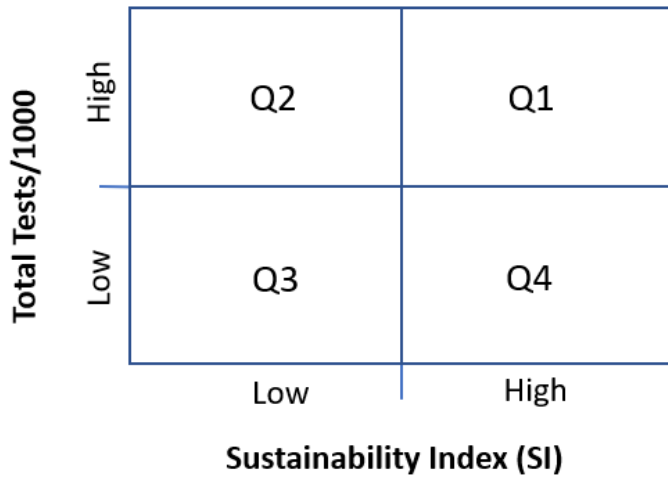

Figure 1. Matrix representation for the two variables: *Total tests/1000 & Sustainability index*

The quadrant depiction of Figure 1 allows us to classify the countries in our sample, as shown in Figure 2. Most countries are classified either in Q1 or Q3, where there are ten countries in each quadrant. The countries in Q2 have SI levels lower than the overall median; however, they conduct more tests than the overall median. There are four countries placed in this quadrant: Italy, the USA, Greece, and Russia. Similarly, there happen to be four countries in Q4 that are Poland, Netherlands, Japan, and South Korea. While these countries have high SI levels, they conduct fewer tests relative to the overall median of all countries.

Figure 2. The distribution of countries across the four quadrants

Combining the two constructs into one in the form of quadrants allows us to analyze how countries in these quadrants differ in two other major indicators of COVID-19 performance: total cases and total deaths. We develop a cross table where we classify the countries in four quadrants according to their status in total cases and total deaths relative to the overall median for both variables. In Table 2, each quadrant is divided into four sub-categories subject to the number of cases and deaths in the countries. Considering the variables total cases and total deaths as proxies for the success of COVID-19, the rows in Table 2 allow us to analyze the performance of countries within each quadrant. We make three different analyses using the quadrant scheme as the basis.

Table 2. Classification of countries in quadrants subject to the number of cases and deaths

	High Cases & High Deaths	High Cases & Low Deaths	Low Cases & High Deaths	Low Cases & Low Deaths
High SI & High Tests Q1	Belgium, Czech Republic, UK, France, Spain, Portugal, Sweden	Austria		Canada, Germany
Low SI & High Tests Q2	Italy, USA			Greece, Russia
Low SI & Low Tests Q3	Argentina, Brazil		Mexico, Romania	China, India, Indonesia, Saudi Arabia, South Africa, Turkey
High SI & Low Tests Q4	Poland	Netherlands		Japan, South Korea

3.2.1. How do Countries in Different Quadrants Differ in Total Cases and Total Deaths?

Considering all four quadrants together, we first investigate how total cases and total deaths change with the country’s sustainability index. We have two plots to illustrate this. Figure 3a (3b) shows total cases (total deaths) relative to the sustainability index. In both plots, to differentiate the high SI countries (Q1 and Q4) from low SI ones (Q2 and Q3), we have used different colors for these pairs. Moreover, we depict the number of tests with the bubble sizes in these graphs. We can make several insights based on the analyses of Figure 3. We observe that total cases and total deaths in general increase with the sustainability index of the countries. High SI countries characterized by blue color (in quadrants Q1 and Q4) tend to have higher cases and higher deaths except for a few countries: Canada, Germany, Japan, and South Korea. Besides, most of these countries conduct a high number of tests relative to the overall median of all countries, as shown by the large bubble sizes. On the other hand, low SI countries shown in orange tend to have lower cases and deaths. The bubble sizes are in general smaller, highlighting that these countries conduct fewer tests than the others. However, some countries are deviating from the general trend here. Amongst the low SI countries, the USA, Italy, Argentina, and Brazil have relatively higher cases and higher deaths. Moreover, Mexico and Romania have higher deaths despite the low cases.

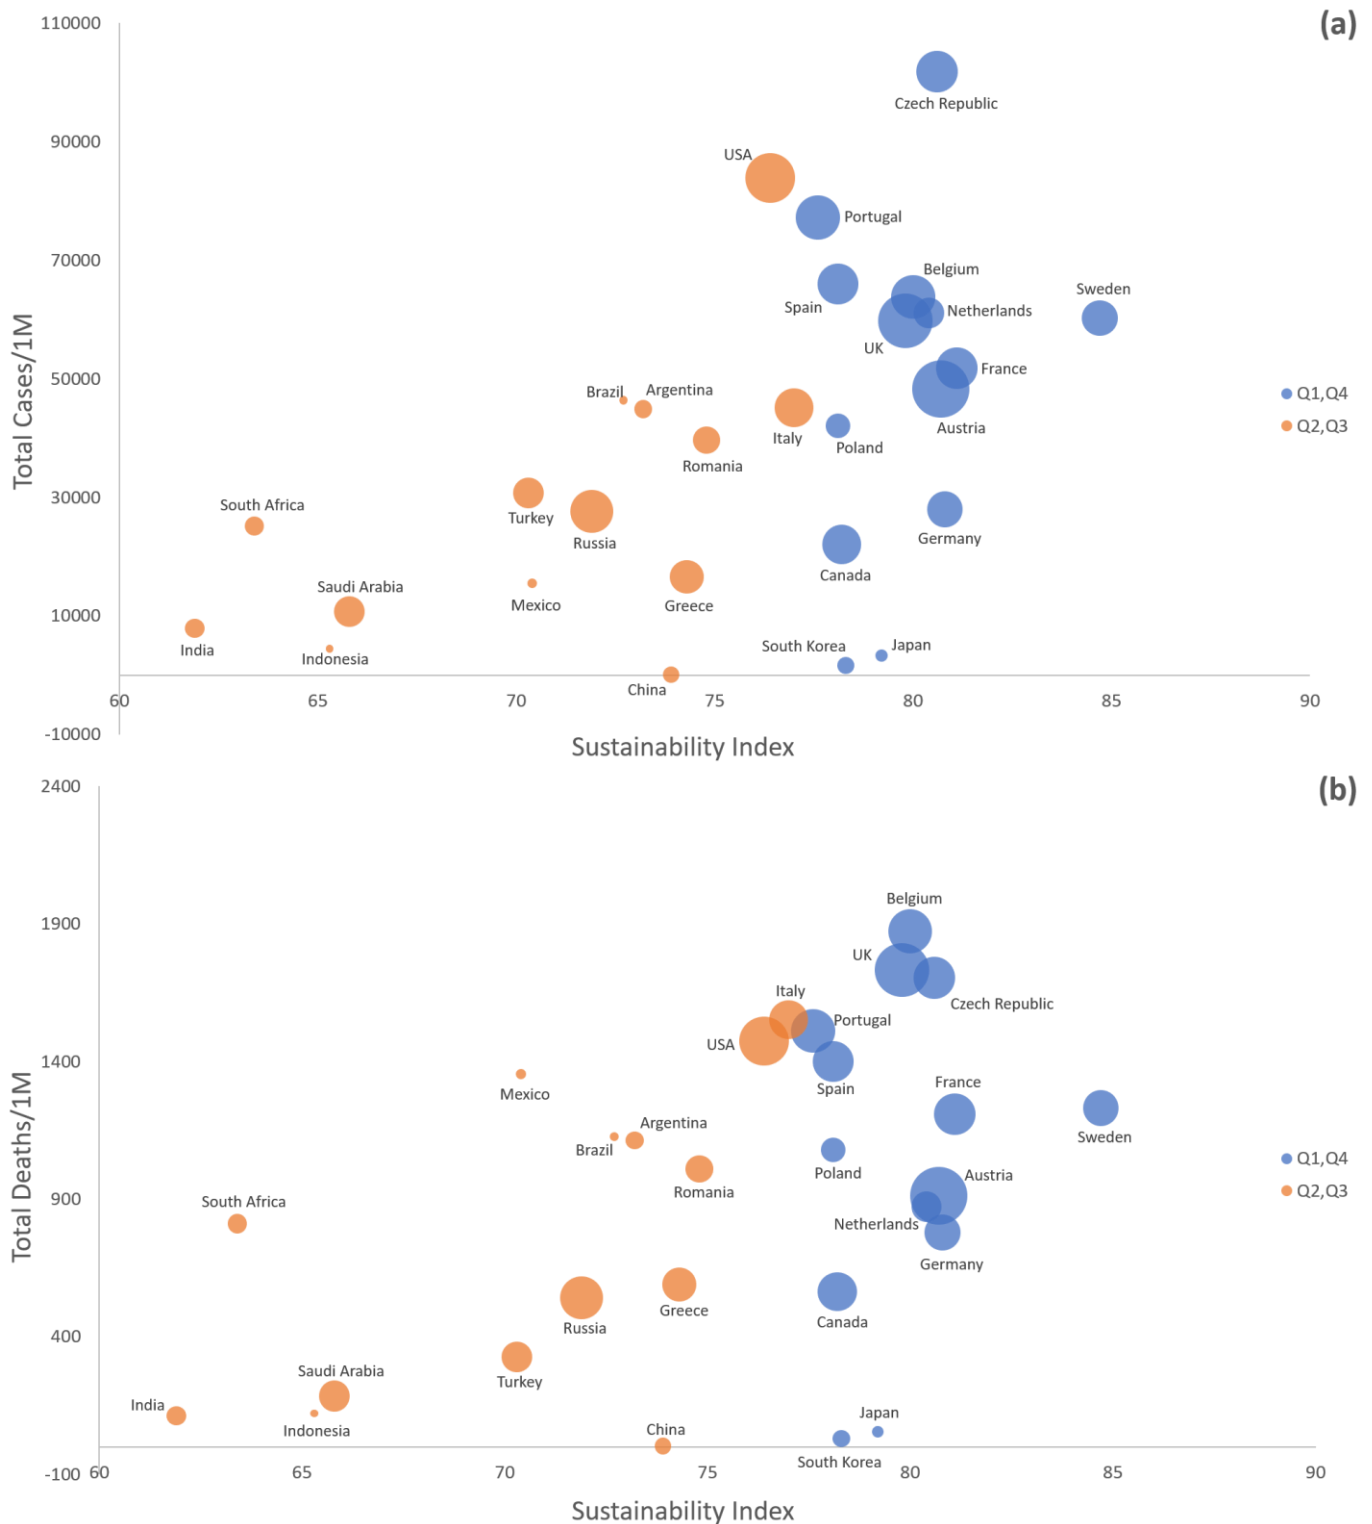

Figure 3. (a) Total cases, (b) Total deaths per one million versus Sustainability index for all quadrant pairs. Bubble sizes represent total tests per 1000 population

While we can observe the connection between outcome measures of COVID-19 (i.e., total cases and total deaths) and the sustainability index via figures 3a and 3b, we further explore the relations between total cases and total deaths in more detail. We plot total deaths versus total cases separately for high SI countries (Q1 and Q4) and low SI countries (Q2 and Q3) in figures 4a and 4b, respectively. Additionally, we show the total tests scaled by thousand population via bubbles. In both plots of Figure 4, we observe total deaths increase with total cases.

Figure 4. Total deaths per one million versus Total cases per one million for countries with (a) high SI, (b) low SI. Bubble sizes represent total tests per 1000 population

Figure 4a shows the countries that have high SI scores relative to the overall median. Among these, the countries in Q1 (i.e., represented with blue bubbles) conduct a relatively high number of tests, whereas those in Q4 (i.e., represented with orange bubbles) conduct fewer tests compared to the median. Most of the high SI countries also conduct a large number of tests residing in Q1. Besides, the countries in Q1 happen to be on the right side of the plot having higher total deaths and total cases per million. Nevertheless, some countries do not fit this general pattern. South Korea and Japan have very low death and case rates. Canada and Germany also deviate significantly from their peers in the same quadrant (i.e., Q1), managing fewer deaths and cases.

The relationship between total deaths and total cases (each measured per one million) for countries with low SI scores is shown in Figure 4b. In this plot, the countries in Q2 (Q3) conduct a high (low) number of tests relative to the overall median number of tests for all countries. Compared to Figure 4a, we observe that most of the low SI countries, which is more than 70% of all, conduct fewer tests. Besides, these countries tend to have lower total deaths and total cases—

however, a few countries deviate from the general pattern. Firstly, Italy and the USA have relatively high case and death rates in this group. In comparing the two, we observe that the USA has much more cases than Italy for approximately the same death rates in both countries. Secondly, Mexico has much higher death rates than its peers in Q2 and the total cases of own.

3.2.2. How do the Policies Associate with Total Cases and Total Deaths for Countries in Different Quadrants?

In exploring the relationship between the prominent COVID-19 related factors (i.e., total tests, total cases, and total deaths) and the sustainability index of countries, we attempt to evaluate the third factor in association with the other two. The newly incorporated factor is the stringency index of the country, showing the strictness of the policies implemented during the pandemic. Figure 5 allows us to observe all three factors in the same plots. In Figure 5a (5b), we draw total cases (deaths) per one million versus the sustainability index for all countries in our sample. We take into account the stringency index as bubbles in this graph. We also differentiate between two quadrant pairs. The high SI quadrants (Q1 and Q4) and the low SI quadrants (Q2 and Q3) are shown in different colors.

A higher stringency index does not seem to change the country’s position concerning the effort (i.e., number of tests) or the response (i.e., death and case rates) measures. The stringency index is composed of several different response metrics such as school and workplace closures, stay-at-home requirements, and restrictions on travels or public gatherings. While separate analyses of individual measures might reveal different effects, the composite measure does not seem to show a pattern in association with COVID-19 related factors or the sustainability index of the countries.

Figure 5. (a) Total cases, (b) Total deaths per one million versus Sustainability index for the high test (Q1 & Q2) and low test (Q3 & Q4) quadrant pairs. Bubbles represent the Stringency Index of the countries

4. CONCLUDING REMARKS

In the battle with COVID-19, countries with high sustainability index were expected to have lower number of cases and deaths. However, our descriptive analyses revealed that the general pattern had been precisely the opposite of what was expected. Although countries with a high sustainability index, in general, have higher overall performance across individual goals, such as SDG 3 (Good health and well-being), they were observed to have difficulties in overcoming the pandemic as many as or even more than the other countries. In this context, sustainable development goals need to be reevaluated considering their widespread effects by the UN. It would also be beneficial to consider this evaluation with a more holistic view. While the individual success of countries is vital in ending the pandemic, we cannot neglect the fact that all countries are part of one whole where there are bottlenecks linked to each other. *Leaving no one behind* needs a more holistic approach in terms of partnerships, which needs a strong emphasis on setting the targets for sustainable development goals.

The general trend for our classification of the countries in the form of quadrants also reveals some exceptions. Among the two types of countries (i.e., high and low sustainability indices), some appear to deviate significantly from the general trend of the group that they belong to, which might imply the role of some other characteristics. Canada and Germany have fewer deaths and cases than their peers in the same quadrant formulated based on the cumulative tests and sustainability indices. Similarly, Mexico, characterized as a country with a low sustainability index and a low number of tests, is found to have higher death rates than the overall median of countries in the same quadrant. While the country's overall stringency index does not seem to correlate with the COVID-19 response measures or the cumulative tests performed, detailed analyses focusing on the country-level characteristics are needed to explore this issue further.

In our analyses, we have considered sustainable development goals as a whole. The abundance of missing data for some individual SDGs and the short time frame to conduct the analyses have been the limitations of our study. For future research, more comprehensive analyses can be made in which sustainable development goals are addressed one by one, which allows each goal to be evaluated within itself. Thus, more effective solutions can be proposed by identifying the specific weaknesses of countries.

SMALL AREA ESTIMATION OF MULTIDIMENSIONAL POVERTY: THE CASE OF CAMBODIA

Karina Acosta

Cornell University, USA, kda27@cornell.edu

ABSTRACT

Many public policies in developing countries are spatially blind. Among the drivers of this blindness is the lack of up-to-date geographical breakdown of data which limits the ability of policymakers to develop and assess impact of policies to tackle poverty at a granulated subnational scale. In this context, this study aims to contribute to the estimation and mapping at a granulated spatial scale of multidimensional poverty in light of the global MPI (g-MPI) measure. The methodological framework encompasses techniques from Small Area Estimation (SAE). Specifically, this study uses Bayesian spatial hierarchical models which allow us to combine information provided by surveys and additional sources of data to estimate poverty indicators that are not formerly targeted by national surveys.

The case of study was Cambodia. We estimated spatial and spatio-temporal predictive models for the years 2000, 2005, 2010 and 2014. The inputs of the models come from two types of information. Type 1 encompasses spatial points of misaligned clusters of household locations, for which the source is the Demographic and Health Surveys (DHS). The DHS provided the main information to measure the g-MPI. The second type of data are the auxiliary predictors, including multiple gridded and polygon information which inform variability of poverty risk across space. Among this group we use corrected nightlight data, accessibility to cities, build-up areas, rice land per family, number of rainy days and population. Additionally, this research compares our geostatistical models with the most commonly used method for poverty mapping as proposed by Elbers, Lanjouw, and Lanjouw (2003). The reason for this comparison is that although ELL has served as a valuable and applicable instrument, it mainly relies on timely census data, which are not periodically available in developing contexts.

This study concludes that the incorporation of survey design could be critical to generate more accurate predictions. Moreover, it finds that more complex spatio-temporal models do not necessarily yield better estimations, specifically in larger time spans. We hypothesize that this is the case because of the natural smoothness effect implicit in these models. We also found that the relatively recent strand of research on the field of geostatistics such as the main models used in this research offer promising tools to overcome data limitations (e.g. census availability). For instance, the rough comparison between the ELL and geostatistics leads to similar predictions of poverty.

1. INTRODUCTION

Development is a spatial phenomenon. There is evidence that location is a major determinant of poverty (Bedi et al., 2007). In spite of continuous efforts from the developing world to generate reliable information on living conditions and poverty, it is still an issue the scarcity of information at sub-national scale and its evolvement over time. Such measures are critical to generate appropriate public policies to confront the persistent spatial inequality, particularly relevant in developing contexts. It is paradoxical that amid the so-called big data era many developing countries are still facing such challenges, a ubiquitous characteristic. An illustration of this situation is Angola, which collected census information for the last time in 2014, 44 years after its previous census in 1970s (Blumenstock, 2016). In this context, a rising demand for accurate and timing development indicators, a needed request for poverty indicators at scale, and a fast pace changing population have facilitated the development of novel branches of research that aims the generation of economic performance and development indicators using non-standard methods and/or data.³⁵

Small area estimations (SAE) have become valuable techniques to understand the subnational distribution of wealth and poverty across time. The concentration of this research is on the subgroup of SAE techniques that uses geostatistical models, which, to best of our knowledge, has not been applied to poverty (as understood in development economics). This study also adds to the literature a comparison between methods, providing estimations of the so-called World Bank method (ELL). Furthermore, it sets out to incorporate spatio-temporal models. This research also aims to contribute to the incorporation of different sources of data into geostatistical models, which has not been found in the surveyed research. Lastly, despite the popularization of indicators such as the Multidimensional Poverty, its estimation has not been explored in the set of techniques of SAE. More specifically, the measure of poverty used envisioned a multidimensional approach in light of (Alkire & Foster, 2011). Therefore, the work presented here provides one of the first investigations into the SAE of multidimensional poverty index, as proposed by Alkire and Foster (2011). In short, this study seeks to contribute to this growing area of research by exploring and extend alternative techniques to the estimation of development indicators at small scales.

³⁵ The United States of America has started the SAIPE program which aims to estimate poverty for USA's districts.

In order to accomplish the goals, this research uses primarily a Bayesian hierarchical model, which enable predictive inference about the spatially continuous and incomplete observed phenomena of multidimensional poverty. It takes advantage of multiple sources of data currently available, such as georeferenced Demographic Health Survey, satellite data and administrative data records to generate estimations of poverty at county level when data is not widely available. The case used for this application is Cambodia, for which such poverty measure is generated for the years 2000, 2005, 2010 and 2014.

Cambodia can be a relevant case of study for the understanding of spatial changes of poverty at small scale for a wide range of reasons. Its recent history and economy have experienced a significant structural transformation, which has caused, in turn, important changes of its development indicators (Clark, 2020). The drop of poverty rate over the last years has exceeded the country's Millennium Development Goal expectations, with a reduction of 31.7pp, from 52 in 2004 to 20.5 in 2011 (World Bank, 2013). Likewise, its Gini coefficient has shown an important reduction within the same period. Such reduction is more salient between 2007 and 2012, dropping from 40.4 to 29 (Harbo & Gjonbalaj, 2019). This paper has been divided into seven parts. The second part introduces a background of research related to the study of small area estimation applied to the case of poverty. It is followed by a description of the main poverty indicator used in this study as well as the methods used. The fourth section describes the sources of data used. The fifth and sixth section present the results and its limitations. It will then go on to the main conclusions drawn from the results.

2. PRECEDING METHODS ON SMALL AREA ESTIMATION (SAE) OF POVERTY

SAE is concerned with the estimation of disaggregated domains when information collected is not representative for these domains. Most surveys are representative at national scale or by state. However, it is common the case that some estimates are necessary at finer scales such as districts or counties.

To better understand poverty mapping, we can draw a distinction between two mainstreams of research. The first group of studies includes unit-level models that rely on a combination of classical statistical techniques. They mostly combine census and survey data using hedonic regression models. This stream has been led primarily by the method developed by Elbers, Lanjouw, and Lanjouw -ELL- (2003). Supplementary extensions such as Empirical Bayes strategies have been grounding on ELL ((Molina & Rao, 2010); (Molina & Rao, 2010); (van der Weide, 2014)). Several applicable cases are encountered in this group in Vietnam (Lanjouw et al., 2017; Minot, 2000), Cambodia (Elbers et al., 2007; Fujii, 2007), Ecuador (Araujo et al., 2006; Elbers et al., 2004), among others. Most of this work is applied to monetary poverty.

On the other hand, the second and later class of studies has forayed into a different direction, where the units of analysis are spatial (polygons or points). It bundles geostatistical models and machine learning algorithms and we call this group space-type models as it focuses on spatial predictions, in contrast to individuals' imputation as it is the case for the ELL and comparable methods. Major improvements in the accessibility to satellite data such as nightlight information has been critical to estimate proxies of areal human development, given that such signals are closely associated to economic performance (Noor et al., 2008; Pinkovskiy & Sala-i-Martin, 2014; Wang & Ma, 2017). In this same line of research are studies that draw estimations from satellite imagery but are not limited to nightlight data. In addition, they include multiple sources of information, such as vegetation indexes, imagery building information, types of roofs, forest cover, precipitation, and roads, among others (Blumenstock, 2016; Jean et al., 2016). A last wave of investigations has made attempts to include phone call records and social media data to proxy socioeconomic conditions (Fatehikia et al., 2020; Hernandez et al., 2017; Njuguna & McSharry, 2017; Soto et al., n.d.; Steele et al., 2017). This strain of research that links SAE and poverty are mostly concentrated on computer science and do not offer precise definitions of poverty, as understood in the development economic literature. Instead, most of them have used wealth indexes as constructed by popularized households' surveys.

This study does not use machine learning techniques, but it has been classified in this sub-group of research given that they intersect on two fronts. First, the unit of analysis are spatial, instead of individuals. Second, the auxiliary predictor come from non-standard sources of data. They differ in the strategy used for estimations. Although each method has advantages and disadvantages, one of the value-added of the geostatistical models is that they allow the interpretation of the influence of covariates on the desired outcome, given the relative simplicity of their specifications.

3. MULTIDIMENSIONAL POVERTY MEASURE AND SAE ESTIMATION

3.1 Estimation of multidimensional poverty

There are multiple measures of poverty. The two larger types of poverty measures are the monetary poverty and the multidimensional poverty. Most of the research on Small Area Estimations of poverty is centered on monetary poverty. Purposely, the global multidimensional poverty index (g-MPI) is the targeted variable of this study. The main reason is the lack of understanding of the changes at a small scale of multidimensional poverty in a shorter frequency than every census in developing countries. The global MPI has the advantage that uses a standard set of indicators and data (DHS) to produce poverty estimates, which can be comparable across time and between countries. A full description of the g-MPI can be found in the publications of Oxford Poverty & Human Development Initiative -OPHI- (Alkire et al., 2018, 2019). Overall, our estimates reflect a generally larger multidimensional poverty in Cambodia with similar trends, when compared to the published g-MPI (Figure 1).

Figure 1. Adjusted headcount ratios (MPI) and headcount ratios estimated versus OPHI

Source: own estimates (dotted lines) and OPHI (n.d.) (smooth lines).

3.2 Predictive model

We propose a hierarchical Bayesian framework to model the probability of being poor from a multidimensional perspective. Consider a binary outcome and let be the number of individuals with the characteristic of interest (multidimensional poverty condition) in cluster c be Y_c , and total population size n_c . Then, we use a sampling adjusted spatial model defined by a beta-binomial model which yields the following marginals:

$$P(Y_c|p_c,d) \sim \text{Beta-Binomial}(n_c, p_c, d) \tag{1}$$

Where p_c describes the probability of being poor in a spatial point c and d attempts to measure the overdispersion of the data. Furthermore, the probability of poverty is given by a spatial model of the form:

$$p_c = p(s_c) = \text{expit}(\alpha + z_c \beta + d(x)^T \beta + S(s_c) + \epsilon_c) \tag{2}$$

This specification accounts for strata fixed effect of the surveys. To enhance the precision of granulated scale, a set of spatial covariates $d(x)^T$ for each location is included. It is worth mentioning that the enhance of the model given is subject to the quality of covariates included and their explanatory power. Finally, $S(s_c)$ describes a spatial random effect at cluster with location c . For the estimation of the spatial model, it was used the standard Matérn covariance as follows:

$$\text{cor}_{\text{Matern}}(s_i, s_j) = \frac{2^{1-\nu}}{\Gamma(\nu)} \chi(\kappa \|s_i - s_j\|)^\nu K_\nu(\kappa \|s_i - s_j\|) \tag{3}$$

s_i and s_j represent the location of two spatial points. Thus, $\|s_i - s_j\|$ represents the Euclidean distance between two clusters. K_ν defines the Bessel function, Γ defines the gamma function, and κ is a standard parameter. As in a standard spatial correlation, Matérn assign higher correlations to closer points in space (Zuur et al., 2017).

Alternatively, we tested a spatio-temporal model. The amplified version of (2) is given by:

$$\log(p_{ct}) = \log(p(s_{ct})) = \alpha + z_{ct} \beta + d(x_{ct})^T \beta + S(s_c) + v_c + \partial_t + \gamma_t + \epsilon(s_c, t) \tag{4}$$

Where $\epsilon(s_c, t) = a\epsilon(s_c, t-1) + \vartheta(s_c, t)$

Compared to (2), (4) includes a space time random effect given by ϵ_{ct} , which follows autoregressive process AR1. Moreover, $\vartheta(s_c, t)$ represents a Gaussian distribution with space dependency and time independent at each defined t .

The most well-known ways to estimate Bayesian models is through MCMC methods. In last years, the introduction of R-INLA has significantly changed the application of Bayesian models, as the method involved speeded time estimations for spatial or spatio-temporal models. The Integrated Nested Laplace Approximation (INLA), method behind R-INLA, approximates outcomes through numerical integration (Rue et al., 2009). This study uses the package R-INLA due to the granularity of estimates which requires large computational scales.³⁶ Particularly relevant in the applications of R-INLA to spatial point processes estimation is the discretization of the continuous space targeted, the level 0 of Cambodia in this case. It is performed through the triangulation of the space. The constrained refined Delaunay triangulation for R-INLA for year 2014 estimations is shown in Figure 2. Although there is still a developing area of research, the discretization of space is important in the final outcomes of the models, as they define the neighbors of the data.

³⁶ More about the R-INLA project can be found at <https://www.r-inla.org/>

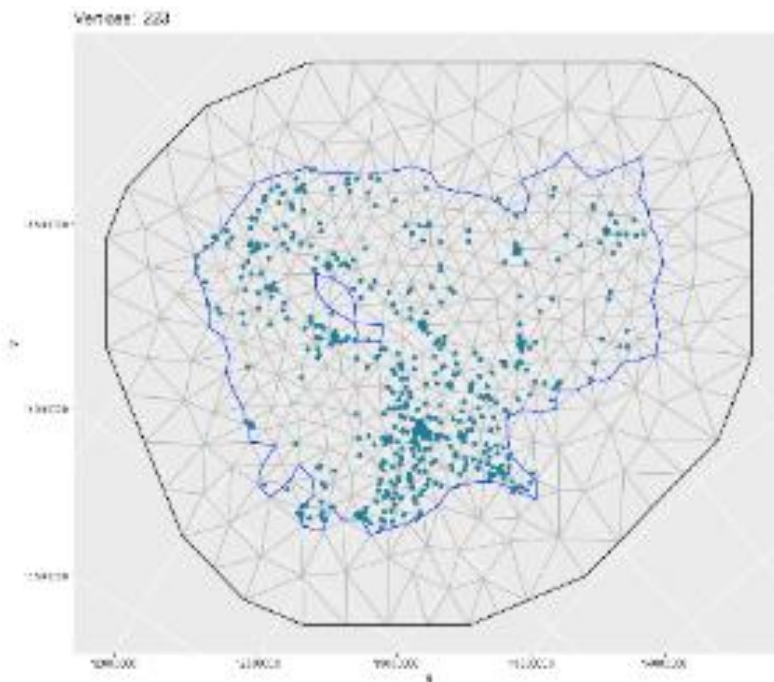

Figure 2. Constrained refined Delaunay triangulation

After prediction at different resolutions were obtained, the data was aggregated at different scales. The method of aggregation is described by equation (5):

$$P_l = \frac{\int p_{(s)} l_{(s)} \partial s}{\int l_{(s)} \partial s} \quad (5)$$

Where P_l is the polygon estimate, $p_{(s)}$ defines the estimated poverty rate for a continuous space S and $l_{(s)}$ describes population.

4. DATA

We classified the data sources into two groups: type 1 data and type 2 data, as follows: **Type 1:** spatial points of misaligned clusters of household locations. The source of this information is the Demographic and Health Surveys (DHS) collected every five/four years is available from 2000 until 2014 in the case of Cambodia. The jittered points where the data is collected is displayed in Figure 3. The DHS data is the source for the response variable. **Type 2:** auxiliary predictors, including multiple gridded information which inform variability of poverty risk across space.

4.1 Type one: *The Demographic and Health Survey*

The main source of information, which includes the variables used to estimate the multidimensional poverty index, is the Demographic and Health Survey of Cambodia collected in 2000, 2005, 2010 and 2014. The strategy used by the CDHS was a stratified sampling in two stages. This implies that the sample was chosen separately from each stratum. In the first stage, a set of Enumeration Areas (EAs) from the Census is randomly selected, and their probability of selection is based on each unit size (number of households in each EA). Moreover, only a random segment of EAs with more than 200 households were selected (largest EAs).³⁷ In the second stage of randomization a fixed number of urban (24) and rural (28) households are selected for each EAs through an equal probability systematic sampling. For the years 2005, 2010 and 2014 the total number of sampling stratum are 38, which corresponds to 19 domains for rural-urban areas. The year 2000 collected information on 34 stratum (17 domains and rural-urban areas). The total number of clusters selected, also called primary sampling units (PSU), each year are: 471 in 2000, 557 in 2005, 611 in 2010, and 611 in 2014. Figure 3 displays the spatial distribution of individual surveyed clusters by year. As expected, and based on the sampling strategy used, a larger proportion of clusters are concentrated in the most populated areas of Cambodia. The DHS also follows a geo-masked strategy of the population. It is, for the purposes of respondents' confidentiality, clusters coordinates are displaced within a 2 Km radius in urban areas and within a radius of 10 Km for rural clusters (Burgert et al., n.d.; Perez-Heydrich et al., 2013).

³⁷ A comprehensive description of the sample design and assessment of sampling weights is described in the surveys' reports: National Institute of Statistics-Cambodia (2006, 2011, 2015).

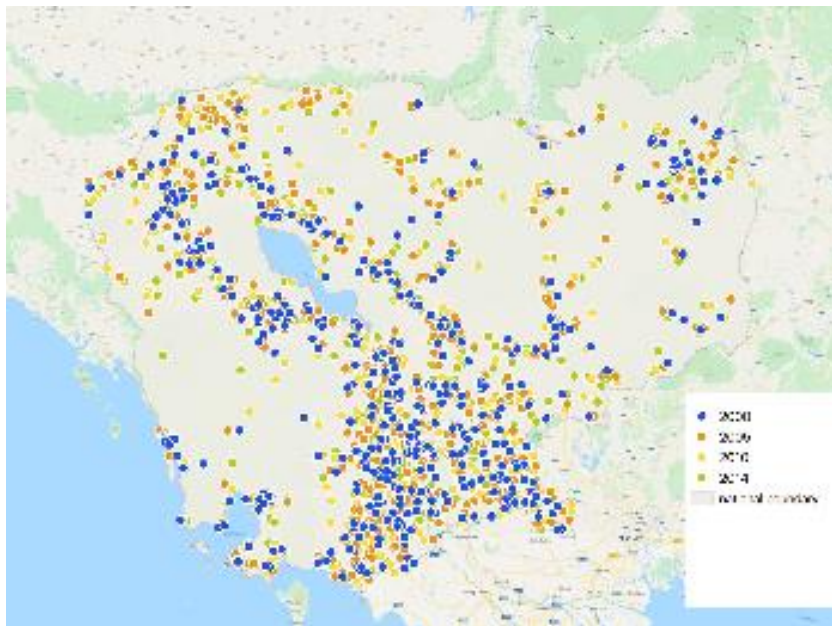

Figure 3. Survey data: geo-masked clusters in Cambodia.

4.2 Type 2 data

Even though we explored multiple sources of variables, and multiple models were tested, the final set of information used was restricted by the WAIC criteria used for models' comparisons. Moreover, as described before, the cluster are randomly jittered around a specific radio for urban and rural areas. To reduce the noise that it could produce, the extraction of the covariates considers the mean within the defined buffer for each cluster location, 5km for urban and 10km for rural points. In the case of the dichotomous variable (urbanicity), it was used the mode of data within a buffer.

Nightlight information. This study uses estimates of the project Shining (new) light on Regional Inequality, Convergence and Development, which produces corrected nightlight data, assuming a Pareto property of the truncated information (Bluhm and Krause, 2020).³⁸ The corrected estimates are produced for the same period and the same spatial resolution as the NOAA original data set. For some years, there are two types of data available, based on the auxiliary flights' information used for the correction. The selected years and respective flights used in our estimates are 2000-F15, 2005-F15, 2010-F18 and 2013-F18.

Accessibility to cities: we have used an open available global map on estimated travel time to cities, made available by (Weiss et al., 2018).³⁹ It includes information for 2015 and is available at a resolution of one by one kilometers. Thus, we have used the same source of information for all years. This strongly assumes that the connectivity did not significantly change over the years. The inclusion of time variability was not possible due to data restriction.

Urbanicity: the main source of information to feed the predictive model is the GHS Urban Centre Database (GHS-UCDB)-UCDB R2019A.⁴⁰ This data characterizes degrees of urbanization for global grids at one by one kilometers (Dijkstra & Poelman, 2014).

Wet days: we use wet days data provided by Climatic Research Unit (CRU) Time Series (TS) v. 4.01 release by CEDA Archive (Harris et al., 2014). The data produces monthly gridded information from January 1901 to December 2016 at a global scale with a resolution of 0.5 x 0.5 degree. In this regard, we have estimated average gridded values for the years/months matching the survey collection timing.⁴¹

Rice field: we included information on number of families with less than one hectare of rice land from the Commune database of Cambodia (2011).⁴² The information is available at the second administrative level, Commune, and only for 2011. As the approach followed before, we strongly assume that the map of rice distribution by family has not changed and, so it was linked to all years analyzed.

Population: The source of information is the population density produced by the project WorldPop (<https://www.worldpop.org/>). The dataset is available a resolution of approximately 1 km at the equator (30 arc-second).

4.2.1 Census data

For the purpose of contrasting, we estimated the alternative frequentist techniques as proposed by ELL. One critical difference between geostatistical models and the ELL method is that the latter's main input is Census data. We used the

5. RESULTS

5.1 Evidence of spatial correlation of poverty

The distribution of headcount poverty at the cluster level is displayed in Figure 4, where some areas, especially those close to the capital of Cambodia Phnom Penh, exhibit significant changes between 2000 and 2014. It can be concluded that the distribution of multidimensional poverty in Cambodia has not been random across space. Even though this scenario suggests that geostatistical models are not spurious, we follow a standard exploratory test to formally identify whether a spatial process would be relevant for our models. Specifically, we conduct a residual spatial analysis of generalized linear mixed model (GLMM) with a binomial link function, using an empirical variogram. The tests for spatial residual correlation of poverty leads us to a spatial specification, supporting the evidence of spatial autocorrelation.

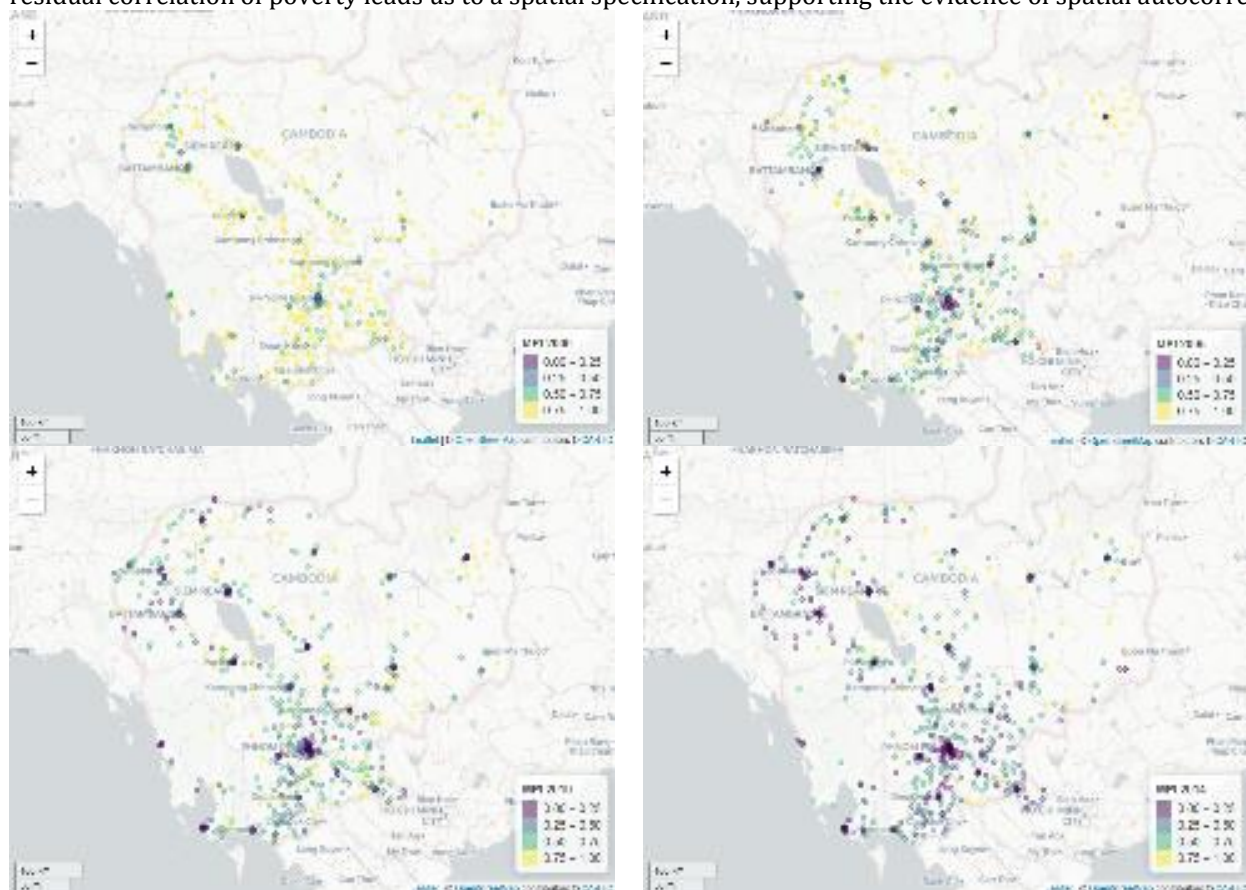

Figure 4. Cluster-level multidimensional poverty of Cambodia 2000-2014

5.2 Results of selected models⁴³

The noteworthy changes of cluster poverty over space (Figure 4) is evident in the estimated gridded maps. A comparison between 2000 and 2014 maps visibly shows such change. In 2000 most of the area has a large proportion of people living in multidimensional poverty -above 80%- (Figure 5). The high monetary and multidimensional poverty rates observed in early maps in Cambodia reflect the aftermath of historical civil conflicts during 1970s. Such conflicts have had long lasting effects on the well-being of Cambodians, ranging from reductions on educational attainment, earning, fertility and health of its population (Islam et al., 2014); all of them associated with the risk of poverty. As a word of caution, notice that areas where non or fewer cluster information is gathered display higher standard deviations of the posterior (lighter colors in Figure 6). In spite of potential large variability of the estimates the results, especially in early years where there are less clusters, results are robust to different comparisons from differences sources that are not provided due to space limitations.

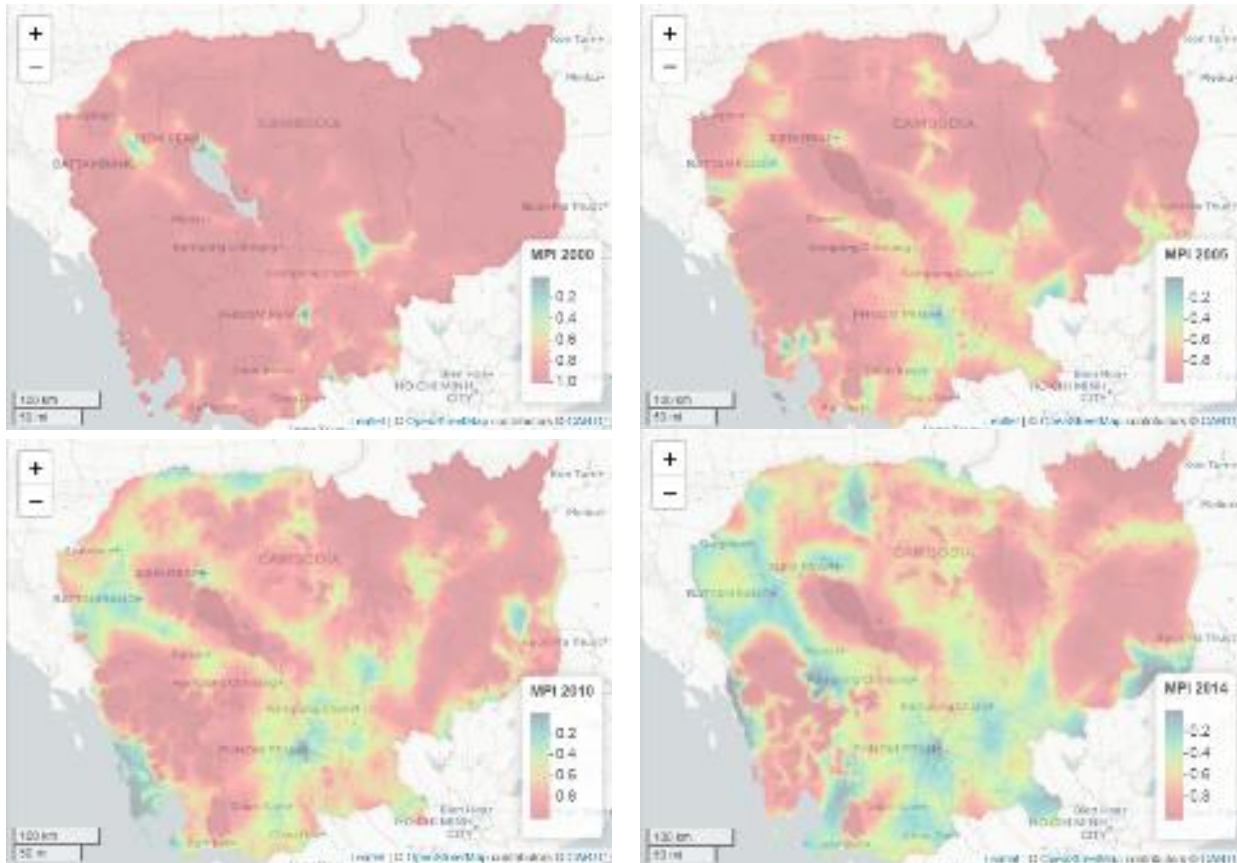

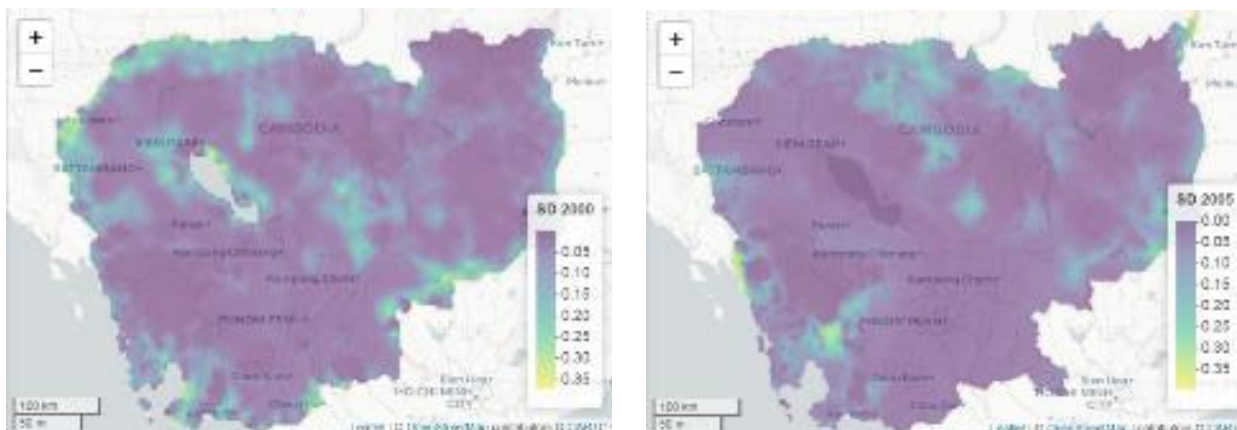

Figure 5. Geostatistical models estimate of headcount MPI 2000, 2005, 2010, 2014

43 The discussions of the results will be limited to the spatial models instead of the spatio-temporal models, because we encountered that spatio-temporal models might generate over smoothing effects, such that it generates poorer predictions than the spatial models within the time span considered. Results of those models are presented in Appendix 5.

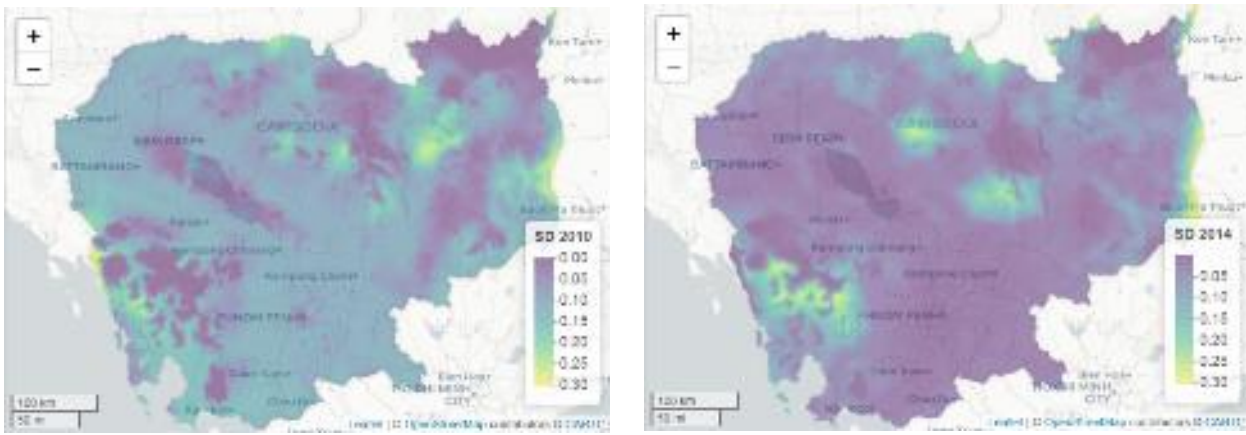

Figure 8. Geostatistical models standard deviations

5.3 ELL versus Geostatistical models

The results at district level from the ELL model and Geostatistical models for 2010 are plotted in Figure 9. The overall pattern of poverty distribution for both estimates are similar. In order to build the model for ELL predictions it was followed the suggested procedure of a stepwise selection (Zhao & Lanjouw, 2006). The final set of variables used for the beta model are listed on the data description section. The adjusted R squared produced by the selected model was 0.5264, which is similar to the R squared encountered in similar applications where it ranges from 0.41 to 0.53 (Demombynes et al., 2008). Both models indicate that districts located in Eastern Cambodia have the largest incidence of multidimensional poverty, with a visible larger variability observed in the Geostatistical predictions. The correlation of measures of these two methods is 0.8.

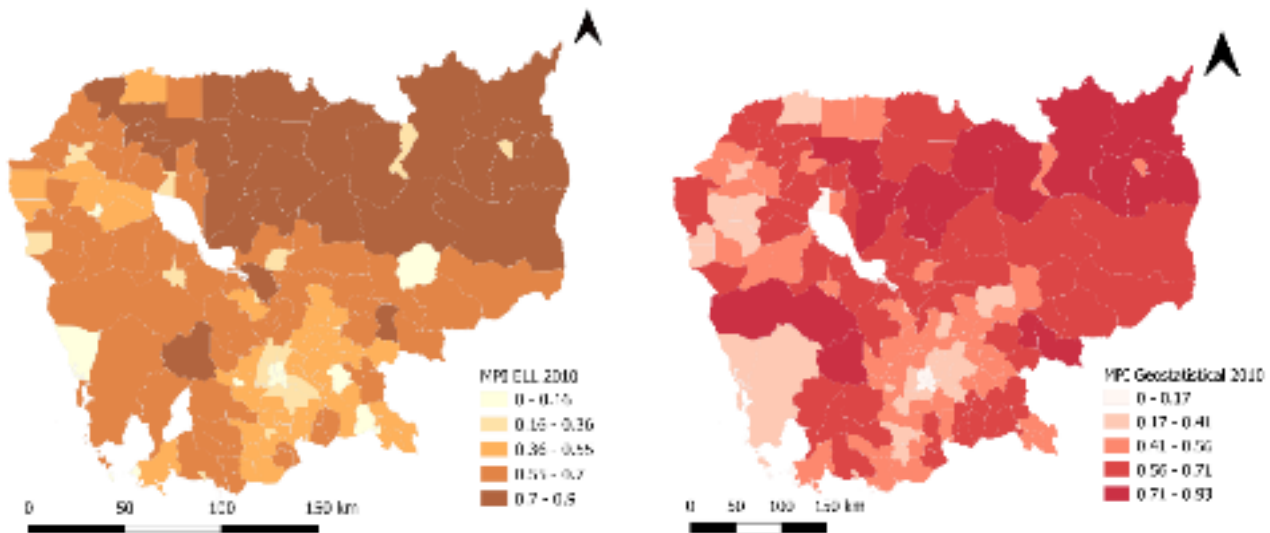

Figure 9. District estimates of poverty using ELL and Geostatistical models 2010

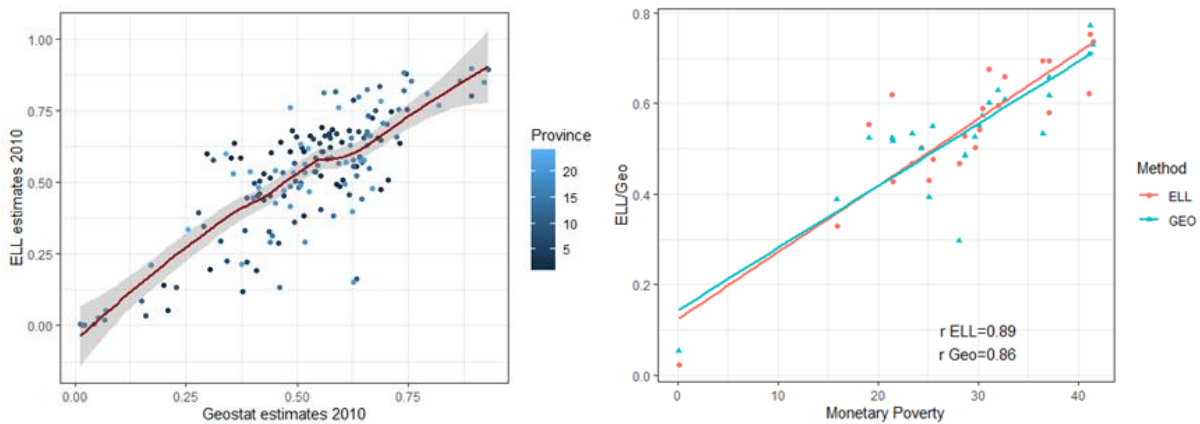

Figure 10. District estimates ELL 2010 versus Geostatistical models 2010

Moreover, results were further aggregated at the province scale. They show that the correlation between the estimates proposed in this study and the ELL method are higher than districts, it was 0.89. Likewise, the strong association between

both sets of estimates and the monetary poverty confirm previous results. The correlation between ELL and geostatistical estimates and the monetary poverty for 2010 are close (0.89 and 0.86, respectively), while the ELL is slightly higher than the geostatistical.

This study does not aim to defend one method over the other, each technique has advantages and flaws. But provided that the ELL can accommodate full census information and can be further combined with survey information and local information, it can be an appropriate method if the data is available. On the other hand, geostatistical models are also subject to error and do not count with the rich set of a census. Yet as exposed in the results, the predictors of these two techniques are very close. The major benefit of the geostatistical models is that they do not rely on census data and can incorporate information from multiple scales, which are increasingly available.

6. CONCLUSIONS

Since its first publication around two decades ago, the ELL method has become and remain as a leading method for the estimation of poverty at subnational scale. Although ELL has served as a valuable and applicable instrument, it still has some limitations that are not effortlessly circumvented in developing settings. Namely, it mainly relies on timely census data, which are not periodically available in developing contexts. Moreover, most of these applications are limited to monetary poverty and, thus, this paper offers a contribution about its applicability for multidimensional poverty. Specifically, for the g-MPI.

The relatively recent strand of research on the field of geostatistics such as the main models used in this research offer promising tools to overcome such common limitation. For instance, the rough comparison between the ELL and geostatistics encountered leads to similar predictions of poverty. Nevertheless, this is a growing research strand that can be improved with access to more data, as recent trends show, as well as more efficient computational tools, like R-INLA. This study shows that within geostatistical models the incorporation of survey design could be critical to generate more accurate predictions. Moreover, more complex time-space interaction models do not necessarily would yield better estimations, specifically in larger time spans. Moreover, this research also offers alternatives to similar studies on machine learning that use less parsimonious models, the predictive power of both strategies seems to be comparable based on the surveyed machine learning publications.

This study also roughly contributes to the discussion about the compatibility between monetary poverty and multidimensional poverty measures. The predictors of the models at a lower scale show a strong correlation, in the case of Cambodia, between both forms of poverty for different years. Such associations are even closer among the tails of poverty distribution, where poorer (top) areas in a multidimensional scale also occupied first (last) positions in the monetary rank. Lastly, although surveys collections, innovative techniques and computational power improvements can allow us to identify and have granulated pictures of poverty more often, it is worth highlighting that they are by no means substitutes of census data, but rather alternative to generate intermediate portraits of the spatial phenomena of poverty (and other indicators). As beautifully synthesized by McElreath (2015, p. 2):

“Rather than idealize angels of reason, scientific models are powerful clay robots without intent of their own, stumbling along according to the myopic instructions they embody. Like with Rabbi Judah’s golem⁴⁴, the golems of science [models] are wisely regarded with both awe and apprehension. We absolutely have to use them, but doing so always entails some risks”.

**A NOTE ON THE EMPIRICAL IDENTIFICATION OF SUB CENTRALITIES
WITHIN CITIES**

Carlos Azzoni, Rodger Antunes

University of Sao Paulo, Brazil

ABSTRACT

Although the traditional Central Business District (CBD) still has the largest single concentration of jobs in most cities, employment has sprawled over space, creating subcenters (SDB). Theoretical models have dealt with this phenomenon, highlighting its effects on wages, land prices, etc. Researchers have proposed empirical procedures to identify the SDB within cities, but no one has become standard in this empirical field. In this paper, we propose a new methodological procedure, based on nonparametric estimators. Our approach does not rely on previous knowledge of the employment distribution and does not use arbitrary threshold values and band sizes. For each cell, we calculate spatial employment averages using kernel functions and distance bands defined by the AIC optimization criteria. We use the quantiles of the distribution of the estimated spatial averages as cutoff values. As a means of validation, we identify SDB for the São Paulo metropolitan area (Brazil) using our method and the method proposed by McMillen and Smith (2003). Our model is more conservative in identifying areas pertaining to SDBs, and presents lower error terms and standard errors relative to those estimated by their methodology.

IMPLICATIONS OF GENERAL RELATIVITY THEORY FOR REGIONAL SPATIAL INTERACTION MODELING

Laurie Schintler, Kingsley Haynes, Rajendra Kulkarni

George Mason University, USA

ABSTRACT

In the last few years, there have been profound leaps in our understanding of the complexity and spatial dynamics in the cosmos. Several recent discoveries have radically shifted our theoretical and empirical views on the inner workings of the Universe. Perhaps most profoundly, the detection of gravitational waves, along with the first photo of a black hole, have finally confirmed Einstein's theory of general relativity. Accordingly, Newtonian gravity has been rendered passe in certain key regards. In particular, Newtonian gravity does not apply for phenomena in the Universe when there is: 1) extreme mass-energy density, 2) strongly curved dynamic space-time, and 3) mass- energy dynamics with $v \sim c$, where v is velocity and c is the speed of light. In such cases, gravitational dynamics are governed by the principles of General Relativity Theory (GRT) rather than Newton's Law of Gravitation. Using suitable analogies, we explore the extent to which similar properties and dynamics apply to spatial socio-economic phenomena on Earth, with a primary focus on spatial interaction in cities and regions. We hypothesize that the above three cases might pertain to megacities or megaprojects; metropolitan areas containing excessive flux in patterns of spatial interaction and travel times; and, regional systems where volume is at capacity. To test this and other possible analogies, we will consider conducting a meta-analysis of calibrated gravity models in the relevant literature, assessing how the performance of models correlate with these and other pertinent factors. We will also discuss how tests of general relativity used in cosmology might be adapted to assess when a standard Newtonian gravity model is not appropriate for characterizing urban and regional spatial interaction. Lastly, several analytical and computational solutions for GRT, along with a variety of so-called modified gravity models to account for the assumptions behind GRT, have been proposed in the literature. We will explore their relevance for spatial interaction modeling in regional science.

**ENHANCING OUR UNDERSTANDING OF A REGIONAL ECONOMY: THE
COMPLEMENTARITY OF CGE AND EIO MODELS.**

Andrew Crawley¹, [Geoffrey J.D. Hewings²](#)

¹University of Maine, Orono, USA. ²REAL and University of Illinois, USA

ABSTRACT

Economic impact models are powerful tools for the assessment of policy changes in regional economies. Computable General Equilibrium (CGE) models have grown in popularity, becoming the dominant choice of practitioners and academics in this field. This popularity has been at the expense of an older class of model, the Econometric Input Output (EIO). The present paper demonstrates how both models, using the same input data, may yield different outcomes. However, the paper suggests that EIO has been underutilized but even though it provides a strong complementary tool accompany that enhance analyses using a CGE approach. This paper urges regional economists to rediscover the EIO model, especially two variants that are described in the paper, and bring them to the forefront of their research agenda.

CROSS-SECTIONAL DEPENDENCE IN GIBRAT'S LAW[Xieer Dai](#)

The Hebrew University of Jerusalem, Israel

ABSTRACT

One of the most conspicuous empirical findings in the social sciences is Gibrat's law or the law of proportionate effect. The idea was developed by (Gibrat, 1931) for French manufacturing firms and concluded that firm growth is a random effect, independent of firm's size. This law is also widely found in cities' growth, income, and wealth. Since Gabaix (1999) and Eeckhout (2004), it has become popular to test Gibrat's law in cities. In general, there are both static and dynamic ways to test Gibrat's law for city's size empirically.

The static approach is to test the distribution of city's size. Distribution of city size is a controversial issue with two common contenders: the Pareto and the log-normal. The law of proportionate growth gives rise to a log-normal distribution. When the process is normalized, and a lower bound is set, the distribution leads to a power law in the upper tail.

This paper provides additional evidence on whether Gibrat's law holds for the growth of broadly defined 'cities' such as MSAs and NUTS regions. This paper extends the random growth model to incorporate both strong (common factor) and weak cross-sectional dependence (spatial dependence). A regional population random growth model with global and individual technological shocks is formulated. Common factors and spatial dependence are derived as a result of interregional migration.

It is shown that if the growth processes of regions obey Gibrat's Law with cross-sectional dependence and when the spatial weight matrix is non-stochastic, the unit root process can still lead to Power Law distribution in the tail.

In the empirical section, I test both static and dynamic hypotheses of the random growth model using three regional datasets of European NUTS 2 regions across 30 years and U.S. counties and MSAs across 50 years. The regional population distributions for these three datasets are characterized as lognormal distributions in the body with a power-law distribution in the tails.

A panel unit root test in the presence of spatial autoregressive error (SFIPS) is proposed. The critical values are tabulated using Monte Carlo simulations. The SFIPS tests and CIPS tests confirm Gibrat's law with strong and weak cross-sectional dependence for NUTS 2 regions and the U.S. MSAs.

**ACCESSIBILITY AND SOCIAL NETWORKS IN FAMILY ADHESION TO
SOCIAL HOUSING: EVIDENCE FROM A BRAZILIAN HOUSING LOTTERY
CASE**

Patrick Nasser, Eduardo Haddad

University of São Paulo, Brazil

ABSTRACT

We investigate how accessibility, measured by the difference of job market Hansen indexes, and social networks, measured by the geographical approximation across different age-bands densities, are related to the final decision of accepting the benefit by the poorest participants of Brazilian housing program “Programa Minha Casa Minha Vida” (PMCMV) in the city of São José do Rio Preto (São Paulo state), where potential beneficiaries were randomly drawn for the year of 2013. From the lists of municipal draws, identified Cadastro Único (Brazilian national register for federal social programs), identified RAIS (Brazilian national register for formal labor activity) and beneficiaries’ information disclosed by state bank Caixa Econômica Federal, we estimate different specifications of Probit models using the difference of job market Hansen indexes between PMCMV households and origin family addresses. Also, we use the 2000’s and 2010’s National Census at the census tract level to create IV-Probit models using the first Census local age densities-bands as instruments for our social networks model. Our results indicate that worse accessibility prospects are related to non-compliance decisions, and we do not reject the null hypothesis for the effect of age-based social networks on compliance besides showing that neighborhoods might affect different age-compositions households differently. From the public policy perspective, these results show that the program might not reach an important part of low-income families’ locational preferences.

RETHINKING CULTURAL POLICY: THE ROLE OF THE CULTURAL INDUSTRY AND SMALL MANUFACTURING COMPANIES

Salma Mhamed Hichri

University of Sfax- LAREQUAD, Tunisia

ABSTRACT

The use of cultural policy as part of economic development and urban regeneration strategies is increasingly an uncontested issue. However, this consensus masks serious dilemmas regarding strategic choices and their implementation in economic and cultural development. Indeed, policy-makers have always considered the cultural economy either as an appendix to the knowledge or creative economy or as a means of improving consumption (Evans, 2009) which implies that art and culture objects are consumer goods that enhance the attractiveness and image of the city. This has led to an increasing polarization and bifurcation of cities culturally and economically around knowledge industries. These focus on high-skilled workers (Allmendinger, 2002; Cullingworth and Caves, 2014) leaving traditional craft skills and the self-employed to the margins (Girard, 2006). This has led to a kind of opposition between the knowledge economy and the material economy (Hudson, 2012).

Moreover, while these policies, too focused on knowledge-based industries, seek to rid cities of the manufacturing heritage and land use, there is a real revival of interest in custom manufacturing, artisanal production, and additive manufacturing (Jakob, 2012; Thomas et al., 2013; Luckman, 2013; 2015; Anderson, 2012). This renewed interest is further supported by an awareness of the vulnerability of consumer-oriented development and the questioning of its sustainability.

In response, we consider that reorienting cultural policy by focusing on the promotion of cultural production is an important opportunity that can reconcile the city with its industrial heritage. This allows cultural policy to reinvent itself and to overcome the limits of a cultural development based on consumption. Thus we are interested in the articulation between the cultural economy and the cultural industry. We show that cities can develop more equitably and sustainably if they consider and recognize their industrial and cultural heritage in their cultural and urban policy. Such a heritage can only flourish in perfect symbiosis with place (Scott, 2004). Indeed, new research supports the growing importance of small firms and small, flexible manufacturers and specific at the place (Mistry & Byron, 2011, Bryson & Ronayne, 2014). From this perspective and based on the analysis of small manufacturing firms in Tunisia, we show that they offer important possibilities for rethinking cultural policy.

**RADICAL ENTREPRENEURSHIP: CHALLENGING CASTE-BASED
DISCRIMINATION AND SOCIO-STRUCTURAL CONSTRAINTS TO
INCLUSION IN RURAL BANGLADESH**

[Grace Mueller](#)

University of Edinburgh, United Kingdom. Cambridge Institute of Sustainability Leadership, United Kingdom. University of Texas at Austin, USA

ABSTRACT

The rise of entrepreneurship as a strategy for development in the Global South is a reflection of growing geopolitical interest in the liberalization of economies and decentralizing state power as a means to maximize global social welfare. While it has been made clear that top-down approaches to ‘empowerment’ through ‘financialization’ often result in failed development attempts and stagnant markets, few studies have sought to understand entrepreneurship as it naturally evolves in its social and cultural contexts. In rural Bangladesh, characteristics of the non-institutionalized entrepreneur merge Western and South Asian market principles, creating a form of relational entrepreneurship that may open new pathways to mobility through dignified personhood creation, gender equality advancements, and economic opportunity not available to previous generations through other forms of labor.

In this paper I show how entrepreneurship among a rural Dalit community plays a significant role in the ability for poor families to change their circumstances. Through the observation of six entrepreneurs over six weeks, I found that entrepreneurs utilize certain behaviors to navigate three primary poles of inequality: economic stagnation and opportunity, social exclusion and inclusion and interdependence and context-specific agency. New freedoms gained through entrepreneurship enable marginalized men, and doubly marginalized women, to challenge the status-quo and negotiate power at a local level, opening new pathways for the study of ‘radical’ entrepreneurship as an avenue for the pursuit of upward mobility amongst marginalized groups in South Asia and elsewhere. This study is relevant to research which explores the role of self employment and small enterprises in creating structural change at a local level, particularly in contexts of extreme marginalization.

**FAMILY FIRMS AND ECONOMIC SPACES - BUILDING BRIDGES
BETWEEN FAMILY BUSINESS AND REGIONAL STUDIES /SCIENCE**

¹Technische Universität Berlin, Germany. ²American University of Sharjah, UAE

ABSTRACT

This paper is a review that searches for common fertile ground between the previously unconnected disciplines of family business and regional studies /science that have experienced delicate approximations in the past five years. Most existing studies linking both disciplines, however, are fragmented, dispersed and scattered not allowing for a systematic assessment of these approximations. Based on their relations to peculiar spatial entities – hereby we mean a superordinate term for spatial factors / structures, spatial process, spatial contexts, spatial scales, spatial settings, spatial policies, and spatial concepts – we are taking stock and attempting to group those studies along an extensive literature analysis. Moreover, we present two systematic attempts model (spatial family model, regional familiness model) already incorporating some of those entities within a single theoretical framework. We conclude that research streams in both disciplines have partly a high degree of overlaps. Therefore, we call for more interdisciplinary work to commonly address research gaps and exchange insights on theoretical, empirical and practical grounds around ideas of ‘Spatial Familiness’ and/or ‘Family Spatialities’.

BOILING HOT! ECONOMY-WIDE IMPACTS OF CLIMATE CHANGE ON COLOMBIAN COFFEE YIELDS

Pedro Levy Sayon

University of São Paulo, Brazil

ABSTRACT

Colombian coffee is renowned worldwide for its quality and delicious taste. It is one of the major crops of the country, being the world's third largest exporter. Although coffee growing is not relevant in terms of GDP, it plays an important role when it comes to employment, with over half a million families benefiting directly from it, potentially more indirectly. Given the importance of this commodity in the economy, global warming has sparked the discussion about how to overcome the coming hindrances imposed by new climate conditions. Using the forecasts of (Sierra, 2019), the present chapter tries to quantify said hardships in an interregional computable general equilibrium framework.

KEYWORDS

Climate change, coffee productivity, general equilibrium, Colombia.

1. CLIMATE CHANGE & GLOBAL WARMING

The term climate change refers to a physical phenomenon in which there are globally long-lasting shifts in temperature, precipitation, cloudiness, amongst other atmospheric conditions, in regard to their historical averages. Contrary to popular belief, it distinguishes itself from global warming in the sense that the latter only encompasses the first of the aforementioned climate characteristics: temperature. Such variations may be caused by many different reasons, such as internal Earth processes, external forces (e.g., solar activity), or, more recently, because of human intervention.

The Goddard Institute for Space Studies (GISS) is a laboratory in the Earth Sciences Division of the Goddard Space Flight Center from the North American Space Agency (NASA) affiliated with the Columbia University Earth Institute. One of the key objectives of the institute's research is the study of climate change in the 21st century and the prediction of long-term change in the average weather patterns resulting from said phenomenon. Bellow, follows a figure prepared by the GISS to illustrate the impacts of human activity on global warming.

Figure 1.1 - Change in Global Surface Temperature Relative to 1951-1980 Averages

Source: NASA's Goddard Institute for Space Studies.

Changes observed in Earth's climate since the early-20th century are primarily driven by human activities, particularly fossil fuel burning, which increases heat-trapping greenhouse gas levels in the atmosphere, raising the planet's average surface temperature. As seen above, there is a sharp detachment of temperatures from the baseline average starting just

before 1980, marking the beginning of human induced global warming. Not coincidentally, greenhouse gases emulate almost the same pattern, starting a couple of decades prior, because there is a strong lagged component correlating emissions and temperature. The following figure is a graphic demonstrating the previous statement.

Figure 1.2 – World Annual CO₂ Emissions

Source: Global Carbon Project, Carbon Dioxide Information Analysis Centre (CDIAC).

Albeit carbon dioxide (CO₂) is not the only greenhouse gas, it accounts for over than 80% out of the total, making it an excellent proxy for measuring emissions. Prior to the Industrial Revolution, the concentration of pollutants was insignificant. The amount of CO₂ released annually remained relatively low prior to the mid-20th century. In 1950, the world emitted just over 5 billion tonnes of this gas – about the same as the US, or half of China’s annual emissions today. By 1990, this had more than quadrupled, with 22 billion tonnes. Since then, they have continued to grow rapidly, totaling now over 36 billion tonnes each year. Growth has slowed over the last few years, nevertheless total emissions have yet to reach their peak.

In this sense, it is relevant to inquire the magnitude of the impact of human activity on climate as well as, reciprocally, the consequences of such new weather conditions on the economy. There is a plethora of studies correlating global warming and productivity, particularly in industries involved in extraction of raw materials, such as farming, logging, hunting, fishing and mining. Furthermore, many developing countries have strongly primary based economies, meaning that those sectors tend to make up larger portions of the country’s gross domestic product (GDP). Amongst such cases, a few examples in Latin America come to mind: Chilean copper, Paraguayan soy beans, and – the particular case of interest for this book’s chapter – Colombian coffee.

2. COLOMBIAN COFFEE INDUSTRY HISTORY

2.1 Formerly

First of all, it should be noted that this subsection, which entails an analysis of Colombian economic history, follows thoroughly the work of (Ocampo, 2015). The most popular story about the origins of coffee in America indicates that the French first brought the seeds to their colonies in Guyana and in the Antilles in the late-17th century. From this starting point, coffee growing spread throughout the continent in the first half of the 18th century. It finally reached Colombia around the middle of this era when the Jesuit Order introduced the crop in its farms at the Eastern Plains (Orinoquía), at the Cauca’s Valley and in other smaller regions.

Coffee growing remained, nonetheless, a minor activity for over a century, not only in Colombia, but also around the world. In European countries, its consumption was restricted in the 18th century to a few sectors of aristocracy, who could bear the high costs of an exotic drink. In 1790, for example, the total world trade in beans was 1.2 million 60kg bags of unripe coffee, a tiny fraction of what it is today. Only in the late-19th century, in the wake of the Industrial Revolution with slow popularization of its consumption in Europe and the United States, began the real history of the coffee industry. In Colombia, its first commercial experience came out as a subproduct of the pinnacle of coffee growing in the Venezuelan Andes after its independence. In fact, the first crops of relevant scale were produced in the Cúcuta region in the 1830s. From there, coffee growing spread first to Pamplona and Ocaña, in Norte de Santander, and later to Santander, Cundinamarca and western Colombia.

During the first years, it is difficult to know the real magnitude of Colombian exports, since much of what was registered as such in Cúcuta customs were actually re-exports of Venezuelan coffee. Although there are higher estimates, it would not seem an exaggeration to affirm that the total production of coffee in Colombia in 1860 was between 30,000 and

40,000 bags. By then, registered exports, including Venezuelan coffee, had reached 55,000 bags. Yet, coffee was still a marginal item within Colombian foreign trade as a whole, since it represented only 4% of total exports. From then, the grain's production experienced three different booms in the 19th century, which generated a significant displacement of the coffee frontier to the interior of the country. The first of these expansions took place in the 1860s. During this period, exports rose to around 100,000 bags but production remained concentrated in Norte de Santander. When the Office of Statistics made the first attempt in 1874 to reliably estimate the country's coffee production, it amounted to about 110,000 bags, out of which 95,000 came from that region.

The second boom took place during the 1870s. This expansion made it possible to increase exports of the grain from 100,000 to 22,000 bags approximately and to turn coffee into one of the important products of Colombian foreign trade: by the end of that decade, it already represented more than 20% of the country's external sales. This growth generated yet another and more significant shift in the production frontier. Albeit Norte de Santander continued to increase its harvests until it yielded 120,000 bags in these years, most of the new production was concentrated in Santander and Cundinamarca, which by the middle of the following decade were producing 60,000 and 40,000 bags, respectively. In the first case, expansion began at the beginning of the decade around Bucaramanga, hence consolidating its economic dominance over this region of the country at the expense of the historic centers to the south of this department. In Cundinamarca, on the other hand, the extension of plantations began a little later. In both regions it was interrupted by the fall in international prices that took place in the early 1880s and the civil war that followed.

Shortly after political order was restored during the Regeneration, the third and most important coffee boom of the 19th century began. The country's production expanded considerably in the 1890s, reaching around 600,000 bags when the Thousand Days' War broke out. By then, it already represented about half of Colombian exports. This expansion coincided with the best international grain prices of the second half of this era. In fact, in the early 1890s, real coffee prices were 40% higher than in the 1870s and almost three times higher than in the mid-19th century.

Other factors undoubtedly played a role in this process. As a reflection of the general crisis that Colombia's foreign trade experienced in the early 1880s, the depreciation of silver in the international market and the subsequent introduction of paper money, the peso experienced a substantial real devaluation. During the initial stage of this process, coffee production costs tended to fall in terms of gold (the international monetary unit), thus promoting plantings. No less important was the landowners' access to credit granted by foreign business houses in conditions that were attractive for that time: 6% annual interest (with 1.5 or 2 additional percentage points of commissions), two years of term and subsequent payment in coffee.

In regional terms, the expansion of the 1890s was the most diversified of the 19th century. The axis of expansion was the west of Cundinamarca (and the surrounding areas of Tolima), which increased its yields from 40,000 to 230,000 bags during these years. Outside this region, production began to expand on an appreciable scale in Antioquia, which by the end of this era was amounting about 90,000 bags. Santander doubled its harvests, until it reached around 120,000 bags. Norte de Santander and Cauca's Valley also participated, albeit on a more modest scale in the peak.

In western Cundinamarca, the expansion followed three different lines. The first of them followed the route from Bogotá to Honda; the second, the province of Tequendama, accompanied by Bogotá River on its descent to the Magdalena River; and the third, the Sumapaz region, followed by the downslope route towards Girardot. Coffee development apparently began in the first of these lines during the 1870s, from where it headed for Tequendama and, to a lesser extent, towards Sumapaz in the late-19th century. In Antioquia, coffee had begun to develop also in the 1870s in the vicinity of Medellín. The expansion of the end of this era, however, was concentrated in southeast Antioquia, especially in Fredonia district. In Cauca's Valley, on the other hand, most of the development then had its epicenter in a geographic depression, in the vicinity of Cali and Palmira.

The first decade of the 20th century did not seem particularly likely to result in a large coffee expansion. Despite the enormous efforts made by the Government of São Paulo in Brazil to restrict planting and defend grain prices, these remained at extremely low levels since 1899. Coffee farms were unproductive and still affected by the greatest civil conflict in Colombian history, and hence were incapable of yielding development. Only the iron discipline imposed by General Rafael Reyes and his attempts to promote new economic enterprises were positive elements for a new export boom.

In spite of the unfavorable elements, the coffee industry took on an unexpected positive turn in the national economy during this period. By the late 1920s, production had more than quintupled, surpassing over 3 million bags. Not only did the crop become Colombia's main export commodity, but also the country itself became one of the world's largest producer (second only to Brazil), the first in soft coffees. In the early-20th century, 3,5% of all coffee in the world was being harvested in Colombian territory. At the end of the decade, this share had risen to 10% and it would continue to grow in the coming years.

This sudden growth implied in a radical change in the agricultural frontier and in the means of production. In fact, increased production concentrated in Antioquia colonization areas in Old Caldas, south of this department and to the north of Tolima and Cauca's Valley. This region had been populated since the early years of independence and by the beginning of the 20th century it had acquired an important volume of dwellers. The settlers initially developed a slash-and-burn agriculture similar to that practiced in other regions of the country, but with some additional commercial activities (pigs fattening, saddlery, etc.). Coffee did not play an important part of this process, even in the late settlement regions (Quindío), since its long gestation period did not adapt to the requirements of the colonization process. Nonetheless, in the early-20th century, the crop expanded rapidly in small and medium-sized properties that had developed in the region thanks to a long process of struggle for land from the settlers against the owners of unproductive

farms, who had the support of the commercial elites of Medellín and later Manizales. Still, this diffusion process of the peasant units did not prevent them from maintaining an appreciable concentration of property in the colonization areas. According to estimates, around 20% of land awards in Antioquia and Caldas between 1823 and 1931 (about 250,000 hectares) favored settlers or small and medium-sized owners (less than 50 hectares).

The advance of coffee in this region during the first three decades of the 20th century was incredible. Antioquia and Caldas went from producing 90,000 bags in 1900 (around 15% of national yields) to 384,000 in 1913 (36%) and 1,622,000 in 1932 (47%). Production from Tolima and Cauca's Valley was about 110,000 bags in 1913 (10% of total), but it was represented mainly by harvests from farms located in the west side of the first and at the south of the latter. In 1932, outputs from those departments were 802,000 bags (around 23% of national yields) and were concentrated in the central mountain range. Besides, the coffee industry started to spread to new regions of the country, especially Cauca, Nariño, Huila, Boyacá and Magdalena. The traditional producing zones in Norte de Santander, Santander and Cundinamarca concentrated 82% of national production at the turn of the century (500,000 bags), yet in 1932 those yields reduced themselves to sole 24% (820,000 bags).

The great bonanza that the coffee economy experienced before the crisis of 1929 was not abruptly interrupted. On the contrary, it kept growing in later decades. In the early 1960s, harvests amounted to a total of 7.8 million 60kg bags of unripe coffee, about three times of what it was in the second half of the 1920s, although it became less dynamic. In fact, production as well as exports experienced a sharp increase throughout the first decades of the 20th century (between 6% and 8% annually), only for harvests to stabilize in smaller 5% growth rates in the 1930s. This started to slow even further, however, in the 1940s, until it reached less than 2% in both the 1950s and the 1960s.

Previous trends were reflected in national portion in world grain production and trade. In the early 1930s, the country concentrated 10% of all exportable yields and 12,4% of coffee foreign sales. Those shares would keep on growing until they had reached their peak at 20% during the Second World War. With loss of dynamism, so did those values start to decline in the postwar period, only to stabilize in the 1960s between 13% and 12%. Noteworthy, even half a century later, not much has changed production-wise, neither in terms of Colombia's placement in the coffee market. Notwithstanding the clear connection between the country's macroeconomic policy and the crop's business cycle, especially in the second half of the 20th century with further development and integration of world financial markets, this will not be covered here⁴⁵. This brief history of Colombian coffee industry served its purpose in demonstrating how the regional distribution of production became what it is and also in foretelling the national role in this commodity's world trade, which will be further detailed the next subsection.

2.2 Currently

Today, Colombian coffee consumption has become a worldwide phenomenon, whose drink is widely renowned for its quality and delicious taste. It is the major crop of the country, who is also a major player in foreign trade of this commodity. Despite coffee growing not making up a relevant portion of the nation's GDP (less than 1%), it plays an important role when it comes to employment, with over half a million families benefiting directly from it, potentially more indirectly when considering interindustry linkages and income induced effects. Because of this product's popularity and importance to the economy, many researchers and enthusiasts started to wonder what may happen to its production in a climate changing setting.

In regard to the general structure of production presented in Chapter 8 (*Chaining Juan Valdez: Linkages in the Colombian Coffee Industry*) of this book, the first relevant characteristic of this product's supply chain is its division between two industries: coffee growing and coffee processing – given the sectorization of the economy in the interregional input-output system (IIOS) for Colombia in 2015. Although the eighth chapter gives a more detailed picture of those two, it is important not only to remember that they are strongly interlinked with one another, but also to investigate what other sectors are connected to them as well as which primary factors they are demanding.

Considering the first of those, coffee growing, its intermediate demands are dominated by basic chemical substances (e.g., fertilizers), agriculture (e.g., coffee seeds), electrical equipment, land transportation (e.g., tractors and trucks), and financial activities, respectively. Those five sectors concentrate almost 90% of total input necessary for coffee growing and are almost entirely provided domestically, with the exception of the chemicals, where around half is imported. This intermediate consumption, however, corresponds to only a third of total expenditure from the industry, whereas the other two thirds are split almost equally between labor and capital, and thus coffee harvesting is in neither way intensive. Finally, it should be pointed out that none of this sector's output are exported, which means that all of its production is absorbed by the local market, a large share by coffee processing, which will be further detailed in the next paragraph.

This next industry, coffee processing, on the other hand, has over 80% of its intermediate demands coming from the previous. The others, in order of relevance, are: coffee processing itself, wholesale and retail trade, financial activities and plastic products (e.g., packaging). When adding the four latter to the former, it accounts for over 95% of the total input necessary. With the exception of financial activities, where almost three quarters are imported (likely foreign banks investing in the crop's production), most of the inputs are provided domestically once more. Differently from growing, intermediate demand here concentrates more than 90% of total expenditure from the industry, followed by capital with 7% and lastly labor with no more than 1%, which makes processed coffee a capital-intensive product. Finally, one more important distinction in this case is that not all the production is destined to the local market. Quite the opposite, it is a very important export for the country, whose relevance will be illustrated shortly.

⁴⁵ For more information on this subject, see (Ocampo, 2015).

Table 2.2.1 – Total Colombian Exports in 2015 (COP Billions)

#	Commodity	Code	COP Billions	Share
1	Extracción de petróleo crudo y gas natural y actividades de apoyo para actividades de explotación	S7	\$37,598.00	32%
2	Extracción de carbón de piedra y lignito	S6	\$11,712.72	10%
3	Fabricación de sustancias químicas básicas	S24	\$ 8,678.10	7%
4	Fabricación de productos metalúrgicos básicos	S27	\$ 8,341.61	7%
5	Elaboración de productos de café	S14	\$ 6,725.24	6%
6	Agricultura y actividades de servicios conexas	S1	\$ 6,574.54	6%
7	Coquización, fabricación de productos de la refinación del petróleo y actividades de mezcla de combustibles	S23	\$ 5,769.66	5%
8	Alojamiento y servicios de comida	S45	\$ 4,850.11	4%
9	Transporte aéreo	S42	\$ 4,146.46	3%
10	Preparación, hilatura, tejeduría y acabado de productos textiles	S19	\$ 2,187.16	2%
11	Actividades profesionales, científicas y técnicas; Actividades de servicios administrativos y de apoyo	S49	\$ 2,172.02	2%
12	Fabricación de productos de caucho y de plástico	S25	\$ 1,778.92	1%
13	Fabricación de aparatos y equipo eléctrico; fabricación de productos informáticos, electrónicos y ópticos	S28	\$ 1,732.52	1%
14	Fabricación de vehículos automotores, remolques y semirremolques	S30	\$ 1,492.23	1%
15	Fabricación de papel, cartón y productos de papel y de cartón; actividades de impresión	S22	\$ 1,462.61	1%
16	Información y comunicaciones	S46	\$ 1,352.06	1%
17	Fabricación de otros productos minerales no metálicos	S26	\$ 1,162.33	1%
18	Fabricación de maquinaria y equipo n.c.p.	S29	\$ 1,071.57	1%
19	Elaboración de azúcar y elaboración de panela	S15	\$ 1,027.38	1%
20	Elaboración de aceites y grasas de origen vegetal y animal	S11	\$ 962.36	1%

Source: IIOS Colombia 2015.

When looking at the previous table, it is possible to note that the top five most exported commodities from Colombia in 2015 are, in order: petroleum, coal, chemical substances, basic metallurgical products and coffee. Albeit the latter is only the fifth in terms of total value, it is the first amongst agricultural products and accounts for over 700,000 tonnes of exported grains. The Atlas of Economic Complexity is a data visualization tool built at the Harvard Kennedy School of Government and powered by Harvard Growth’s Lab that allows users to explore global trade flows across markets and track these dynamics over time. The next two figures were produced using this platform and will display, respectively, the destination countries of that commodity and the relative importance of Colombian coffee in terms of total exported value in 2015.

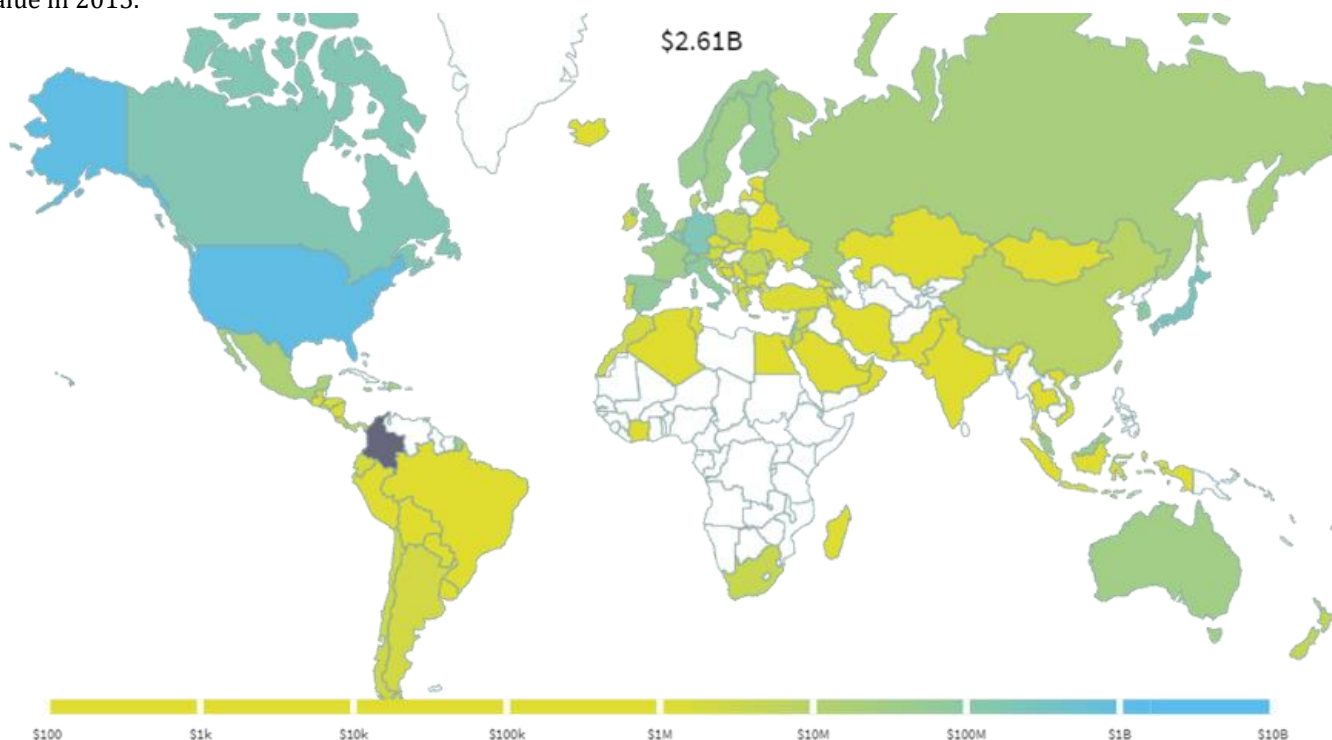

Figure 2.2.1 – Absolute Destination of Colombian Coffee in 2015 (USD)

Source: The Atlas of Economic Complexity.

Figure 2.2.2 – Relative Origin of Coffee Exports in 2015 (USD)

Source: The Atlas of Economic Complexity.

The first of those pictures shows that Colombian coffee is primarily consumed in the United States, in Canada and in Japan, followed by Western Europe, Australia, Russia and China, which means that most of its importers are developed countries whose *per capita* income is enough for their denizens to acquire a prime quality product such as this. The second image displays Colombia as the world’s third largest coffee exporter, second only to Brazil and Vietnam. Yet, as will be shown in the next section, the latter only produces robusta grains (*Coffea canephora*). And whilst the former’s coffee is the same as Colombian – arabica beans (*Coffea arabica*) – its quality is significantly smaller.

3. UNDERLYING HARVESTING MECHANISMS

There are many different ways with which climate affects coffee productivity. The Climate Institute is an Australian organization whose main goal is to conduct scientific research on climate change. It also informs the public of key findings in order to provide decision-makers with effective information on how to counter the coming hindrances of such phenomenon as well as aid them in policy prescription so that many of said hardships can be avoided. The entity published a report in 2016 in which the author evaluates the possible effects of climate change on coffee farming. It estimated that by 2050 half of the present farming land will be rendered useless for the crop and that by 2100 wild coffee will become extinct. It also provided a schematic illustrating how this will unfold.

Figure 3.1 – Coffee Farming in a Changing Climate

Source: (Watts, 2016).

The underlying mechanisms of coffee harvesting are further explained in (Bunn, Läderach, Rivera, & Kirschke, 2015). The Climate Central, another organization whose focus is analogous to that from the aforementioned Climate Institute,

produced yet another report in order to disclose the findings from the authors of this paper. There, they describe in more detail the channels with which climate change affects coffee yields. First, the rising temperature damage the beans. Also, the more frequent droughts lower the crop's growth. And lastly, the advancing pests, particularly the coffee borer beetle (*Hypothenemus hampei*), stress the plant, reducing productivity.

Moreover, the authors also simulate the reduction of coffee farming land for arabica beans by 2050. They create three different scenarios: one in which there are no changes to the current baseline, another in which there are gradual cuts in emissions, and yet a third one with dramatic cuts. Respectively, those scenarios yield 58%, 49% and 43% of loss each, meaning that even in such a case where emissions are diminished drastically, inertial effects of climate change will still imply in depletion of over than 40% of terrain suitable for this crop. The authors generated the future climate data by downscaling a general circulation model (GCM), which is a type of climate model that employs a mathematical algorithm of the general circulation of the planetary atmosphere or ocean.

Afterwards, they operated this model for the representative concentration pathways (RCP) 2.6, 6.0 and 8.5, which are greenhouse gas concentration (not emissions) trajectories adopted by the Intergovernmental Panel on Climate Change (IPCC), namely those three distinct scenarios described in the above paragraph. Finally, they analyzed impacts for latitude, altitude, regions and land-use classes to hypothesize future impact scenarios on global coffee production. With those results in hand, the article displays a series of maps illustrating coffee suitability and how it will change by 2050, which are all presented below.

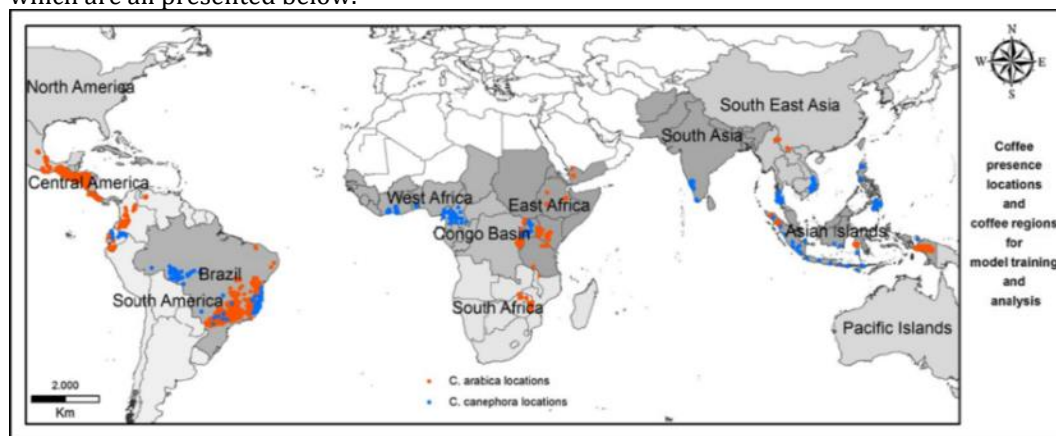

Figure 3.1 – Coffee Presence Locations

Source: (Bunn, Läderach, Rivera, & Kirschke, 2015).

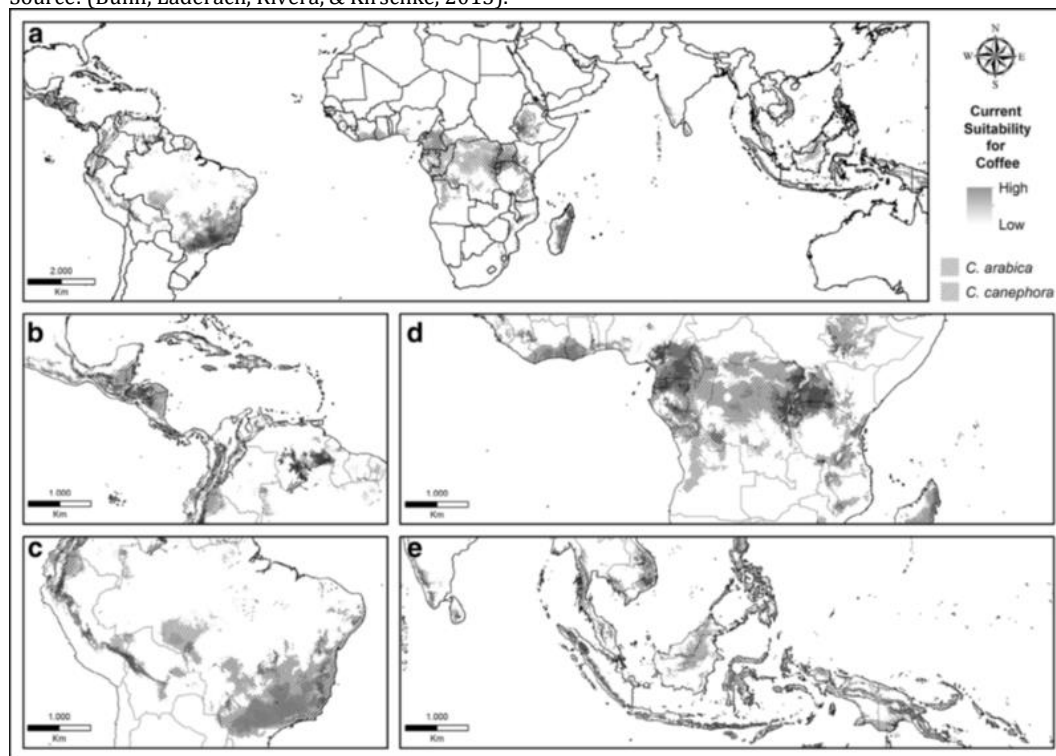

Figure 3.2 – Current Coffee Suitability

Source: (Bunn, Läderach, Rivera, & Kirschke, 2015).

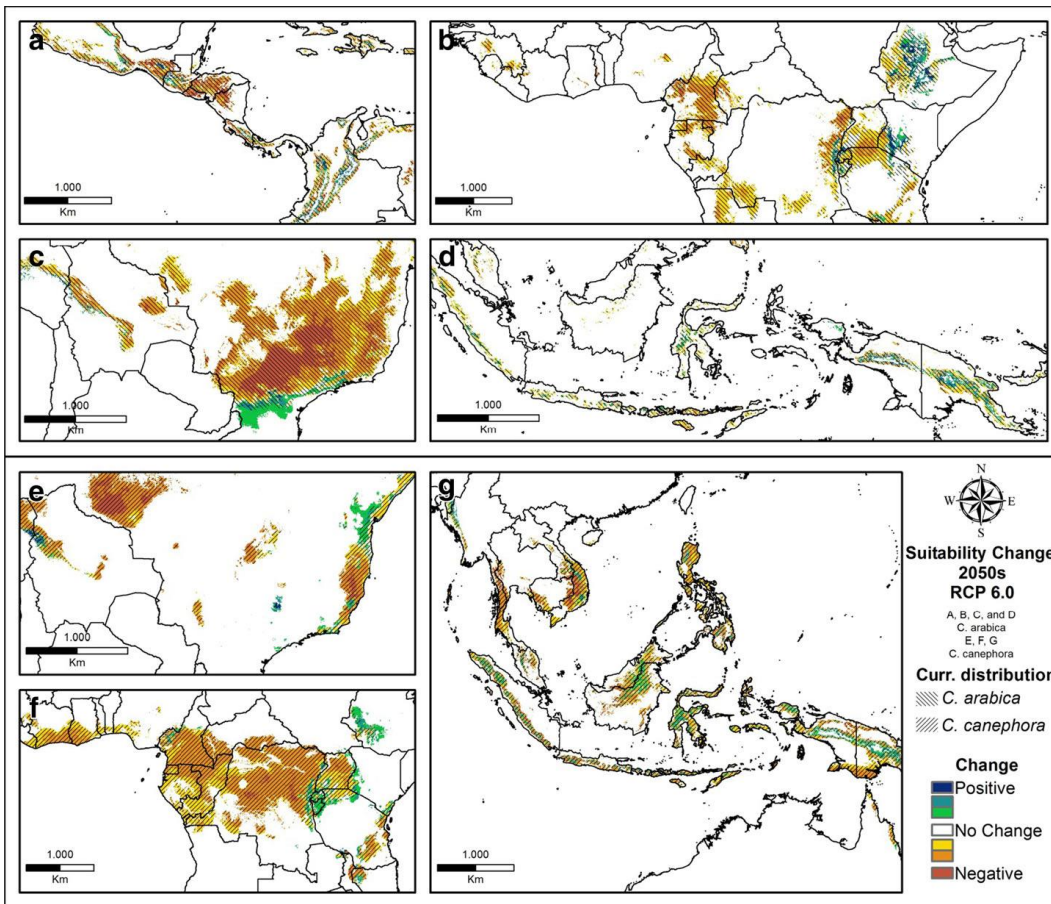

Figure 3.3 – Suitability Change by 2050 (RCP 6.0)

Source: (Bunn, Läderach, Rivera, & Kirschke, 2015).

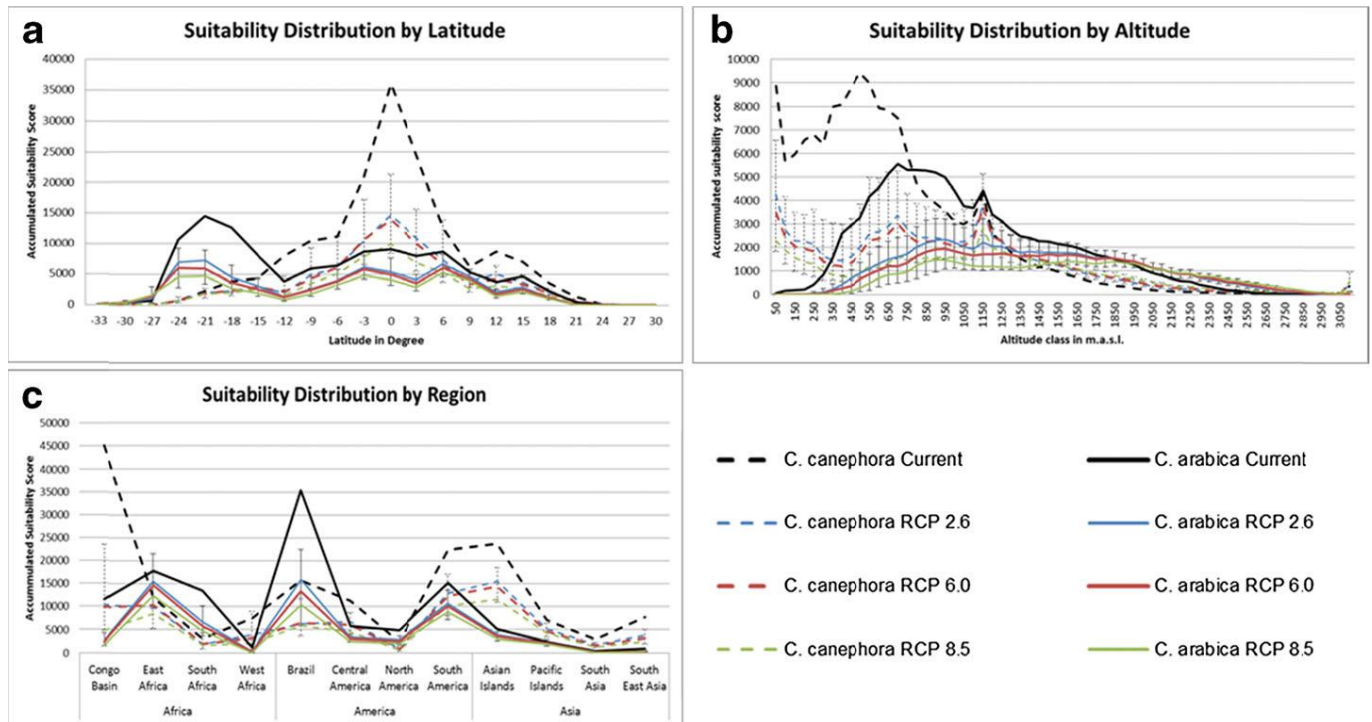

Figure 3.3 – Suitability Distribution by Latitude, Altitude and Region

Source: (Bunn, Läderach, Rivera, & Kirschke, 2015).

As can be seen in the images above, Colombian coffee is composed mainly by arabica beans. It was also previously mentioned that, regardless of scenario, this species will likely experience a great reduction of farmable area. The paper, nonetheless, does not place its focus on Colombia, whose coffee suitability is shown to undergo positive changes overall

in figure 3.2. Ergo, comes the previously posted question: what may happen to the country's popular crop in different RCP alternatives? The co-author of this book's chapter tries to answer that question in (Sierra, 2019) by providing a multi-step model to forecast total coffee yields in each of the nation's 1,123 municipalities.

The simulation uses two different inputs: precipitation and temperature. Water comes in the first step of the model, in which its absorption by the plant is calculated. After that, the output of the previous step determines the production of photosynthate using a measurement called Leaf Area Index (LAI). This, in turn, is what causes the coffee to flourish. Then, temperature comes in to influence growth, as well as the dynamics of production and the life cycle of the coffee borer beetle. When all five sub-models have been completely integrated, they yield coffee productivity, measured in kilograms by hectare. The author provides a schematic to enhance the understanding of his model, as well as how each of those steps communicate with one another and with its inputs.

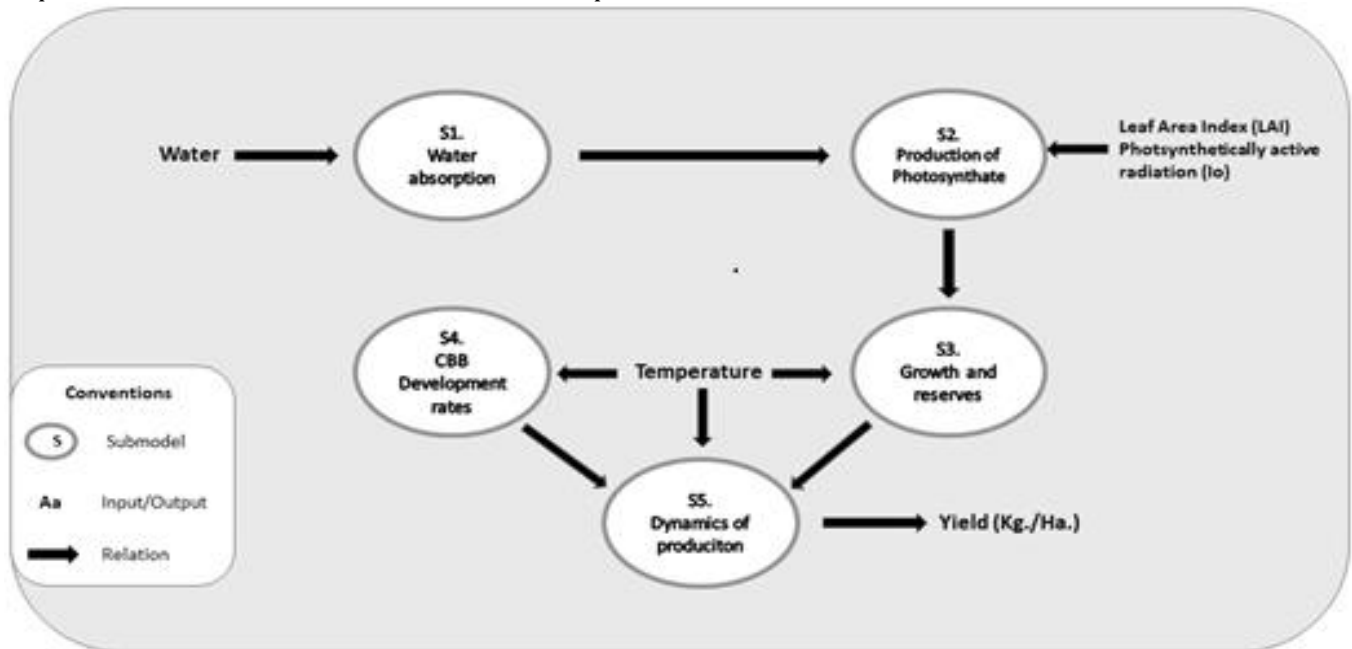

Figure 3.4 – Proposed Model for Coffee Yields

Source: (Sierra, 2019).

Previous forecasts have estimated an increase between 4% and 24% in coffee yields on a national level. However, with over 500 municipalities producing this crop, this model predicts the expected outputs with a high degree of heterogeneity. Not only latitude plays a major role in coffee suitability, but also altitude, as was shown in the pictures of this section. Colombia is a vast country, but more so when it comes to topology, having peaks as high as the Andean mountain range and valleys as low as sea level. This only makes it all the more interesting to imagine the possible outcomes of global warming in such a diverse region. Especially when, contrary to logical expectations, a changing climate in this specific case brings benefits to a particular crop.

Lastly, it is important to note, nevertheless, that what matters for the coming simulation is not the total coffee yields as outputted by the forecasting model, but instead percentage changes. Therefore, for the exercise performed here, first there is an aggregation of the outputs provided by the co-author in order to observe them on a departmental level. After that, they are transformed into a variation of productivity relative to a baseline scenario, which is observed by the IIOS for Colombia in 2015. These are, then, inputted in an already calibrated general equilibrium model using the same database. The shock itself, as well as its results and interpretations will be further detailed in the coming section.

4. CLIMATE SHOCK, RESULTS & ANALYSIS

After all the previously described steps have been completed, there is now a fully implementable computable general equilibrium (CGE) productivity shock. Out of the 32 departments and the capital district in Colombia, only 18 of them are affected. It varies from a decrease of almost 23% to an increase of a little over 21%, and affects only the coffee harvesting industry (remembering, from the second section, that there are two sectors involved in coffee in Colombia – growing and processing). This happens because due to the aforementioned mechanisms through which global warming and humidity affect the crop's output, it only makes sense for a primary-based industry to be influenced. Moreover, it should be noted that the computations are all simulated with a long-term closure, given that climate change is, by itself, a perennial phenomenon. The following two figures illustrate the inputs of the model discriminated by region and the role of topology in its composition, respectively.

Table 4.1 – Productivity Shock by Department

#	Department	Shock
R1	Antioquia	-7.98
R5	Boyacá	15.28
R6	Caldas	-0.94
R7	Caquetá	-0.03
R8	Cauca	-5.70
R9	Cesar	4.36
R11	Cundinamarca	-10.37
R12	Chocó	0.29
R13	Huila	-21.38
R16	Meta	4.27
R17	Nariño	-5.92
R18	Norte de Santander	15.86
R19	Quindío	-1.91
R20	Risaralda	-0.54
R21	Santander	22.73
R23	Tolima	-16.28
R24	Valle del Cauca	6.16
R26	Casanare	0.83

Source: Own elaboration.

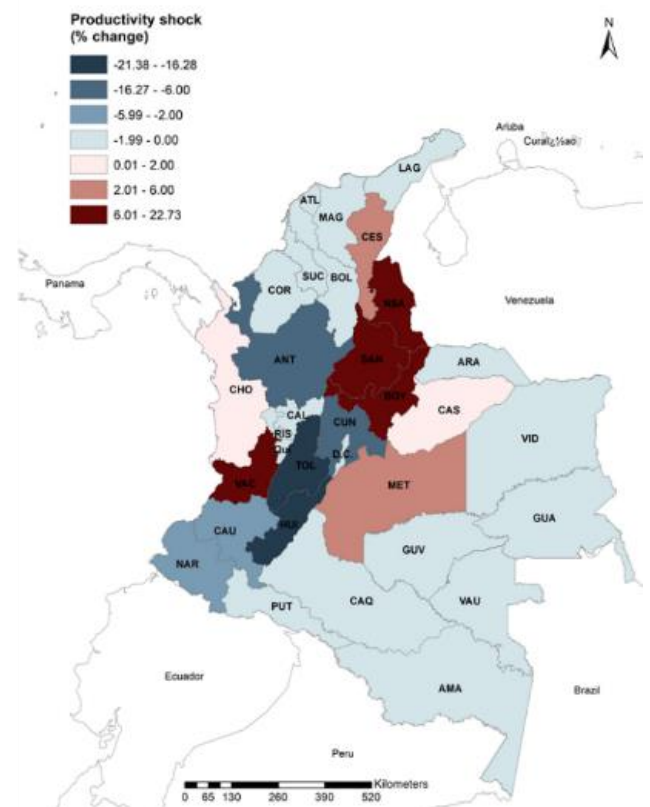

Figure 4.1 – Topology and Productivity Shock

Source: World Atlas.

As it is possible to notice in the two previous images, there is a clear overlay between the country’s altitude and the climate shock. This happens because due to Colombia’s unique topology, higher regions tend to have colder temperatures, even when close to the Equator. In other words, departments whose heights are closer to the sea level are already suitable for coffee and will experience a drop in productivity, whereas the Andean mountain range will see its lands become farmable for coffee.

Another detail that leaps into the eyes of an attentive reader is the fact that in both pictures the productivity shock is presented in shades of blue for negative values and shades of red for positive ones, which is at least strange given standard data coloring conventions. Actually, this is on purpose: due to the computable general equilibrium model's structure, negative values should be interpreted as an increase in productivity, and vice-versa. For instance, as the simulation will take place in all input augmenting technical change, a positive value observed for the shock in table 4.1 means that coffee growing will require more inputs to produce the same level of output. Again, the reverse logic applies to negative values.

Additionally, this was already mentioned, but it is essential to underline that the only industry affected by the initial productivity change is coffee growing. Hence, all other effects captured by the model are indirect or induced by the optimization of each agent's objective functions given the new set of restrictions – those equations are all specified in the methodological chapters of this book. Finally, the results of the CGE simulation will be presented in the coming paragraphs. First, there are the macroeconomic effects, more specifically in GDP and its components. After that, there is the regional distribution of this impact and how it relates to the national results. And lastly, there are the sectorial results which evaluate how each industry is affected by a change in coffee productivity.

Figure 4.2 – Macroeconomic Results

Source: Own elaboration.

The schematic above provides a clear view of how each macroeconomic variable influence product in the new equilibrium. It provides both variations relative to themselves in the baseline scenario and how much they contribute, in absolute, to total percentage change in GDP. Also, the top line represents the income approach computations, whilst the bottom one covers expenditure. The first relevant information here is that this shock induces an 0.212% increase in national income. Interestingly, though, less than 10% of this variation is due to the shock in all input augmenting technical change. More than 80% comes from capital and around 11% comes from taxes on the income side. On the other hand, almost 85% of total growth in GDP is captured by an increase of 0.267% in household consumption when looking at expenditure. The rest comes from investment (21%), exports (15%), government spending (5%), and imports influence this change negatively (-26%) as it also rises in absolute terms.

Figure 4.3 – Contribution to GDP Change by Origin of Shock

Source: Own elaboration.

The previous graphic illustrates the decomposition of total impact on product amongst the different departments affected by the initial input of the model. It should be easy to realize that this is a very different number from that observed in the productivity shock in table 4.1. As was mentioned just previously, the latter makes up only a small portion of the GDP's change. Therefore, what is being shown above is actually the aggregate effect in each of those regions after the algorithm finishes iterating and the economy reaches convergence once again. In other words, each of those values account for not only the change in coffee growing yields in its respective department, but also the difference in labor and capital from the income side, or, alternatively, variations in household consumption, investments, government spending, exports and imports from the expenditure's approach.

The most relevant region in terms of impact is Huila, whose contribution alone accounts for almost 45% of total increase in GDP. Looking only at departments which influence the product's variation positively, it is followed by Tolima, Antioquia, Cauca, Cundinamarca, Nariño, Caldas, Quindío, and Risaralda. Together, those nine yield a change of 0.271% in national income. On the decrease side, Santander is the most significant of them all, with around two thirds of total impact on GDP. Analogously, it is followed by Valle del Cauca, Norte de Santander, Cesar, Boyacá, and Meta. These six accumulate a negative variation of 0.059%. When subtracting the latter from the former, the already mentioned total impact on product is obtained. Albeit other regions generate no relevant effect on GDP, that does not mean that they do not experience changes in the distributions of their gross regional product (GRP), but this will be demonstrated shortly.

Top 5		
#	Department	GRP ($\Delta\%$)
R13	Huila	3.295
R23	Tolima	1.286
R11	Cundinamarca	0.320
R33	Vichada	0.311
R22	Sucre	0.291

Bottom 5		
#	Department	GRP ($\Delta\%$)
R9	Cesar	-0.119
R18	Norte de Santander	-0.193
R19	Quindío	-0.232
R6	Caldas	-0.281
R21	Santander	-0.305

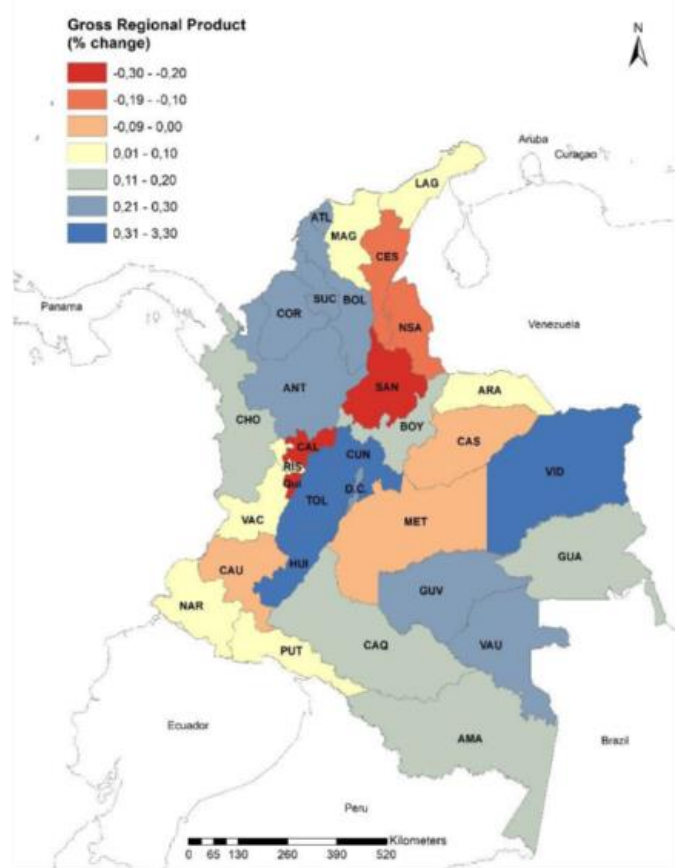

Figure 4.4 – Gross Regional Product Percentage Change

Source: Own elaboration.

Similar to the contribution to GDP, Huila and Tolima are the departments whose GRP has increased the most, which also emulates the largest productivity gains with the initial shock. They are followed by Cundinamarca, a region whose contribution to national income in the simulation, counterintuitively, is second to Antioquia and Cauca (besides the already mentioned previous two). This happens, nevertheless, due to the share of those departments' product in the economy. In other words, even though Cundinamarca's growth relative to itself was higher than Antioquia and Cauca, the latter two's share in the country's GDP is larger, which means that a smaller percentual variation still yields higher absolute effects in Colombia. To further enforce this argument, fourth and fifth biggest GRP percentage changes are Vichada and Sucre, respectively, which do not even appear in figure 4.4 given the small contribution they pose to income in this scenario.

On the reduction side, Santander occupies the bottom of the list, also replicating the pattern observed in figure 4.3 and in table 4.1. It is followed by Caldas, Quindío, Norte de Santander and Cesar, out of which only the latter two play a relevant role in reducing Colombia's GDP. The others do not amount to a significant impact in the national income for the same reason described previously: their economies are relatively small when compared to other departments. Another detail that is worth mentioning is the fact that, with the exception of the top two, no other region displayed a percentage change in GRP greater than one in module. This means that even with spatial heterogeneity amongst product growth and shrinking, overall results tend to be small, which is consistent with the CGE model's structure, as the shock takes place only in coffee farming. Finally, it should be noted that the geographical results also overlap the country's topology as shown in figure 4.1. Now, this section will place its focus on sectoral results, exploring interindustry linkages in the Colombian economy.

Figure 4.5 – Impact on Activity Level by Sector

Source: Own elaboration.

Evidently, the most impacted sectors are coffee related, namely growing and processing. What comes as a surprise, though, is the fact that in spite of the initial productivity shock happening only in the first of these industries, the latter presented higher percentage change in activity level in the new equilibrium. It reached around 4.5% growth rate, whereas the farming branch stayed a little below 4%. This happens because of the crop’s supply chain in Colombia and the strong connection between those activities.

As was stated by the end of the second section of this book’s chapter, most of all output from coffee growing goes to processing, meaning that it does not benefit from increased productivity in other sectors and hence from increased demands for unripe beans. Whilst the other industry provides its products to different consumers and is more integrated in the national economy. Furthermore, about one third of total harvesting expenses are destined to labor, which means that a smaller necessity of inputs in this particular activity induces income effects in the form of salaries to the families. Ironically, this result does not affect the sector that originated it in the first place as only a minority share of its sales comes from final demand, which is not true for coffee processing.

After the top two, the most affected industries are: real estate, beverages and tobacco, entertainment, water supply, mill products, fishing, processing and preserving of meat, and human health and social work activities. Interestingly, all those eight displayed an increased activity level no higher than 0.5% each. In other words, after coffee related sectors benefit from the shock, the impact is relatively homogenous amongst many other activities, and it is likely explained by the same mechanisms responsible for growth in the previous two: increased demands for their products and cheaper inputs now available.

Another curious observation here is that even in the ten least affected industries, five of them still yielded positive results, with only four showing no relevant signs of increased or decreased activity level and one lone sector presenting itself in a shrunk state relative to the initial equilibrium – mining of coal and lignite. Ergo, when comparing sectoral and regional results, there is a clear difference: the former is much more heterogenous, not only in magnitude, but also in direction as many departments showed a decrease in GRP.

Figure 4.6 – Impacts of Primary Factor Mobility

Source: Own elaboration.

Finally, the last analysis presented in this section regards primary factors mobility, as can be seen above. Labor’s behavior, portrayed on the figure’s left side, also reflects Colombian topology, as if workers are migrating from lower departments to mountainous regions in search of new jobs now provided by a physically rising coffee growing industry. Capital stock, as shown in the image’s right side, also contemplates this phenomenon, but more departments are receiving investment, particularly those in the Amazonian Colombia.

5. CONCLUSIONS & POSSIBLE NEXT STEPS

Colombian coffee has an interesting history, as it was brought to America by the French, but its first commercial experience in the country came out half a century later almost accidentally as a result from one neighbor’s successful enterprise. From then, the industry experienced a series of transformations in the coming couple of centuries as the nation was molding itself politically and economically into what it is known today as contemporary Colombia. At the same time, the second half of the 20th century along with the last couple of decades have seen the emergence of a worldwide debate regarding the contribution of human activity to a natural phenomenon called climate change. Throughout these years, the scientific community has established a clear causation relationship between those two and started posing incommodious questions to leaders and policy-makers around the world, whose answers would define actions that could prevent some of the coming hindrances imposed by such new weather conditions, thus diminishing the loss of mankind’s life quality on Earth. This chapter tried to answer a few of those inquiries, in particular those regarding the prospects of the crop responsible for one of the world’s most popular drinks: Colombian coffee.

As expected from a chapter in this book, the chosen methodology is a CGE model whose parameters were calibrated using the national IIOS from 2015. The inputs for the climate shock were provided by (Sierra, 2019), in which the long run scenario was simulated using a multi-step model encompassing the many stages of development from the plant. Intriguingly, even with heterogeneity amongst different regions, the productivity variation in coffee growing is overall positive in Colombian territory, which is due to the country’s particular topology. The results from this exercise were presented in the previous section, though it is safe to express that this last characteristic, height, played a major role: as the temperatures become warmer, lower regions will become unsuitable for harvesting, whereas the Andean mountain range will potentially experience a sharp increase in yields. It is also important to note that despite macroeconomic results being relatively small – which is consistent with the given inputs – they are heterogenous amongst different departments, replicating the pattern from the previous statement. The sectoral results were more homogenous and coffee related industries (growing and processing) were most positively affected by the shock, which is expected given the production structure of this commodity.

Finally, this work is not free of limitations. While reading this chapter, it may be reasonable to assume that climate change portrays, contrary to popular belief, a positive scenario for Colombia. Nevertheless, this is not the scope of the analysis.

Even if working in a general equilibrium framework, i.e., accounting all markets' equilibria simultaneously and not only the coffee industry, the inputs of the model reflect a situation in which the latter is the only effectively affected by future climate characteristics, whilst everything else will remain unaltered, which is a very strong assumption. While this does not necessarily invalidate the results encountered, it certainly raises questions in a sense of what would happen to other sectors in this setting, not only as an indirect result through coffee productivity increase, but also as a direct consequence of those new weather patterns, thus rendering this exercise as a milestone for future analysis of the same nature.

As for next steps *per se*, this work could also be subject to development itself through the accomplishment of a few additional exercises. Amongst such cases, the first example that comes to mind is the introduction of a more detailed analysis regarding the difference between production quantity and quality. In the entirety of this research as well as in the simulation that powers the climate shock, various scenarios are only comparing difference in total crop yields, but they do not take into account that these outputs are not automatically the same. For instance, even if coffee farming moves up the hill towards the Andean mountain range, those newly planted beans do not necessarily reflect the same quality as those harvested closer to the sea level, which may result in a very strong difference in the drink's flavor. This effect will reflect on the commodity's price, which is also a measurement for productivity that could be used in the CGE's structure. Moreover, the model does not take into account any uncertainty, ergo rendering the shock a deterministic exercise. By integrating a stochastic module into the simulation, given by the standard deviations of the multi-step prediction process, results come out not as one single outcome anymore, but as a wide set of different possible scenarios, with various probabilities of occurrence for each of them, which makes them all the more credible as, in reality, randomness occupies an important place. Lastly, this CGE framework also makes room for inputting land as primary factor, enriching the already carried out analysis, although this last suggestion strongly relies on data availability for calibration.

REGIONAL ECONOMIC DISPARITIES IN COLOMBIA

Andrea Otero, Jaime Bonet, Luis Galvis, Javier Perez

Central Bank of Colombia, Colombia

ABSTRACT

This paper studies changes in income inequality in Colombia over the 2010-2019 period from a regional perspective. It focuses on how labor and non-labor (pensions, transfers, among others) income contributed to the reduction of income inequality, measured through the Gini coefficient, within most of the main cities of the country. Although, the current Covid health and economic crisis are acting as a severe negative shock, significantly affecting economic performance and social indicators, this paper highlights what worked in the previous decade in the path to achieve social cohesion and regional development, that can be replicated after the current events.

We follow Bourguignon and Ferreira (2004) to model the main decisions of the household that determine their income in a system of equations that we estimate sequentially for each of the cities of interest. Our results show that inequality was reduced within all the largest 13 cities of Colombia except one, in which non-labor income played a significant role in increasing inequality. The determinants of this reduction vary by cities, given that in some cities the main driving force were changes in non-labor income, while in others it was due to changes in the factors that determine labor income.

URBAN TRAVELERS GO TO THE BEACH: REGIONAL EFFECTS OF DOMESTIC TOURISM IN COLOMBIA

Eduardo Sanguinet¹, Luis Galvis², Inácio Araújo³, Eduardo Haddad³

¹Universidad Austral de Chile, Chile. ²Banco de la República, Colombia. ³FIPE, Universidad de Sao Paulo, Brazil

ABSTRACT

The aim of this document is to address the role played by domestic tourism as a mechanism of interregional transfers of income. In Colombia, domestic tourism flows follow a pattern of origin in the central regions to destinations in the periphery. One of the main tourist destinations is the Caribbean Coast, which exhibits the worst socioeconomic indicators in the country. It is expected that the injection of resources, through tourists' expenditures, will contribute to systemic effects in the destination regions. There is little empirical evidence of such regional impacts of tourism in Colombia, with most of the existing studies adopting qualitative methods. Those that use quantitative techniques do not consider a systemic approach to calculate regional impacts. In this sense, the aim of this paper is to analyze the regional impacts of the consumption patterns of expenditures by Colombian tourists, focusing on the Caribbean region, using an interregional input-output model, together with data from the Encuesta de Gasto en Turismo Interno (EGIT) 2014-2015. The empirical evidence found in this work contributes towards the study of the domestic tourism to inclusive economic growth in terms of socioeconomic characteristics of jobs and income generation, both direct and indirectly. This is important to provide insights for the formulation of tourism-related regional policies. The results suggest that domestic tourism can be considered as an important channel to produce a more efficient allocation of resources to improve income distribution in Colombia. We conclude that regional policy strategies aimed at the tourism sector may be relevant to the local development of the Colombian Caribbean.

THE REGIONAL SOCIO-ECONOMIC OUTLOOK OF MEXICO: INEQUALITIES DURING THE PANDEMIC LOCKDOWN, 2020

[Carlos Bustamante-Lemus](#)

National Autonomous University of Mexico-Institute for Economic Research, Mexico

ABSTRACT

This work intended to provide, particularly to scholars from abroad, a general outlook of Mexico's economy and regional socio-economic inequalities throughout this country. Once being understood these, it is expected to understand why is it that the high numbers of contagious cases cannot still be lowered, and Mexico is today one of the nations among the worst numbers of Covid-19 contagious and deaths in the world.

The COVID-19 Pandemic has hit social life and economic activities worldwide. However, the impacts caused in the LDCs have probably been harder than in the more developed nations. This paper proposes that backward states' institutions like Mexico, governing a territory and people with many shortages in infrastructure of several types and with enormous gaps between rich and poor people, then, have faced the Pandemic and measures adopted with many problems in their implementation to combat and control it.

In this paper, we propose that Covid-19 has hit harder in those agglomeration urban centres and mostly within the peripheral urban settlements in them due to problems such as poverty overcrowding housing, scarce basic infrastructure, and services there, and their need to commuting every day. The delays in trying to lower the contagious tendency became even harder due to people's ignorance and discredit for their governments and politicians, and negative reactions upon the State's measures to avoid further contagious.

Once all this outlook has been understood, this paper will look at the South-Eastern part of Mexico as one focus to alleviate inequalities and purposes for better integration of backward regions to the whole country's recovery.

ECONOMIC CRISIS AND RESPONSES OF THE MEXICAN STATES UNDER THE COVID-19 PANDEMIC

José Gasca-Zamora

National University Autonomous of Mexico-Institute for Economic Research, Mexico. President of Mexican Association in Sciences for Regional Development (AMECIDER), Mexico

ABSTRACT

Due to the extraordinary measures that the Federal Government undertook in Mexico to mitigate the spread of infections caused by the COVID-19 pandemic, productive and social activities considered non-essential were suspended, which had an impact on the contraction of economic activity. Although estimates have been prepared that offer an idea of the decline of the economy at the national level, based on aggregate indicators, there is no perspective that accounts for the magnitude of the impact in the different regions of the country. In this work, a methodological proposal is applied to understand the economic performance of the gross domestic product (GDP) of the states of Mexico and their productive sectors during the period of greatest restrictions imposed by the health emergency COVID-19 during 2020.

The main purpose of this paper is to estimate the degrees of impact on the economic activities of the states of Mexico during the stage of greater social confinement and productive inactivity in 2020. It is not a projection, but an exercise of ex ante measurement that allows explaining the levels reached by the regional economic contraction. Although some of the sectors and businesses have been able to reactivate one year after the pandemic began, a period of greater inactivity was recorded during the second quarter of 2020, a period in which the government's confinement provisions were accentuated, social distancing and regulation of non-essential activities. Likewise, the measures implemented by the state governments in order to cushion the adverse effects caused by this situation are analyzed.

The results show heterogeneous impacts on the performance of the economic activity of the Mexican states level associated with their productive structure and the proportion of their branches subject to greater government regulations. For their part, the actions of the state governments were mainly oriented towards temporary and reactive measures to favor affected social and economic sectors, but also those that present conditions of high vulnerability. Public policies in subnational government scale show that were mainly aimed at poor population, the unemployed, as well as small businesses.

REGIONAL ECONOMIC IMPACTS IN MEXICO CAUSED BY FLOODS ON AGRICULTURE: AN INTEGRATED APPROACH VIA SPATIAL AND CGE MODELING

ABSTRACT

The economic impacts of natural disasters are broader than direct physical destruction. Disregarding the indirect and macroeconomic effects can seriously underestimate the total consequence over the society. This paper aims to address global and regional economic impacts in Mexico caused by productivity reductions on agricultural sector as consequence of floods occurred in 2020 in the Mexican States of Chiapas and Tabasco. Instead focused on direct economic losses, our study tackles the assessment of indirect and economic repercussions by productivity reduction on agriculture. We present a methodology in two integrated steps. In the first part, we developed a spatial analysis to measure the direct impacts of floods on the cropland areas based on open and freely available datasets provided by GADAS-USDA, LandScan and Copernicus. In the second stage, we access the indirect effects by translating the cropland losses in falling productivity of the primary factors used in the agricultural sector, through a Mexican interregional Computable General Equilibrium (CGE) model – BMMX. Our results show, between others, a contraction of 0.002044% in the national GDP, equivalent to 26 million dollars (USD, 2013) and -190 employed people. As expected, the greater losses in terms of production, employment, income and consumption were concentrated in Chiapas and Tabasco but they also propagated to other southern States of Mexico. In addition, positive economic effects were observed in the States of northern Mexican showing economic gains from substitution. Our results show in detail the spillover effects that agriculture losses, caused by natural disasters, a flood event in our case, can have into both the regional economies and the national economy of Mexico. A quantification of these impacts can contribute to design holistic strategies for risk management and the adoption of better public policies at both regional and national level. Finally our works expose the utility that nowadays have the spatial CGE modelling, which working together with engineering and GIS models, are being positioned as a key tool to measure the indirect impacts of disasters.

KEYWORDS

Mexican agriculture, CGE modelling, economic losses, floods, spatial analysis.

1. INTRODUCTION

Intense hydrometeorological phenomena represent an important threat regarding to social and economic losses worldwide, having caused most of the climate-related disasters in recent decades, especially floods, hurricanes and storms events (Aguilar and López, 2020; CRED, 2015, CEPAL, 2014). In addition, climatic change, caused by human activity, can increase the vulnerability of the population of several countries to those phenomena (Bresch, 2009). In Mexico, hydrometeorological disasters have been recurrent and are the biggest cause of economic losses. Estimates suggest that 31 million of people and over 41% of its territory are exposed to hydro meteorological phenomena, which includes not only the main urban centers but also rural areas, especially in the winter, when hurricanes and convective storms or cold fronts bring intense rainfalls to these regions (Bonasia, 2019). Considering the period between 2000 and 2015, according to data from Mexican government, 93% of economic losses were associated with hydrometeorological phenomena, including chemical, geological and other phenomena.

In the last twenty years, the Mexican states of Veracruz, Tabasco and Chiapas has presented the greatest economic losses due to hydrometeorological disasters as tropical cyclones and intense rains and floods. In addition, those states present remarkable socioeconomic vulnerabilities, such as low income and lack of community mitigation actions. (Novelo-Casanova and Rodríguez-Vangort 2016; Aparicio et al, 2009). In 2020, Tabasco and Chiapas suffered from the floods after heavy rains caused by the hurricane Eta, which was estimated to be the one of the worst in the last fifty years⁴⁶.

⁴⁶ To more information, see: <https://mexiconewsdaily.com/news/overflowing-rivers-create-worst-flooding-in-50-years/>; <https://atalayar.com/en/content/floods-and-landslides-affect-mexican-states-tabasco-and-chiapas>, and

Agricultural sector of Mexico is exposed to various hydrometeorological perils, which can cause considerable economic impacts both at regional and national level, in the producers and in the family economy. Damages in agricultural sector can interrupt the production cycle in other industries as food, services and livestock products, reducing production, profits and generating unemployment, among other effects. The occurrence of floods, especially in rural regions tends to cause a slowdown or paralysis of agricultural activity by damaging crops, cattle and other animal's meat production, destruction of machinery and land, and not allowing workers to carry out their activities. In particular, floods have been the cause of significant losses of agricultural land and pasture in recent years in the states of Tabasco and Chiapas, according to data from the General Directorate of Risk Analysis of Mexico.

Thus, we paid special attention on the damage that floods can cause in the agricultural sector and in the economic repercussions of this damage. The economic impacts of natural disasters are broader than direct physical destruction and, disregarding the indirect and macroeconomic effects, can underestimate the total impact of disasters to society. Our paper proposes a methodology to estimate the high-order economic effects that productivity reduction on agricultural sector, caused by a flood event, can have over the whole economy and how this shock can propagate to other industries, sectors and geographic regions. We particularly applied our methodology to the case of 2020 floods occurred in Chiapas and Tabasco, in Mexico.

Our methodological approach consists of two stages. In the first stage, we use a spatial analysis to measure the direct impacts of floods on the cropland areas (the percentage of cropland areas lost by floods) by using geo-located datasets provided by GADAS-USDA, LandScan and Copernicus. In the second stage, we access the indirect effects of this occurrence by using the BMMX model, a full interregional general equilibrium model developed for Mexico (Haddad et al., 2019). We couple the spatial analysis with the BMMX model by translating the percentage of losses in agricultural areas into technological shocks on productivity of primary factors (capital and labor) of the regions affected by the flood event, in our hand-on case, Chiapas and Tabasco. Finally, BMMX model allows us to see the economic channels through which shocks propagate within Mexican economy and quantify the size of the indirect consequences. Now a day, CGE modeling is settle as one of the best frameworks to estimate indirect impacts of natural disasters (Jonkman et al., 2008; Haddad and Teixeira, 2013; Jonkhoff, 2009; Pauw, K. et al., 2011; Carrera et al, 2015; Leon et al., 2021) and we believe their use are becoming a standard for indirect impacts modeling.

We have found a contraction of 0.002044% in the Mexican GDP, equivalent to 26 million dollars (USD, 2013) as consequence of productivity reduction on agricultural sector caused by 2020 Floods in Tabasco and Chiapas. The greater losses in terms of production, employment, income and consumption were concentrated in Chiapas and Tabasco but they also propagated to. Positive economic effects were also observed specially in the States of northern Mexican.

The paper unfolds as follows. Section 2 reviews Mexican flood background focused on the State of Tabasco and Chiapas; Section 3 presents the in detail the methodology to integrated spatial analysis with CGE modeling to estimate indirect impact of productivity reduction in agricultural caused by a flood event ; Section 4 presents and discusses the results and finally Section 5 exposes the conclusions of the paper.

2. FLOODS IN TABASCO AND CHIAPAS

Mexico is a country greatly affected by natural disaster, especially earthquakes and floods which cause, according to the UNDRR (2015) – United Nations Office for Disaster Risk Reduction, an annual average loss of 1,350 and 870 million dollars respectively. From 2000 to 2021, the Mexican government issued 2,350 emergency declarations, 92% related to hydrometeorological disasters. In the case of the Mexican States of Tabasco and Chiapas, 90% and 65% of those declarations correspond to flood and rain events. As seen in Figure 1, Chiapas and Tabasco are located in the southern part of Mexico, being overall characterized by a humid tropical climate, with rainfall that can average more than 3,000 mm per year.

According to data from the Direction of Analysis and Risk Assessment of Mexico in the period 2000 to 2015, the greatest economic damage in the states of Chiapas and Tabasco was due to hydrometeorological phenomena, mainly due to tropical cyclones, extreme rains and floods. Figure 2 shows the flood hazard index for Mexico provided by CENAPRED, which exposes to Tabasco and the northeast of Chiapas with a very high flood index.

In 2007, a major flood event hit Tabasco and Chiapas States causing economic losses estimated on 2,918 million dollars according to CENAPRED (2018), being one the most expensive disaster in the last 40 year in Mexico. Furthermore, in 2011 and 2013, floods events caused in Tabasco losses estimated on 740 and 31 million dollars respectively.

In 2020 took place the most recent flood event that has hit Tabasco and Chiapas regions, causing very important losses which has not still been well defined and studied in the literature. Part of those losses are addressed in this paper, specifically those regarding to indirect losses caused by productivity reduction in agriculture of the region affected.

Tabasco has an average annual rainfall that range from 2,000 to 4,500 mm, being the Mexican State with the highest level of precipitation. In addition, its topographic and hydrographic characteristic contribute to floods since the Tabasco plain presents scarce slopes and is located in the confluence and deltas of several rivers like Grijalva, Mezcalapa, Carrizal, Samaria among other. On the other hand, the destruction of the ecosystem is another cause of floods in Tabasco given that deforestation, caused by livestock and crop activities, affects water runoff in the basins, vegetation does not consume water, it goes down the river and quickly increase the flows. In the case of Chiapas, the northeast region of the state

presents rains throughout the year and in the remaining state, abundant rains in the summer season. Depending on the state's region, the average annual rainfall ranges from 1,200 mm to 4,000 mm (INEGI, 2021).

Figure 1 – Selected States – Chiapas and Tabasco, Mexican Southeast Region.

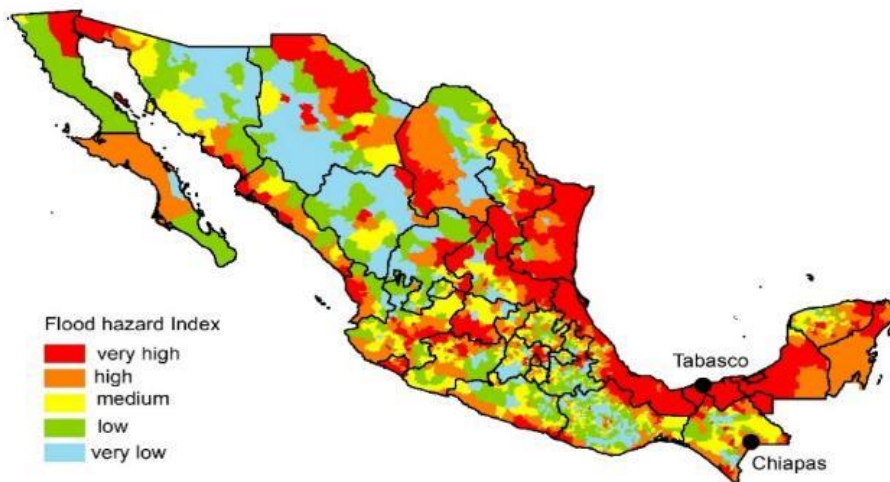

Figure 2 – Flood hazard index for Mexico.

Source: CENAPRED 2016

Other natural factors that aggravate floods consequences are the evolution of river beds, as they become sedimented, the elevation of sea level, the untreated effluent flows from metropolitan areas, etc. Cumulative effects are also possible due to total non-recovery from previous floods. This effects had a clear example on the 2007 and 2008 floods in Mexico, particularly affecting road structures, cropland, pasture areas and agricultural production (Zapata et al., 2011).

3. METHODOLOGY

This section is divided into three parts. The first part presents the spatial analysis and the database used to measure the direct impact of the 2020 floods in Chiapas and Tabasco, Mexico, on the agricultural production of these States. The second part presents and discusses the BMMX model, which is used to assess the indirect impacts of this disaster. Finally, the third part shows the integration procedure between the spatial analysis and the BMMX model, in order to estimate the indirect economic consequences a flood event.

3.1 Direct impacts of floods – a spatial analysis

To estimate the direct impacts on the agricultural sector of an economy caused by a major flood event, we propose a spatial analysis that harnesses free spatial datasets available worldwide, in order to estimate the cropland areas affected

by the event. In addition, although a flood event can damage several assets as buildings, machinery, etc., of the agricultural sector, impacts on the land component can lead a large productivity reduction given its majority importance in this sector. Therefore, our assumption at this point is that the reduction of the croplands extension will be directly proportional to the decrease in the productivity of primary factors within the agricultural sector, as shown in equation 1 (section 3.3). Bellow, we describe the spatial analysis carried out over the Mexican regions of Tabasco and Chiapas affected by a major event occurred in 2020 around the months of October and November.

The spatial analysis begins by estimating a croplands grid of the area under study using the data provided by the Global Agricultural and Disaster Assessment System – United States Department of Agriculture (GADAS/USDA). The panel **a** of Figure 3 shows the croplands extension estimated for Tabasco and Chiapas with a resolution of 500 meters. Once extracted croplands, we use LandScan data to apply a population density filter that removes the cropland cells that intersect with population densities higher than 100 inhabitants per square kilometer. Landscan (Panel **b**) provide a geo-located population density dataset with a 30 arc second resolution ($\approx 1 \text{ Km}^2$). Our assumption is that cells with a population density higher than 100 have a low probability to be a cropland. The next step is to intersect the cropland grid previously filtered by LandScan with the flood extension map provided by Copernicus (Panel **c**) to obtain the cropland cells affected by the flood event (Panel **d**).

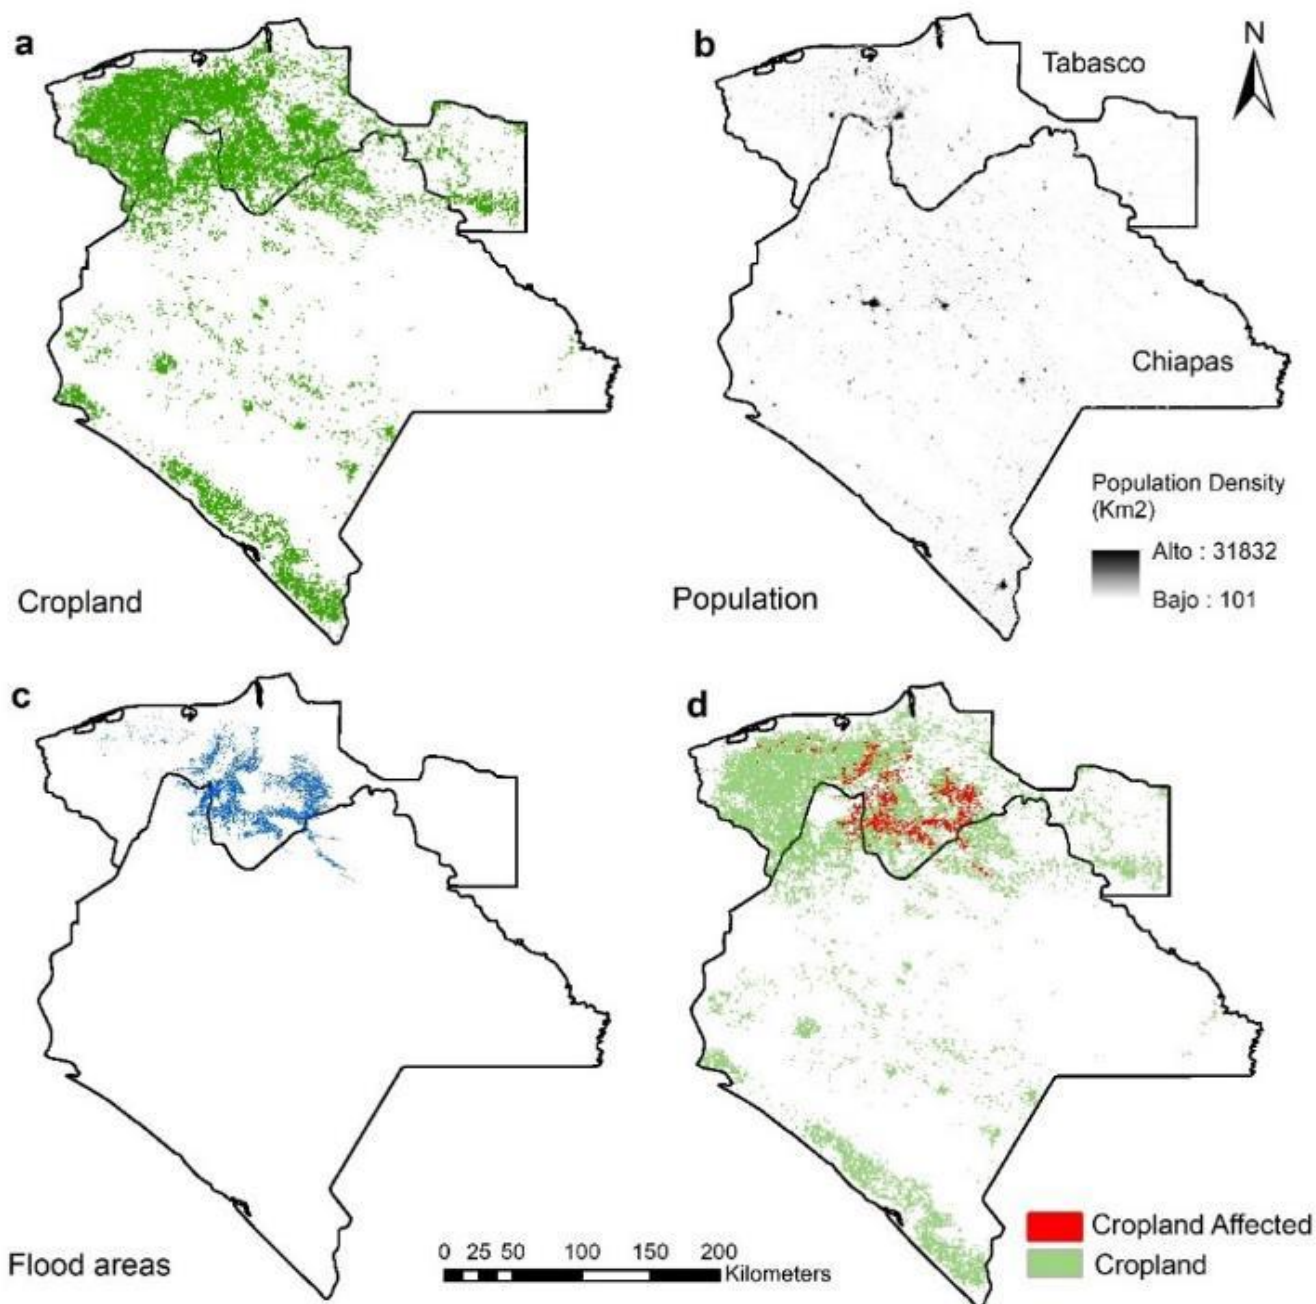

Figure 3 – Spatial analysis of croplands affected in Tabasco and Chiapas by a major flood in 2020

Panel **a** shows the estimated croplands based on data obtained from GADAS – USDA with a resolution of 500m. Panel **b** shows a 30 arc second grid ($\approx 1 \text{ Km}^2$) with the population density provided by LandScan. Panel **c** shows the mapping of the flooded areas carried out by Copernicus through its Emergency Management Service (EMS). Panel **d** shows the estimation of croplands affected by the major flood event of 2020 that hits Tabasco and Chiapas.

In our analysis, we are interested in estimating the percentage of the total croplands affected by the flood event so that we compute this value as the ratio between the number of cropland cells affected and the total number of cropland cells (after being filtered by LandScan). We found an allocation of 13% and 3% of croplands affectation respectively for Tabasco and Chiapas.

3.2 Data sources of spatial analysis

The GADAS is a web-based Geographic Information System (GIS) which integrates a vast collection of data, including precipitation data, vegetation index, crop masks, land cover data, irrigation and water, elevation and infrastructure, political data, and others. The USDA, through its Foreign Agricultural Service (FAS), provide the information available on GADAS based on the use of satellite imagery and remote sensing data. FAS, through GADAS, delivers monthly estimates of area, yield and production for 17 distinct commodities in over 160 countries around the world. In our case, we used the cropland 500m mask.

LandScan is a dataset that provides the global population distribution with a resolution of approximately 1 km (30" X 30"). Using updated demographic and geographic data together with remote sensing imageries, LandScan uses multivariate dasymetric modeling techniques to disaggregate census counts within different levels of administrative boundaries.

Copernicus is a European Union initiative with the support of the European Space Agency (ESA) and the European Environment Agency (EEA) orientated to developing information services based on satellite Earth Observation and in situ (non-spatial) data. Copernicus provides information on natural disasters such as forest fire or floods, and monitors the environment on land, sea and in the atmosphere. The Copernicus Emergency Management Service (EMS) Mapping addresses emergencies worldwide resulting from natural or man-made disasters.

3.3 The indirect impacts - the BMMX model

The BMMX model, an interregional computable general equilibrium model (CGE) for Mexico (Haddad et al, 2019), is a fully operation spatial CGE model developed under a theoretical structure similar to Haddad (1999) and Haddad and Hewings (2005).

The BMMX was built from an Interregional Input-Output Table for Mexico (Haddad et al, 2019), with base year in 2013. The estimation of the Interregional Input-Output Matrix for Mexico (IIOM-MX) is based on the Interregional Input-Output Adjustment System (IIOAS) method. The IIOAS method was developed to estimate interregional input-output systems under conditions of limited information (Haddad, 2017). For the particular case of Mexico, the authors used data from national and regional accounts provided by the Instituto Nacional de Estadística y Geografía (INEGI) for the years 2013 and 2014. The data consist mainly of the Supply and Use Tables (SUT) at the national level, and regional data on sectoral Gross Regional Product (GRP) and macro regional aggregates.

The BMMX model recognizes the economies of 32 Mexican States from a bottom-up approach - where national results are obtained from the aggregation of regional results. The BMMX identifies 37 sectors in each Mexican State, one representative household for each State, regional governments and one federal government, and a single foreign area that trades with each Mexican States. The model has local primary factors used in the production process, according to regional endowments (capital and labor). The regional and sectoral classification are shown in the Annex.

The behavioral structure of economic agents in the BMMX model is given by microeconomic assumptions, which can be subdivided into producers, households, government, investment and external demand, following Haddad and Araújo (2020).

It is assumed that, in each State, there is a representative optimizer producer operating for each sector of the model through optimizing behavior (minimizing costs), being able to produce multiple products (commodities). The production function is modeled by a nested structure, which, at the top, is coordinated by a Leontief function making the separability between intermediate inputs and primary products (capital and labor), in other words, there is not exchange between these two types of inputs. However, there is a possibility of substitution within these inputs, for example between the capital and labor factors, which is determined by a Constant Elasticity of Substitution (CES) function.

Household consumption is allocated across different sectors (both external and domestic) according to linear expenditure system (LES) demand functions, derived from the maximization of a Stone-Geary utility function. Similarly, the hypothesis of the existence of a representative optimizing consumer in each region of the model is used. The substitution between domestic and imported consumption is given by differences between domestic and foreign price levels, this also occurs with the demand among the Mexican States (interregional).

In each region of the model, it is assumed that there are two distinct agents that characterize government consumption, the federal government and the regional government. The model also contains equations that determine the level of investment in each sector for each region. However, the investment is considered fixed in the short-term analysis used in this work. For exports, the model distinguishes between traditional and non-traditional export sectors.

BMMX is used in our approach to propagate the damage in flooded agricultural areas, in our case caused by the 2020 floods in Tabasco and Chiapas, through the entire Mexican economy, and for being able to measure their regional and national consequences. The main channels of propagation of the general equilibrium effects involve changes in the prices of primary factors, affecting the firms' competitiveness (sectoral production), the demand for these factors (employment level) and thus, the household consumption and income (Haddad et al., 2013).

Following, let's see how we introduce the direct impacts caused by the flood in the cropland areas into the BMMX model as shocks of reduction in the technological productivity of the primary factors. In other words, how we integrate the spatial analysis with our CGE model.

3.4 Integration of the spatial analysis and BMMX model

In the first stage, the spatial model was used to project the direct impacts of floods through the percentage of cropland areas affected by them, as observed in Tabasco and Chiapas, in October/November of 2020. Now, in a second stage, we translate this percentage of decrease in the agricultural areas into technological productivity shocks of primary factors in the CGE modelling.

The integration procedure between the spatial analysis of cropland affectation and the CGE model, BMMX is based on the next argument. Since that the agricultural production depends highly on the land factor, when this factor is prevented from being used, the use of other factors (capital and labor) is also interrupted in this production. Then, we can assume that the size of the shock observed in the land component is very similar to the level of the total shock in the primary production factors. This assumption simplifies the integration of models given that, for this particular case, we don't require information of labor and capital stock affectation.

Thus, we propose to compute the total productivity shock caused to primary factors of agricultural sector with the next expression, which is in accordance to Carrera et al. (2015):

$$\% \text{ Losses in productivity of primary factors} = \frac{\text{flooded ares in cropland}}{\text{total cropland areas}} \times \frac{\text{estimated affected days}}{365} \quad (1)$$

The spatial analysis gives us the percentage of agricultural areas affected by the 2020 floods in the Mexican States of Chiapas and Tabasco, which were -13% and -3%, respectively as shown in section 3.1. In addition, given that floods in 2020 may have affected production equivalent to the period of a harvest in these States, as suggested by Carrera et al., (2015), we assumed that effect of floods over the crops could be felt for an average period of 6 months (approximately 182 days). Based on these estimates, the shocks of the productivity drop of the primary factors in Tabasco and Chiapas agricultural sectors are 6.5% and 1.5%, in that order. In the model structure, the increase in productivity is given in negative values, which implies the need for less work to produce a certain quantity of product. In a similar way, we can interpret the positive values as an increase in the quantity of product that the same number of workers will be able to produce.

In order to estimate the short-term consequences of flood effects, the simulations were carried out under a standard short-term closure, where the capital stock, labor supply, population, investment, government spending, technology and agent preferences are fixed. In this closure, regional employment is driven by variations in wage rates among the Mexican States, which indirectly determine regional unemployment rates and, therefore, impact regional income. Household consumption follows household disposable income, circulating the income flows.

Although we are focused on a short-run analysis, the directions of results of our comparative static analysis will be similar in long-term, of course with the differences due to magnification effects of losses at long-run if no mitigation actions are taken.

Next section presents and discusses the results obtained mainly in terms of the variation of activities at national, regional and sectoral levels.

4. RESULTS

According to our simulations, the reduction in national GDP (-0.002%) and in employment (-0.0004%) in Mexico caused by productivity reduction on agricultural sector as consequence of floods in 2020 in Tabasco and Chiapas were estimated on -0.002% and 0.0004%, which, in absolute values mean 26 million dollars (USD, 2013) and -190 employed people, respectively.

The losses observed imply a reduction in the trade balance, with a decrease of -0.002134% in exports and an increase of (0.004117% in Mexican imports. Regarding the welfare of national residents, there is a decrease, with a reduction in real household consumption (-0.000514%) and a raise in the consumer price index (0.000846%). Table 1 summarizes the macroeconomic effects of the fall in agricultural productivity in Chiapas and Tabasco, resulting from the floods.

Figure 4 shows the regional impacts on the GRP, aggregate employment, nominal consumption and in the families' income. It is possible to observe that the greatest negative impacts on the GRP occurs in Chiapas (-0.060502%) and Tabasco (-0.029775%), regions directly affected by the floods, however, other Mexican States located in the south are indirectly affected as Yucatan and Quintana Roo with a GRP contraction of -0.000879% and -0.000342%. On the other hand, GRP increases in other States mainly in the northern Mexico, such as the case of Sinaloa (0.001649%), the main Mexican agricultural producer.

Table 1 - Macroeconomic Impacts of floods (in percentage change)

Real GDP	-0.002044
Real household consumption	-0.000514
Real government consumption - Regional	0.001793
Real government consumption - Federal	0.001084
Export volume	-0.002134
Import volume	0.004117
National employment	-0.000407
Consumer price index	0.000846
Investment price index	0.000436
Regional government demand price index	0.000569
Federal government demand price index	0.000569

The same pattern of regional impacts is verified for employment, consumption and income, as shown in Figure 4, where the biggest reductions are in Tabasco, Chiapas, Yucatan and Quintana Roo while the States with the greatest gains are: Sinaloa, Michoacan de Ocampo and Zacatecas.

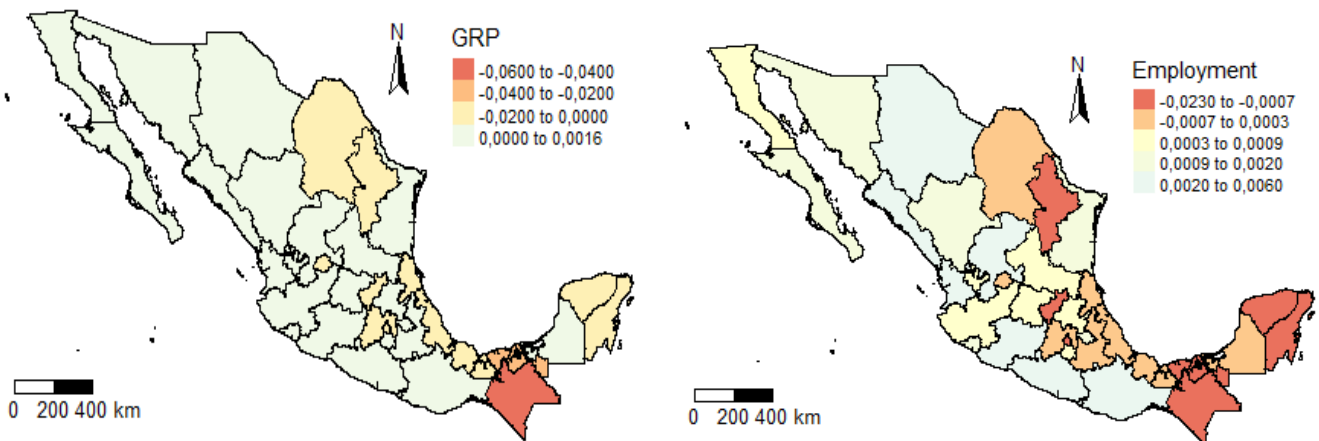

Figure 4 – Gross Regional Product (GRP) and employment

In relation to nominal consumption and income of households, losses are also concentrated in the States of Chiapas (R7) and Tabasco (27), and in their neighboring States like Yucatan (R31) and Quintana Roo (R23), as can be seen in Figure 5. The other Mexican States, mainly those located in the North, show an increase in consumption and income of households, which can be explained by the competitiveness gains indirectly achieved by these States from the decrease in agricultural productivity in Chiapas and Tabasco.

Figure 5- Variations in household consumption and income

From the sectorial point of view, and given the economic links among the regions and sectors, as shown in Figure 6, the reduction in agricultural production in Tabasco and Chiapas as consequence of floods propagates throughout the economy producing negative impacts not only on the agricultural sector but also on the production of other sectors strictly related to agricultural activity, such as forestry services (-0.105039%), water supply, gas to the final consumer (-0.004596%), manufacture of textile (-0.003821%), livestock products (-0.003611%), food industry (-0.003246%). Only three sectors registered positive variation: health and social assistance services (0.00092%), education (0.00101%), public administration (0.001427%).

Figure 6- Activity level in the Mexican economy by sectors

Sectorial variations differ among Mexican States, as can be seen in Figure 7, in which the average variations of the sectoral production are presented using four groups: agricultural and livestock activities (AGR), industries (IND), services (SERV) and other activities (OTH).

It is observed that the activity level of the agricultural sectors decreases in Chiapas and Tabasco as a direct consequence of the shock. Another State in southern Mexico that also showed a reduction in the agricultural and livestock activities (AGR) was Yucatan (-0.00083%). The other States showed an increase in AGR, these increases being greater in those located in the North of Mexico compared to the South, as is the case of Sinaloa (0.008965%) – the State with the largest increase in AGR. We obtained that the agricultural sector⁴⁷ (S1) of Chiapas and Tabasco, suffered a fall in production of -6.54% and -1.56% respectively, values which are very similar to the magnitude of shocks applied to primary factors as consequence of floods. We believe that those results are reasonable and for one side, are in concordance with the real behavior of the economy and for the other one, verify our assumption of modeling regarding to the high and direct relation between the reduction of land crop and the agricultural production level.

In relation to the performance of the industrial sector (IND), we noted losses in the activity level of all Mexican States, being greater in the region where the Tabasco and Chiapas Flood took place, it is, in the southern of Mexico. The variations in the level of activity in the sector services (SERV) also follows the regional pattern, with increases in production in States in northern Mexico and declines in the States of Chiapas, Tabasco, and in other southern States. Services reductions occur due to links between some segments of services and agricultural and livestock activities, such as trade services (S23 and S24), transportation (S25), financial and insurance (S27). In relation to other activities (OTH), impacts distribution are most negative in the southern States as shown in Figure 7.

⁴⁷ According the regional and sectoral classification present in Annex.

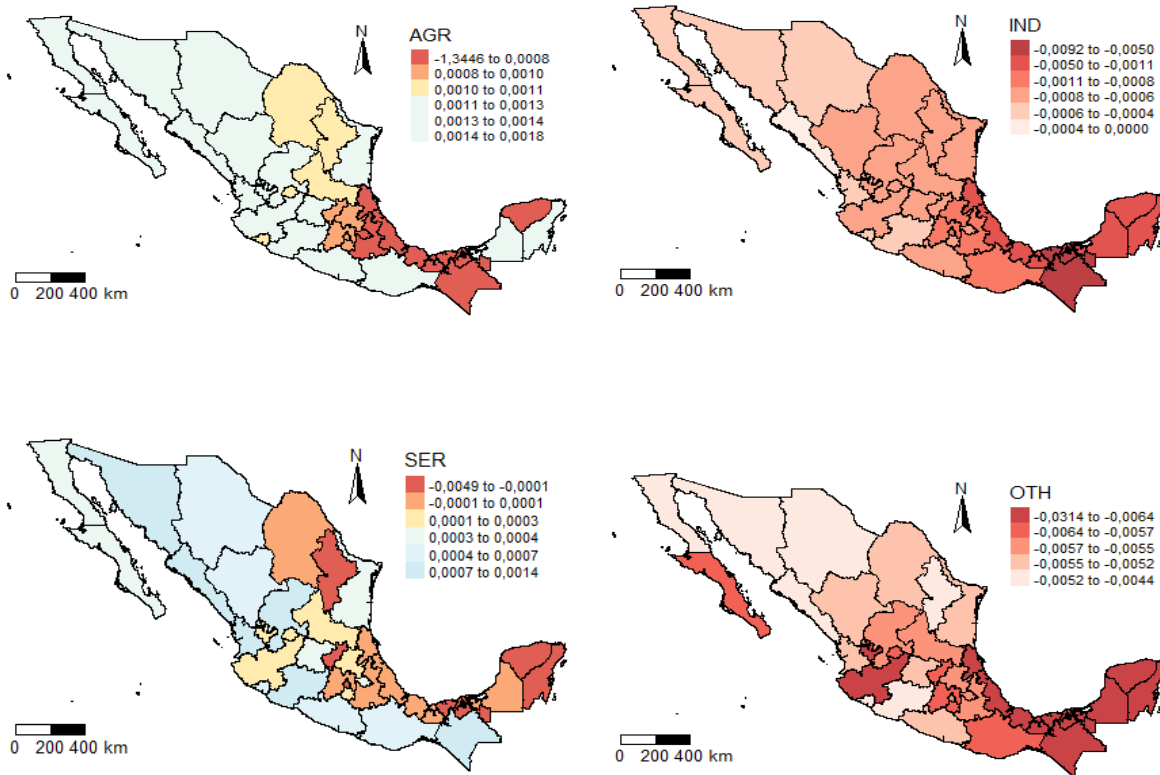

Figure 7 - Average performance of all sectors: agricultural and livestock activities (AGR), industries (IND), services (SERV) and other activities (OTH)

5. CONCLUSION

In this paper we have presented a useful methodology to quantify the indirect economic impacts caused by a major flood event, focusing our attention on how the floods can affect the agriculture and how these losses can propagate through other economic sector and regions of a country. We applied this methodology to study the recent 2020 floods that hits the states of Tabasco and Chiapas, in Mexico.

We have successfully integrated a spatial analysis of direct damage with a CGE model, the interregional general equilibrium model of Mexico (BMMX), to estimate the economic channels through which direct losses in agricultural sector can cascade within the Mexican economy. To evaluate the direct effect, specifically the cropland affectation, we carried out a spatial analysis based on the exploitation and combination of free available GIS datasets from GADAS-USDA, LandScan and Copernicus, obtaining an affectation of 13% and 3% of agricultural areas in Tabasco and Chiapas respectively. Cropland affectation was integrated to the interregional CGE model BMMX based on the assumption that reductions of croplands extension are directly proportional to the productivity decrease of primary factors within the agricultural sector. This assumption simplified the integration of models without a significant reduction in accuracy as shown in the results section. In addition, as proposed by Carrera et al. (2015), the productivity shock on agricultural sector was calculated considering a time period of six months, resulting in productivity shocks of 6.5% and 1.5% in Tabasco and Chiapas.

Although agricultural activity is not the main activity performed in Tabasco and Chiapas, we have shown how a shock in agricultural productivity, resulting from the 2020 floods, has an impact in Mexican economy, estimating a GDP contraction of 23 million dollars, around 190 loss jobs, and losses in production, and other economic variables, not only in the States affected by the flooding, but also in other States, especially in the southern region of the country as Yucatan and Quintana Roo. We also provide quantitative results of negative and positive impacts related to prices, exports, consumption, income, and production, at regional and sectoral levels, which can be useful for a better understanding of regional and national economic implications.

The evaluation of indirect impact and losses, resulting from recurring events, can contribute to the adoption of public policies for a better and holistic disaster risk management in the counties by addressing, in addition to physical destruction of assets, the indirect effects that catastrophic events can trigger. The reality of climate change, aggravating existing natural conditions, places a major burden of adaptation on the agricultural sector, which repercussions, as shown in this paper, can be felt through an entire economy. Nowadays, there are multiple plans and actions designed to increase the resilience of the countries to direct consequence of disasters, however, plans and programs to increase resilience for the indirect losses, if they exist, lag far behind. Methodological developments to contribute to a better understanding of

indirect consequences of disaster are the kick-off to include those aspects within a holistic resilience facing natural disaster.

ABSTRACT

Initial Remark

These three aspects about time establish the three parts of the present paper. The stress is placed on time, not on space. Yet not because we exclude space but only to have it subordinated to time aspects, which means they will only be considered in so far as time dilucidation shall require some pointing to underlined a territorial trait or set of traits therein involved.

Let us recognize since the beginning that -as a matter of fact- quite a number of steps are almost everywhere underway in Latin America, yet we will focus on those impacting upon our Latinamerican regions, mostly: (A) some of Mexico, and then (B) some other countries, particularly upon Bolivia, Argentina and Chile –even when some potential is actually present in some others which will just eventually be referred to.

FIRST PART: WHAT HAS HAPPENED

A. In Mexico.

There exists a bordering region between Sonora and Chihuahua states, in the extreme North of Mexico, which it is called Bacadéhuachi. It became known because it started to be referred as having a high lithium potential. Indeed for some people, one amongst the highest at world level. Yet as we will see later, the the initially amount assumed of 243 million tons has been seen as a blunt exaggeration. Of course, the main characteritic traits will be dealt with along the paper itself.

B. In Latin America.

The most important lithium area in the rest of Latin America is settled in a place called ‘Salar de Uyuni’. It is shared among the following three countries: Bolivia, Argentina and Chile. This has been subjected to a much more systematic and careful exploration. It has reported a detailed established amount of 24million tons. The paper will give some of its key specificities.

SECOND PART: WHAT NOW HAPPENS

In general terms, it should be said that, partly due to Covid-19, and partly to putting off the initial somehow imaginative enthusiasm; now it seems clear that the lithium potential in the whole of Latin America is not one of the highest global levels, but rather a much more modest and below among the general levels at world scale. Yet not much more has been contributed sofar. As a matter of fact, we witness a stagnant situation Covid intevening.

THIRD PART: WHAT SHALL HAPPEN?

This is obviously the toughest (?) question. However some broad trends should be made explicit: (a) the urgency of a gradual and progressive general move towards cleaner sources of renwable energies, (b) the increasing techological developments related to the production of clean or hibrid vehicles for transportation as well as industry machinery; (c) the awareness that a post-covid be epoch will be sooner or later approaching, which in some aspects will pushing forward an ever higher interest in extra terrestrial positive and/or more risky facts and threats.

Regular Session: RS02.2 - Infrastructure, transportation and accessibility

ABSTRACT

Guinea-Bissau is a poor country with agricultural-base economy. The government has elaborated development policies aimed at improving the country's comparative advantage and poverty reduction. These policies resulted in US \$1 billion infrastructure investment program in 2015. This study aims to analyze the socioeconomic impacts of this program using a dynamic micro-simulated computable general equilibrium model. Our results show positive impact of infrastructure investments on the level of economic activity, productivity, and sectoral spillovers. The funding schemes determine these outcomes as they contribute to increase wealth accumulation as well as to mitigate in the long-term the urban and rural households' poverty.

KEYWORDS

Infrastructure investment. Poverty. CGE modeling. Guinea-Bissau.

1. INTRODUCTION

The economists have placed infrastructure as a primary determinant of macroeconomic performance and individual wellbeing (Rosentein-Rodan, 1943; Aschauer, 1989; De la Fuente and Estache, 2004). For instance, the roads availability may allow production to be expanded, because roads can be used to the goods transportation purpose between the urban center and the field. This may create job opportunities in both rural and urban environment. As employment grows with the poor households' participation, the poverty incidence rate may decrease. Thus, the vulnerability of the poor to income shock must be reduce by investing in physical infrastructure (Jalan and Ravallion, 2002; World Bank, 2002; Ali and Pernia, 2003).

This study focuses on Guinea-Bissau economy. Guinea-Bissau is a least developing country in West Africa characterized by low macroeconomic performance and high level of poverty. Its gross domestic product (GDP) per capita and the Human Development Index are US\$ 600 and 0.424, respectively, placing it in the low human development category worldwide, ranking 177th out of 189 countries. The life expectancy at the birth is 46 years and more than 69 percent of the population live in absolute poverty - less than two dollars a day. The low infrastructure services may explain these results: from a total of 2,755 km of existing highways, only 22 percent is asphalted, 80 and 66 percent of the population does not have access to basic sanitation facilities and electricity, respectively (World Bank Development Indicators, 2017).

Back in 2015, however, the Guinean government, together with its development partners, tackled the development challenges by increasing infrastructure investment. It elaborated an ambitious investment program in new infrastructure to encourage the transformation of this poor economy into a competitive one, with food self-sufficiency and less poverty and social inequality (GUINEA-BISSAU, 2015). The government aims to (i) mitigate the existing bottlenecks through the construction of the new port, urban-rural roads, priority land routes and inland waterway shipping, and (ii) accomplish urban development by building economic poles in order to establish them as epicenters of economic activity.

The purpose of this study is to provide macro-micro level evidence of infrastructure public investment in a developing country with the agriculture-based economy. Our study fits in the context of the growing economics literature that infrastructure impact economic outcomes (Van de Walle, 1998; Songco, 2002). According to this literature, infrastructure creates production facilities and stimulates economic growth (BARRO, 1991; Prud'Homme, 2004).

Infrastructure impacts economic results both directly and indirectly. Directly, infrastructure availability increases the factor productivity and aggregate product, as well as household income and consumption (Romp and de Haan, 2005; Warner, 2014). These direct effects are widespread and intense in developing countries where the technology of production is not still convex.

Indirectly, infrastructure can have several effects on socioeconomic variables. For instance, the individuals can use income from increased productivity to invest in the education of their children. The construction of a new infrastructure (transport and the road condition) may influence the school attendance rate, learning environment and students' outcomes (Earthman, 2004; Miguel and Kremer, 2004).

Although these positive effects of infrastructure, the empirical evidence of public infrastructure investment on economics outcomes goes back to the studies of Aschauer (1989a, 1989b), Munnell (1990a), which first show public infrastructure

investment to have positive effects in different context. Munnell (1990b), Nadiri and Mamuneas (1994), and Wolff (1996) confirm these results.

However, subsequently some studies (e.g., Garcia-Mila and McGuire, 1992; Holtz-Eakin, 1994; Morrison and Schwartz, 1996; Garcia-Milà, McGuire and Porter, 1996) have reported insignificant impact of infrastructure public investment on economic activity, which generated a mix of findings. Therefore, while Devarajan, Swaroop, and Zou (1996) point out that, holding global government spending constant, increasing government expenditures tends to lower the economy long run growth rate, Canning and Pedroni (2004) show for pairs of countries that infrastructure stimulates long run growth. Calderon and Serven (2010) also findings a positive correlation of 0.35 between GDP growth and infrastructure quantity index in African countries.

The public infrastructure investment has positive effect on the level of economic activity because it complements the private investment (Aschauer, 1989; Erden and Holcombe, 2005), instead of decreasing it as advocates the crowding out hypothesis (e.g., see Cavallo and Daude, 2011; Everhart and Sumlinski, 2001).

By analyzing the long-term trends in the development of South Africa's economic infrastructure and its relationship with the country's long-term economic growth, Perkins, Fedderke, and Luiz (2005) reported positive relationship between the two variables, that is, infrastructure is important to support economic activity in a growing economy. Ndulu (2006), in its turn, places the infrastructure as a potential mechanism that can help foster stronger economic growth in Africa.

The recent empirical findings from infrastructure public investment have to do with the refinement given to the method that best reports the results, ranging from the choice of the functional form to the details of relevant empirical methods. Some authors, such as GU and Macdonald (2009), resort to a dual approach to estimating the effects of public capital on production, since earlier studies by Aschauer (1989) used primal approach, which allowed only to estimate the production function as to deduce the contribution of public capital in terms of output in the economy (JOANIS, 2017).

This study aims to analyze the macroeconomic, sectoral, and household level implications of the public infrastructure investment in Guinea-Bissau. Our study builds specially on those applying computable general equilibrium (CGE) framework to evaluated impact of policies on economic outcomes in poor countries (Sangare and Maisonnave 2018; Go et al, 2016; Chitiga 2016).

We contribute to the existing literature in several directions. First, we contribute by developing the BISSAU-DYN model, a dynamic recursive micro-simulated CGE model, which is the first CGE model applied for this economy. The choice of this version is justified by three reasons: (i) the effects of building a new infrastructure may be lagged and thus take some time to manifest in the economy. With this model, we will be able to understand the behavior of relevant economic variables over time and its structural effects, such that it is possible to provide evidence for socioeconomic policies; (ii) Guinea-Bissau is a typical example of a small open economy that accompanies exogenous shocks. Such an economy is unstable and this instability stems from several reasons including, but is not limited to the, domestic institutions fragility that affects economy performance either at starting point or overt time, and the recursive dynamic model may best represent the structure of this economy; and (iii) as for a long period the potential policy effects could not be analyzed due to lack of adequate data, the application of the CGE framework will also fill this empirical gap. Moreover, the CGE model has the advantage of allowing to analyze interconnections between sectors and to investigate both the direct and indirect impacts of the infrastructure investment policies.

Second, although governments have been practicing economic policy with the aim of promoting the development of the productive forces important to fight against structural poverty, few policies are focused on the sectors to which the households find its source of income. By concentrating on both rural and urban sectors, we will be able to provide instructive micro level evidence for the elaboration of public policies consistent with the reality of each households.

Finally, our study analyzes the economic implications of new infrastructure investments and the different funding mechanisms. This gives us an additional advantage because we can understand how a government in a poor country like Guinea-Bissau may rationalize its scarcity resources to boost productive investments. In addition, the agricultural production, whose share in the GDP is about 60%, is the main source of the household's income in Guinea-Bissau. The present investment program is expected to contribute to poverty alleviation since it deals with transportation infrastructure, which is essential for the flow of agricultural production. Thus, by identifying sectoral returns of infrastructure investments, we will provide evidence to assist in orienting incentives for the development of sectors with higher productivity or whose employment of the population reduces the existing poverty rate.

The remaining of this study is structured as follows: In section 2 we present the CGE model used for simulation, the calibration procedures, closure, and the database. Section 3 reports and discusses the results and Section 4 concludes the discussion.

2. METHODOLOGY

We analyze the impact of new infrastructure investment on socioeconomic outcomes by using the CGE framework as proposed by Savard and Adjovi (1998) and Savard (2010), who first introduce the positive externalities associated to the public investment in infrastructure into national-bilateral CGEs models. The foundations of this model stems from neoclassical assumptions in the tradition of Dervis, De Melo and Robinson (1982). These authors appropriated from an analytical framework developed almost a century ago by Leon Walras (Shoven and Whalley, 1973; De Melo, 1988; Decaluwe, Martens, and Savard, 2001).

We will use a dynamic recursive CGE model as in Boccanfuso *et al.* (2014). However, our model has its own specificities since it is based on country with different socioeconomic characteristics. As in Savard (2010), the key assumptions of this model concern infrastructure spending, externalities of public infrastructure, and the budget

constraint faced by government to funding this infrastructure construction. For the first assumption we seek to understand how infrastructure investment occurs and how we can model it. The second one is drawing from the set of non-exhaustive following questions: Are there public infrastructure investments externalities? How do they propagate in the model? These questions are answered by choosing and appropriate externalities functional form.

The budget constrained assumption represents the idea that the resources for infrastructure investments are not a gift for government. They are supposed to come from government revenue. If they do not come from this source and if the government decides to pursue its policy initiatives, it must find ideal funding source either through fiscal instruments or transfers from other agents. We present these assumptions below.

We assume that the government funds its investments program through its revenues (Yg_t) that come from several sources, such as direct taxes on household (Tdh_t) and firms' incomes (Tdf_t), indirect taxes on industry production ($Tip_{j,t}$), taxes on commodity ($Tic_{i,t}$), and imports duties on commodity ($Tim_{i,t}$). Therefore, Equation (1) says that an amount spent on a new building is supposed to depend on the government's ability to collect taxes. To what extent taxes scale impacts the economic activity is a subject matter under investigation in some simulation scenarios. In addition, there are receipts as remuneration of public capital ($Ypkt$) and transfers from other agents (Tri_t), typically households ($Trgov,h,t$), firms ($Trgov,f,t$), and the rest of the world ($Trgov,row,t$).

$$Yg_t = Tdh_t + Tdf_t + Tip_{j,t} + Tic_{i,t} + Tim_{i,t} + Ypkt + \sum_i Tr_{i,t} \quad (1)$$

where $\sum_i Tr_{i,t} = Tr_{gov,h,t} + Tr_{gov,f,t} + Tr_{gov,row,t}$

Income taxes are described in Equations 2 and 3 as linear function of total incomes of households ($Yh_{h,t}$) and firms ($Yf_{f,t}$), respectively. Note that the marginal rate ($ttdh1_{h,t}$) are different from the average rate of taxation for any non-zero intercepts ($ttdh0_{h,t}$) that are fully index to changes in the consumer price index (Cpi_t).

$$Tdh_{h,t} = Cpi_t^n \cdot ttdh0_{h,t} + ttdh1_{h,t} \cdot Yh_{h,t} \quad (2)$$

$$Tdf_{f,t} = Cpi_t^n \cdot ttdf0_{f,t} + ttdf1_{f,t} \cdot Yf_{f,t} \quad (3)$$

Government also may funding its policy through a tax applied to the value of each industry production (Equation 4). Taxes on production therefore are industry j unit cost ($Pp_{j,t}$), excluding taxes directly related to the use of capital and labor, but including other taxes on total aggregate output of industry j ($XST_{j,t}$).

$$Tip_{j,t} = ttip_{j,t} \cdot Pp_{j,t} \cdot XST_{j,t} \quad (4)$$

where, at time t , $ttip_{j,t}$ is tax rate on the production of industry j .

Finally, the government can implement two types of taxes on products or commodities. Taxes applied on the sales value at domestic market include margins (trade and transport margins) and custom duties (Equation 5). In a static version of the model, the production and sales taxes may be emerged and modeled accordingly, restricting the government's ability to carry out double taxation at the stage of production and at the final consumption. However, as the goal is also to check each funding source and its effect on model variables over time, we separate production from sales taxes in the dynamic version of the model.

$$Tic_{i,t} = ttic_{i,t} \left[\left((Pl_{i,t} + \sum_{ij} Pc_{ij,t} \cdot tmrg_{ij,i}) Dd_{i,t} + ((1 + ttim_{i,t}) Pw_{i,t} m_{i,t} e_t + \sum_{ij} Pc_{ij,t} \cdot tmrg_{ij,i}) IM_{i,t} \right) \right] \quad (5)$$

where, at time t , $Pl_{i,t}$ is the price of local product (excluding all taxes on products); $Pc_{ij,t}$ is the purchaser price of composite commodity (including all taxes and margins); $Pw_{i,t}$ is the world price of imported product (expressed in foreign currency); $Dd_{i,t}$ is the domestic demand for commodity i produced locally; e_t is the exchange rate; price of foreign currency in terms of local currency; and $IM_{i,t}$ is the quantity of the product imported. $ttic_{i,t}$ is a tax rate on commodity; $tmrg_{ij,t}$ is the rate of margin i applied to commodity i ; and $ttim_{i,t}$ is the rate of taxes and duties on imports of commodity

In our model, part of the government revenue that comes from transfers is obtained without any counterpart since it is not explicitly related to a specific form of agent behavior. So, the sign of these transfers between government and non-governmental institutions depend on the economic characteristic of Guinea-Bissau and may be positive or negative depending of national data characteristics contained in social accounting matrix (SAM) that may have positive or negative values. The households and firms' transfers to government are defined as a proportion of their disposable incomes. Like income taxes, these transfers are supposed to represent contribution of the social program and, for modeling purposes, they are treated in the same way (Equation 6 and 7).

Government transfers from rest-of-the-world (ROW) are addressed differently because they can be derived from the other nature regardless of its income. All forms of aid (or interest-bearing external loans) to Guinea-Bissau are the ROW transfers to the country. Technically, these transfers are initially set equal to their SAM values ($Tr^0_{gov,row}$) and grow each period at the same population growth rate (pop_t), being indexed fully to the consumer price index (Equation 8).

$$Tr_{gov,h,t} = Cpi_t^n \cdot tr^0_{h,t} + tr^1_{h,t} \cdot Yh_{h,t} \quad (6)$$

$$Tr_{gov,f,t} = \gamma^{TR}_{gov,f} \cdot Yf_{f,t} \quad (7)$$

$$Tr_{gov,row,t} = Cpi_t^n \cdot Tr^0_{gov,row} \cdot pop_t \quad (8)$$

where, at time t , $tr^0_{h,t}$ represents transfers by type h households to government (an intercept); $tr^1_{h,t}$ is the marginal rate of transfers by type h households to government; and γ_t^{TR} is the share parameter (or transfer functions).

Current government budget or deficit (positive or negative savings - Sg_t) constraint equation (Equation 9) show deficit used entirely for public investment as difference between revenue and its expenditures, which consist of transfers to non-governmental agents ($Tr_{gov,agn,t}$) and current expenditures on goods and services (G_t).

$$Sg_t = Yg_t - Tr_{gov,agn,t} - G_t \tag{9}$$

There are now important elements to look at the model default closure, in order to define the behavior over time of the model variables that adjust to meet the current policy. We assume that public expenditure is exogenous and grows over time as population growth rate. The amount of public investment in infrastructure (ITgt) will be allowed to change when it is changed the closure as to take into account the fiscal instruments. From the above relationships, the government can adjust the current budget or deficit as funding mechanism. Equation (10) considers the two funding sources.

$$ITg_t = Sg_t + Deficit \tag{10}$$

As in Boccanfuso *et al.* (2014), we assumed that if infrastructure construction is fully funded only with public savings, the government will not change its debt stock and will not incur in deficit from one period to another. However, if government resorts to debt stock, it should not only get a deficit, but the amount of debt should increase from one period to another depending on the interest rate charged on the initial loan.

We will return in the next section with the discussion of scenarios of simulation and model closure. What is most interesting to emphasize now is the statement that public investment can have externalities, which is the cornerstone of this study. The externality assumption was brought up by Savard (2010), and subsequently adopted by Estache, Perrault and Savard (2012) and Boccanfuso *et al.* (2014) and set as follows:

$$\theta_{i,t} = \left(\frac{Kg_t}{Kg_{t-1}} \right)^{\varepsilon_i} \tag{11}$$

where, at time t , $\theta_{i,t}$ is the externality (or sectoral productivity effect) set as a function of the ratio of current stock of public capital (Kg_t) over public capital of the previous period (Kg_{t-1}), and ε_i is a sector-specific elasticity. The values of these parameters will come from Harchaoui and Tarkhani (2003) study who estimated externalities by sector for Canadian economy. This choice is justified, mainly, because there is no data at the sectoral level that allow such estimation for the Guinean economy. However, since the literature recurrently reveals decreasing returns in the public infrastructure investment and the present study is about a developing economy where returns are still increasing, the use of elasticities estimated for developed country can be considered as conservative (Estache, Perrault, and Savard, 2012, p.5).

The current stock of public capital is the sum of stock of public capital of the previous period, which grows at a rate of the level of investment required to maintain the capital stock (g_{kg}), and public investment in new capital of the previous period (ITg_{t-1}), both terms associated with a discount factor, which is the depreciation rate of public capital (δ_g) - Eq.12:

$$Kg_t = Kg_{t-1}(1 + g_{kg})^t(1 - \delta_g)^t + ITg_{t-1}(1 - \delta_g)^{t-1} \tag{12}$$

The motivation to use the externalities function (as in Eq.11) is due to its role in increasing the total factor productivity. The causality can be described as follows: a new investment program in the infrastructure carried out by the official government, that is, increase in ITg , will increase the public capital stock through the time and generate a positive production externality (captured by parameter θ_i). This force appears in the value-added ($Va_{i,t}$) equation (Eq.13) through this theta parameter, so that:

$$Va_{i,t} = \theta_{i,t} A_i L d_{i,t}^{\alpha_i} K d_{i,t}^{1-\alpha_i} \tag{13}$$

where A_i is the scale parameter; $L(d_{i,t})^{\alpha_i}$ and $K(d_{i,t})^{1-\alpha_i}$ the labor and capital demand by industry i , respectively; and α_i the Cobb–Douglas parameter. Hence, like in Boccanfuso *et al.* (2014), an increase in θ_i represents a Hicks neutral productivity improvement.

This formulation is also commonly used in the empirical literature estimating externalities parameters of infrastructure public investment on the total factor productivity (see Lynde and Richmond, 1993b; Bajo-Rubio and Sosvilla-Rivero, 1993; Gramlich, 1994; Herrera, 1997 among others). Estache, Perrault and Savard (2012) argue that adopting this formulation in the CGE framework implies that investment in infrastructure can act as a source of comparative advantage since the function is sector specific. This is important for the development policies to maximize the capacity of the sectors and to exploit the resulting gains even at household level.

It is worth noting that externalities from past public capital stock are calibrated in the A_i parameter of the $Va_{i,t}$ function, non in $\theta_{i,t}$ function, since the externality measured by θ_i represents the portion associated with the new investments of 100 million per year for 25 years, the investment time-calendar. In other words, every \$ 1 spent on infrastructure construction will have effects on total factor productivity through the θ_i , affording the scale of production A_i . The externalities arising from the same amount of new public investment are again added to the value of A_i , which already carries the effects of past investment, and impact for the economy must be greater than the previous period. In the dynamic environment, however, it is expected that the effects of θ_i will be smoothed due to adjustment in the factor market, since $\theta_{i,t}$ is exogenous in $Va_{i,t}$.

The specification is completed by introducing the dynamics in the model. If the government uses the surplus of its revenue resulting from a year of good growth as a public investment, the current GDP should increase. In this case, a standard static model would count for modeling the externalities of public investments. However, with the evidence that public investments do not have an explicit correlation with contemporary GDP, this scenario is unlikely to occur, first because governments have announced investments in public works to boost their economies during the reception and do not have time to wait for golden periods to start such investments and, second, because the majority of public investments are operational only several years after expenditures have occurred. For example, after announcing the

package of new public investments in infrastructure construction, a road may take 7 years to be completed; an airport may take more time, and so on for other investment categories. This delay makes the impact of public investments to be no instantaneous. An appropriate theoretical framework should be called. Therefore, it is the existence of important lags of several years between expenditures on public investment and completion of the capital stock the main motivation behind the choice of the dynamic CGE model.

The introduction of the dynamic implies that the model considers the dynamics of investment and endogenous accumulation of capital, as well as the savings dynamics and the accumulation of wealth over time. As labor force as well as technological progress are time-indexed, the model is no longer concerned with comparative static analysis, but with the cumulative effects on the economy of current policy.

The evolution of capital stock is modeled through the investment demand functions (Eq. 14) as in Decaluwé *et al.* (2012), where the volume of new type of capital allocated to business-sector industry is proportional to the existing stock of capital ($Ind_{k,i,t}$). The proportion varies according to the ratio of the rental rate ($R_{k,i,t}$) and the user cost of that capital ($U_{k,i,t}$ - Tobin's q), which depends on the price of new capital (or replacement cost of capital - PK_t^{new}), the rate of interest ($IR_{k,t}$), and the rate of depreciation (Eq.15).

$$Ind_{k,j,t} = \phi_{k,i} \left[\frac{R_{k,j,t}}{K_{k,j,t}} \right]^{\sigma_{k,j}^{INV}} Kd_{k,j,t} \tag{14}$$

$$U_{k,j,t} = PK_t^{new} (\delta_{k,j} + IR_{k,t}) \tag{15}$$

where, at time t, $\phi_{k,j,t}$ is the scale parameter (allocation of investment to industries) and $\sigma_{k,j}^{INV}$ is the he elasticity of private investment demand relative to Tobin's q.

The level of investment demand at time t is used in the capital accumulation rule equation (Eq. 16), which states that stock of capital in industry i in period t + 1 is equal to the stock in t, minus depreciation of capital ($\delta_{k,j}$), plus the volume of new capital investment in the t.

$$Kd_{k,j,t+1} = Kd_{k,j,t}(1 - \delta_{k,j})Ind_{k,j,t} \tag{16}$$

$$Lcs_{t+1} = Lcs(1 + n) \tag{17}$$

The dynamic specification is completed through another set of update variables that grow at a constant rate per period, governed by official population growth rates over time which enters the model as a free parameter n. We use this parameter to introduce the labor force growth (Lcs_{t+1}) in the usual way as in Equation 17.

2.1 Data base and model closure

We use data from two sources: International Food Policy Research Institute (IFPRI) and World Bank. With the support of the IFPRI, the SAM of Guinea-Bissau to be used in this study was built by Cabral (2015), from the African Growth and Development Policy Modeling Consortium (AGRODEP), and it provides a comprehensive information on the country's economy in the 2007⁴⁸. It has 22 sectors, 9 production factors and 85 accounts, classified into the following six accounts: factor, institutions, activity, domestically sold commodity, export commodity, and accumulation. Each account represents the agent's relationships determining the dynamics of the economy in the period in question.

The factors of production are offered in the market and their effective use for production represents costs in terms of wages and rent; they are remunerated conventionally, that is, paid based on their marginal costs; the revenues are transferred to households in the form of factor income. The households' income, already in the accounts of the institutions, comes from two sources: wages and transfers from the government.

After the receipts, the income is used by the households in several ways: one part is destined for the payment of taxes, another for the consumption of domestically offered commodities and another for savings. In addition to normal operations, firms receive subsidies and pay taxes to the government, which they also receive from households and the ROW. Through redistributive policies, the government transfers can go as income to households, subsidies to companies, and accumulates international reserves that can be used for a variety of purposes, mainly for offsets between residents and non-residents or the ROW. The government consumes and saves part of its revenues. International capital entering the country can be used to buy domestic production (exports) or to fund domestic consumption (investment). The accumulation accounts and their interconnections with the other matrix vectors complete the interconnection of the flows.

For the micro-simulation purpose, we use the 2014 official minimum wage to disaggregate households in six urban and six rural types (Table 1) and then emerge the resulting shares with every rows and columns in the SAM as to obtain a new level of consumption and income for every household, generating an updated SAM for the current minimum wage base year.

Table 1 - Household disaggregation by minimum wage

Household 1	H1	≤ 1 minimum wage	50,000*	0.018
Household 2	H2	≤ 2 minimal wages	100,000	0.036
Household 3	H3	≤ 4 minimal wages	200,000	0.072
Household 4	H4	≤ 6 minimal wages	600,000	0.218
Household 5	H5	≤ 8 minimal wages	800,000	0.290
Household 6	H6	≤ 10 minimal wages	1,000,000	0.363

Source: Authors elaboration. *:50,000 is the current official minimum wage in 2014.

48 The Social Accounting Matrix of Guinea-Bissau is obtained by request. Interested parties can access: <http://www.agrodep.org/dataset/2007-social-accounting-matrix-sam-guinea-bissau>.

The main general observation for households is that we respect the initial classification that there are two types of workers (skilled and unskilled) and two types of households (urban and rural). Therefore, in terms of the treatment of the labor market, all urban households offer skilled labor, while their rural counterparts offer unskilled labor. The reason for disaggregating workers in several types is that it allows to visualize which sector demands more the labor offered by poor households, for example. We could observe that, for a given total supply of factors, the agricultural sectors demand more unskilled labor from the rural environment, while the industrial and service sectors demand more skilled labor. The public infrastructure investment program is evaluated by considering different scenarios. The base year is 2014, and the program covers the period from 2015 to 2025, with investments already applied between 2015 and 2017. It is worth to emphasize that it is the effects of public investments aimed at building new construction infrastructures that are widespread in the models and that those investments for rehabilitation or maintenance are not considered. As an effect, the model can carry the cumulative effects of the infrastructures being built as well as their impacts at the end of the program. The projection for 2030 is carried out as to consider the lag and dissemination of public investments after the program is completed. Table 10 summarizes the main infrastructure scenarios to be simulated in the model.

Table 2- scenarios of infrastructure investment simulations

Simulation 1: reference Scenario	
Business as Usual	Growth of 2 % per year of the 2015–2030 period (from t to t + 16)
Simulations 2, 3, and 4: Scaling up new public investment	
Scenario 1	10% increase in public investment program from 2015 to 2030
Scenario 2	3.3 % increase in public investment program from 2015 to 2030
Scenario 3	6.7 % increase in public investment program from 2015 to 2030
Simulation 5, 6, 7,8,9 and 10: funding schemes	
Scenario 4	\$1 billion investment program of 16 years funded 100% by debt
Scenario 5	\$1 billion investment program of 16 years funded 50% by debt and 50 by sale taxes
Scenario 6	\$1 billion investment program of 16 years funded 50% by debt and 50% by transfers from abroad
Scenario 7	\$ 1 billion investment program of 16 years funded 50% by debt and 50% from firm tax
Scenario 8	\$1 billion investment program of 16 years funded 50% by debt and 50% from income tax
Scenario 9	\$1 billion investment program of 16 years funded 50% by debt and 50% from production tax

Source: Authors elaboration.

Simulations: 2, 3, and 4: An amount of 1 billion announced for 10 years corresponds to a 100 million investments per year. In this case, new public investments are made based on a 10 per cent increase in public spending per year from 2015 to 2030 (*Scenario 1*). In order to consider separately the effects of the investments already made and those planned, the time-calendar of this program is divided in two periods, from 2015 to 2018 and from 2019 to 2025. In the first 3 years the government invested 33 million and should invest the remainder 67 million in the upcoming years. The shock size of 3.3 per cent corresponds to the proportion of money spent on public investments over the program budget in the first period (*Scenario 2*), and 6.7 per cent is the proportion of the remainder spending over this budget in the second period (*Scenario 3*).

Simulations 5, 6,7, 8, 9, and 10: That public investments may raise indebtedness is what underlies the present scenarios. The goal is to conduct a comparative analysis of various funding schemes for implementing the government program in 2015. By comparison, we assume that the official government can use different fiscal instruments and external resources to fund its investment package, as well as its current deficit. We also assume that the government has access to domestic private funding and other external resources. It is not the level of the current deficit that the government will use for its policy purposes, but rather the proportion of public debt to household, firms and to the rest of the world. Of course, if these shares increase then the current public debt should increase and in the next period the government must either cease investing or will incur in high deficits. The extent to which private funding can increase the public deficit will depend on the interest rate. If it is unsustainable, that is, if the interest rate of the economy grows faster than the resources the government can earn as a benefit of the program, an increasing budget imbalance is expected as the government continues its investment initiatives. Otherwise, there will be a level of public revenue compatible with the current deficit and the public investment program is sustained.

Scenario 4 considers the case where the government uses the 100% of debt to fund its program for 16 years. in scenario 5 the government uses half the debt and half comes from indirect sales taxes as the funding mechanisms. In the next scenario the government mixes the debt and external resources, the half coming from each source. In scenarios 7 and 8 there is the possibility of taxing firms and households, respectively, at a margin corresponding to 50% of their incomes as resources needed for investments. To complete the required resources, the government must still increase its debt by 50%. in the last scenario 9, half of the resources available for funding comes from the public debt and the other half from production taxes.

The simulations of the scenarios 1,2 and 3 are performed by considering the follow model closure. As the shock is done directly on the ITg, the new investment in infrastructure and consequently savings is kept fixed. Therefore, if initial ITg is 100 and the government decides to increase by 10 per cent that amount without changing its deficit, the savings should increase by 10 per cent. Keeping public expenditures as well as transfers as constant, according to (3), government revenue should increase by the same proportion. Meanwhile, for simulations from 5 to 10 (scenarios 4 to 9), we let ITg

to adjust to balance government current accounts and then scaling taxes and debt. That involves uncovering optimal levels of taxes and loans that would match a 10 percent increase in ITg.

3. RESULTS

A policy can have different effects for the sectors and for the main macroeconomic aggregates. Thus, after the presentation of the simulated macro results, the results at the sector level are reported subsequently. We start the discussion with the results of scenarios 1, 2, and 3, which represent a government decision to scale up new infrastructure investments for the comparative advantages promotion and poverty reduction purpose. These scenarios represent an increase in public investment by 10%, 3.3%, and 6.7%, respectively.

Next, we turn to the funding mechanisms, which are resources the government obtains to the infrastructure investment accomplishment purpose. In scenario 4 government uses the 100% of debt to attend its investment objectives, while in the scenario 5 he mixed debt and indirect sales taxes half from each funding source. In the scenario 6 the government mixes the debt and external resources, the half also coming from each source. In scenarios 7 and 8 the policy authorities use taxes from firm and household incomes, while in the scenario 9 funds comes from the public debt and production taxes.

3.1 Scaling up new public infrastructure investment

3.1.1 Macroeconomic results

The Table 3 shows that the effects of new investment on standard macroeconomic aggregates depend on the shock size and the period the government decides to increase the new public investment. *Ceteris paribus*, an increase in public investment will raise the production by the construction sector and produce externalities in subsequent periods in the model.

In the second year of the policy execution, the growth generated by the construction of the new infrastructure is high with an increase in GDP of 0.454, 0.154 and 0.309%, respectively for scenario 1, 2 and 3, compared to the BAU scenario. This is followed by positive growth generated by externalities of the investment program from the third year, which continues even after the program has been completed. However, as we move further in time the externalities effects are decreased given that there is public capital depreciation.

We that the amount required for investment purpose may not completely comes from public deficit, given that growth will increase government income and hence funding needs are below the amount announced for the investment program. We can see from Table 4 that government real income increases during greater economic growth periods and faster afterward to a maximum of 1.142, 0.369, and 0.759%, respectively for scenarios 1, 2, and 3 at the end of the simulation in 2030.

The increase in income is directly influenced by the stronger GDP growth, which is also positively impacted by higher factors productivity and aggregate employment (Table 5). The deficit has increased as a result of these policies. However, current deficit starts to decrease even if funding needs are still present at the end of program in 2025, since GDP has shown a good performance through the program period, which provides enough additional government revenues to fund its investments (Table 6).

In terms of the infrastructure investment funding mechanisms, the first important observation in this analysis is that funding sources produce similar effects for most macroeconomic and sectoral variables. The most obvious cases are the GDP (see Table 4). Productivity plays a crucial role in the behavior of macro and sectoral outcomes. We observe that increase in GDP is supported by the positive aggregate productivity and less by the additional employment, as in the case of scenarios 5, 7 and 8. In these scenarios, the percentage changes in composite employment in the last year of simulation are negative. Government revenue as an additional funding source declined in the first three years of the policy, but from 2019 to 2030 we observe a positive and persisted percentage change in government revenue.

Table 3 - Gap compared to BAU scenario for real GDP (GDP_Real)

3.1.2 Sectoral Results

We analyzed the sectoral results in terms of value added (VA), factor returns, and exports performances, verified after each shock. Two things are evident in these results. First, we found that the construction and transportation sectors absorbed more from the shocks of new investments at the end of the simulation, whether in terms of VA or factor returns. This implies that part of the public investment is retained and reinvested in the construction sector, which was the focus of current policy.

The values of the transport sector are due to the direct link between construction and transport sectors. The structure of our model, with a consistent macro closure, public investments in construction is expected to act on economics in the same way as public investments in the transport sector. This is justified because many construction services depend on transport logistics to be effective. Therefore, as production in the construction sector grows, production in the transportation sector should grow accordingly, to a lesser or greater extent. The values of the electricity-water sector are not surprising, since water and electricity are intermediate inputs in construction. An increase in investment in construction sector will increase the demand for these inputs, leading to an increase in its sectoral production.

Table 7 - Gap compared to BAU scenario for sector results at the end of simulation

Variable	Value added (VA)			Factor return (FAC)			Exports (EX)		
	1	2	3	1	2	3	1	2	3

Source: Authors elaboration. Model results.

The second general observation is that current policy increased sectoral factor returns and created structural changes in the economy in the long run, as it caused a significant increase in the production of non-traditional sectors, such as the food and beverage sector. Consequently, we observed an important change in the composition of the country's export grid. That's because, Guinea-Bissau, like many West African countries, is a net food importer, which means that the domestic food supply is historically lower than the population's demand. Current policy would reverse this situation. The country will produce food in quantities above what is necessary for domestic consumption, that is, the country is a net exporter of food.

3.2 Scaling up new public infrastructure investment and funding schemes

In this section, we analyze the results of scenarios 1 to 3 and those of scenarios 4 to 9 from the comparative perspective of economic activities, income, cost of living and the externalities that carry the potential of public investments for the production side. Both the increase in investment policies and the funding schemes adopted had a positive impact on the level of economic activity, with scenarios 1 and 6 showing greater effects that persisted over time (Figure 1). After an initial period of positive impacts on the level of economic activity, the effects of scenarios 4 and 5 reduced from 2015 to 2017 period and then recovered until 2020 where they remained stable until 5 years after the program is completed. Scenario 8, in turn, lost its initial impact on the aggregate product more sharply, but is scenario 2 which had the least positive effects on economic activities.

Figure 1 - Gap compared to BAU scenario for real GDP (GDP_Real)

Source: Authors elaboration. Model results.

We start to look at externalities at the end of the simulation, in the same sense that the effects of new public investments are spread in the model after the program is completed in 2030. It is possible to observe that all scenarios produce positive productivity externalities for sectoral variables (Table 8). However, we can also note that each sector responds differently to the shock performed and that the size of the shock is not sector invariant. In the Column 2 representing *scenario 1*, externalities are most absorbed by all agricultural sectors, especially Millet and Rice (0.385), Cotton (0.240), Other agriculture (0.490), Breeding-hunting (0.394) and Cashew nuts (0.296). Percentage changes relative to the BAU scenario of the industrial and service sectors are not negligible, but they are lower than those of the agricultural sectors. Externalities are lower for real estate and services to firms and public administration, both with a percentage variation of 0.017 five years after the policy in question.

Small changes occur when we moved to scenarios 2 (3.3% increase in new public investment) and 3 (6.7% increase in new public investment), because in these cases externalities are reduced for both sectors, but the order of impact size remains as in the scenario discussed in the previous paragraph. As they share the same production technology, the externalities of the Millet and Rice sectors are the same for all scenarios. Overall, the externalities are higher if the government only increases its investments by 10% compared to debit and taxes funding schemes, although these policy options also have positive and non-neglecting impacts on the economy sectors, as we can see from the columns of scenarios 4 through 9.

Table 8 - Gap compared to BAU scenario for externalities of public investment (theta) at end of resolution in 2030

Theta	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5	Scenario 6	Scenario 7	Scenario 8	Scenario 9
Millet	0.385	0.131	0.262	0.345	0.353	0.377	0.333	0.317	0.304

Source: Authors elaboration. Model results.

We also assess the results at the household level by focusing on three variables, namely individual income and consumption and the consumer price index. The households' income from 2015 to 2030 are represented in Figure 2, which shows that both policies are different income effects from one household to other. However, we note first that scenarios 1 to 4 and scenario 6 have positive impacts on households' incomes, while scenario 5 and scenarios from 7 to 9 reduced their incomes. Second, scenarios that produce positive effects do so less intensely than scenarios producing negative results, that is, positive percentage variations are deeper than negative percentage variations. Moreover, the percentage of income variation of the poorest households is higher when policies produce positive effects and lower when income-effects are negative. It is worth emphasizing that scenarios 1, 2 and 3 provided best results for this economy.

Figure 2 - Gap compared to BAU scenario for households' real income

Source: Authors elaboration. Model results.

The consumer price index (Figure 3) it decreases for the 2015 to 2018 period, increases between 2018-2020 and remains stable until the end of the simulation for all policy options, except for scenario 1 and 6 that present similar price effects as shown by the two overlapping lines in the positive area of the graph.

Figure 3 - Consumer price index - variation compared to BAU

Source: Authors elaboration. Model results.

The extent to which new investment and the way they are funding affect the living conditions of the population is a question under investigation. In Table 9, 10% increase in new public investments without specifying the source of funding will further damage the poorest rural and urban households, whose consumption have declined by -0.078% and -0.055% percentage, respectively, compared to the BAU (Column 2). Note that an increase of 3.3% in new public investment, as represented by Columns 3 reduces by -0.026% the consumption of rural households receiving up to 1 minimum wage, by -0.003% the consumption of rural household receiving by up to 2 minimal wages, and by -0.018% the consumption of urban household receiving up to 1 minimum wage. In general, as the wage range grows, more is the positive impacts the household can get from the increase in new public investments. However, this result changes completely when government adopts fiscal instruments since each policy option is producing different impacts on households' consumption.

Funding using 100% of the debt will benefit all households, but the poorest in both rural and rural areas will increase more their consumption than the richest ones, that is, those whose minimal wages is higher (scenario 4 – Column 5). However, when the government uses the mix debit-sales taxes, only the poorest rural household and the poorest urban household were affected as the consumption of other household are reduced: the wealthiest household will have their consumption reduced by -0,739 percent over the BAU scenario. Meanwhile, funding public investment with 50% of external resources and 50% of the official deficit (scenario 6) will reduce by -0,081 and -0,058% the consumption of rural and urban households with less than 1 minimum wage, respectively, while increasing the consumption of their counterparts on the opposite tail by 0.047 and 0.095%.

Table 9 - Gap compared to BAU scenario for households' real consumption (CH) at the end of simulation in 2030

Household consumption	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5	Scenario 6	Scenario 7	Scenario 8	Scenario 9
Rural household 1: ≤ 1 minimum wage	-0.078	-0.026	-0.053	0.849	0.333	-0.081	0.254	-0.236	0.344

Source: Authors elaboration. Model results.

In contrast, we observe that -0.895 and -0.763% are the consumption reductions that incur rural and urban households that receive higher wages in income distribution as a result of increasing firm tax, which will benefit the poorest

households in the city and in the field (scenario 7). If the government funds its policies with tax on household income, it is only the rural household with highest (receiving up to 10) minimum wage that have its consumption increased by 0.551 percent, as the other households have been hit negatively with substantial consumption losses (Scenario 8). Although none of the urban households have obtained substantial gain, overall, this policy negatively affects more the rural households receiving up to 10 minimal wages. In scenario 9 we can see that the Column 8 pattern is repeated, since only the poorest households have experiment positive gains, with percentage change in their consumption of 0.344 for rural and 0.398 for urban households receiving less than 1 minimum wage.

In short, public investment in infrastructure is responsible for increasing the level of economic activity, household consumption, and externalities. This result is in agreement with the findings of Boccanfuso *et al.* (2014), but also with the standard economic literature that states that developing countries that need to accelerate their catch-up process should rely on the participation of public capital, which serve as a kind of complementarity with private capital, instead of substitutes.

When the country is poorer, this complementarity should be more intense in the key economic sectors, such as construction. As a result, increasing new public investment will increase private investment as well as output per worker and may result in self-sustaining economic growth. Scenarios of new types of public investment suggest that these effects are propagated in our model even at micro level. In fact, the new public investment effects persisted over time and spilled over into households' income and consumption gains, including for rural households with the lowest minimal wages.

The simulations of funding mechanisms corresponding to the increase of public investments bring mixed results. While scenarios 5 show that using the already distribute gains to increase finance investments will not bring immediate gains, other scenarios show that redistribution and prosperity gains can be achieved through taxes increase. In both cases, the results show taxation methods as a way to control production and income and increase long-term welfare. Findings in this sense go back to the study by Diamond and Mirrless (1971), and recently Hafner *et al.* (2015) and Bosua *et al.* (2012).

4. CONCLUSIONS

This study aims to analyze the effects of public investments on socioeconomic, sectoral, and household level outcomes based on the Guinea-Bissau government investment program in infrastructure that are in operation since 2015 as to address the numerous development challenges in promoting national comparative advantage and increasing the citizen's standard of living.

Simulation results show that investment in infrastructure has a positive effect on the economy. The impacts are spread from one period to another by increasing the sectoral total productivity and the externalities that have sustained the sectoral production over time. At the beginning of each period, the execution of public investment projects raised the public deficit, but we see that this deficit is drastically smoothed out follow up the depreciation of public capital period. Moreover, the results also show that the poorest households benefited most from the investments made, both in terms of consumption and income, which suggests the potential of this policy to reduce poverty and generally to promote socioeconomic development.

In general, it is suggested that the way in which the government directs its development projects to promote the country's comparative advantages as to reconcile higher sector productivity and employment will be important in determining the economic performance in the following periods, as the sectors responded more or less to the policies adopted. Thus, a national development policy aimed at increasing household aggregate income and income through infrastructure investments can serve to stimulate economic growth, even in long-term, while affecting the pattern of household consumption.

The way as the policies will be funded will be important for the government that wants to maintain its long-term account balance, so that it is possible to carry out its current expenses and signal to its partners its ability to honor the signed external commitments. While external funds seem to help the government to meet its objectives, it can in the long-term become problematic as it depends on external variables such as interest rates which is completely beyond the government's control. Thus, if the official government intends to keep appropriating external resources as a funding source and if the external interest rate rises to such a level as to compromise the ability to pay the current debt, there will be a period when he will be required to declare default. This could damage the country's image in the international creditors' square. Funding by taxation of production and firm is not recommended to develop economies whose sectors are incipient, as it may inhibit the application of private capital and eliminating the initial impacts of the policy. The income taxes-based funding suggests having positive impact on economic activity. However, if the goal is to reduce poverty in the short term, the government should adopt appropriate fiscal instruments that do not weigh on the real budget of households.

However, confirmation of this hypothesis requires more detailed studies. The results of this study indicate that infrastructure investment has positive long-term impact on several socioeconomic variables and productivity, but when the government adopt funding schemes, results shift from one sector to another. Internally, it will be necessary to understand how the design of the institutional situation in Guinea-Bissau has contributed to the country's economic development. As for the model, further studies will be required, introducing more policies options or scenarios and to consider the level of qualification of the worker and how earnings from labor market can be redistributed, including between the gender.

A SPATIAL MISMATCH ANALYSIS FOR CURITIBA METROPOLITAN AREA BASED ON ACCESSIBILITY TO FORMAL JOBS INDEXES

[Luiz Pedro Couto Santos Silva](#)¹, [Alexandre Alves Porsse](#)²

¹ Federal University of Juiz de Fora, Minas Gerais, Brazil, luizpedro_5@hotmail.com; ² Federal University of Parana, Parana, Brazil, Porsse@gmail.com

ABSTRACT

This study investigated potential economic gains in the labour market of the second largest Metropolitan Area of the south of Brazil, the Metropolitan Area of Curitiba, which had a long experience in adopting Transit Oriented Development policies for its urban consolidation. Guided by a Spatial Mismatch Hypothesis, the main objective of this study was to investigate the effects of gravitational accessibility indexes to formal job opportunities in monthly wages for workers of the study in the year of 2017. We applied a consolidated methodology that considers a rich set of geographic information to deal with theoretical issues of determinants of spatial configuration, and allow to observe, in 2SLS models with mincerian specifications, the effects of agglomeration economics by different magnitudes: geographical sub area, educational level and transport mode. The results suggest the existence of potential economic gains related to better accessibility to formal job opportunities. The transport mode and the educational level are also determinant to the magnitudes of such effects on monthly wages for those workers, which related to the spatial unevenness access to job opportunities, might be a source of economic inequality among the Metropolitan Curitiba Area citizens.

KEYWORDS

Accessibility to Formal Job; Spatial Mismatch Hypothesis; Urban Labour Market

1. INTRODUCTION

Cities of emergent countries have had huge issues on their respective urban consolidations since the beginning of most of its processes, mainly in metropolitan areas, where the unevenness spatial distribution of accessibility to opportunities evidence big challenges to suppress economic inequalities (Hernandez, 2017; Fan et al., 2018; Pereira et al., 2020).

The Spatial Mismatch Hypothesis (SMH) claims that spatial unbalances between dwellings and workplaces within some social groups may be harmful for their respective job market outcomes (Kain, 1968). This hypothesis has provided useful analytical fundamentals to better understand the effects of unequal access to job opportunities in economic inequalities (Gobillon et al., 2007; Duarte, Silveira-Neto, 2020; Holzer, 1991; Matas et al. 2010).

This hypothesis has shown adherence for Brazilian large cities, since some of them have evidenced: spatial concentration of job opportunities with non-equitable distribution of transport infrastructure (Haddad and Barufi, 2017); periphery of housing location from essential urban infrastructure to poor individuals (Pacheco, 2019); and concentration of such infrastructures and job opportunities for individuals who live in central areas and aren't low-skilled qualification (Sachsida et al. 2008; Barufi and Haddad, 2017).

In the south of Brazil, the city of Curitiba had planned and implemented an urban expansion process based on Transit Oriented Development (TOD), when hierarchized land use by distance to a road infrastructure, aiming to avoid overloading of such infrastructures. Curitiba also implemented the public transport system so-called Bus Rapid Transit (BRT) since 1974, building exclusive bus lanes, fast landing platforms and bus integration terminals, which together aim to encourage the use of public transport among its citizens and improve the flow of private cars and buses on the whole transport infrastructure. The BRT system has gained increasing popularity worldwide (Cervero and Kang, 2011).

TOD policies in the urban consolidation of Curitiba resulted in an employment polycentric spatial structure (Thomé, 2020), and regional economic policies encouraged the emergence of industrial poles in surrounding cities of Curitiba (Firkoski, 2002; Carmo and Moreira, 2020), which fomented geographical integration for the Metropolitan Area of Curitiba through its transport infrastructure.

The objective of this study is to measure the existence and magnitude of effects of accessibility to formal job opportunities on monthly wages for the Metropolitan Area of Curitiba (MAC), and bring resources to assess the sources of such effects, given that its spatial configuration, together with transport infrastructure - determinant mechanisms for a SMH - show different aspects of other Brazilian Metropolitan Areas (Boijosly et al., 2019; Pereira et al., 2020).

This study used the databases of the Origin-Destination Survey and RAIS for MAC in 2017, in addition to geographical information about its rivers network, aiming to implement the empirical methodology developed by Haddad and Barufi (2017), by estimating the effects of accessibility indexes on wages in mincerian equations, dealing with the endogeneity issue between these two variables with 2SLS models.

The results suggest the existence of positive effects of accessibility on wages. Groups of individuals that had at least frequented a university had lower inequalities in the potential of catching such effects on wages. Transport modes are also determinant for such potential in economic gains.

The six sections of this article are divided in: this introduction, a literature review that grounds this investigation, a brief contextualization of the MAC, the empirical strategy used by this study, the results obtained and the final remarks.

2. LITERATURE REVIEW

The urban geography provides useful evidences for understanding economics aspects of regions, such as jobs outcomes and its implications. The Spatial Mismatch Hypothesis, introduced by Kain (1968), aims to investigate labor market outcomes implications of social segregation faced by minority groups on the location of their job and residences. Thus, the interaction of these respective locations with the spatial configuration of the area of interest might be a mechanism that explains social and economics inequalities, as long as they have heterogeneous accessibility conditions.

Differences in accessibility conditions between zones of a city may influence on the choice of location of firms and residences. Fujita and Ogawa (1982) state that firms might endogenously choose areas with higher potential in economic gains due to agglomeration effects. Given that such effects are supposed to provide higher profits to firms, Melo and Graham (2009) defend that in equilibrium, agglomeration effects should increase worker's wages. In this framework, Lucas and Rossi-Hansberg (2002) suggest that the productivity level of zones will be positively related to the employment level of its neighbor zones. Consequently, as long as individuals that work on places with great productivity face higher commuting costs due to the values of their hourly wage, in mixed land use equilibrium, these workers should endogenously choose to live closer to areas with more job's densities.

Geography may also influence on the decision of firms for hiring workers in large urban areas. Zenou (2002) defend that commuting to jobs can be exhaustive for workers, implying that travel time is positively related with this exhaustion, and may negatively influence the respective worker's productivity, and therefore, on firm's profit. Therefore, in the seek of profit maximization, firms will discriminate workers whose dwelling are located too far from their headquarters.

From the above discussion, if we assume that: 1) agglomeration economies have positive influence on urban wages; 2) local of dwellings are endogenously determined by individuals who earn higher wages; and 3) firms discriminate workers based on their respective local of dwelling, jobs that offer the highest wages will be more accessible opportunities to individuals who have economic conditions to live close enough to the respective firms. Therefore, this phenomenon will foster economic inequality in urban areas.

Empirical evidence has shown that this mechanism is reasonably applicable for Brazilian cities. Pereira et al. (2020) discuss that in the 25 largest metropolitan areas of Brazil, higher accessibility to formal jobs opportunities is provided to areas where the residents with higher monthly wages live, and that the spatial distribution of transport infrastructure tends to be concentrated on central regions, which are evidences of a spatial configuration pattern for Brazilian large cities, where poor individuals tend to live on suburbs. Hernandez (2017) defends that structural constraints in urban areas tend to directly affect the potential of individuals to lift their economics conditions up.

As what see to be a consequence of such spatial configuration and urban infrastructure distribution for Brazilian large cities, Barufi and Haddad (2017) found strong negative relation between monthly wages and commuting travel time between residences and job. These authors also claim that wages are higher for individuals that live in work cities than for those who live in dormitory cities, reinforcing evidences that the statement of endogenous choice of place of dwellings near to zones with higher density of jobs (Lucas and Rossi-Hansberg, 2002) holds in Brazilian large cities, such as a pattern of low densities of job opportunities in suburb areas.

However, measuring SMH only by commuting time between place of dwelling and work has analytical weakness. It is important to control for individual characteristics, transport mode and the endogeneity of individuals who choose their respective place of residence (Holzer, 1991, Ihlanfeldt, 1992). Simultaneity between the variable that quantifies the SMH and job's outcomes might bias the effects of the SMH toward zero (Ihlanfeldt and Sjoquist, 1998).

Regional and urban economics studies have been outlining endogeneity issues through the use of econometric instruments that observe geographic and historical characteristics of their respective study areas (Duranton and Turner, 2011; Burchfield, 2006; Baum-Snow, 2007). The power of such approach comes from the reasonable assumption that early regional geographic characteristics play important roles on the respective human occupation.

In a SMH investigation, Haddad and Barufi (2017) have used rivers network information of Metropolitan Area of São Paulo (MASP) as instrument for dealing with simultaneity between accessibility indexes and wages, given that the rivers of that area became important transit corridors for its transport infrastructure network in the early 20th century. In a SMH investigation for the city of Recife, Duarte and Silvera-Neto (2020) claimed that the rail roads' network of this area in the 19th century were a decisive agent for the present accessibility infrastructure, because it reflected the best routes in the face of soil conditions. In both SMH investigations, the coefficient that represents the measure of accessibility increase after controlling the endogeneity bias between job outcome and the measure of accessibility.

If there is a historical-geographic aspect that exogenously determines the present spatial configuration or infrastructure of an urban area, so this exogenous aspect can be powerful for dealing with the theoretical issue of spatial equilibrium determinants (Lucas and Rossi-Hansberg, 2002; Ihlanfeldt and Sjoquist, 1998, Haddad and Barufi, 2017).

3. METROPOLITAN AREA OF CURITIBA, SOME STYLIZED FACTS.

With 1,9 million inhabitants, Curitiba is the main economic city of the Metropolitan Area of Curitiba, which is the second largest metropolitan area in the south of Brazil, with over 3,6 million inhabitants. In the first half of 20th century, the city of Curitiba has implemented urban master planning plans that aimed to bring infrastructure and connect its central area with dispersed districts, through large avenues on a linear urban expansion. From 1970's on, Curitiba had adopted urban

master planning plans that focused on sustainable mixed land use, defining the localities of residences and economic activities based on the level of road infrastructure near to them.

This city has also implemented the public transport system called Bus Rapid Transit (BRT), that built exclusive bus corridors in the main avenues of Curitiba, aiming to provide more speed on travel for both bus and car transport modes. Therefore, the disciplined urban expansion of this city, that conciliated hierarchized land use with the BRT system, followed Transit Oriented Development policies, that aimed to optimize the use of its road infrastructure and promoted poli centric configuration of employment (Thomé and Porsse, 2019).

In the 70's decade, policies for fostering industrial parks resulted in the Industrial park of Curitiba, in its southwestern board, and in the city of Araucária, located in the west board, such as discussed by Carmo and Moreira (2020). Firkoswk (2002) claim that later in the 90's the city of São José dos Pinhais, located in the southeast board of Curitiba, was also benefited by these industrial incentives.

This economic integration designed the Metropolitan Area of Curitiba's geography, with some concentration of qualified jobs in the metropolitan cities located in the limits of Curitiba (Nojima, Moura and Silva, 2009). Since the implementation of the BRT in 1974, the integration of Curitiba's transport system was most focused on the neighbor cities, having its expansion to peripheral metropolitan cities started from the 1990's.

Figure 1 shows that the urban expansion of MAC resulted in a spatial distribution of income in which the central region of the city of Curitiba have most of the high-income residents.

The limiting cities of Curitiba are the ones that show incomes similar to the central region of the Parana's capital at most, evidencing effects of the early economic and physical integration with this city. There is also spatial correlation between BRT corridors and incomes.

Figure 2 shows a dispersed distribution of formal jobs over Metropolitan Area of Curitiba. This might be a result of the industrial policies that had started from the 1970's, as well as the urban planning master plans adopted by the city of Curitiba (Thomé and Porsse, 2019). This distribution over the observed area is favorable for good accessibility to formal job opportunities, if the transport system is effective in connecting the different zones of this Metropolitan Area.

4. DATA AND EMPIRICAL STRATEGY

4.1 Data

This study had three different sources to form the databank. Information of individual socioeconomic characteristics, transport mode, travel time, dwelling and work locations came from the 2017 Origin-Destination survey (OD survey) of Curitiba, conducted by the Institute of planning research of Curitiba (IPPUC). This survey collected information about 17 municipalities of Metropolitan Area of Curitiba in 955 zones. For the present analysis, 5,604 observations were used from this sample, representing over 641 thousand residents.

Information about formal jobs⁴⁹ came from the 2017 Annual Social Information Relation (RAIS), which is provided by the Brazilian ministry of labor. This databank contains very detailed information about firms and workers, including their respective workplace, allowing for geocoding each⁵⁰ formal job of Metropolitan Area of Curitiba, making it possible to estimate the number of jobs in each of the 954 zones of the Origin-destination survey. The third data source consisted of geographic information of rivers in the study area. It is described in the sub-section about the econometric instrument used in this study.

4.2. Empirical Strategy

This empirical analysis used Ordinary Least Square and Two Stage Least Square regressors to evaluate causality between accessibility to formal jobs and monthly wages in MAC. The econometric models follow specifications based on Mincer (1974):

$$\ln W_{imj} = \varphi + A\delta_{imj} + X\beta_{imj} + \varepsilon \quad (1)$$

where W represents the \ln of the monthly wage of individual i , who uses the transport mode m to reach workplace j , and is explained by the accessibility index of the individual's workplace zone j , in addition to an array of individual characteristics X , which contains: i) a dummy variable that indicates whether the individual is male; ii) a dummy variable that indicates one of the 7 individual's level of education; iii) the age of the individual in \ln ; iv) the \ln of the individual's age squared; and v) two dummy variables that give information about the respective work areas of the individuals: one for those who live and work in the same place and another that indicates whether the individual works in a Rural Census Sector.

The quantification of Spatial Mismatch is based on a measure of accessibility, which consists of gravitational accessibility indexes based on Hansen (1959), that aims to observe available opportunities:

$$Amj = \sum_{j=1}^{954} \frac{E_j}{d_{ij}(t)} \quad (2)$$

49 In Brazil, this job category has rights and guarantees by law, being considered as better job opportunities than informal jobs. However, the RAIS database is limited to observe only formal jobs.

50 A total of 89% of the total sample in the RAIS databank was geocoded. 11% of the geocoded jobs did not present consistency of their respective location.

where A is the accessibility index for workers of zone j , of modal m , that is explained by E , the quantity of formal jobs in zone j , which is divided by an impedance function d , that ponders the availability of each formal job by the mobility conditions between zones i and j :

$$d_{ij}(t) = e^{\alpha t} \tag{3}$$

thus, d_{ij} is the linear distance between zones i and j , explained by the mean commuting time between these zones in two log-log Ordinary Linear Squared models, for the modes: 1) Private Vehicles, that encompassed cars, taxis and motorcycles trips; and 2) Public Transport, composed by all the trips made by BRT users and Metropolitan buses. The time information for the trips of both observed modes were collected from the OD survey, feeding two quadratic mean travel matrixes, making it possible to have two different estimated α .

Table 2 - Descriptive Statistics of the main variables of databank

	Private		Public		Total	
	Mean	Std. Dev	Mean	Std. Dev	Mean	Std. Dev
Acessibility Private Vehicle	13,098	10,428				
Acessibility Public Transport			8,136	7,842		
Monthly Wage (R\$)	2,519	2,173	1,643	1,477	2,038	1,876
Distance from residence to CBD	11,613	7,842	12,592	7,662	12,219	7,508
Travel time (minutes)	29	20	49	34	40	30
	Individuals	(%)	Individuals	(%)	Individuals	(%)
Expanded Sample	289,614	47,14	351,682	54,83	641,296	100

Source: Own elaboration, from OD survey and RAIS 2017.

It is shown in Table 2 that accessibility is higher among Private Vehicle users. These individuals also have higher average monthly wages than Public Transport users. Individuals who use Private Vehicles face 20 minutes less than Public Transport users on average.

Taken together, this set of information brings some evidence of implications of mobility conditions on jobs outcomes (monthly wages). The mechanism starts from the travel time, which directly depends of the transport mode. Figures 3 and 4 show the spatial distribution of the accessibility indexes for Private and Public transport modes. These indexes are the observed formal jobs pondered by the impedance function in equation (2). Therefore, in the MAC transport infrastructure, Private Vehicles provide higher accessibility to formal jobs than Public Transport users. Such as the formal job spatial distribution, the accessibility indexes are dispersed over MAC, and they see to be positively related to the road infrastructure. Thus, it is expected that the accessibility indexes have positive effects on monthly wages, as they represent potential effects of economics of agglomeration in the job market (Melo and Graham, 2009; Haddad and Barufi, 2017).

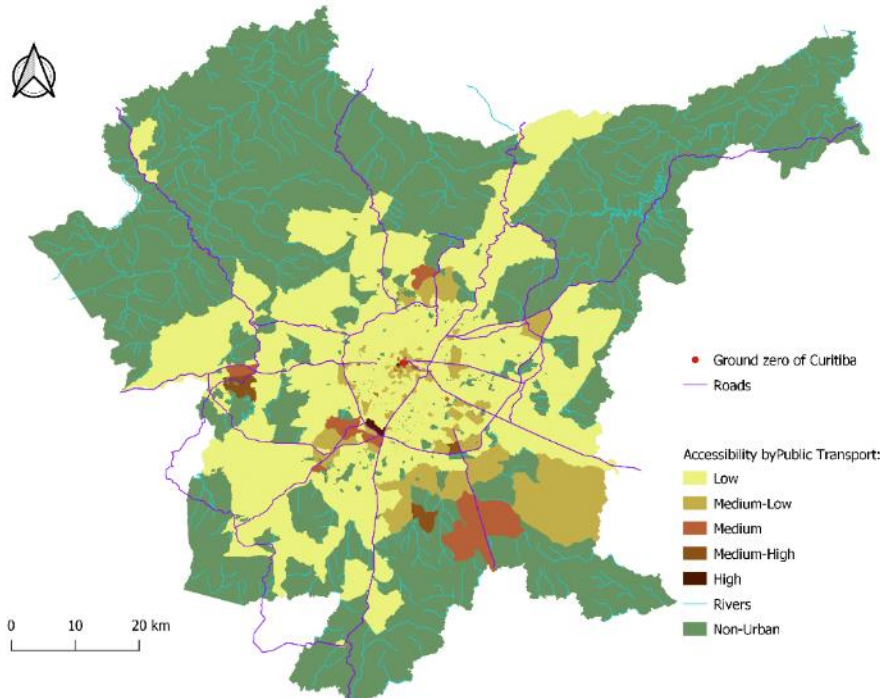

Figure 4 - Accessibility indexes for Public Transport users in CMA.

Source: Own elaboration from the data base.

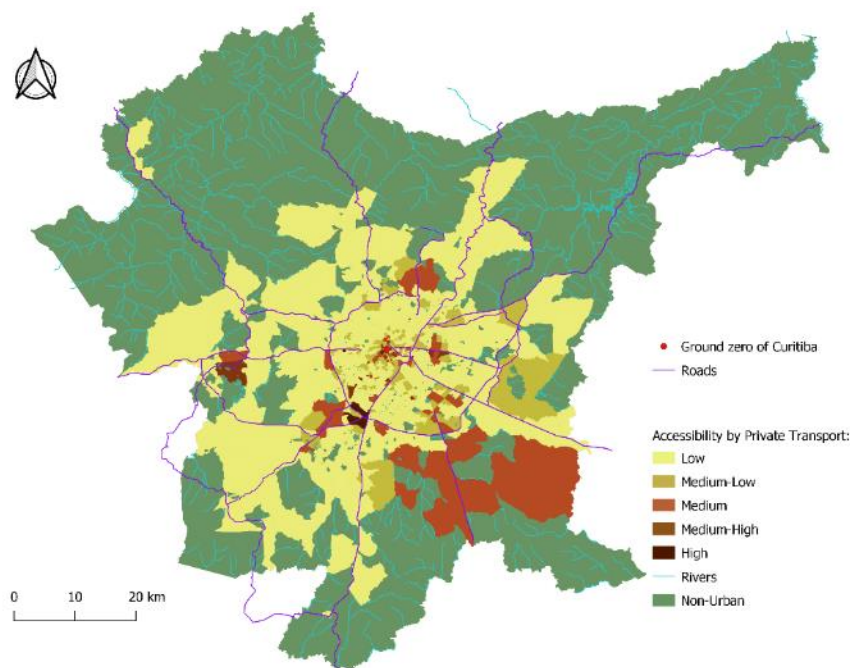

Figure 5 – Accessibility indexes for Private Vehicle users in CMA.

Source: Own elaboration, from the data base.

We assume the hypothesis of simultaneity between the accessibility indexes and monthly wages, which might cause bias on an econometric estimation in equation (1). Therefore, Mincerian equations were also tested with 2SLS models, using a geographic instrument.

In addition to the described methodology, we also tested the hypothesis of different magnitudes of such effects on monthly wages, which are based on workers' level of qualification. Therefore, we created two skilled-based groups: 1) Skilled 1, that are individuals who had at least started or even completed a bachelor course, in addition to individuals who had completed a postgraduation education; 2) Skilled 2, with individuals who had completed a bachelor or a postgraduation course. As base line, we created non-skilled groups: for individuals who haven't started a bachelor course in comparison to Skilled 1; and individuals who haven't completed a bachelor course for Skilled 2.

With the skill-based groups indicated by dummy variables, we had interacted them with accessibility indexes predicted in two⁵¹ first stage equation of 2SLS models, that used the geographic instrument as the exogenous variable. After that, four 2SLS models were obtained, with two models for each transport mode, aiming to measure possible differences of the measures of accessibility between non-skilled group against Skilled 1 and and non-skilled group against Skilled 2.

4.3 The Instrument

As mentioned in section 2, Regional and Urban studies that face the problem of simultaneity have been outlining such issue with historical and geographical information as instruments. Therefore, the strategy to deal with the issue of simultaneity adopted by the present study is the one developed by Haddad and Barufi (2017) for the MASP, by using geographical information of rivers network, assuming this aspect as being decisive on the present spatial configuration of the observed area by their study.

The Metropolitan Area of Curitiba is located in a very irregular mountain topographic site, which is 935 meters above sea level. This geographical condition implied in strong difficulties for transporting commodities from and to this area at the first steps of its urban consolidation, in the 19th century, as discussed by Karpinski (2011). Rivers brought transport solutions for early explorers, and influenced on the location of its first villages and farms, as related by (Schimidlin et al., 2009). Thus, human occupation and transport infrastructure were encouraged to be close of the rivers.

⁵¹ For the Public and Private Transport modes.

Figure 6 – Accessibility to formal jobs and Linear Distance to Curitiba CBD

Source: Calculated from the Databank.

Given the historical and geographical configuration of the study area, we assume that rivers exogenously influenced on the present location of its firms and residences. Therefore, as well as Haddad and Barufi (2017), the strategy to observe this variable was by computing the distance of each zone centroid to the closest river, and adding such distance to the distance from the closest river bank to the CBD of the city of Curitiba⁵², traversing the network of rivers shown in Figures 4 and 5. This procedure was made to all of the 954 zones of this study area. The resulted variable from this procedure presents negative correlation with both the accessibility indexes, as is illustrated in figure 6.

5. RESULTS

According to the results obtained by the main linear coefficients of interest, there are positive effects of better job accessibility on monthly wages for all of the workers of CMA. There are also higher effects on workers who have commuted to workplace by private vehicles and completed a bachelor course.

5.1 The Spatial Mismatch effects on workers of Metropolitan Area of Curitiba

The models in panel A of Table 2 tested the linear prediction of the accessibility indexes by the instrumental variable in addition to the independent covariates set in equation (1). The first stage tests indicate significant linear negative correlation between distance to CBD through rivers and both of the accessibility indexes, which suggests some contribution of the instrument to deal with endogeneity.

In panel B, OLS and 2SLS coefficients predict ln of monthly wages with the X set of individual information in equation (1) as control variables. All of the accessibility indexes coefficient are significant at 1% level, and OLS and 2SLS models have different magnitudes of effects of the accessibility to job opportunities in the monthly wages. As we assume endogeneity between monthly wages and the accessibility indexes, due to higher power of dwelling location response to workers who earn higher wages, it is theoretically expected that if an endogenous model computes information of individuals who have chosen to face longer travels to work in order to consume local amenities, then it tends to vanish the effects of the accessibility measure on monthly wages (Sjoquist, 1992; Holzen, 1991).

If the 2SLS models are better than OLS models to estimate the causality of accessibility to formal job opportunities on monthly wages, thus higher magnitudes of the coefficients that observe the Spatial Mismatch on job outcomes are expected, because they correct part of the bias generated by endogeneity. In Panel C, robust F statistics and R partial testes suggest that the models with instrumented variables contribute significantly to predict wages.

⁵² The Central Business of this city in the edge of the economic formation of CMA. In the early years of its urban consolidation, merchants used to meet in the CBD to trade commodities, and explorers, to rest from long trips. In the recent spatial configuration, this central area still plays an important role on the location of jobs for the city of Curitiba, as claims Thomé and Porsse (2019).

Table 2 – Results of OLS and 2SLS models with tests

Panel A: Main first stage linear coefficients	OLS	OLS		
In Accessibility Index (Dependent Variable)	Private	Public		
In Distance to CBD through Rivers	-0.194***	-0.226***		
Adjusted R squared	0.155	0.186		
F Statistics	3,460	4,589		
Panel B: Main linear coefficients	Model 1	Model 2	Model 3	Model 4
	OLS	OLS	2SLS	2SLS
Transport Mode:	Private	Public	Private	Public
In Accessibility Index	0.038***	0.036***	0.126***	0.112***
Instrumented by distance to CBD through rivers:	NO	NO	YES	YES
Number of observations	2,579	3,025	2,579	3,025
Adjusted R squared	0.267	0.246	0.254	0.227
F Statistics	6,251.96	6,024.78	-	-
Panel C:	Adjusted R2	Partial R2 (Shea)	Robust F statistics	Prob > F
In Distance to CBD through Rivers (Private)	0.155	0.122	15.034	0.000
In Distance to CBD through Rivers (Public)	0.186	0.160	48.661	0.000

Obs: Additional controls for Panel B models: age, age squared, gender, level of education dummies, sector of activity, dummies to indicate if the individual works and lives in the same zone, dummies to indicate if he works on an urban zone, constant term. Sampling weights are applied to the estimation.

Therefore, the coefficients obtained in models 3 and 4 in Panel B are used by this analysis to measure the Spatial Mismatch effects in monthly wages of workers in the Metropolitan Area of Curitiba who commuted by private or public transport modes, attributed to economics of agglomeration effects (Melo and Graham, 2009; Haddad and Barufi, 2017).

Given the existence of spatial heterogeneity in the level of accessibility to formal job opportunities (Figures 4 and 5) among zones of work, the values of the 2SLS models indicate economic advantages for specific workers in MAC, due to their respective workplace and transport mode. The hypothesis for such effects on monthly wages is that these accessibility indexes synthesize agglomeration economics effects, mainly from the transport infrastructure and the density of jobs for each zone. Therefore, this structural mechanism for individual economic earnings, related to the spatial configuration of the study area (formed by the distribution of jobs, dwellings and transport infrastructure), is a source for economic inequality among MAC citizens.

Models 3 and 4 suggest some difference on potential earnings due to the transport mode. As long as these linear coefficients represent some sensitivity of the monthly wages by the magnitudes of the accessibility indexes at each workplace, and taking in consideration that workers who commuted by public transport have lower mean wages and accessibility than those who used private transport (Table 2), we found some evidence that transport mode can also be a source for economic inequality in the study area. Transport mode effects on the labor market outcomes corroborate the findings of Haddad and Barufi (2017) and Matas et al. (2010), where the mechanism might be related to lower efficiency in commutation along the urban space for the public transport mode.

5.2 Results for the Spatial Mismatch within transport mode based on Skill level

The models in Table 3 aim to investigate more specific effects of agglomeration economics based on groups of educational level: Skilled 1 and Skilled 2. Therefore, by interactions between the accessibility indexes and individual educational levels, the dummy coefficients aim to test the hypothesis of more effects of the measures of accessibility on individuals who had at least started a bachelor course (Models 1 and 2) or concluded bachelor course (Models 3 and 4), with both groups being compared to non-skilled groups.

Within transport mode groups, the results in Table 3 suggest the existence of higher effects of the measures of accessibility on monthly wages for Skilled 1 workers, and even higher effects for Skilled 2 workers.

Table 3 – Results of 2SLS models and tests, with interaction dummies for skill level

Models with interaction dummies indicating skill level:				
	Model 1	Model 2	Model 3	Model 4
	Skilled 1	Skilled 1	Skilled 2	Skilled 2
Transport Mode:	Private	Public	Private	Public
In Accessibility Index x Skill dummy	0.100***	0.188***	0.170***	0.210***
In Accessibility Index (Instrumented)	0.087***	0.050***	0.085***	0.072***
Coef. Ratio (Skill dummy x Index and Index):	1.14	3,76	2	2,91
Number of observations	2,561	3,017	2,561	3,017
R squared	0.258	0.256	0.259	0.249
First Stage Tests for In Distance to CBD through Rivers as instrument:				
Adjusted R2	0.155	0.194	0.154	0.192
Partial R2 (Shea)	0.055	0.138	0.079	0.153
Robust F statistics	16,745	56,309	24,756	63,639
Prob > F	0.000	0.000	0.000	0.000

Source: Own Elaboration, from the database. Notes: p-Value<0.1*, p-Value<0.05** and p-Value<0.01***.

Obs: Additional controls for the 2SLS models: age, age squared, gender, level of education dummies, sector of activity, dummies to indicate if the individual works and lives in the same zone, dummies to indicate if he works on an urban zone, constant term. Sampling weights are applied to the estimation. Skilled 1 correspond to individuals who had started or completed a bachelor course, as well as completed a postgraduation course. Skilled 2 correspond to individuals who had completed a bachelor or completed a postgraduation course.

In this comparison within transport mode groups, it is also possible to quantify the differences of magnitudes of such economic gains based on skill level, observing the ratio between the accessibility indexes resulted by dummy interactions and the accessibility indexes. From this, the lowest differences of potential economic gains based on skill level is among private transport users, when potential economic gains between skilled 1 and non-skilled individuals are compared in Model 1.

In models 3 and 1, the differences in potential economic gains between Skilled 2 and the non-skilled individuals that used private cars suggest higher differences in economic gains than between Skilled 1 and non-skilled individuals that also used this transport mode. But the opposite is valid for public transport users in Models 2 and 4, which indicate that within individuals of this transport mode group, skilled 1 workers had higher differences in potential gains.

Therefore, differences in economic gains among skill level-based groups are higher for the public transport users. A reasonable source for such outcome in MAC's job market may be related to spatial equilibrium determinants, as we suppose the existence of endogenous choice of place of residence location for this study area, where wealthier individuals had shown preference to live in areas that with more intense BRT infrastructure (Figure 1).

The differences in economic gains for public transport users may reflect the existence of spatial segregation⁵³ among them (Hernandez, 2017, Pereira et al., 2020; Gobillon et al., 2007). The spatial and job markets equilibrium determinants discussed by Lucas and Rossi-Hansberg (2002) and Zenou (2002) may also play a role in such differences, if richer individuals have more response power in the housing market, choosing to live in areas with more densities of job opportunities, given that the TOD policies of Curitiba and MAC regional integration had also incentivized the creation and growth of employment centers and industrial poles, with the provision of transport infrastructure (Thomé, 2020; Firkowski, 2002; Carmo and Moreira, 2020).

Therefore, by having a bachelor or postgraduation course, the economic inequality related to the spatial configuration of the study area decreases, because it allows for the access to more job opportunities, and consequently, for more decision-making power for high skilled⁵⁴ individuals. Among transport modes, the inequality in potential economic gain is lower for the private transport users, which may reflect more efficiency in intraurban travels, if compared to public transport.

6. FINAL REMARKS

There was a trend in Brazilian metropolitan areas, of consolidating their urban spaces under unplanned spatial expansions, with lack of economic resources, that in the present reflect on spatial uneven access to urban infrastructure, resulting in spatial inequalities of economic opportunities. We investigated the effects of heterogeneous accessibility levels among the workers of Metropolitan Area of Curitiba on their respective monthly wage in 2017, in order to understand such economic effects in a metropolitan area that is considered a good reference on urbanization strategies worldwide.

The present investigation found empirical evidence of positive effects of the measures of accessibility to formal jobs on monthly wages for the study area. We attribute such causality to agglomeration effects, related to the spatial density of formal jobs and transport infrastructure. Such effects on the observed uneven spatial distribution of accessibility might be a source of economic inequality in the Metropolitan Area of Curitiba.

We also found different magnitudes of such effects on the monthly wages based on social groups. Skill level and transport mode matter for the accessibility effects of formal job opportunities on economic earnings. High Skilled Individuals that traveled to work by private vehicles had the lowest unequal potential economic gains in the labor market attributed to the observed effects of accessibility. Such inequality in potential economic gains is stronger among public transport users, but it decreases among those who were high skilled.

The implications of the spatial configuration of Metropolitan Area of Curitiba on the job market corroborate a Spatial Mismatch Hypothesis. Therefore, even though the study area has had innovative urban consolidation policies, there is necessity of spatial relocation of job, dwellings or infrastructure, to achieve an urban space that promotes equal opportunities of potential economic gains in such labor market. Future researches could investigate the magnitudes of the needed spatial relocations, as well as identify effective policies to vanish geographic barriers on the local labor market.

⁵³ It is important to state that the decision of the local of residence is not necessarily strongly based on the proximity to the near BRT infrastructure in MAC. However, it is reasonable to affirm that in this area, such infrastructures were prioritized to be allocated in central areas, where in parallel, high income individuals lived even before the existence of the BRT system, in 1974. After that, the Curitiba TOD urban expansion policies usually suggested more densities of job and dwellings near BRT infrastructures.

⁵⁴ Which were defined in this study as workers who had at least started a bachelor course.

ACCESSIBILITY INDEX TO ITALIAN UNIVERSITIES**Massimiliano Rossetti, Greta Scolari, Mario Boffi, Matteo Colleoni**

University of Milano-Bicocca, Italy

ABSTRACT

The Italian University Network for Sustainable Development (RUS) has carried out for the first time a national survey about university commuting. Thirty-seven universities joined the survey and almost 70.000 questionnaires have been collected. Years of academic mobility management policies and research show that universities may be seen as important players able to contribute to the definition of urban and metropolitan policies concerning mobility and accessibility. In this connection, the research shows the need to focus on students commuting in a comparative perspective in order to highlights the role of the universities – together with other institutions – in the mobility planning. The linkage between the right to education and the right to mobility makes it essential to sustain the latter in order to promote better academic performances, in a context characterized by high level of commuting and the absence of a serious national housing policy for students. The essay focuses on the definition of three synthetic indices: the accessibility index, the quality of life index and the sustainability index. After having identified the most important university areas within the Italian context, the focus has been on the comparison among them in terms of territorial and structural features and, eventually, of the commuter's behaviour. Even though specific issues characterize each context, students preferably move by public transit. However, the accessibility index shows important differences in the access to the university. The index – which takes into account the time, the cost and the frequency of the travel – shows that the most accessible areas are Siena, Bologna e Pavia, confirming their nature of university towns defined by a high level of transfer students and active travel. The quality of live index – which summarize the accessibility index and the satisfaction of the travel, shows that the areas with the highest level of quality of live are both, the university towns and some regional university areas such as Milan and Turin. To conclude, the sustainability index provides a global assessment of the commute within the areas. In particular, it summarizes the accessibility and the quality of life indices, and additional elements such as structural features (density of public transport) and environmental features (kg of CO2 emitted per year during the commute). According to the quality of life index, the most sustainable areas are the university towns and some regional university areas such as Milan and Rome. The other areas are characterized by low levels of sustainability, due to the use of private modes of transport, greater home to university distance, higher level of CO2 emissions, and higher costs of the commute. In a context characterized by the increasingly relevance of the university in the field of the mobility management, studying university commuting is essential in order to identify new solutions to enhance the accessibility to the university and to promote sustainable mode of transport. In this connection, universities are no longer considered simply as attractors, but as active players within the governance of the mobility.

THE PRACTICES OF THE MANAGEMENT CONTROL SYSTEM AT THE LEVEL OF LOCAL AUTHORITIES IN THE ERA OF ADVANCED REGIONALIZATION

Maha Assaad Idrissi¹, Omar Taouab², Youssra Oudda²

¹L'ecole nationale de commerce et de gestion, Morocco. ²IBN Tofail University, Morocco

ABSTRACT

All over the world, whether in developed or developing countries, decentralization occupies the same space of interest and arouses the same enthusiasms as a social project in order to consolidate local development. Decentralization understood as a technique of administrative organization corresponds, according to Dupuis and Guédon (1991) to "the attribution of a certain autonomy to communities which are administered freely by elected councils, under the control of the government". It therefore implies a transfer of skills from the central level to local authorities. Like businesses, the quest for performance concern also local authorities. For several years, performance has been at the center of modernization and restructuring projects for public organisations, in particular local authorities, with the aim of achieving solid local development. In Morocco, the decentralization process has been initiated since independence, the reform began in a significant way in the local authorities by the adoption in 1976 of the municipal charter until 2011 with the entry into force of the new constitution, then in 2015 with the adoption of advanced regionalization which leads to an administrative division and the adoption of organic laws; Law 111-14 relating to regions, Law 112-14 relating to prefectures and Law 113-14 relating to municipalities. The implementation of these reforms is accompanied by the emergence of new management control practices in local and regional authorities which will be forced to set up an effective management control system to monitor their performance. to implement modern management tools and methods that are used in private organizations and adapted to the specificities of local authorities in order to contribute to local development (new public management). In this research work we will clarify the practices of the management control system at the level of local authorities, its evolution and its impact on their performance. Because of the new strategy adopted on the national level which aims at the implementation and the success of the site of the advanced regionalization. This research project seems interesting to us to deal with, in order to describe the different aspects of the concept of the performance of local authorities and to sketch the different performance tools used in them and see what purpose and mission they meet.

THE SUBNATIONAL CROWDING OUT EFFECT OF MINING WINDFALLS ON LOCAL TAX EFFORT: DOES THE LEVEL OF LOCAL PROVISION OF PUBLIC GOODS MATTER?

Mauricio Oyarzo¹, Dusan Paredes²

¹School of Business Administration, Universidad de Concepción Campus Chillán, Avenida Vicente Méndez 595, Chillán, Chile, mauriciooyarzo@udec.cl; ²Department of Economics, Universidad Católica del Norte, Avenida Angamos 0610, Antofagasta, Chile. dparedes@ucn.cl

ABSTRACT

Although the resource curse offers evidence for the national crowding out generated by resource windfalls from mining, subnational crowding is not fully understood. This knowledge gap is problematic because these windfalls should cover the negative externalities that exist in host zones. Additionally, these communities have different fiscal responsibilities due to the mining industry's environmental, economic, and social costs. This article estimates the subnational crowd out of mining windfalls on local tax collection by considering different levels of fiscal responsibility. We employ panel data for 322 Chilean municipalities between 2008 to 2019 using an exogenous rule for assigning mining windfalls in order to attribute causality. Our results confirm the crowding out hypothesis. First, a US\$1.0 increase in mining windfalls results in a US\$0.2 decrease in the property tax collected. Second, subnational crowding out is twice as high in municipalities with a high level of fiscal responsibility; a US\$1.0 increase in windfalls crowds out US\$0.4 in non-resource revenue. Third, considering the influence of nearby neighborhoods and the spatial interdependence, crowding out is four times higher than non-spatial estimations. These results call for local policies that consider the fiscal capacity of a municipality in order to disincentivize undesirable behavior from extra resource revenues.

1. INTRODUCTION

Mining production is intimately related to an extensive list of local negative externalities, which without the presence of institutional compensation mechanisms, would unequivocally affect the quality of life of the local population. The impact on the ecosystem and the environment, namely, an increase in waste production, the depletion of water resources, and a lack of fossil fuel energy sources (Ghorbani and Kuan, 2016; Tapia, Davenport, Townley, Dorador, Schneider, Tolorza and von Tümpling, 2018) are some examples of externalities. The health risks in children and adults exposed to heavy metal dust are especially relevant in those locations close to extraction (Tapia, Valdés, Orrego, Tchernitchin, Dorador, Bolados and Harrod, 2018). In social terms, these communities also have higher levels of economic inequality, alcoholism, AIDS, prostitution, child labor, poverty, and worse educational outcomes among other negative externalities (Pegg, 2006; Luffn, 2015; Oyarzo and Paredes, 2018).

Another considerable effect of the mining industry, albeit less documented, is the strategic behavior developed by low-tier governments in regard to tax collection (for example, van der Ploeg and Poelhekke, 2017; Masaki, 2018). In Chile, the fiscal and institutional capacity to collect local taxes that do not come from the mining industry coupled with low territorial decentralization is particularly concerning as it gives rise to subnational crowding out (Oyarzo and Paredes, 2019).

Governments employ different mechanisms to compensate local host communities, including obligating the mining industry to provide monetary compensation via non-ad valorem property taxes on mineral concessions. In Chile's case, these *mining patents* (hereafter mining windfalls or MWs) are tied to the 1993 Chilean mineral law #19,143 and consist of an annual payment per hectare meant for the extraction and/or exploration of ores. Mining windfalls directly benefit the local governments where the mining concessions exist and by institutional design are not sensitive to price fluctuations; therefore, they represent an essential source of extra income for mining towns. However, the remote location of these mining municipalities, a weak fiscal capacity, and a low presence of qualified human capital in their respective local administrations might be factors in MWs not having a positive influence on their economic development. The literature alludes to this by pointing out that mining municipalities have the worst performance in public education (Oyarzo and Paredes, 2018), a limited local provision of public goods (Paredes and Rivera, 2017), and lower rates of entrepreneurship (Oyarzo, Romaní, Atienza and Luffn, 2020).

As a particular case of the median-voter model, subnational crowding out corresponds to a cross substitution between an additional income (via a non-matched grant from resource windfalls) and the effort made by host localities in collecting local tax (Mogues and Benin, 2012; Oyarzo and Paredes, 2019). This article improves and deepens what was developed by Oyarzo and Paredes (2019). We use the external grant from MWs to understand to what extent a non-matched grant crowds out local taxes, conditioned to the low-tier government's responsibility to provide public goods. The external grant undoubtedly increases the public-goods provision and should improve key indicators of local development in hosting zones. The conditioned analysis by fiscal responsibility is done for two key reasons. First, strong centralization and continuous central transfers such as fiscal equalization mechanisms from the upper-tier government to subnational governments would allow for a reduction in fiscal efforts that have a high socio-political cost (OECD, 2009). Second, the limited fiscal autonomy that low-tier governments have in budget decisions means that these transferences are insufficient, considering the policy's design and spatial asymmetries are directly related to reducing inequality (OECD, 2013).

Following these arguments, we take advantage of an institutional rule that classifies municipalities according to the local capacity to provide public goods (SUBDERE, 2015).⁵⁵ We employ this exogenous criterion to define groups of cities with different capabilities to satisfy the local population's requirements. This allows us to evaluate the magnitude of subnational crowding out with lasting effects on hosting zones, which are negatively impacted, among other things, by the adverse effects of the mining industry on the environment.

We test our hypothesis using 322 Chilean municipalities from 2008 to 2019, which corresponds to approximately 93% of all low-tier governments.⁵⁶ The dependent variable corresponds to property tax (PT), one of the primary local incomes for cities in Chile and which accounts for nearly 22% of the Municipal Permanent Income (Ingresos Propios Permanentes or IPP).⁵⁷ Additionally, these resources are a direct result of local collection efforts, as budget management is an exclusive responsibility of local administrations. The PT is calculated using a property's appraisal value and is earmarked for low-tier governments (Servicio de Impuestos Internos, 2018). Municipalities can improve the tax system by updating the appraisal values of properties (Servicio de Impuestos Internos, 2020).

To attribute causality between resource windfalls and local taxes, we take advantage of the exogenous allocation rule for assigning MWs in hosting municipalities in order to deal with endogeneity concerns via the spatial distribution of mining exploitation and extra revenues (Dahlberg et al., 2008). This rule earmarks 50% of the mining patents for the low-tier government (municipalities) where mining concessions are located. The remaining 50% goes to the corresponding mining region (Congreso Nacional de Chile, 1992). To deal with the remaining endogeneity from unobservable variables affecting local public expenditures or measurement errors, we use an exogenous rule to classify the subnational governments according to the Under-secretary for Regional and Administrative Development (SUBDERE, 2015). We use High Provision Responsibility (HPR) and Low Provision Responsibility (LPR) classifications to label the municipalities based on their capacity to provide public goods. We then estimate the incidence of resource windfalls over local tax revenues and whether this strategic behavior is maintained vis-à-vis different specifications and econometrics techniques. We also employ static and dynamic estimations which consider the influence of both recent and past resource windfalls on current local tax collection via temporal lags over the dependent variable. We use municipal fixed effects to control for time-invariant unobservable effects such as local leadership characteristics, among other local factors, and we control for heteroskedasticity via a robust variance estimator in cluster form.

The results are robust, and they do not reject crowding out effects. First, a US\$1 increase in MWs results in a US\$0.2 decrease in PT. Second, this subnational crowding out is twice as high in municipalities with a high level of fiscal responsibility. A US\$1.0 increase in MWs crowds out US\$0.4 in non-resource revenue. This result is even more relevant considering that 40% of the mining municipalities correspond to subnational governments with high fiscal responsibility (HPR). The results for cities with LPR are not significant. Third, if we consider the influence of nearby neighborhoods and the spatial interdependence among low-tier governments, the crowding out is four times higher than non-spatial estimations. These results call for local policies that consider the capacity of the local provision of public goods to disincentivize undesirable behavior resulting from extra resource revenues. In addition to the fiscal impact, the mining industry's adverse effects on the ecosystem and the local population is a matter of discussion in the creation of policies that promote economic development without the cost being transferred to future generations.

The paper is organized as follows: the next section presents a literature review on the mining industry's impact on the environment and local populations in developing countries. In section three we describe the data while section 4 describes methodological concerns. We then present the results in section 5. In section 6 we summarize our main findings and the resulting political implications.

2. LITERATURE REVIEW

2.1 Mining industry and economic sustainability in Chile

The ecological impact of the mining industry in Chile has increased notably since the 1970's when copper-tailings dumps were simply abandoned due to insufficient environmental regulation. For example, in the Elqui river basin of north-

55 For more information see: Resolution No. 178 from BCN Chile. Available here: <https://www.leychile.cl/Navegar?idNorma=1079104>

56 We have excluded some municipalities from the analysis because of information limitations and the presence of islands. The information corresponds to the National Municipal Information System (SINIM).

57 Despite the apparent low contribution of the property taxes on IPPs, it is especially relevant considering that most of the income received by municipalities in Chile comes from conditional grants by the upper-tier government.

central Chile, tailings dumps were left throughout the alluvial plains of the rivers and creeks until the 1990's (Oyarzún et al., 2012; Bastida, 2002). Other examples include the conflicts surrounding the Pascua-Lama gold mining project at the Chilean-Argentinian border in 2009 (Urkidi, 2010), the stakeholder participation process within the Environmental Impact Assessment System in Chile (Lostarnau, 2011) or the development of industrial ecology strategies in the copper mining industry (Reyes-Bozo et al., 2014). The negative impacts on the environment have undoubtedly left an ecological debt. Since 1980, and under the pressure of different NGOs (e.g., the Center for Research and Planning for the Environment and the Institute of Ecology) progress was made in drawing attention to the negative impacts of mining activity on the environment. However, the ambiguous environmental regulation and the lack of a unified environmental protection initiative did not result in robust policy, but rather specific responsibilities assigned to individual institutions. From a national perspective, it was not until 1989 that environmental policy was consolidated under the Chilean Association of Industrial Producers. The subsequent policy managed to encourage, albeit with nuances, mining companies to deal with the harmful effects of the production process. Large companies mostly adopted these initiatives, allowing them to comply with international standards. Smaller mining companies, however, often did not, and so environmental management was not a universal priority. However, the significant ambiguities in regard to environmental responsibility and the central government's lack of coordination to designate a common entity for environmental regulation (at least ten government entities shared that responsibility) maintained a status quo in the industry (Lagos, 1990).

With the arrival of democracy in 1990, the new government administration formed CONAMA, a commission that established a legislative and institutional framework on environmental matters, which was then consolidated into The Environmental Basis Law in 1994. Law 19,300 created an environmental framework for the mining industry, which eliminated certain ambiguities that affected environmental regulation and disincentivized some of the practices that negatively affected the local host zones. It includes standards on emissions and environmental quality as well as procedures (via the Environmental Impact Assessment System, SEIA) for the authorization of new and existing projects that impact the environment. Procedures were regulated for the intervention of entities tasked with regulatory matters that impact the environment, the declaration of saturated areas, pollution prevention, decontamination plans, environmental damage, and compensation claim procedures.

Mining and especially copper production have since experienced substantial growth with Chile being one of the countries with the highest capture of foreign investment (US\$18 billion) between 1990 and 2002 (Ghorbani, 2016). This upward spiral in copper mining inevitably led to increased water and electricity consumption and increased waste production. Another significant milestone in environmental legislation was the enactment of Law No. 20,417 in 2010. These regulations were amalgamated into a legislative framework and include the creation of a single environmental responsibility system and an environmental impact measurement procedure, in addition to improved SEIA procedures. The law also includes regulation regarding the preservation and protection of natural resources, the establishment of protected areas, biodiversity, water resources, as well as bureaucratic matters that facilitate increased transparency and public participation. Chile has since signed a series of agreements that promote sustainable development in mining including one in 2013 with the United States, one of Chile's leading investment partners (Ghorbani, 2016). From a subnational perspective, the compensation mechanism towards mining municipalities aims to deal with the mining production's negative externalities. This mechanism and its implications at the local level are detailed in the next section.

2.2 Compensation mechanism and institutional design

Literature on the resource curse acknowledges that revenue from resource windfalls must be used to compensate hosting municipalities for the negative externalities associated with the exploitation of natural resources (Hughes, 1975). This extra income is an essential portion of the local budget of a hosting subnational government and allows them to not raise taxes on inhabitants (Stinson, 1977). The principal resource windfalls in Chile come from the mining industry and the principal benefactors are low-tier governments. For example, the revenue from MWs accounted for nearly 40% of the total local revenue collected in mining municipalities in 2019. This fact illustrates the importance of resources from the mining industry in local finances, especially the local budget and in regard to public management. Nevertheless, the empirical evidence for extra revenues in mining municipalities are mixed: Paredes and Rivera (2017) find that the expenditure in public services for recreational or cultural activities increases by only US\$0.5 for every US\$1 from MWs, while Oyarzo and Paredes (2018) find that in the margin, mining municipalities have a worse educational performance than non-mining municipalities. Although they are less exploited, resource windfalls promote perverse incentives within low-tier governments by crowding out PT in mining municipalities. Each dollar collected from MWs in the current period crowds out between US\$0.6-US\$0.9 of residential PT in the future (Oyarzo and Paredes, 2019). However, this paper does not consider the fiscal responsibility of low-tier governments or the particularities of subnational governments in providing public goods, especially in host zones.

The quality of the institution therefore plays a central role in the wellbeing of the local host community. Papyrakis and Gerlagh (2006) show that windfalls derived from a commodity's price boom crowd out several determinants of long-term incomes. The literature also shows that resource rich countries cannot convert their non-renewable natural resources into productive assets, primarily because of failures in policy. Collier and Goderis (2012) reinforce this aspect via a cross-country analysis in which the combination of poor local governance and high-rent commodities such as minerals and oil can precipitate a resource curse in the long run. For example, Boschini et al. (2007) find that the resource windfalls from minerals are the most detrimental to economic development, especially within the context of weak institutions. On the other hand, Boschini et al. (2013) show that the undesirable effects of the mineral industry can be

reversed by strengthening said institutions. Fiscal responsibility therefore becomes non-trivial, especially when considering the heterogeneity of subnational governments and their particularities.

The theory of political clientelism highlights the use of windfalls in municipalities where an incumbent politician has to decide if resource rents will be consumed or distributed as patronage via an increase in public employment (Robinson, Torvik and Verdier, 2006a, 2014b; Robinson and Verdier, 2013). In this model, the increase in fiscal income is a factor of the resource price which is exogenously determined by the commodities' world markets. In Chile, the national legal normative does not allow low-tier government tax collection from either resource production or profit, but rather through mining patents. Therefore, the international fluctuation in the mineral price has no direct impact on the subnational budget. The literature also highlights that extra incomes can increase public debt and cause political myopia, especially in democracies with re-election prospects. Political myopia in the context of budget management and public debt is depicted in the literature and yields discrepancies in politicians' planning horizons that lead to debt build-up (Acharya and Rajan, 2013; Aguiar et al., 2014; Rieth, 2014). Although there is a growing wave of literature aimed at identifying specific channels impacted by resource windfalls (e.g., van der Ploeg and Poelhekke 2016; Fleming and Measham, 2013; Fleming, Measham and Paredes, 2015), there is no consensus on whether local governments prefer to spend these resources in national or local public goods or rather increase local investment in (or transfers to) public education and health. Therefore, it is important and necessary to consider the quality of institutions, and even more so when resource windfalls represent an essential part of the municipal budget.

3. DATA

Our research considers a spatial panel with 322 Chilean municipalities from 2008 until 2019, provided by the National Municipal Information System (SINIM). Table 1 shows the number of High Provision Responsibility (HPR) and Low Provision Responsibility (LPR) aligned using the SUBDERE criterion and by the mining condition. According to the table, the mining municipalities present a low variability when considering the provision of public goods or fiscal responsibility: between 93 to 119 municipalities for HPR and 141 to 172 for LPR. It should also be noted that the non-mining municipalities show more variability and are decreasing over the period under analysis: the HPR group starts with 42 municipalities in 2008 but ends the period with 16.

Table 1. Mining and non-mining municipalities by levels of provision responsibility, 2008-2019

	Non-mining		N _{nm}	Mining		N _m	N
	HPR	LPR		HPR	LPR		
2008	42	46	88	93	141	234	322
2009	29	38	67	106	149	255	322
2010	28	21	49	107	166	273	322
2011	25	19	44	110	168	278	322
2012	23	17	40	112	170	282	322
2013	20	18	38	115	169	284	322
2014	22	16	38	113	171	284	322
2015	22	16	38	113	171	284	322
2016	21	14	35	114	173	287	322
2017	20	15	35	115	172	287	322
2018	17	15	32	118	172	290	322
2019	16	15	31	119	172	291	322

Note: HRP: High Provision Responsibility; LPR: Low Provision Responsibility. Both are based on SUBDERE Taxonomy, time-invariant. The non-mining and mining conditions are time-variant.

Likewise, the LPR group starts with 46 municipalities but ends the period under analysis with less than half. It is essential to highlight that most of the local governments in this category are mining municipalities as the others do not receive extra income via windfalls.

Figure 1 details the participation of mining and non-mining municipalities in the sample. The relative increase of those categorized as mining municipalities stands out, rising from 72.7% to 90.4 at the end of the period under analysis.

Fig 1. Non-mining and mining municipalities, 2008-2019

Source: Data from Sinim (2019).

We know consider the categorization of municipalities according to fiscal responsibility (see Figure 2). There are no substantial differences in the number of municipalities in either category (HPR, LPR) for non-mining subnational governments. The opposite is true for mining municipalities: LPR municipalities maintain sustained growth through 2010 and then stabilize until the end of the period.

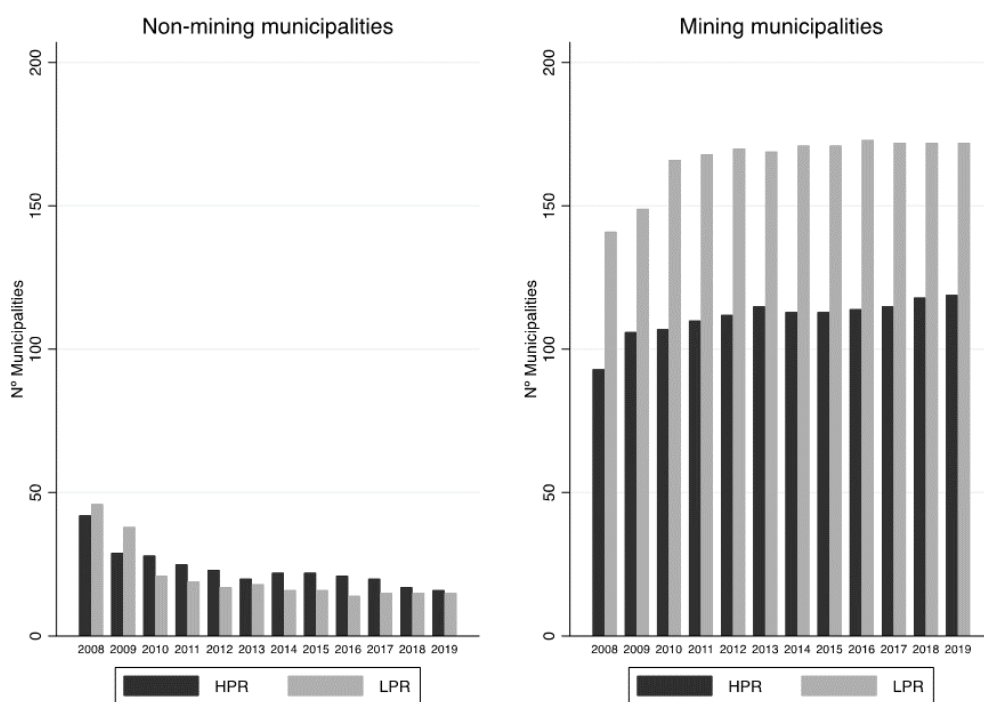

Fig 2. Non-mining and mining municipalities by Provision Responsibility, 2008-2019

Source: Data from Sinim (2019).

Note: HPR: High Provision Responsibility. LPR: Low Provision Responsibility.

3.1 Dependent variable

The dependent variable corresponds to the PT collected by each municipality. These resources are generated by local governments, where each municipality has a greater capacity in decision-making. In the context of a non-federal country as Chile, low-tier government can improve the tax system by updating the appraisal values of properties (Servicio de

Impuestos Internos, 2020) or via oversight of commercial PT payments (Biblioteca del Congreso Nacional de Chile, 2018). Municipalities can also invest resources, such as the use of tow trucks to control illegally parked vehicles, although this depends on the provision capacity or fiscal capacity of the local government (Cortes and Paredes, 2016). Table 2 and Figure 3 highlight the summary statistics of PT between 2008 until 2019. Non-mining municipalities have a higher collection of PT than mining municipalities, which constitutes the first sign of significant differences in the collection of local income other than extra income via windfalls. If we consider fiscal responsibility, the previous tendency only persists for the HPR municipalities: non-mining municipalities collect on average US\$7,230,293 while mining municipalities collect less than half (US\$3,209,467). The opposite situation is true for the municipalities classified as LPR: the mining group collected more than twice as much local income (US\$313,464) as non-mining municipalities (US\$115,461).

Table 2. Summary statistics of the dependent variable. 2008-2019

Property Tax (US\$)	Non-Mining			Mining		
	Mean	Std. Err	N	Mean	Std. Err	N
All municipalities	3,905,605	486,101	535	1,474,823	70,820	3,329
PT by PR levels:						
HPR	7,230,293	866,431	285	3,209,467	164,894	1,335
LPR	115,461	7,502	250	313,464	10,480	1,994

Note: Property tax at the municipality level (US\$). HPR: High Provision Responsibility; LPR: Low Provision Responsibility. Both are based on SUBDERE Taxonomy, time-invariant.

Fig 3. Descriptive statistics of PT by non-mining and mining municipalities. 2008-2019

Source: Data from Sinim (2019).

Note: PT: Property Tax.

Figure 4 depicts the dependent variable's descriptive statistics considering the exogenous criterion to define mining municipalities and exogenous taxonomy using SUBDERE criteria to classify the subnational government based on their capacity to provide public goods to the local population. For HPR municipalities and until 2018, the PT collected is higher for non-mining municipalities. Mining municipalities collected more PT in 2019 but the difference is not significant. The opposite case is true for LPR: mining municipalities collected more PT, and the difference is significant according to the confidence interval.

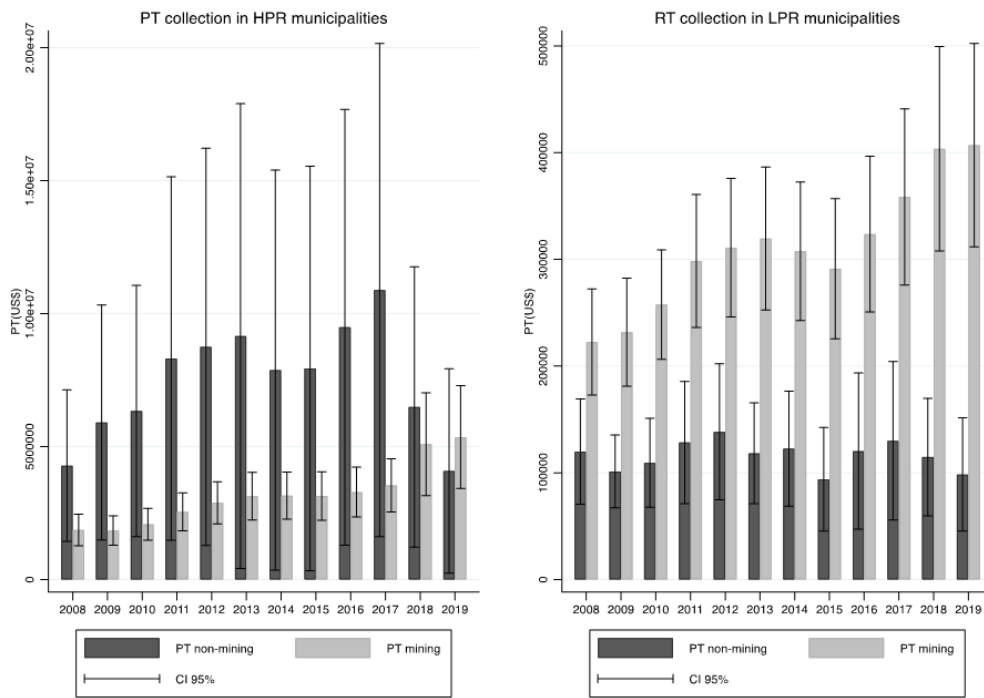

Fig 4. Descriptive statistics of PT in non-mining and mining municipalities by Provision Responsibility. 2008-2019

Source: Data from Sinim (2019).

Note: HPR: High Provision Responsibility. LPR: Low Provision Responsibility. PT: Property Tax.

When considering the dependent variable (Figure 5), there is evidence of significant global spatial-temporal autocorrelation via Moran's I throughout the period under analysis. A positive coefficient indicates the presence of spatial autocorrelation in the data (Anselin, 1988). According to Moran's I coefficients, there is a significant and positive correlation between the PT and the spatially lagged PT, which accounts for spatial autocorrelation in the local tax collection, which is persistent over the period under analysis.

Fig 5. Spatio-temporal Moran's I for PT across Chilean municipalities, 2008-2019

Source: Data from Sinim (2019).

Note: The line depicts the Moran's I coefficients estimate considering an inverse distance weight matrix under 9999 random permutations.

At the local level, we present the local Indicator of Spatial Association via a LISA Cluster map in Figure 6 which plots the local Moran's I and which allow us to identify localized map regions where data values are positively or negatively associated with one another (Anselin, 1995). The results show that the clusters high-high (red) and low-low (blue) in the PT collection are persistent over all periods; namely, a spatial cluster concentrated near Santiago with a higher local

collection, and a spatial cluster with a lower local collection in the center-south of the country. These results are persistent and indicate a lasting effect in the local tax capacity over the twelve years.

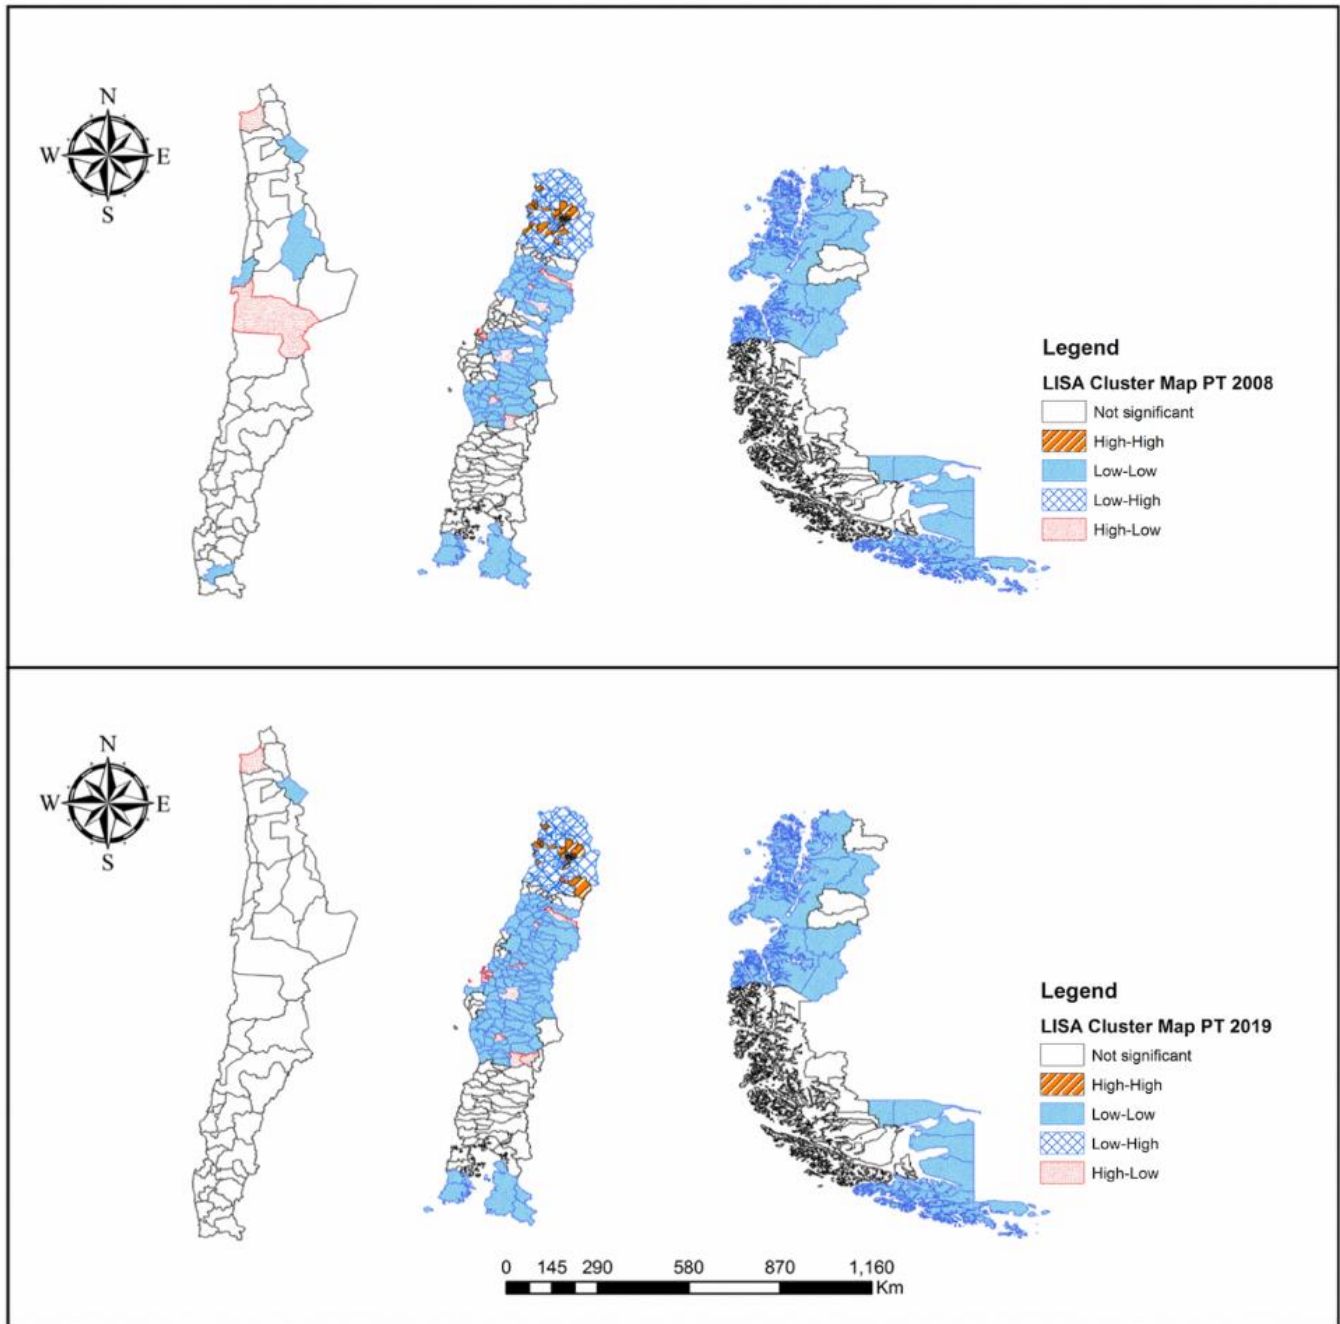

Fig. 6. Lisa Cluster Map for PT, 2008–2019

Source: Data from Sinim (2020).

Note: We consider the inverse distance weight matrix under 9999 permutations. PT: Property Tax.

3.2 Explanatory variables

The most important explanatory variable corresponds to the collection of MWs as it allows us to test the crowding out hypothesis, namely, the negative incentive from the resource windfalls on collecting other local income via PT. Subnational governments have limited autonomy in the collection of and management of its income, unless it is local such as PT. We should also highlight the MW collection considering its distribution and heterogeneity through time and between groups according to local provision capacity. Table 3 depicts the summary statistics of the MWs according to the capacity of the provision in public goods. The higher collection of mining patents corresponds to the municipalities categorized as HPR, although the difference is relatively low if we compare it with the other groups.

Table 3. Summary statistics of MWs in mining municipalities. 2008–2019

	HPR						LPR						N _M
	Mean	Std.Err.	P5	Median	p95	N _{HPR}	Mean	Std.Err.	P5	Median	p95	N _{LPR}	
2008	125,264	41,943	222	8,625	745,099	93	105,976	24,034	331	9,947	704,722	141	234
2009	119,952	37,612	197	8,745	592,736	106	106,995	23,329	506	12,782	696,369	149	255
2010	135,892	41,957	482	10,273	698,632	107	118,691	25,129	864	12,256	640,934	166	273
2011	167,143	50,634	504	12,633	989,168	110	149,836	29,941	527	15,322	798,713	168	278
2012	181,582	55,708	216	12,894	1,070,065	112	168,550	35,373	647	16,655	848,802	170	282
2013	178,227	54,930	202	12,687	1,043,163	115	170,201	35,132	733	16,527	847,389	169	284
2014	168,248	52,137	217	11,792	962,042	113	145,585	31,201	542	12,669	826,731	171	284
2015	145,519	45,655	439	11,167	718,772	113	130,477	28,423	439	9,874	729,315	171	284
2016	140,531	45,027	340	9,813	731,936	114	122,467	26,875	335	9,388	766,580	173	287
2017	144,911	46,688	334	11,172	661,452	115	119,991	26,937	327	9,397	662,071	172	287
2018	146,214	47,789	73	10,362	738,742	118	139,298	30,761	295	7,869	834,524	172	290
2019	134,668	43,835	138	9,857	636,511	119	128,991	28,710	334	7,293	836,838	172	291

Note: Mining windfalls (MWs) (US\$). HRP: High Provision Responsibility; LRP: Low Provision Responsibility. Both are based on SUBDERE Taxonomy, time-invariant.

Table 4 depicts the summary statistics of the explanatory variables. The higher windfall collection of US\$140,552 corresponds to mining municipalities. It is also important to highlight that 53.3% of non-mining municipalities have less capacity to provide public goods as compared with only 40.1% of mining municipalities. To control for other local income, we add the municipality’s own income (net IPP) and a fiscal equalization mechanism (FCM). The net IPP corresponds to the revenue generated autonomously in each low-tier government through local residential and commercial property taxes, (net) MW, local fees (e.g., vehicle registration permits and driver’s licenses), and a gambling tax, among other things. The second local income is the FCM, namely the fiscal equalization mechanism which offsets differences in revenue-raising capacity by redistributing local revenue across subnational governments (Oyarzo and Paredes, 2018, 2019). The higher IPP collection (US\$13,100,000) corresponds to non-mining municipalities with more than double that collected by mining municipalities (US\$ 5,719,076), although with a lower level of heterogeneity. The opposite case is true for the FCM: both groups collect approximately US\$4,800,000 each, although non-mining municipalities have a higher variance. We employ proxies using agglomeration economies via population, density, and socioeconomic characteristics such as the poverty index. In population terms, both groups reach similar levels. However, if we consider density, the differences are significant. Mining communities show a low density since the industry is usually located in peripheral areas with a low population. The figures for municipal poverty are lower for non-mining municipalities, although they are only one percentage point below that of mining municipalities (16.7%).

In regard to the professionalization index, there are no substantial differences between mining and non-mining (25.9% and 28.3%, respectively) groups. The expenditure on municipal workers for non-mining municipalities is double (US\$5,669,787) that of mining municipalities (US\$2,891,346). One-third of mining municipalities are located in coastal areas, while 25% of non-mining subnational governments are located in coastal areas. The distance to Santiago is not significant. In regard to the proxy by political influence, there is a higher level of political alignment between the local and central governments in non-mining municipalities (43.7%) compared to mining municipalities (36%).

Table 4. Summary statistics of explanatory variables. 2008–2019

Variable	Non-Mining		Mining	
	Mean	Std. Err.	Mean	Std. Err.
(1) Local finance and economies of scale				
(US\$) MW	0	0	140,552	7,473
(D) Groups (HPR=1; LPR=0)	0.467	0.022	0.599	0.008
(US\$) Own incomes net (IPP)	13,100,000	1,378,240	5,719,076	222,151
(US\$) Fiscal Eq. M. (FCM)	4,722,331	211,538	4,902,403	117,294
(#) Population	68,391	3,539	51,671	1,513
2) Local social characteristics				
(%) Poverty	15.1	0.5	16.7	0.2
(Km2) Density	4,327	239	389	25
(D) Coastal municipalities	0.247	0.019	0.296	0.008
3) Municipal endowment and favoritism hypothesis				
(%) Professionalization	25.9	0.4	28.3	0.2
(US\$) Municipal workers	5,669,787	393,602	2,891,346	71,758
(Km) Distance to Santiago de Chile	422	24	499	8
(D) Coalition	0.437	0.021	0.360	0.008
N	535		3,329	

Note: Explanatory variables at municipal level (US\$). Professionalization corresponds to the percentage of individuals qualified as professionals (college degree). The coalition is a dummy variable by municipalities aligned to the central government in political terms. D: Dummy variable.

Figure 7 depicts the resource windfalls according to the SUBDERE taxonomy. During the period under analysis the highest collection of MWs corresponds to the municipalities with the most significant capacity to provide public goods,

namely HPR. However, between groups, the confidence intervals overlap, indicating the absence of significant differences. This increases the importance of controlling for these differences by considering other variables.

Fig 7. Descriptive statistics of MW by Provision Responsibility at the municipal level, 2008-2019

Source: Data from Sinim (2019). Note: MW: Mining Windfalls. HPR: High Provision Responsibility. LPR: Low Provision Responsibility.

According to Figure 8, in 2019 the spatial distribution of mining patents for municipalities with the highest supply capacity is concentrated in the mining regions in northern Chile. The municipalities with the lowest supply capacity are, to a lesser extent, concentrated in municipalities in the extreme north and south.

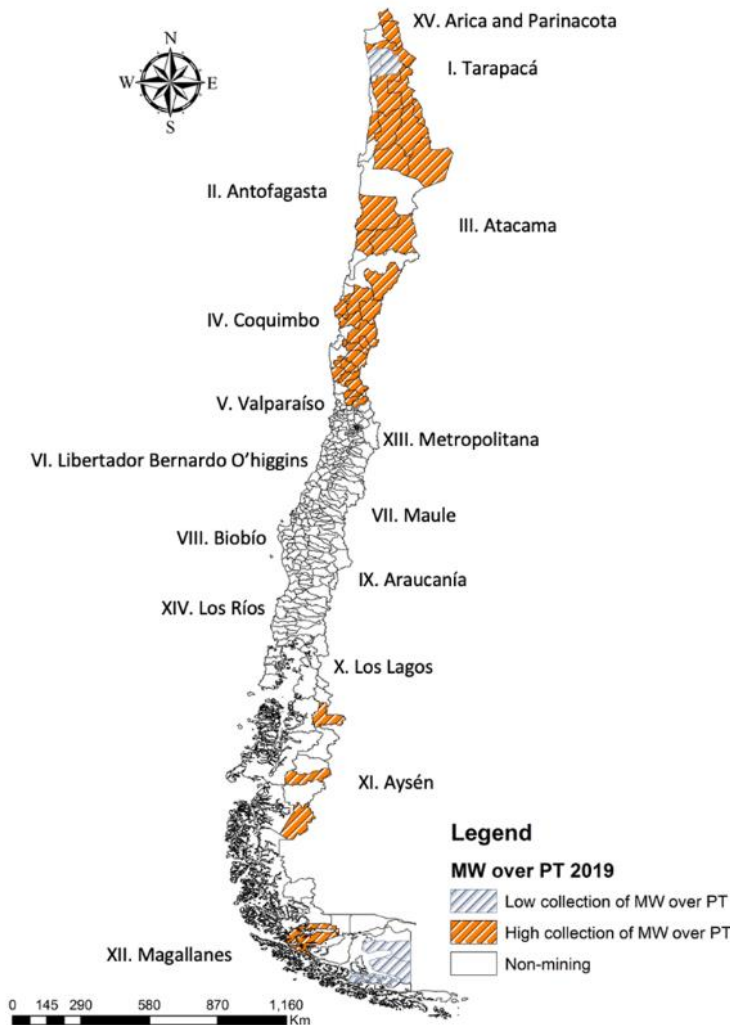

Fig. 8. Spatial distribution of MW over PT in mining municipalities (%) in 2019

Note: MW: Mining windfalls. PT: Property tax.

We must also consider economies of scale and how they impact the provision of public goods. Figure 9 shows the empirical distribution via the local population's Kernel density and distinguishes between mining and non-mining municipalities. Mining municipalities present a higher density at the beginning of the distribution, which confirms the low population density in extraction zones. Far fewer highly populated mining municipalities exist. These results highlight the importance of controlling for the size of the population in terms of economies of scale in the provision of public goods.

Fig 9. Kernel density estimates of the population across mining and non-mining municipalities, 2019

Source: Data from Sinim (2019).

According to Figure 10, when considering quintiles in the spatial distribution of mining patents, the concentration and low variability of the largest tax collections in the northern part of the country are confirmed. This pattern remains relatively stable and persistent both at the beginning and the end of the period.

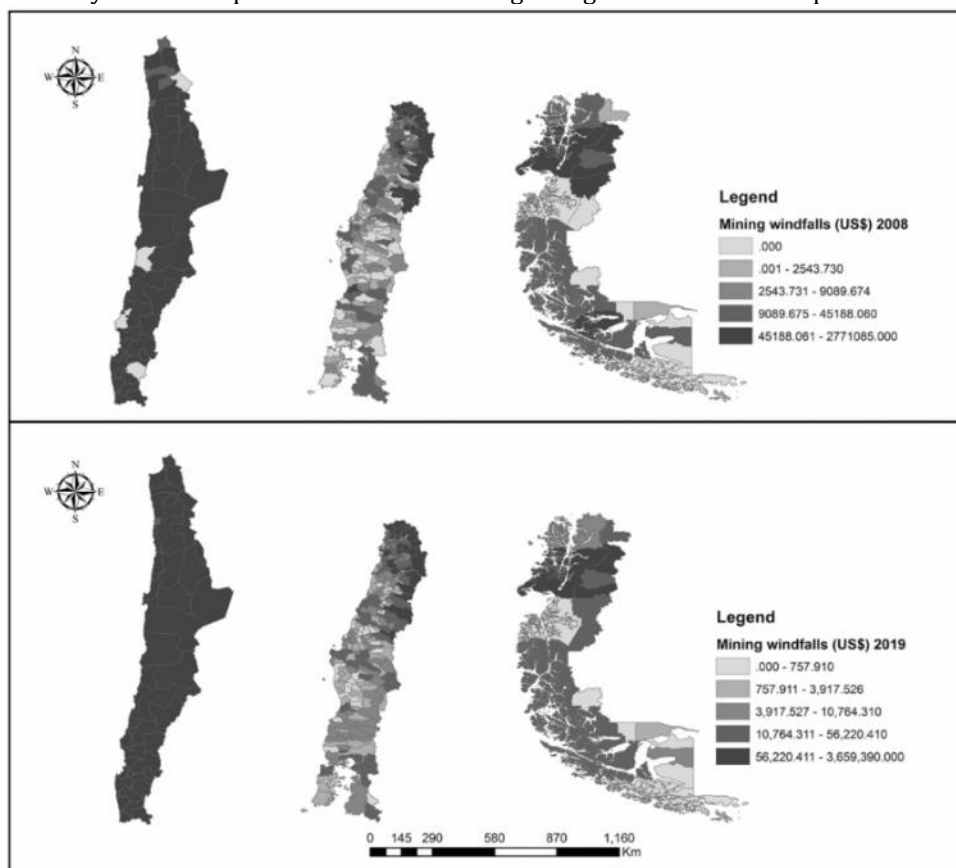

Fig 10. Spatial distribution of MW in Chilean municipalities by quintiles, 2008–2019

Source: Data from Sinim (2019).

Finally, when considering the spatial distribution of the mining municipality category in persistence and change terms between 2009 to 2019 (Figure 11), it is important to note that the municipalities that abandon mining are persistent in the southern part of the country. Whereas when considering the temporal dynamics of becoming a mining locality, there seems to be no such definite pattern.

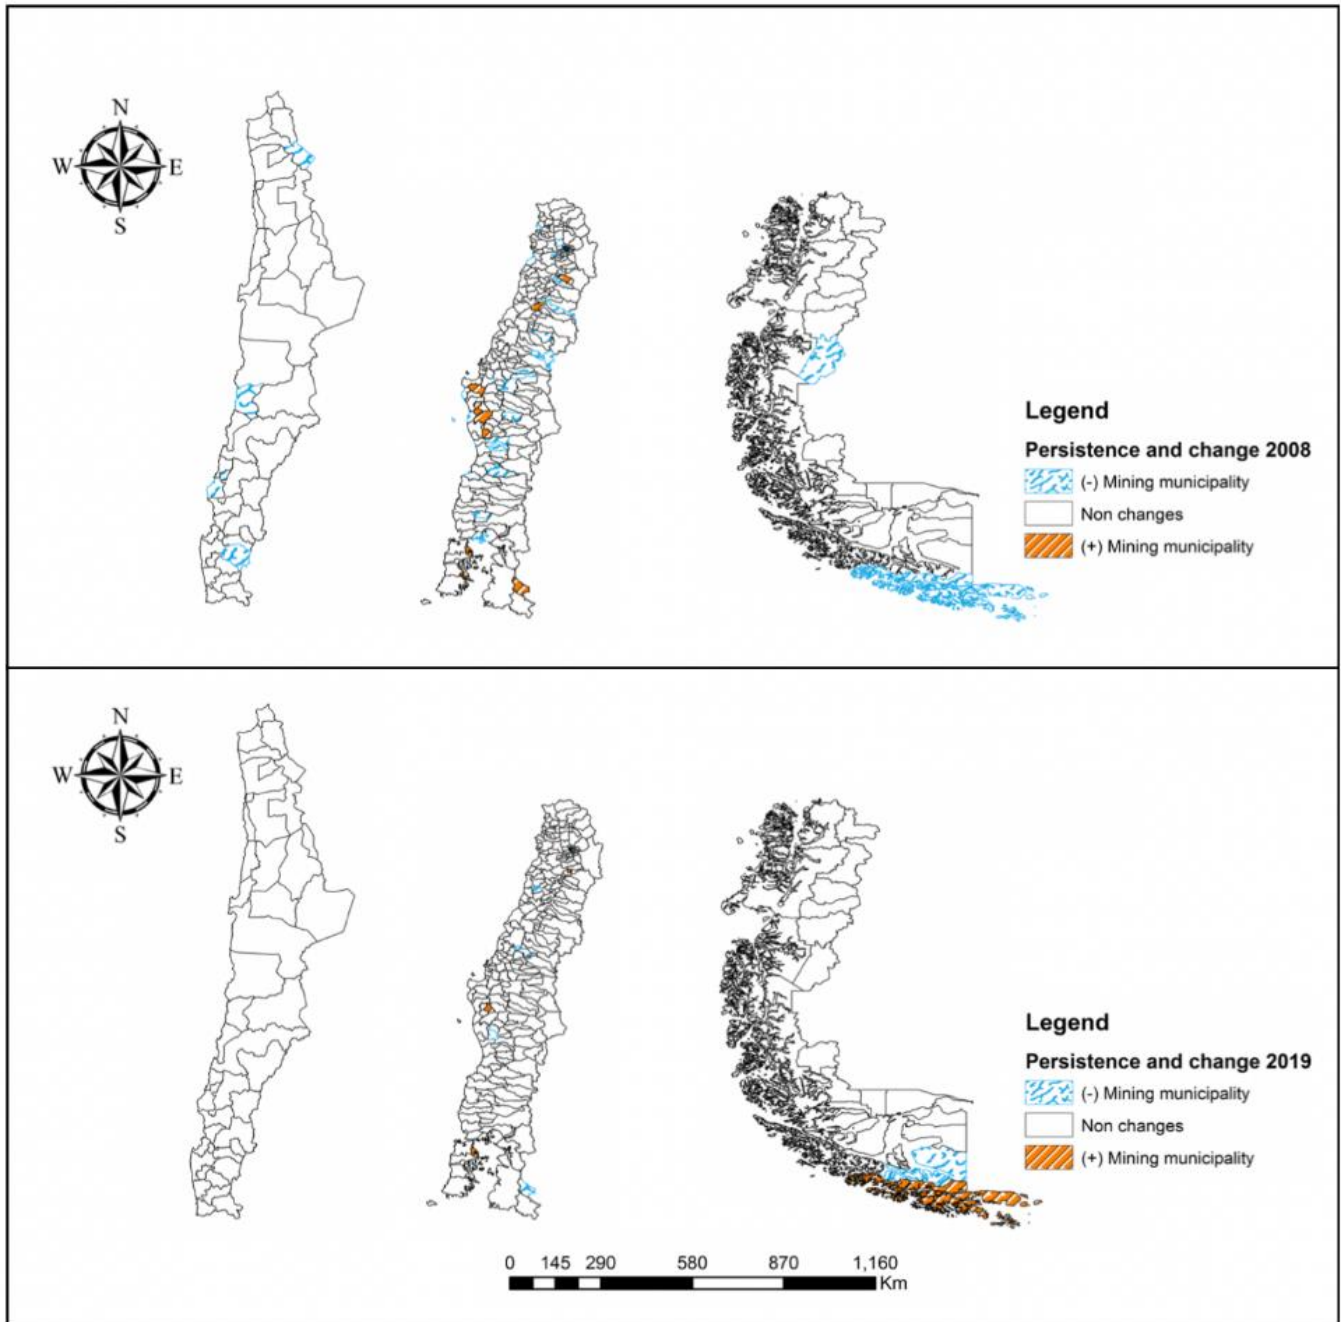

Fig. 11. Spatial distribution of mining category, persistence, and changes across Chilean municipalities, 2009-2019

Source: Data from Sinim (2020).

Note: (+) correspond to municipalities that change of category to mining municipality. (-) correspond to municipalities that change of category to a non-mining municipality.

4. METHODOLOGY

To identify the causal effect of the MWs on the collection of PT we employ two exogenous criteria. Namely, we take advantage of the exogenous allocation rule for categorizing mining municipalities according to the Chilean Mining Code and the exogenous taxonomy proposed by SUBDERE to classify the subnational governments according to their capacity to provide public goods to the local population. Using both criteria, we identify the subnational crowding out hypothesis and evaluate this undesirable effect against different econometric models. Considering that subnational governments consider previous decisions regarding the collection of local taxes when making current decisions (Buettner and

Wildasin, 2006), we first approximate the subnational crowding out between PT and MWs by estimating the following equation (1):

$$PT_{it} = \beta_0 + \beta_1 MW_{it-1} + \beta_2 d_{it} + \beta_3 (MW_{it-1} \times d_{it}) + \mathbf{x}_{it}\boldsymbol{\theta} + t + m_i + \epsilon_{it} \quad (1)$$

Where PT_{it} corresponds to the property taxes collected by a low-tier government i in year t ; MW_{it-1} represents the MWs collection lagged one period by a mining locality i in year $t - 1$. d_{it} corresponds to a fixed effect of 1 or 0 according to the exogenous allocation rule and the mining municipality category. To capture the marginal effect of mining patents on mining municipalities, we use the interaction between the MWs collection lagged one period and the fixed effect indicator d_{it} . The vector \mathbf{x}_{it} includes control variables accounting for local finance and economies of scale, local social characteristics, municipal endowment, a favoritism hypothesis and all variables that impact the tax collection on the dependent variable under analysis: namely, net IPP and the FCM, population, the population squared, the poverty index, proxies for agglomeration economies, a coastal municipality fixed effect, efficiency and professionalization indicators, and public workers in local governments. t corresponds to a time fixed effect that accounts for structural shocks and m_i represents the low-tier government time-invariant random effect. Finally, ϵ_{it} corresponds to the error term.

However, the previous equation ignores the effect of providing public goods developed by low-tier governments. The following equation (2) adds this effect:

$$PT_{it} = \beta_0 + \beta_1 MW_{it-1} + \beta_2 d_{it} + \beta_3 tp_{it} + \beta_4 (MW_{it-1} \times d_{it}) + \beta_5 (MW_{it-1} \times PR_{it}) + \beta_6 (d_{it} \times PR_{it}) + \beta_7 (MW_{it-1} \times d_{it} \times PR_{it}) + \mathbf{x}_{it}\boldsymbol{\theta} + t + m_i + \epsilon_{it} \quad (2)$$

Where PR_{it} corresponds to the dummy variable equal to 1 if the local government is classified as HPR and 0 for LPR. In this sense, we add the interactions between $(MW_{it-1} \times PR_{it})$, $(d_{it} \times PR_{it})$ and the triple interaction as $(MW_{it-1} \times d_{it} \times PR_{it})$ to report the marginal effect for mining municipalities categorized with HPR and LPR. The two previous equations do not consider the dynamic component underlying the past collection of local taxes in the current collection. The following dynamic equation (3) is depicted via the Blundell-Bond system-GMM approach (Blundell and Bond, 1998):

$$PT_{it} = \beta_0 + \beta_1 MW_{it} + \beta_2 d_{it} + \beta_3 PR_{it} + \tau PT_{it-1} + \mathbf{x}_{it}\boldsymbol{\theta} + t + m_i + \epsilon_{it} \quad (3)$$

We consider PT_{it} an additional explanatory variable. The dependent variable lagged in one period PT_{it-1} serves as an inertia test or inertia hypothesis (Wooldridge, 2010). We present the marginal effects of this equation for all municipalities and HPR and LPR separately against multicollinearity problems.

The specifications above do not consider the spatial autocorrelation or spatial interdependence underlying the variables under analysis. In this context, the MWs are spatially concentrated in mining hosting zones according to Chile's geographical features, namely in the extreme north and south of the country. These particularities will negatively affect the local collection of other non-resource incomes, promoting the substitution of local incomes that might have a higher political and/or economic cost to collect (van der Ploeg and Poelhekke, 2017). To deal with these concerns, we employ a spatial econometric technique in a dynamic panel context that allows us to report the spatial effects, namely, direct, indirect, and total in the short and long run of the MWs via the following equation (Elhorst, 2012):

$$PT_{it} = \beta_0 + \beta_1 MW_{it} + \tau PT_{it-1} + \phi \sum_{j=1}^n w_{ij} PT_{i,t-1} + \rho \sum_{j=1}^n w_{ij} PT_{jt} + \mathbf{x}_{it}\boldsymbol{\theta} + \sum_{k=1}^K \sum_{j=1}^n w_{ij} x_{jtk} \gamma_k + t + m_i + \epsilon_{it} \quad (4)$$

Where ϕ corresponds to the parameter of the dependent variable lagged in space-time, w_{ij} is a distance-based spatial weights matrix, ρ is the spatial autoregressive term according to the dependent variable, $w_{ij} x_{jtk}$ corresponds to the explanatory variables' spatial filter, and γ is the parameter that accounts for the k spatially lagged explanatory variables. This equation corresponds to the Dynamic Spatial Durbin Model, which allows us to control for an inertia hypothesis, introduce the spatial filters in space-time, and control for bias by omitted variables that potentially exhibit spatial dependence in a general framework (LeSage and Pace, 2009).

While this model allows us to control for potential spatial autocorrelation, it is necessary to obtain the marginal impacts of the variables under analysis (direct, indirect, total) in a dynamic context. The direct impact reports the changes in the i th unit under the analysis of the MW_{it} on the local collection of RP_{it} . This can be seen as the average impact of the MWs on PT. The indirect impact corresponds to the spillover or feedback of the j th unit under the analysis of the MWs on non-resource incomes ($j = i$), namely the average impact of the nearest neighborhood. The total impact is the direct and feedback effects of the MWs on PT. We obtain the marginal effects of standard errors using MC simulation (Belotti et al., 2013). Finally, this model considers the sequential effects of the dependent variable over their current values lagged in time, space, and space-time.

5. RESULTS

Table 5 depicts the results for equation 1 and includes the robust and corrected standard errors in parenthesis. According to our hypothesis, we expect past resource windfalls via MWs to crowd out the contemporaneous collection of the PT. The three columns present static panel estimations and the marginal effect of mining patents on the dependent variable considering controls in progressive form. The first column considers only controls for local finance and economies of scale (1), meanwhile the second and third columns consider (1) + (2) local social characteristics and (3) municipal endowment and a favoritism hypothesis. In all estimations, the effect of the past collection of MWs ($d_{it} = 1$) harms the contemporaneous collection of local taxes. However, our results are only significant when all of the controls are considered; for each dollar collected via mining patents in $t - 1$, US\$0.2 is crowded out in the current collection of PT.

Table 5. Static panel data estimation results for PT

Note: All variables at the municipal level. MW_{it-1} represents the mining patents collected by a mining municipality i lagged one period. d_{it} correspond to fixed-effect by mining municipalities. ⁹Controls by columns: **(1) Local finance and economies of scale:** Net IPP (US\$), FCM (US\$), population (#), and square population. **(2) Local social characteristics:** % poverty, density per km2, coastal municipalities (D), plus (1). **(3) Municipal endowment and favoritism hypothesis:** professionalization (%), municipal workers (US\$), distance to Santiago (km), coalition (D), and (1) + (2). All estimations include yearly dummies. Robust standard errors in parentheses.⁵⁸ Significance levels: ⁺ $p < 0.1$, * $p < 0.05$, ** $p < 0.01$,*** $p < 0.001$.

Figure 12 depicts the results in graphical terms. The confidence intervals for the mining municipalities are stable and confirm the crowding out hypothesis but only for regression 3 (R3).

Fig. 12. Marginal effects on PT model 1, 2008-2019. (Eq 1)

Source: Data from Sinim (2020). Note: R1, R2, and R3 consider different specifications adding controls in the progressive form: **(1) Local finance and economies of scale:** Net IPP (US\$), FCM (US\$), population (#), and square population. **(2) Local social characteristics:** % poverty, density per km2, coastal municipalities (D), plus (1). **(3) Municipal endowment and favoritism hypothesis:** professionalization (%), municipal workers (US\$), distance to Santiago (km), coalition (D) and (1)+(2). CI 90%.

Equation (2) includes the effect of the level of fiscal capacity in the local provision of public goods, and Table 6 reports these results. The last two columns confirm the crowding out hypothesis and the importance of the local capacity in the provision of public goods, namely for HPR ($d_{it} = 1 \times PR_{it} = 1$) each dollar collected via MWs in the past crowded out

⁵⁸ We present only fixed effects estimations that do not include time-invariant factors: distance to Santiago, coastal municipalities and the fixed effect by subnational governments. The results for random effects estimations are available and can be requested from the authors (only for static models).

US\$0.4 in the current collection of local taxes. This result is significant as the crowding out effect is almost double the previous table, which illustrates the importance of considering a local government’s capacity in terms of provision. Figure 13 also depicts the stability of the estimations for the HPR group. The mining municipalities are otherwise categorized as LPR without significant results in any of the estimations.

Source: Data from Sinim (2020). Note: R1, R2, and R3 consider different specifications adding controls in the progressive form: **(1) Local finance and economies of scale:** Net IPP (US\$), FCM (US\$), population (#), and square population. **(2) Local social characteristics:** % poverty, density per km2, coastal municipalities (D), plus (1). **(3) Municipal endowment and favoritism hypothesis:** professionalization (%), municipal workers (US\$), distance to Santiago (km), coalition (D) and (1)+(2). CI 90%.

Table 7 depicts the results for equation 3 and correspond to the dynamic panel via system GMM. The results for all municipalities as well as for HPRs in the short and long term depict the crowding out hypothesis: for each dollar collected

via MWs (mining patents), US\$0.2 in local taxes is crowded out in the short run. In the long run, this increases to US\$0.4. We should also highlight that the results for the LPR group were significant (US\$0.2) but only in the long term. These results are available in Figure 14. The confidence intervals are also much tighter now.

Note: The dynamic panel estimations consider controls: **(1) Local finance and economies of scale:** Net IPP (US\$), FCM (US\$), population (#), and square population. **(2) Local social characteristics:** % poverty, density per km². **(3) Municipal endowment and favoritism hypothesis:** professionalization (%), municipal workers (US\$), and coalition. CI 90%.

The spatial autocorrelation underlying our variables of interest as well as the spatial interrelation amongst low-tier governments might also influence our results. Chile's geographical characteristics and the spatial clusters of the PT collection affect these estimations. We cannot rule out the spatial autocorrelation in the PT collected by municipalities because of the previous evidence regarding the general and local spatial autocorrelation. In order to account for this hypothesis, we employ an econometric model that considers the spatial autocorrelation independent and explanatory variables and the inertial hypothesis via the Dynamic Spatial Durbin Model (DynSDM). This model allows us to report the spatial impacts on the short and long term over the interest variables. Table 8 depicts the results according to equation 4 which considers three specifications by columns, two of which are restricted and one complete: 1) a time-lagged dependent variable in the model (τPT_{it-1}); 2) a space-time lagged dependent variable ($\phi \sum_{j=1}^n w_{ij} PT_{i,t-1}$); and 3) both a time-lagged and space-time lagged dependent variable ($\tau PT_{it-1} + \phi \sum_{j=1}^n w_{ij} PT_{i,t-1}$) in free form. For the three specifications, the autoregressive coefficient ρ is significant and within the limits of stability.

We analyze the unrestricted model (see Table 8, column 3) based on the information criteria. As we indicated in the methodology section, the coefficients are not directly interpretable. For this reason, Figure 15 depicts the marginal impacts according to the spatial effects, namely direct, indirect, and total in the short and long term. We fail to obtain significant results for the direct marginal effect at either temporal location. The opposite is true for the indirect and total effect which are both significant and negative in the short and long term. In the short term, for each dollar in MWs collected for a nearby neighborhood, approximately US\$1.4 of PT is crowded out in $t + 1$. The total impact considers the feedback and spillover effect and in this situation US\$1.6 of PT is crowded in the short term. Finally, in regard to the subnational crowding out in the long term, the results for the indirect and total effects are negative and significant. Both effects indicate that the subnational crowding out as a cross substitution between PT for MWs in t is around US\$1.2 and US\$1.3 in $t + 1$.

Note: All variables at the municipal level. MW_{it-1} represents the mining patents collected by a mining municipality i lagged one period. ⁹Controls: **(1) Local finance and economies of scale:** Net IPP (US\$), FCM (US\$), population (#), and square population. **(2) Local social characteristics:** % poverty, density per km². **(3) Municipal endowment and favoritism hypothesis:** professionalization (%), municipal workers (US\$), and coalition (D). Marginal effects standard errors in parentheses computed via MC simulation for 1 and 3 columns, the standard error to the column 2 computed via delta method. We consider the inverse distance weight matrix. Significance levels: + $p < 0.1$, * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Fig. 15. Spatial effects of MW on PT for unrestricted DynSDM model (Eq 4)

Source: Data from Sinim (2020). Note: We consider the inverse distance weight matrix. *Controls:* **(1) Local finance and economies of scale:** Net IPP (US\$), FCM (US\$), population (#), and square population. **(2) Local social characteristics:** % poverty, density per km². **(3) Municipal endowment and favoritism hypothesis:** professionalization (%), municipal workers (US\$), and coalition (D). Marginal effects standard errors computed via MC simulation.

6. DISCUSSION AND CONCLUSION

This research evaluates to what extent extra revenue from resource windfalls crowds out PT collection, considering two exogenous criteria, namely mining category according to the Chilean Mining Code and a SUBDERE taxonomy to classify low-tier governments according to their capacity of provision of public goods. The windfalls that a mining municipality receives correspond to non-matched grants for those that have a significant non-renewable resource extraction. By their very nature, mining activities generate adverse effects on the environment; however, mining patents represent a compensation mechanism for negative externalities and are primarily aimed at improving the living conditions of the local population. We use panel data for twelve years, namely 2008-2019, and we test the crowding out hypothesis on mining patents and the local collection of PT. To evaluate this impact, we define a control group as non-mining municipalities that do not receive extra incomes as well as a subcategory HPR or LPR to ensure causality in our estimates. To test the robustness of the results, we use different econometrics models, and we add autoregressive terms that account for an inertia hypothesis via a dynamic estimator for panel data and spatial dynamic econometric models.

Our results are robust and confirm the crowding out hypothesis in relation to the intensity of the local provision of public goods. First, for each US\$1 increase in MWs, there is a US\$0.2 decrease in PT. Second, this subnational crowding out doubles in municipalities with a high level of fiscal responsibility. A US\$1.0 increase in MWs crowds out US\$0.4 in non-resource revenue. The results for municipalities categorized with a low level of fiscal responsibility are not significant. Third, if we consider the influence of nearby neighborhoods and the spatial interdependence amongst low-tier governments, the crowding out is four times higher than non-spatial estimations. The cross substitution between MWs for PT reaches US\$1.6 and US\$1.3 on average in the short and long run. Our results imply that windfalls from the Chilean mining industry generate undesirable incentives for the future collection of PT. This aligns with Oyarzo and Paredes (2019) who identify the crowding out hypothesis but do not consider the importance of fiscal responsibility. However, it should be highlighted that we have 12 years of municipal level self-reported data from SINIM to capture the undesirable behavior, and so the results should be taken with caution.

Our research highlights several implications for Chilean low-tier governments, specifically in relation to municipal local tax collection behavior. Local policies should consider municipal capacity in the local provision of public goods and/or the fiscal responsibility to disincentivize undesirable behavior resulting from extra resource revenues, rather than spatially blind policies that reinforce regional inequalities (Atienza et al, 2020). The results also suggest that subnational tax collection actions are dependent on past actions where the spatial heterogeneity of the country plays a relevant role

in the collection, especially in extreme areas of the country, in municipalities with multiple shortcomings and asymmetries such as in the provision of public goods, the endowment of human capital, and the cost of living.

EFFECTS OF BANKING CONCENTRATION ON MICRO AND SMALL FIRMS IN BRAZIL

Tyago Carmo, Santos Gervasio

Federal university of Bahia, Brazil

ABSTRACT

The objective of the article is to analyze the effect of concentration at the local level on the supply and credit costs of micro and small firms in Brazil. In addition, an evaluation will be made of how concentration affected by profits firms. The literature indicates that the banking monopoly increases credit restrictions for smaller firms. However, this same literature also signals that large banks facilitate credit conditions for young firms. The database consists of information from the banking system, micro and small firms and the regional characteristics of each municipality. The bank concentration index were calculated at the level of municipalities. The literature uses primary data, but this study uses secondary data. The application of secondary data encouraged the use of weights to construct the supply and credit cost variables of micro and small firms at the municipal level. The methodology will be used in the application of four econometric models. The first three analyzes verify the impacts of the banking structure on the finances of micro and small firms, controlling the heterogeneity of the municipalities and the problems of similarity. The results show a low supply and a high cost of credit, in addition to a reduction in the profitability of micro and small firms in the face of the power of banking monopoly. The results differ from the creditor-debtor literature. On the other hand, they approach of traditional literature. In view of this evidence, the fourth analysis evaluating efficiency banking as a hypothesis for rationing credit to smaller firms from the monopoly power of banks. The study verifies the cost efficiency of banks at the municipal level through the analysis of the stochastic frontier. The efficiency index found is higher than 1. The literature indicates that when efficiency indexes are higher than 1, banks operate with above average costs. Thus, the last model estimates the impact of the bank inefficiency index on the credit cost of micro and small firms. The results show that the increase in bank inefficiency increase credit costs for small, medium and large firms in Brazil. Another verification this study was the combination of monopoly and bank inefficiency indexes. The results show that the increase in monopoly power increases the cost of credit and continues to grow with increasing sector inefficiency, but in proportion less. Thus, this study signals the rationing of credit to micro and small firms in Brazil is more explained by the monopoly power of banks than the inefficiency of the sector. However, it is necessary that future studies analyze the correlation between monopoly power and the inefficiency of the Brazilian banking sector.

LOCATION DETERMINANTS AND SUSTAINABILITY: AN EXPLORATORY APPROACH

[Josep-Maria Arauzo-Carod](#)

ECO-SOS (Universitat Rovira i Virgili), Spain

ABSTRACT

This paper analyses location determinants of firms at local level focusing on role played by sustainability issues in shaping these decisions. The contribution to empirical literature is the identification of specific locational patterns driving decisions of sustainability-oriented firms. This is accomplished by using data for new firm entries in Catalan municipalities between 2004 and 2013. This paper is about this type of example, municipalities of the same country with no relevant differences in terms of environmental policies easily explained due to lack of local attributions on that issue. In these cases, the switch to environmental-friendly activities is no longer explained by policy decisions, but by spatial characteristics that favour some activities over others in view of asymmetries at industry level and act as location determinants.

Firms' location determinants have received an increased attention in recent years in view of the positive role played by entering firms over job creation and GDP expansion. Although empirical contributions have considered both internal or external location determinants, in this paper we will focus on the later. Concretely, we will analyse the role played by characteristics of the areas where firms locate or may locate. As these previous determinants have been largely discussed by several scholars we do not attempt to go further in that direction, but to explore a new path that has received little attention until now. We refer to the way in which sustainability dimension and changing social attitudes in developed countries may boost firm creation (and, therefore, location) in these industries. We hypothesize that not all territories have the same capacity to attract new firms, and not all firms locate following the same areas, giving priority to certain industries may benefit some areas. As there is a growing pressure towards specialisation in more sustainable activities, our results proxy future trends for firms' location patterns in many European countries.

SPATIAL ORGANISATION OF THE INNOVATIVE BUSINESS IN THE URBAN AREA – NEW FRAMEWORK

[Maria Kubara](#)

University of Warsaw, Faculty of Economic Sciences, Poland

ABSTRACT

Empirical analysis suggest that the spatial organization of the innovative industry is not stable over time. Over the years clusters of firms are shifting in terms of shape, density and their relative importance. All those alterations look like an evolutionary change in the spatial pattern of the business setting. Location decisions of the individual firms from the innovative industry aggregate into a herd-like behavior of the whole branch. Dynamic actions of the large group of companies are not really explainable by the current theoretical consensus.

In this paper I will analyse the spatiotemporal pattern of the location choices in a highly innovative business branch situated within an urban area. Although it may seem that for such a progressive industry like technological start-ups the office location should not play any major role, there is an evidence that this industry as a whole is creating intriguing non-random spatial patterns, that are gradually changing over time. I will investigate this non-stable spatial structure using a dataset consisting of individual-level information about the technological start-ups founded in Warsaw between 2010-2018. The empirical analysis will be conducted with a usage of machine learning methods supplied with more traditional econometrical framework. I will discuss the fluctuations in the general structure, presence of clusters, their location within the city and their temporal (in)stability.

Considering the evolutionary changes in the entrepreneurial herd behaviour I will propose a new framework which will allow for a deeper understanding of the urban organisation in the innovative business branches. Creating of such is needed due to the shortcomings of the currently prevailing theories. Classical and behavioural theories, New Economic Geography, evolutionary and co-evolutionary approaches – all of these are modelling the individual decisions about where to locate business in a context of unbounded space. Anyhow it seems that considering only stable-state, individual level solutions does not allow for deciphering the group behaviour of entrepreneurs. Especially in a restricted urban area those models do not seem to explain the temporal changes of the firms' organisation very well. In this paper there will be a solution proposed to tackle those shortcomings.

THE GEOGRAPHY OF MANUFACTURING PRODUCTIVITY SHOCKS IN COLOMBIA

Carlos Eduardo Espinel Campos¹, Eduardo Amaral Haddad², Inácio Fernandes de Araújo Júnior²

¹Federal University of São Carlos, Brazil. ²University of São Paulo, Brazil

ABSTRACT

The objective of this paper is to understand how productivity shocks in the manufacturing sectors propagate across Colombian regions. According to Caliendo et al. (2018), fluctuations in aggregate economic activity may come from a wide variety of aggregate and disaggregated events. These events can reflect underlying changes that are sectoral in nature or are actually specific to a sector and a region. The heterogeneity of these potential changes at the sectoral and regional levels implies that the sectoral and regional composition of an economy is fundamental to determinate their aggregate impact. In this paper, we quantify, through a detailed CGE model of the Colombian economy (BM-COL model), the impacts of changes in the total factor productivity (TFP) on its manufacturing sectors. We evaluate the impacts of changes in productivity in the manufacturing sectors, classified according to their technological intensities, in each Colombian Department. Mapping of regional TFP elasticities will bring additional insights to the understanding of the role regional-specific policies related to manufacturing activities play in the Colombian economy. From the simulation results, it is possible to identify potential trade-offs between regional equity and efficiency. While some manufacturing sectors promote GDP growth and reduce inequality, others only foster economic growth at the expense of higher inequality. It is also possible to analyze the existing patterns of regional competition and complementarity. There is a more intense pattern of competition among Colombian regions, since increases in productivity of the manufacturing sectors in a given region, in most cases, tend to have a negative impact on GRP elsewhere. The analysis also reveal different dimensions of Colombia's economic concentration: Bogotá D.C., as capital of the country, plays a prominent role, followed by the regions of Antioquia and Valle del Cauca, with higher shares of GDP (together, these territories concentrate approximately 50% of the country's GDP). From a sectoral point of view, manufacturing sectors with a higher technological intensity (also more capital intensive) are concentrated in these regions as well, posing further structural challenges for pursuing a higher-quality insertion on global value chains with less spatially concentrated benefits.

THE ROUTINE TASKS IN LABOR MARKETS AND THE GENDER WAGE GAP IN BRAZIL

ABSTRACT

Despite the increase in female participation in the Brazilian labor market and a reduction in the average wage gap between men and women, there are gender inequalities in the distribution of workers within sectors and occupations and different degrees of formalization of employment (Bruschini, 2007; Itaboraí; Ricoldi, 2016). Some studies associate the reduction of the wage gap with a set of skills of women in certain occupations, making them more able to face technological challenges (Black; Spitz-Oener, 2010). We aim to identify the factors that are related to the reduction in the wage gap by turning our attention to the tasks performed by men and women. Could tasks associated with occupations with a greater female presence allow women better reactions in terms of variation in the rate of wages and the rate of formal employment in the face of a series of technological challenges? Tasks are classified into three types (Gonzaga; Guazioli, 2019): non-routine abstract (NRA), non-routine manual (NRM), and routine (R). Non-routine tasks are expected to be positively related to increased rates of variation in wages when there is greater access to the internet. The empirical strategy uses the National Census (Censo), and involves two steps. Firstly we estimate the variation in the average wages of men and women, considering the characteristics of the labor market in each 412 micro-regions between 2000 and 2010. We do it to attempt to reduce the influence of the demographic changes and unobservable characteristics of individuals. Secondly, we verify whether there is a relationship between the variation in wages and the type of task performed in each occupation. The results indicate that in markets more specialized in routine tasks the growth of wages and job formality for women is higher than for men. The results are robust to the inclusion of regional internet density as an independent variable. Moreover, we find that internet density is positively correlated to higher wage growth for women.

1. INTRODUCTION

In the last two decades, we have seen increasing female participation in the Brazilian labor market and a slight reduction in the average wage gap between men and women. In 2010 women received 67.7% of men's income and in 2019 occupying 43.7% of jobs they received only 77% of the value of men's income (IBGE, 2010; 2020). The average monthly income of employed women (IBGE, 2010) in 2010 was R \$ 1074.00 (US \$ 606.78) and the men's was R\$ 1587.00 (US \$ 896.61). In 2019, average women's earnings were R\$ 1,985.00 (US \$ 503.07), 77.69% of men's ones which were R \$ 2,555.00 (US \$ 647.67) (IBGE, 2020).

The wage gap is more expressive in some sectors of activity. In the Scientific and Technical sector, in 2010 women occupied 45% of jobs and received an average of 63% of the men's earnings. The sector of personal and domestic services, which is the worst average earnings, women are 84% of the employed workforce, earning an average of 52% of the men's (IBGE, 2010). In the domestic services sector, with informality involving 72.5% of workers, only 26.5% of employed women are in the formal market, receiving 92% of men's income. In the informal market, women receive only 82% of the men's equivalent income.

The literature identified a strong relationship between occupational segregation and wage differential (Anker, 1998; García-Mainar, Montuenga and García-Martin, 2019). Thus, the concentration and the segregation's drives are studied as part of the inequalities concerns and politics (Browne, 2006; Borrowman and Klasen, 2020; Das and Kotikula, 2019). Blau e Kahn (2016) suggest that explanations reported in the literature, e.g. schooling, experience, activities, type of occupation are not enough to understand the phenomena and new factors would be used to explain the differences in outcomes.

In most developed countries we can observe a rising segregation by skill specifically in employment prospects with impacts over the local labor market (Schlitte, 2011). The segregation does not seem to be fully explained by differences in skill levels between men and women. However, women concentration in certain occupations with lower wages, fewer opportunities for promotion is associated with the wage gap but it also might be an indicator that women's work is socially and culturally devalued (García-Mainar; Montuenga; García-Martín, 2018).

In development countries there still are several and diverse kind of constraints to women's participation in labor market (Leone and Baltar, 2006; Bruschini, 2007; Madalozzo, 2010; Itaboraí; Ricoldi, 2016) hence it is important assess whether the drivers to the segregation and gender inequality in Brazilian labor market could affect women's abilities to face the contemporary competition of jobs.

Within the many possible approaches to gender inequality in the labor market, the analysis of the characteristics of the tasks performed in each type of occupation might not be explored enough. Cognitive tasks, which require greater skills that are not easily replaced by technology, in turn, would be negatively correlated with the probability of being informal and would be an important feature in explaining the wage gap between formal and informal sectors (Sullzbach, 2020).

The task approach has also been applied to the analysis of the effect of new technologies on the labor market. One of the possible effects is the educational and training requirements to apply for jobs (Spitz-Oener, 2006; Zeyer-Gliozzo, 2020). Another one is about the changing abilities to face new technologies and the new requirements to survive through the changes in the world of work (Acemoglu and Restrepo, 2019; Autor and Price, 2013).

We aim to identify the factors that are related to the reduction in the wage gap by turning our attention to the tasks performed by men and women. Could tasks associated with occupations with a greater female presence allow women better reactions in terms of wage growth and increased formal employment, in the face of a technological challenge?

To answer the question our empirical strategy uses Brazilian National Census (Censo). We generate an instrumental variable (iv) similar to Autor, Dorn, and Hanson (2015) and Autor and Dorn's (2013) strategies to have measured how specialized in routine job activities a local market is. We consider the characteristics of the labor market in every 412 micro-regions between 2000 and 2010 attempting to reduce the influence of the demographic changes and individuals' unobservable characteristics. We verify whether there is a relationship between the variation in wages and the type of task performed in each occupation.

Our results indicate a positive and significant correlation between women's salary growth and non-routine manual tasks and a negative correlation with routine tasks. It means that when women are concentrated on activities that involve non-routine tasks, the rates of change in wages are positive. Otherwise, the concentration on routine tasks is correlated with the fall in the change in wages.

The paper is organized in three sections, beyond the introduction and final remarks. The first presents an overview of the participation of women in the Brazilian labor market, according to the sectors of activity in and also according to the type of task performed. The goal of the second is to suggest an approach to technological influence over the local labor markets. The third describes the model and its results.

2. BRAZILIAN WOMEN IN LABOR MARKET

2.1 Activities

The activity rate⁶⁰ in Brazil in 2010 was 76% for men and 55% for women, according to data from the Demographic Census (IBGE). Female activity increased by 6 percentage points in relation to data from the previous census (2000), indicating an increase in female participation in the labor market. But there are gender inequalities that persist in all sectors of economic activity. Some of these inequalities are related to the industry or sector of economic activity in which men and women are inserted, as well as their wages and rate of formalization of employment.

As for the sector of activity, there is a higher proportion of women employed in Personal and Domestic Services, Education and Health, as illustrated in Figure 1. This figure shows the proportion of women in relation to the total number of employees in each sector of economic activity in the Brazil in 2000 and 2010.

60 Proportion of population of working age, employed or looking for a job

Figure 1: Women insertion on the labor market in Brazil (2000 - 2010)

In the two years represented in the previous figure, the sector with the highest female participation was that of Domestic Services. This sector is the one with the lowest average earnings (with average monthly values below those of a minimum wage⁶¹) and the worst rate of formalization of employment (Figure 2) among non-agricultural sectors, according to data from the last two demographic censuses.

Figure 2: Formalization of employment by sector of activity (Brazil, 2000 - 2010)

61 The Brazilian minimum wage was R\$ 360.00 in 2000, in updated values for 2010. Women employed in the Domestic Services sector received average salaries of approximately R\$ 180.00, and men, R\$ 240.00. In 2010, the minimum wage was R\$ 510.00 per month. The average salary of women employed in the Domestic Services sector was R\$ 450.00, and that of men, R\$ 650.00.

Regarding employment status, there was an increase in formalization in the period from 2000 to 2010, for both women and men (Table 1). This positive variation in the number of formal job positions increases social security for workers in all sectors of activity.

Despite the positive consequences on the way in which women enter the labor market, the scale of the change was not sufficient to reduce gender inequalities. The increase of 7% observed in the formalization rate among women was less than the 10% observed among men.

Table 1: Status of employment, proportion of workers by gender (Brazil, 2000 - 2010)

Status of employment	2000 (%)			2010 (%)		
	Male	Female	Total	Male	Female	Total
Employees (formal contract)	39	41	40	49	48	48
Military ^a	05	09	06	04	08	06
Employees (no formal contract)	23	29	25	18	25	21
Self employed	30	18	25	26	18	23
Employers	04	02	03	02	02	02
Total number of workers	37,432,477	22,266,415	59,698,892	46,747,788	33,753,227	80,501,015

Source: IBGE, demographic census data (2000 and 2010). Note: (a) Military and statutory civil servants.

Gender inequalities are a structural feature of the Brazilian labor market. In general, regardless of the sector of activity, women receive lower incomes than men in the same occupation. According to data from the 2010 demographic census, the average monthly income of employed women was R \$ 1,074.00 (US \$ 1,879.50), while that of men was R \$ 1,587.00 (US \$ 2,777.25). This difference in remuneration between women and men is more expressive in some sectors of activity, as shown in Figure 3.

Figure 3: Wages by sector of activity (Brazil, 2000 - 2010)

The female workers, however, have a higher level of education than the average for men. These data can be checked in Table 2, that presents statistics on the Brazilian labor market in 2000 and 2010.

Table 2: Statistics for the Brazilian labor market, 2000 - 2010

Higher education among women does not guarantee that they will enter the labor market in formal positions, nor that they are better paid. Despite suggesting that there has been a reduction in inequality in educational access, this phenomenon contributes to the perpetuation of gender inequalities in labor relations.

2.2 The tasks

The tasks are classified into two groups depending on the skills required from a worker to perform them: (i) routine tasks; (ii) non-routine tasks. According to Spitz- Oener (2006), non-routine tasks can be more analytical, interactive or manual intensive. Hence, it is possible to find more than one classification criteria. To describe the Brazilian labor market, we classify tasks into three groups: non-routine abstract (NRA), non-routine manual (NRM) and routine (R) tasks.

The set of skills demanded from workers that perform NRA tasks on a daily basis includes creation, evaluation and interaction, which cannot be simulated by a computer. One typical example of an NRA-intensive occupation is the activity of a teacher. NRM tasks depend on manual skills and don't follow a specific pattern, so workers that perform this kind of task can't be easily replaced by machines either, as is the case of a bus driver, for example. Finally, routine (R) tasks are the ones that can be performed by a computer or a machine instead of a person. These basic characteristics of tasks are the reason why non-routine tasks (NRA and NRM) are expected to positively relate to wage growth when there is greater access to the Internet, because these tasks are complemented by technology, unlike routine tasks, which are replaced by technology.

Figure 4 illustrates the proportion of tasks that workers performed on their main jobs in a daily basis in Brazilian labor markets (2000 and 2010). There is an evident change in the distribution of tasks among women in the informal labor market. Between 2000 and 2010, women apparently switched from performing more routine tasks to concentrate in non-routine tasks. In the formal labor market, they are more often performing NRA tasks, while in the informal market, they perform more NRM tasks. The distribution of tasks among men remained similar over the years. We also note that men do more routine than non-routine tasks.

Figure 4: Proportion of Tasks (Brazil, 2000 - 2010)

We also analyze workers' characteristics according to the type of task they usually perform more frequently. Table 3 shows the distribution of workers by gender and status of employment, in three scenarios established based on the relative importance of tasks in the main occupation. We take the 75th percentile of each task proportion, and interpret that group of workers as "people who are very concentrated in this type of task, compared to other tasks".

In Panel A (Table 3) we analyze the distribution of workers who do much more routine tasks than non-routine tasks ($R > 0.75$ means that among all the tasks performed by these workers, the proportion of routine tasks is bigger than 75%). In Panels B and C, we analyze the distribution of workers with $NRA > 0.75$ and $NRM > 0.75$. Note that the female participation is bigger in these two groups than in the first one. This means women are more concentrated in non-routine tasks, while men seem to be more frequent among workers who concentrate in routine tasks.

Table 3: Proportion of workers by gender and status of employment according to the type of task they execute the most

	Female, 2000		Male, 2010		Female 2010		Male, 2010	
	Mean	sd	Mean	Sd	Mean	sd	Mean	sd
Panel A: R > 0.75								
Informal	0.2647	0.0407	0.5294	0.0919	0.2633	0.0429	0.4108	0.0966
Panel B: NRA > 0.75								
Formal	0.2039	0.0223	0.2888	0.0449	0.2544	0.0308	0.3493	0.0213

Panel C: NRM > 0.75								
Formal	0.1254	0.0529	0.2317	0.0946	0.1858	0.0504	0.2948	0.0748
Informal	0.2328	0.0436	0.4101	0.1055	0.2224	0.0380	0.2970	0.0853

Source: prepared by the authors based on demographic census data (2000 and 2010).

Figure 5 shows how skills demanded from women and men differ in some industries. Note that the first four sectors of activity (Domestic Services, Education, Health and Other Personal Care and Social Services) are the ones with the greatest female participation in the Brazilian labor market. The next four (Transports, Fishing, Extractive and Construction) are the sectors with the least proportion of female workers. In all sectors with a greater participation of women (the stereotypes of female work), we found a greater presence of NRA and NRM tasks. In other sectors, women also perform more non-routine activities than men.

Figure 5: Proportion of tasks by gender in selected sectors (Brazil, 2000 - 2010)

3. MEASURING THE LOCAL MARKETS EXPOSURE TO TECHNOLOGY

The variable indicating exposure to computerization was constructed following Autor, Dorn and Hanson (2015) and Autor and Dorn (2013) and measures the degree to which local markets are historically specialized in routine job activities. We start with 594 4-digit occupational categories in the 2010 census that were classified by Reis (2016) according to the description of job tasks given by the Brazilian Code of Occupation (COD). Each occupation is described by a set of tasks separated into routine, manual, and abstract categories. The variable RTI_k is an index increasing in the participation of routine tasks in the occupation k :

$$RTI_k = \ln \ln (T_{k,t}^R) - \ln \ln (T_{k,t}^M) - \ln \ln (T_{k,t}^A)$$

Where T_k^R , T_k^M and T_k^A are, respectively, the routine, manual, and abstract tasks inputs in occupation k in year t . To distinguish high and low participation of routine tasks in each occupation, we use a binary indicator for occupations in the upper 66th percentile of the RTI_k distribution. The final variable used in the regressions is the microregion j employment share measure equal to the fraction of the local market’s employment assigned to routine task-intensive occupations:

$$RSH_{jt} = \left[\sum_{k=1}^K L_{jkt} I(RTI_k > RTI^{p66}) \right] \left(\sum_{k=1}^K L_{jkt} \right)^{-1}$$

Where L_{jkt} is total employment in microregion j , at time t , in occupation k , and $I(\cdot)$ is an indicator function taking value equal to one if the occupation was classified as routine intensive.

We expect that historical differences in industry specialization across microregions persist over time, suggesting an instrumental variable approach that uses information in previous decades regarding the routine task intensity in different industries. Consider the share of routine tasks among workers in industry i given by $R_{i,t-1}$ and the employment in industry i in the local market j given by $E_{i,j}$. The instrumental variable suggested by Autor and Dorn (2013) follows a Bartik-type structure that combines the national value of $R_{i,t-1}$ in all Brazilian states except the one that includes microregion j and the industry employment in the region, so that the instrument is given by:

$$ivRSH_j = \sum_{i=1}^I E_{i,j,t-1} R_{i,-j,t-1}$$

Information on occupations in the Brazilian census is less extensive than in developed countries since codes and definitions have changed over time. It is possible to map the occupational codes in the 2010 census to the 2000 data and 1991 data using cross-paths made available from the Brazilian Institute of Geography and Statistics (IBGE). To incur in minimal loss of information, the construction of RSH_j and RTI_k use the 2000 census and the 1991 census data is used in the $ivRSH_j$ variable. The availability of personal computers in the early nineties was severely halted by import tariffs, which declined in the first half of the decade with a broad trade liberalization program. We are comfortable using the 1991 industry structure as an instrumental variable correlated to potential computerization inside firms in the following decade.

The second technological change in the labor market we consider in this article is the roll-out of broadband internet. Starting in 2007 the Brazilian Communications Regulatory Agency (Anatel) provided information per municipality for the number of broadband internet subscriptions. The variable used in our exercise is the density of access which counts the subscriptions per 100 households.

The variables used to construct the instrument for $Internet_{j,2007}$ come from the 2000 census and include the average household ownership rate of personal computers and the ownership of telephone landlines. We link this information to the 1999 MUNIC data from IBGE on infrastructure at the city level, which indicates the presence of internet providers in the municipality. In the early 2000s the main mode of internet access was dial-up services. We create an instrument for internet density in 2007 that uses the chance of access to dial-up in area j in 2000. That final variable consists of the following product:

$$ivInternet_{j,2000} = Computers_{j,2000} \times Telephones_{j,2000} \times Provider_{j,1999}$$

Figure 6 (Graphs A1 and A2) shows the correlation between instruments and variables of interest in the data. One should note that the chance of connecting to the internet in 2000 is small and varies across regions. Even though the technology of access changed from 2000 to 2007, both in quality and access mode, $ivInternet_{j,2000}$ and $Internet_{j,2007}$ are positively correlated.

The statistical offices in Brazil do not collect data on information technology (IT) investment at the establishment level. The intuition behind our choice is that historical knowledge of computers should persist in a region, providing workers with higher affinity to IT once the latter is adopted by firms. Moreover, there is substantial heterogeneity in technology provision across regions since the initial expansion of network services relied on the local infrastructure of landlines bought by each private company from regional-level public services.

Figure 6: Correlation between instruments and variables of interest in the data

Finally, we provide a check of the mechanism linking gender gaps in the labor market and technology exposure. Our working hypothesis is that in markets where women concentrate on non-routine tasks, female labor should be in an advantageous position facing technological changes. Figure 7 (Graphs A3 and A4) shows in the horizontal axis the regional difference in female minus male share of routine job tasks in 2000 or $\Delta_g Share_routine_{2000j}$.

Figure 7: Gender gaps in the labor market and technology exposure

As expected, there are differences across markets, but the average value of $\Delta_g Share_routine_{2000j}$ is negative. Interestingly, the correlation between $\Delta_g Share_routine_{2000j}$ and RSH_{j2000} is negative, and the relationship between $\Delta_g Share_routine_{2000j}$ and $Internet_{j2000}$ is positive. The data suggest that broadband expansion could have benefited women in markets where their relative participation in non-routine tasks was higher and possibly complemented by internet use. We assess this relationship in the next section with regression exercises.

4. ECONOMETRIC ANALYSIS

The empirical strategy of this study was developed in two stages. In the first stage we estimate the variation between 2010 and 2000 average wages and job formality of men and women, considering the characteristics of the workers in the local labor market. In the second stage, we check whether there is a relationship between the growth in wage and formalization of employment and the type of task most frequently performed in the region.

For each census year and gender group we run the following regression with ordinary least squares:

$$\log(y_i) = b_0 + b_1 age_i + b_2 age_i^2 + \sum_1^k \alpha_k edu_dummy_{ik} + \mu_j + u_i \quad (1)$$

$$emp_i = b_0 + b_1 age_i + b_2 age_i^2 + \sum_1^k \alpha_k edu_dummy_{ik} + \mu_j + u_i \quad (2)$$

where y_i are earnings of worker i , and emp_i is a dummy indicating with one whether the worker has a formal job. The covariates include age, age squared, dummies for educational levels, and a dummy for each microregion μ_j . The coefficients for μ_j capture average log wages in equation (1) and formalization rate in equation (2) in the local labor market, netting out the demographic changes in experience and education of workers. This first step serves to calculate the decennial growth of wages and formal employment: $\Delta \mu_j = \mu_{2010j} - \mu_{2000j}$.

The dependent variable for the second step of the exercise is the difference over time between women's and men's average outcomes or $\Delta \mu_j$, given by $\Delta_g \Delta \mu_j$. We call this difference the gender gap, since a higher $\Delta_g \Delta \mu_j$ indicates that women's situation is improving, or their average wages (or job formalization) are growing faster than men's average wages (or job formalization).

We estimate the following equation using two-stage least square:

$$\Delta_g \Delta \mu_j = \delta_0 + \delta_1 RSH_{2000j} + \chi_j \beta + \gamma_s + \varepsilon_j \quad (3)$$

Where RSH_{2000j} is constructed as the proxy developed in Autor and Dorn (2013) for the specialization in routine tasks in a local market. The instrument for RSH uses the product of the industry employment structure in the previous decade and the routine share of jobs in the industry in the 1991 census. We include in the specification the dummies for states γ_s , and covariates x_j that represent the characteristics of the area such as changes between 2010 and 2000 in the logs of industry, services, and agriculture output, and the changes in the share of unskilled workers, share of high-school drop-out, share in workers in urban areas, share of young workers, and share of young unskilled male workers.

As discussed previously, routine tasks are prone to be substituted by technology while also concentrating male workers. We conjecture that in markets specialized in routine tasks the growth of wages and job formality for women will be higher than for men, hence we expect a positive δ_1 estimate in equation (3).

To further the argument that technology has improved women’s position in the labor market by a greater extent than men’s position, we consider a more direct measure of technological advancement given by the density of access to broadband internet. We have information for the number of subscriptions per 100 households for broadband access in each Brazilian city starting in 2007, which we aggregate to form $Internet_{2007j}$. We estimate the relationship between the difference in women’s and men’s $\Delta\mu_j$ and internet density in the local market. As discussed previously, internet access only expanded in Brazil after the privatization of telecommunications companies starting in 1999.

We run the following extension of equation (3) in the regression with two-stage least square:

$$\Delta_g\Delta\mu_j = \delta_0 + \delta_1 RSH_{2000j} + \delta_2 Internet_{2007j} + x_j\beta + \gamma_s + \varepsilon_j \tag{4}$$

We also perform a check of the mechanism that connects the reduction of the gender gap and the realization of job tasks by women. Using the distribution of jobs in 2000 we calculate the difference between the share of routine tasks in jobs held by women in the local market j minus the share of routine tasks in jobs held by men in the same region in 2000, given by $[\Delta_g Share_routine_{2000j}]$. We estimate the following equation with ordinary least square:

$$\Delta_g\Delta\mu_j = a_0 + a_1 \Delta_g Share_routine_{2000j} + x_j\beta + \gamma_s + \varepsilon_j \tag{5}$$

We expect that in markets where women start with a higher relative concentration in routine tasks the improvement in the gender gap over the decade will be smaller, hence a_1 should be negative. Table 4 shows the basic statistics of the variables of interest. We stress that the growth in earnings for women was higher than for men across the board. Nevertheless, female labor is still allocated more heavily in informal positions and this source of inequality in job quality has not improved over the decade.

Table 4: Basic statistics of the variables of interest

	(1)	(2)	(3)	(4)
	$\Delta_g\Delta_t$ Log earnings	$\Delta_g\Delta_t$ Formal job	RSH	Internet Density
Mean	3.43	-0.04	0.34	12.84

Note: Author's calculations with census data. All variables are dated from the beginning of the period in 2000. Gender gaps in wages and job formality consider the change between the 2010 minus 2000 census. 413 observations from microregion level. Population weighted statistics.

Table 5 shows the results for coefficient estimates in equations (3) to (5). In the first two columns we have the values for δ_1 where the dependent variables are gender gaps in wages and job formalization rates, respectively. Comparing two local markets, an increase of 1 percentage point in the presence of routine-intensive jobs improves the gender gap in 19 percentage points for wages and 16 percentage points for formalization rates. The results are robust to the inclusion of internet density in the model specification. In effect, a local market with 10 more internet connections corresponds to 2 percentage points relative gain for female wages, while there is no gain in female job formalization. Finally, in columns (5) and (6) we show estimates for a_1 . In a local market where women started with an extra 10 percentage points higher share of routine tasks, we find that the gender gap in wages has worsened by 3.5 percentage points.

5. FINAL REMARKS

The Brazilian labor market's statistics indicate that jobs remain segregated and unequal, as expected in the gender literature. We searched for potential explanations to the reduction in gender wage gap since the 2000s studying the tasks usually performed in different occupations. Analyzing the distribution of workers and tasks in Brazil we present evidence that women are performing more non-routine tasks than men instead of routine tasks.

Bearing this in mind we shed light on the relationship between the routine task-intensity in local labor markets, the use of technologies, and gender wage gaps. We contribute to the gender wage gap studies by using instrumental variables to analyze the mechanism that connects the reduction of the gap and the realization of job tasks by women. The independent variable of interest (share of local employment in intense routine occupations) and the instrumental variable used are already established in the literature.

Our application of the technique to analyze the improvement of women's situation in the labor market is the novelty in the study. The results indicate that in markets more specialized in routine tasks the growth of wages and job formality for women is relatively higher than for men. Moreover, we find that when comparing local labor markets, in places where women perform more routine tasks, their relative growth in wages is reduced.

The findings are robust to the inclusion of regional internet density as an independent variable in the specification. We use internet density as a proxy to the recent technological changes the labor market and find that job changes related to this technology seem to not affect negatively women's earnings or formalization of employment. In effect, internet density is positively correlated to the relative improvement of female wages.

CHINA SHOCK AND FEMALE LABOR MARKET PARTICIPATION IN BRAZIL

Juliana Cristofani, Ana Claudia Polato e Fava, Monica Yukie Kuwahara

Federal University of ABC (UFABC), Brazil, juh.cristofani@gmail.com, ana.fava@ufabc.edu.br,
monica.kuwahara@ufabc.edu.br

ABSTRACT

Brazil was a successful case of economic growth based on import substitution. At the end of last century and after a period of growth stagnation, trade liberalization became a policy to help lower inflation by increasing competitiveness. Recently, with the China shock, the country economy has been exposed to greater competition. In a similar period, an increase of 12 percent in the proportion of formalized female workers took place on Brazilian labor market. The effects of China shock in the US labor market have been widely researched, but there are not so many studies of these impacts in the developing world. Since Brazil has been affected by trade with China through two channels – increase in exports and imports – there may have been some compensatory effects in Brazil that lead to different results from those observed in developed countries. This paper explores the variation of China Shock between Brazilian local labor markets (or microregions), to identify whether the expansion of Chinese participation on international trade was able to improve the women's conditions in the Brazilian labor market between 2000 and 2013 – measured by the proportion of women formalized, the wage ratio of female to male workers – being the first study to assess how the two channels of China shock affected the outcomes of Brazilian women, with data from the Brazilian formal labor market (Rais) and information on trade flows between Brazil and China (BACI database).

KEYWORDS

China shock, Female formal workers, Gender wage ratio.

1. INTRODUCTION

Brazil remained closed to international trade to promote its economic growth (World Bank, 2008). Even though it carried out a trade liberalization in the 1990s, focusing on an inflation control policy based on the pegged exchange rate, the country retreated, reestablishing the protectionist import tariff policy (Kume, 1998). At the beginning of this century, Brazil intensified its trade relations with China, with the latter becoming one of Brazil's main economic partners (Pautasso, 2010). The commodity boom and the increase in Chinese demand boosted the Brazilian economy (Hiratuka and Sarti, 2016), with China positively affecting the Brazilian labor market via commodity exports (Costa et al., 2016). The Brazilian trade liberalization in the 1990s resulted in the worsening of the Brazilian workforce outcomes (Cavalcanti et al., 2020; Gaddis; Pieters, 2017). However, it produced an improvement in the relative position of women in the labor market since they were less affected than men (Gaddis and Pieters, 2017). Cavalcanti et al. (2020) observe a drop in wage premiums for men and women due to the tariff reduction of the 1990s related to a greater drop in the wages of male workers.

Unlike the trade liberalization in the 1990s, the intensification of trade with China coincides with a growth in formal employment (Maciel and Oliveira, 2018). In the same period, we observe an improvement in the participation of female workers in the formal sector by 12% between 2000 and 2013 (Rais, 2021). However, Benguria and Ederington (2017) observed a wage reduction in the Brazilian workforce, with the adverse effects pulled by men, reducing wage differences in favor of women. The reason for the smaller impact would be associated with the greater presence of female workers in less affected sectors (Benguria and Ederington, 2017).

In this context, this paper explores the variation of China Shock between Brazilian local labor markets to identify whether Chinese international trade expansion was able to improve the female formal labor market conditions in Brazil between 2000 and 2013. The identification strategy used was developed by Autor et al. (2013) and Costa et al. (2016), creating variables that relate the changes in trade flows between Brazil and China to the Brazilian employment outcomes. This is the first study to analyze how the two channels of China Shock affected the relative position of Brazilian female workers. We use administrative data from the Ministry of Labor (Rais) and information about the trade flows between Brazil and China from the BACI database developed by the *Centre d'Etudes Prospectives et d'Informations Internationales* (CEPII). The unit of measurement of this analysis is the microregion, which is a grouping of economically integrated municipalities, allowing the use of a panel data structure for the estimations. To check female labor market conditions, this paper explores female formal employment and female to male wage ratio. We also control by microregional factors such as age, schooling, average wages of the formal labor force, and a cubic polynomial of income per capita, during the initial period. Our findings suggest that the China Shock has worsened the entry of women into the formal market in Brazilian microregions most affected, especially due to the imports channel. For those who remained in the formal market, the

influx of Chinese imports has improved the relative position of women in terms of their average monthly wages. To a certain extent, the exports channel also impacts women in the formal market, but in an adverse way.

2. TRADE SHOCKS IN BRAZIL AND GENDER DIFFERENCES IN LABOR MARKET

This paper is related to the literature on labor market adjustment to trade shocks. The Brazilian labor market adjustment to trade shocks provides an interesting contrast to the case of developed countries due to the differences in labor market structures (Dix-Carneiro, 2019; Costa et al., 2016). Indeed, Brazil has a large informal sector, comprising about half of the workers in 2000 (Costa et al., 2016). However, there is a positive labor market adjustment – in terms of wage gains and formalization – due to a boom in the demand for commodities (Costa et al., 2016).

In the trade liberalization in early 1990, Brazil experienced a gradual and uneven reduction in import tariffs (Dix-Carneiro, 2019; Kovak, 2013), but it remains a relatively protected economy (Dix-Carneiro, 2019; Kume, 1998). Depending on the period analyzed, the average import tariff dropped from 55 in 1987 to 10 percent in 1994 (Kume et al., 2000), and from 31 in 1990 to 13 percent in 1995 (Dix-Carneiro, 2019).

Assessing the main results for Brazil, the literature finds that the effects of the 1990's trade opening are negative for the workforce. Arbache and Corseuil (2004), using a household survey (PNAD), find that the penetration of imports from this period reduced the industrial workforce's employment and wages. With a different approach, using the Brazilian demographic censuses of 1991 and 2000, Kovak (2013) shows that workers from regions more exposed to the tariff reductions of 1990 experienced a greater relative drop in wages, when compared to those less exposed to trade.

This shock also influences informality and unemployment. According to Ulyssea and Ponczek (2018), in the medium term, the tariff reduction causes an increase in the proportion of informal workers and unemployment in more exposed regions. In line with this, Dix-Carneiro and Kovak (2017), when monitoring data from the formal market (Rais) and censuses, find that the adverse effects tend to persist in the medium and long term, concluding that in regions most affected by tariff drops, workers in the formal sector displaced by the shock, after long periods without a job, tends to be employed in informal jobs.

The rise of China was an important event in global economy (Dix-Carneiro, 2019; Costa et al., 2016; Autor et al., 2013). After the seminal paper of Autor et al. (2013), the series of adverse trade shocks in the U.S. economy was known as China Shock. Most papers have consistently identified that the rising competition in manufactured goods from China has damaged the U.S. manufacturing labor market, with the regions and industries most exposed to this trade shock experiencing relatively greater declines in employment and wages (Autor et al., 2013; Acemoglu et al., 2016; Brussevich, 2018).

The Brazilian trade liberalization and the China Shock are events unlike to be experienced again soon (Dix-Carneiro, 2019). Even though Brazil remains a relatively protected economy (Dix-Carneiro, 2019; Kume, 1998), it has experienced another trade shock after its liberalization with the rise of China (Costa et al., 2016). China became Brazil's major trade partner (Pautasso, 2010; Costa et al., 2016). Using a Brazilian household survey data, Paz (2019) finds that the Chinese imports penetration reduces the level of employment and the hourly wages of the workforce. At the same time, with demographic census data, Costa et al. (2016) show that manufacturing workers from Brazilian microregions that were more exposed to the Chinese import penetration face a slower growth in their wages, when compared to those less exposed regions.

However, as well noticed by Costa et al. (2016) and Pautasso (2010), China has also been a source of a large demand shock. Indeed, the Brazil-China trade partnership has adversely affected the labor market regions where imports from China have risen in competition and has positively affected the labor market of commodities exporter regions with faster wage growth and job formalization (Costa et al., 2016). These authors find that, between the years 2000 and 2010, a US\$ 1,000 per worker increase in exports to China led to a 1.58 percentage points growth in the workforce wages (Costa et al., 2016).

Although there is a lot of interest in the adjustment of labor markets to trade liberalization and China's shock to Brazil, little attention has been given to the impact of these labor market adjustments on the relative position of women in the labor market. Regarding the 1990 trade liberalization, two papers look at the changes in the relative position of women in the labor market: Gaddis and Pieters (2017) and Cavalcanti et al. (2020). The first one found that a decline in trade protection by 1 percentage point tends to reduce the female labor force participation by 2 percentage points, while for male workforce, this value is more than 4 pp (Gaddis and Pieters, 2017). Meanwhile, Cavalcanti et al. (2020) observed that men face a wage reduction that is 0.531 pp higher than the wage reduction for women, reducing the gender wage gap over time.

Benguria and Ederington (2017) found that the labor market adjustment to the China Shock due to increasing imports competition in Brazil impacted positively the gender wage gap, with a relative decline of around one percentage point in the regions more exposed to trade. Our paper is the first to measure the impact on women's labor market relative position due to labor market adjustments to the rise of exports and imports from China.

3. EMPIRICAL STRATEGY

3.1 Identification Strategy

We use the identification strategy of Autor et al. (2013) e Costa et al. (2016). This strategy is based on a trade theoretical model⁶² which considers each local labor market as a small open economy, allowing the creation of metrics that relate the variations in trade flows between Brazil and China with the structure of the local labor market in the period prior to the shock (2000, in this case). Here, we define local markets as microregions, which is a grouping of economically integrated municipalities (Costa et al., 2016; Dix-Carneiro et al., 2018).

China Shock in Brazil is spread by two exogenous channels. On the first channel, an increase in competition of local markets is expected, due to the influx of Chinese manufacturers in the country. On the second channel, there is an increase in Chinese demand for Brazilian commodities, which tends to have a positive impact on the local economy, especially in agricultural sectors (Autor et al., 2013; Costa et al., 2016).

By adopting some simplifications developed by Autor et al. (2013) and Costa et al. (2016), we obtain the following variables, which measure how the formal employment of each Brazilian microregion is exposed to trade between Brazil and China. IS_{mt} represents the influx of Chinese imports in Brazil, and XD_{mt} , the increase in Chinese demand for Brazilian exports:

$$IS_{mt} = \sum_j \frac{L_{jm,2000}}{L_{j,2000}} \frac{\Delta I_j}{L_{m,2000}} \quad (1a)$$

$$XD_{mt} = \sum_j \frac{L_{jm,2000}}{L_{j,2000}} \frac{\Delta X_j}{L_{m,2000}} \quad (1b)$$

ΔI_j represents the variation in the volume of Chinese imports to Brazil between 2000 and 2013 in thousands of US\$ ($\Delta I_j = V_{CjB,2013} - V_{CjB,2000}$) while ΔX_j shows the variation in the volume of Brazilian exports to China ($\Delta X_j = V_{BjC,2013} - V_{BjC,2000}$). Then, we weighted the trade flows by the formal workforce structure in Brazil during 2000, where $L_{jm,2000}$ is the total workforce in sector j and microregion m , $L_{j,2000}$ the total workforce in sector j and $L_{m,2000}$ the total workforce in microregion m .

Thus, using the microregion (m) and year (t) as the unit of measurement, we apply a first difference model for the estimates, represented by the following equation:

$$\Delta Y_{mt} = \beta_1 IS_{mt} + \beta_2 XD_{mt} + Z'_{m2000} \beta_3 + \varepsilon_{mt} \quad (2)$$

On the right side of the equation, we have IS_{mt} and XD_{mt} , which are the metrics of competitive exposure created by Autor et al. (2013). We also control for the formal workforce characteristics by microregion in 2000 - represented by the vector Z'_{m2000} - such as the average age, the proportion of workers with a high school degree, and a college degree, and their average monthly wages. To represent the productive structure of microregions in the period prior to the shock, we use a cubic polynomial of income per capita (Costa et al., 2016).

On the left side, the dependent variable (ΔY_{mt}) takes on two different formats. To estimate how the China Shock has influenced women's entry in the formal labor market, $\Delta Women_{participation}$ represents the variation between 2000 and 2013 in the proportion of female workers in the formal market by microregion (m). To assess whether there has been a wage advance for these women in relation to men, the dependent variable is transformed into $\Delta \ln Wage_{female/male}$, which indicates the log change in the ratio of female to male wages in each microregion (m).

Following Costa et al. (2016), to control for possible unobserved state trends that may be linked to the dependent variables, we add fixed effects for the twenty-seven Brazilian states in some specifications. Standard errors are also clustered by mesoregions, allowing the existence of spatial correlation between microregions. We expect the parameters of interest (β_1 and β_2) to be positive and statistically significant, as it would be an indication that more women are occupying the formal labor market and getting better wages compared to their male counterparts, due to the China Shock. We also consider the possibility that variations in the pattern of trade between Brazil and China (represented by ΔI_j and ΔX_j) are capturing changes in the Brazilian economy - such as productivity growth in a specific sector j , or changes in consumption patterns associated with increased income in Brazil (Costa et al., 2016). To deal with this possible endogeneity, we employ the instrumental variables strategy, suggested by the literature (Autor et al., 2013; Acemoglu et al. 2016; Costa et al., 2016).

Thus, we instrumentalize the IS_{mt} and XD_{mt} metrics, replacing the variations in trade flows between Brazil and China by ΔI_j^* and ΔX_j^* , which are calculated by the variation (2000 - 2013) of how much China exports (imports) to all countries in the BACI database, except Brazil. This strategy is valid, since the China Shock in Brazil maintains a correlation with trade flows between China and the rest of the world, but these flows are exogenous to the Brazilian labor market in 2000. We have the following instruments:

$$ivIS_{mt} = \sum_j \frac{L_{jm,2000}}{L_{j,2000}} \frac{\Delta I_j^*}{L_{m,2000}} \quad (5a)$$

$$ivXD_{mt} = \sum_j \frac{L_{jm,2000}}{L_{j,2000}} \frac{\Delta X_j^*}{L_{m,2000}} \quad (5b)$$

3.2 Data

We use administrative data from the Ministry of Labor (Rais), which is a census of the Brazilian formal labor market at an individual level, collected annually. For the dependent variables, we use the number of workers and their respective average monthly wages, disaggregated by gender in the years 2000 and 2013. We also use a consumer price index (IPCA), sourced from the Brazilian Institute of Geography and Statistics (IBGE), to deflate the wages in 2000, so that they are represented in 2013 reais.

⁶²See Autor et al. (2013).

For the controls, we use characteristics of the Brazilian formal workforce during 2000 available at Rais, and to calculate the cubic polynomial of income per capita, we use data from the 2000 Brazilian demographic census, sourced from IBGE, which contains information about formal and informal labor market and other socioeconomic aspects.

The unit of analysis for this study is the microregion, which is a regional classification developed by IBGE by grouping economically integrated municipalities, defined by the literature as Brazilian local labor markets (Costa et al., 2016; Dix-Carneiro et al., 2018). To ensure that there were no major variations in the microregion’s boundaries between the years 2000 and 2013, we use the minimally comparable areas (AMC), provided by Dix-Carneiro et al. (2018), which group some microregions that changed between 1980 and 2010. By matching the municipalities of Rais with the AMCs, we obtain a sample of 411 Brazilian microregions⁶³.

We use trade data between countries from the BACI database, developed by the *Center d’Etudes Prospectives et d’Informations Internationales* (CEPII), which reconciles the information declared by importing and exporting countries to the UN statistical division (Comtrade). They have information on the total annual value of bilateral trade flows between more than 200 countries in current US\$ 1,000, for products classified under the six-digit Harmonized System (HS6) since 1995.

To calculate the metrics of China Shock and its instruments, we use the variation between 2000 and 2013 of Brazilian imports from (exports to) China in thousands of dollars (US\$), as well as the variation of all other BACI’s countries exports to (imports from) China. We deflate this data using the US GDP deflator, provided by the US Bureau of Economic Analysis, considering 2013 as the base year. To finish the calculation of the IS_{mt} and XD_{mt} metrics, we had to transform the BACI data of tradable products into j sectors of activity. For this reason, we construct a concordance between the BACI product codes (HS6) and the Rais economic activity codes (CNAE 95), obtaining 227 tradable sectors⁶⁴.

3.3 Descriptive Analysis

When calculating the China Shock metrics for each of the Brazilian microregions, as described in equations (1a) and (1b), we construct figure 1, which shows how these regions trade with China, both in terms of imports (left side) and exports (right side). We observe that the Brazilian microregions trade with China in different ways, depending on their productive structure in the period prior to the shock, corroborating the empirical strategy adopted.

As expected, regions more intensive in manufacturing production during the year 2000 were relatively more affected by the China Shock imports channel, with emphasis on the states located further south and southeast of Brazil, marked in dark blue on the left-side map of Figure 1. For the exports channel, we observe on the map on the right side that the region most affected was the Brazilian middle west, known for its agricultural production.

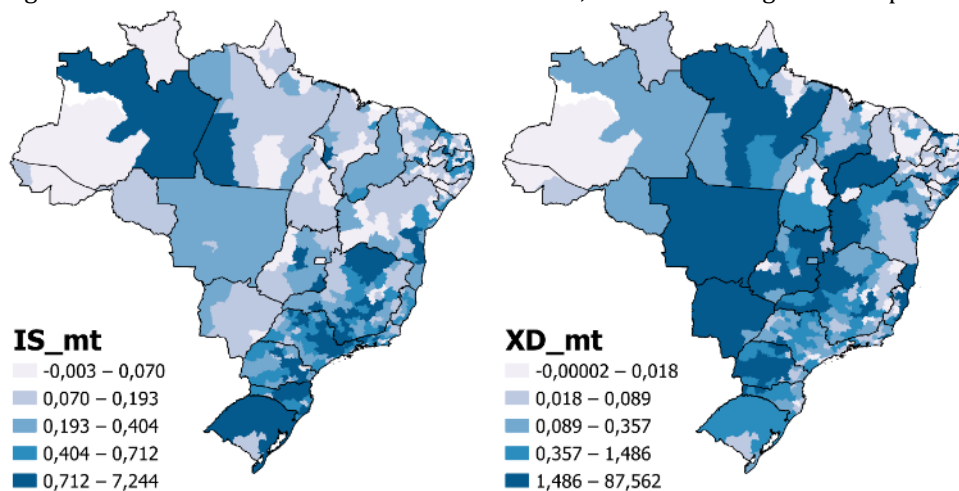

Figure 1 - Geographic Distribution of China Shock’s Metrics (IS_{mt} e XD_{mt}) by quintile

Sources: Rais microdata and BACI database, 2021.

Analyzing the descriptive statistics of women’s participation in the formal labor market and the wage ratio between male and female formal workers, it is possible to notice a positive evolution in favor of female workers. Table 1 contains information on the variables that represent the formal labor market in each of the Brazilian microregions, during the years 2000 and 2013, used to estimate the main models of this study.

63 We dropped *Lencois Maranhenses* and *Japura*, tiny microregions registering only services on Rais. Because of that, their China Shock metrics were missing.

64 Waste and scrap (HS6) could not be concorded with the CNAE, as they are not inputs for the recycling industry. As Costa et al. (2016), we remove these HS6 from IS_{mt} and XD_{mt} , and consider recycling as non-tradable (services).

Table 1 – Description and Summary of Variables by Microregion

Variable	Mean	Std. Dev.	Min	Max
Δ Women _{participation}	0.0387	0.0805	-0.2492	0.3167
Women Participation 2000	0.3823	0.1177	0.1049	0.7867

% Workers with College Education	0.0513	0.0327	0.0040	0.3129
Income per Capita	158.01	91.07	27.55	571.51

Sources: Rais microdata, Brazilian Census and BACI database, 2021.

Observing the evolution of the dependent variables used for the estimates, there was an increase in the participation of female formal workers. In the initial period, about 38.23% of the formal workforce was made up of women, with this proportion increasing around four percentage points, from 2000 to 2013. For the wage ratio between female and male workers, there was also a positive evolution of approximately 10 percentage points over the same period in favor of women, with these earning about 78.18% of what their male colleagues received during the initial year.

Based on these data, it is also possible to understand some characteristics of the formal labor workforce in each Brazilian microregion in 2000. These workers were, on average, 34 years old, and had low levels of education, with only 24.45% of the workforce achieving a high school degree, and 5.13% of them getting a college degree. The average monthly wages of these workers were also low, with a nominal average wage of 416 reals and the highest wage in the period at R\$ 1,176.95. In turn, the average income per capita, considering the entire population, reached the average nominal value of R\$ 158, 01.

Women and men are usually concentrated in different sectors of activities, with more women occupying the services sector (Madalozzo, 2010). Figure 2 shows the mean proportion of women in the formal market employed in each sector, during the years 2000 and 2013 (a) and the mean of the gender wage ratio by sector and year (b).

Figure 2 – Outcomes of Women in the Formal Market by Sector of Activities – 2000 and 2013

Sources: Rais microdata, 2021.

In terms of participation, women were much more concentrated in services activities during both years, where about 48% of workers in this sector were women in 2013, while in agriculture and extractive activities, the proportion of female workers was only 14% at this same year. In manufacturing activities, 27% of workers were women in 2013.

However, when we compare how women’s participation is evolving through time, we notice that in tradable sectors, which are directly affected by China Shock, the proportion of female workers has grown by approximately four percentage points in agriculture, extractive and manufacturing activities, while in the sector with the highest concentration of women (services), the growth was of 2 percentage points.

Observing the gender wage ratio, the wage gap between men and women is bigger in the manufacturing sector, with women receiving a little less than 80% of what men received in both years. In the agriculture and extractive sector, the wage inequality among genders is small, with women receiving 90% of their male colleagues’ wages, without significant

variations during the period. Lastly, in services activities, we can see the biggest variation, with women receiving 78% of a man’s wage in 2000 and in the next period, this value was about 89%.

4. RESULTS

4.1 Main Results

In this section, we present the estimates of the China Shock effects on the proportion of women in the formal market (Panel A, Table 2) and on the female to male gender wage ratio (Panel B, Table 2) by microregion, between the years 2000 and 2013. The coefficients and standard errors of all tables are multiplied by 100, so that they can be interpreted as the approximate effect of an increase of US\$ 1,000 in imports (exports) per formal worker on variations of the dependent variables in percentage points. Besides, through underidentification and weak identification tests, we corroborate the validity of instruments.

Table 2 – Main Results: Effects of China Shock on Female Formal Workers by Microregion

Notes: This table displays estimated effects of China Shock (IS_{mt} and XD_{mt}) on changes between 2000 and 2013 in women’s participation in the Brazilian formal labor market (Panel A) and in the gender wage ratio of formal workers (Panel B). Column (1): Estimation by OLS; Column (2): Estimation by OLS, with state fixed effects; Column (3): Estimation by 2SLS; Column (4): Estimation by 2SLS, using the Frisch-Waugh-Lovell Theorem (FWL) to partialize exogenous regressors (state dummies). As controls, we use the average age, proportion of workers with at least high school degree or at least college degree, and the average monthly wage of formalized workers and a cubic polynomial of per capita income per microregion in 2000. N = 411 microregions. Standard errors in parentheses, clustered by mesoregions (91 clusters). Coefficients and standard errors are multiplied by 100, so that they roughly represent percentage point changes. *** p < 0.01, ** p < 0.05, * p < 0.1. Sources: Rais microdata and BACI database.

Panel A in Table 2 summarizes the estimates of the first difference model, reporting the impact of IS_{mt} and XD_{mt} - and their respective instruments - $ivIS_{mt}$ and $ivXD_{mt}$ - on the proportion of female workers in each microregion m . The results indicate that the China Shock produces a negative effect on the entry of female workers into the formal labor market in Brazil.

When estimating the model by ordinary least squares (OLS, Column 1), we observe that the microregions most affected by the IS_{mt} channel incurred a drop of 0.699 pp in the participation of women in the formal market, while in the places most affected by XD_{mt} , the effect on women was -0.052 pp, with greater significance. After adding state fixed effects (Column 2), the results are maintained, but with higher magnitudes.

Using the two-stage least squares (2SLS) strategy, in the last two columns, the results for microregions most affected by the export channel lose statistical significance, while for those more intensive in Chinese imports, the effects are relatively less robust when compared to OLS models. In our preferred specification - 2SLS model with state fixed effects (Column 4) - an increase of US\$ 1,000 in imports of Chinese products per worker led to a drop of 0.647 percentage points in the proportion of female formal workers, with 10% of statistical significance.

On the second panel of Table 1, we notice that the impact of the imports channel was positive and significant (5%) on the gender wage ratio in all specifications, while the exports channel was significant only in Column 1, estimated by OLS. In Column 4, with estimations using 2SLS and state fixed effects, we find that an increase of US \$ 1,000 in imports of Chinese products per worker led to a rise of 2.54 percentage points in the gender wage ratio, in favor to women.

By these results, it seems that the China Shock has worsened the entry of women into the formal market in Brazilian microregions, with the effects of the import channel being relatively greater on this population. For those who remained in the formal market, there are indications that the influx of Chinese imports in Brazilian microregions has improved the relative position of women in terms of their wages, when compared to their male colleagues.

To a certain extent, the exports channel also impacts women in the formal market, but in an adverse way. This result must be interpreted with caution, since we find significance only in models estimated by OLS, which may be contaminated by some Brazilian economic aspects that happened in the same period (Costa et al., 2016).

These conclusions are compatible with the literature of trade shocks impacts on women in Brazil, in which Gaddis and Pieters (2017) find adverse effects on the participation of both men and women, due to the 1990 trade opening. Benguria and Ederington (2017) find that the increase in Brazilian demand for Chinese imports, linked to the China Shock, reduced the total labor force wages in Brazil, reaching men more intensely, causing a relative improvement for women.

Considering the possibility that China Shock has affected Brazilian economic sectors in different ways, the literature has carried out empirical tests to check whether trade shocks have led to a reallocation of workers among sectors (Costa et al., 2016). In this way, we subdivided the sample into three major sectors (s): agriculture and extractive activities, manufacturing, and services, repeating the estimates from the previous section, using the same microregional controls in the initial period and the China Shock metrics.

Table 3 summarizes the results estimated by 2SLS with state fixed effects for women’s formal participation (Panel A) and the gender wage ratio (Panel B) for each sector of activities and microregion. In general, we could not find strong statistical evidence that there has been a relocation of women in the formal market among sectors during this period.

Table 3 – Results: Effects of China Shock on Female Formal Workers by Sector and Microregion

Observations (Panel A)	401	408	411
Observations (Panel B)	378	404	411

Notes: This table displays estimated effects of China Shock (IS_{mt} and XD_{mt}) on changes between 2000 and 2013 in women’s participation in the Brazilian formal labor market (Panel A) and in the gender wage ratio of formal workers (Panel B) by major sector and microregion. All models were estimated by 2SLS, using the Frisch-Waugh-Lovell Theorem (FWL) to partialize exogenous regressors (state dummies). Column (1): Effects on agricultural and extractive sectors; Column (2): Effects on manufacturing sector; Column (3): Effects on services sector. As controls, we use the average age, proportion of workers with at least high school degree or at least college degree, and the average monthly wage of formalized workers and a cubic polynomial of per capita income per microregion in 2000. Standard errors in parentheses, clustered by mesoregions (91 clusters). Coefficients and standard errors are multiplied by 100, so that they roughly represent percentage point changes. *** p < 0.01, ** p < 0.05, * p < 0.1. Sources: Rais microdata and BACI database.

Regarding women’s participation in formal work – represented by the variation between periods (2013-2000) of the relative concentration of female workers in sector s and microregion m – we found significance only for the services sector (Column 3, Panel A), suggesting that an increase of US\$ 1,000 in imports from China is associated with a 0.856 pp drop in the participation of women in this sector of activities.

Analyzing the evolution of the relative wages of women in the formal market – calculated as the variation between 2000 and 2013 of the gender wage ratios for each sector and microregion – we find again some significance for only one of the sectors: manufacturing. According to the second column of Panel B, an increase of US\$ 1,000 in exports would have reduced the gender wage gap by 0.529 pp, disadvantaging women in terms of wages.

We may not find consistent effects of China Shock on women's outcomes across major sectors because the sectorial composition of employment did not change throughout this period. However, if the services sector has become more developed in these thirteen years that we have evaluated, due to the shock, the effect may be positive for women allocated to this sector.

To check this possibility, we estimate the effect of China Shock on total formal employment of each sector, through a simple regression (OLS) and compare these results with the share of women in the formal market in each sector in 2000. If the sector more affected by the China Shock is the same which employed more women in 2000, we corroborate our hypothesis. The resulting coefficients and the share of female workers in each major sector during 2000 are shown in Table 4.

Table 4 – Testing the Composition Effect

Major Sectors	IS_{mt} Coefficient (1)	XD_{mt} Coefficient (2)	Women’s Share: 2000 (3)
Agriculture + Extractive	-0.00163	-0.0709	0.141
Manufacturing	-1.33**	0.0265	0.279
Services	1.41**	0.0475	0.406

Notes: This table displays estimated effects of China Shock (IS_{mt} and XD_{mt}) on changes between 2000 and 2013 in total formal workforce participation in the Brazilian labor market by major sector and microregion, in Columns 1 and 2, estimated by OLS. Standard errors in parentheses, clustered by mesoregions (91 clusters). Coefficients and standard errors are multiplied by 100, so that they roughly represent percentage point changes. *** p < 0.01, ** p < 0.05, * p < 0.1. In Column 3, we have the share of women in the formal market by major sector in 2000. Sources: Rais microdata and BACI database.

When comparing the coefficients that indicate the effects of the China Shock on the total employment of each sector with the share of women allocated to them in 2000, we find evidence that favors our hypothesis. Although we did not find

effects for the XD_{mt} channel, we observe that the other channel (IS_{mt}) shows an increase on the participation of formal workforce in services by 1.41 percentage points, with 40.6% of the workforce being made up of women in 2000. In this way, women are being affected due to the income effect: China Shock increases the income of families, which demand more services. As this sector employs relatively more women, they are more benefited in the formal labor market.

4.2 Heterogeneities

In the previous section, we observed the average effects of China Shock on the female insertion in the formal labor market, in each Brazilian microregion (Table 2). However, as these regions have different structural and productive characteristics, it is important to verify whether the effects on women also vary, depending on these characteristics. We have selected some microregional structural characteristics in 2000, and separated the data into terciles, to know the effects on women of regions more or less affected by the chosen characteristics. In all specifications, models are estimated by two-stage least squares (2SLS), with all controls. Table 5 shows the results for women in microregions with a higher proportion of more educated and less educated workers (Columns 1 and 2), in the richest and the poorest microregions (Columns 3 and 4), and those regions more or less populated (Columns 5 and 6).

Table 5 – Heterogeneity Results by Structural Characteristics: Effects of China Shock on Female Formal Workers by Microregion

	More Educated	Less Educated	Richest Microregions	Poorest Microregions	More Populated	Less Populated
	(1)	(2)	(3)	(4)	(5)	(6)
<i>Panel A: $\Delta Women_{participation}$</i>						
IS_{mt}	-0,158	-1,13**	-0,671	0,385	-0,085	-0,455
	(0,285)	(0,568)	(0,529)	(0,991)	(0,245)	(1,10)
XD_{mt}	0,035	0,018	0,076**	0,031	0,250	0,012
	(0,068)	(0,054)	(0,031)	(0,344)	(0,185)	(0,118)
<i>Panel B: $\Delta \ln Wage_{female/male}$</i>						
IS_{mt}	0,684	4,35**	3,32***	7,44**	1,82*	7,79**
	(1,02)	(1,85)	(1,25)	(2,98)	(0,936)	(3,13)
XD_{mt}	-0,086	-0,462***	-0,057	-1,94	-0,012	-0,415
	(0,131)	(0,147)	(0,135)	(1,87)	(0,300)	(0,307)
Observations	137	137	137	137	137	137

Notes: This table displays estimated effects of China Shock (IS_{mt} and XD_{mt}) on changes between 2000 and 2013 in women’s participation in the Brazilian formal labor market (Panel A) and in the gender wage ratio of formal workers (Panel B) by microregion. All models were estimated by 2SLS, in microregions more (1) and less (2) educated, richest (3) and poorest (4) and in more (5) and less (6) populated. As controls, we use the average age, proportion of workers with at least high school degree or at least college degree, and the average monthly wage of formalized workers and a cubic polynomial of per capita income per microregion in 2000. Standard errors in parentheses, clustered by mesoregions. Coefficients and standard errors are multiplied by 100, so that they roughly represent percentage point changes. *** p < 0.01, ** p < 0.05, * p < 0.1. Sources: Rais microdata and BACI database.

Regarding the evolution of the participation of women in each microregion, only a few specifications were significant, according to Panel A. For the gender wage ratio (Panel B), we find interesting results, especially through the imports channel (IS_{mt}), since most of the coefficients were higher than those of the main specifications – 2.54 pp with 5% of significance (Table 2, Panel B, Column 4).

In Panel B, we found no evidence that the gender wage ratio in microregions with a higher concentration of employees who have a college degree were affected by the China Shock. On the other hand, we find that the trade shock has been quite positive for female formal workers from low education regions in terms of wages, since the IS_{mt} channel has an effect of 4.35 pp on the gender wage ratio, and a slightly negative effect due to the XD_{mt} , of -0.462 pp.

Regarding regional differences in income per capita, both in richer and poorer microregions, the effect of IS_{mt} on relative average women’s wage was positive, but to a greater extent in the poorest regions, with a 7.44 pp increase in gender wage ratio at 5% significance (Panel B, Column 4). For microregions with different population sizes, the effects are similar, with the IS_{mt} increasing the gender wage ratio by 7.79 pp in less populated areas at 5% significance (Panel B, Column 6), and by 1.82 pp in the most populated microregions (Panel B, Column 5), with less significance.

In Table 6, we create terciles for each of the major economic sectors defined in the previous section, separating the microregions more intensive in the production of agricultural and extractive goods (1), in manufacturing (2), and in services (3). In microregions specialized in manufacturing, the effects were significant in both panels, with results presenting the same conclusions as the main specifications.

Table 6 – Heterogeneity Results by Productive Characteristics: Effects of China Shock on Female Formal Workers by Microregion

	Specialized in Agricult. + Extract.	Specialized Manufacturing	in	Specialized in Services

	(0,371)	(0,382)		(0,363)
Observations	137	137		137

Notes: This table displays estimated effects of China Shock (IS_{mt} and XD_{mt}) on changes between 2000 and 2013 in women’s participation in the Brazilian formal labor market (Panel A) and in the gender wage ratio of formal workers (Panel B) by microregion. All models were estimated by 2SLS, in microregions specialized in agriculture and extractive activities (1), in manufacturing (2) and in services (3). As controls, we use the average age, proportion of workers with at least high school degree or at least college degree, and the average monthly wage of formalized workers and a cubic polynomial of per capita income per microregion in 2000. Standard errors in parentheses, clustered by mesoregions. Coefficients and standard errors are multiplied by 100, so that they roughly represent percentage point changes. *** p <0.01, ** p <0.05, * p <0.1. Sources: Rais microdata and BACI database.

We already expected this result on the gender wage ratio, since the influx of Chinese imports tends to be negative for the total manufacturing workforce (Costa et al., 2016). However, as there are fewer women in this sector of activity, they tend to be less affected than men by the shock, with relative wage improvements (Brussevich, 2018).

4.3 Robustness Checks

In the robustness test, we made modifications to the instruments (5a and 5b), to see how sensitive the results are to changes in the countries that trade with China. We chose three different groupings of countries. The first is the variation in trade flows between China and South American countries (Argentina, Bolivia, Chile, Colombia, Ecuador, Paraguay, Peru, Uruguay, and Venezuela), chosen by Benguria and Ederington (2017) as their main instrument. Then, we added another 10 countries⁶⁵, to verify the trade between China and Latin America. Finally, we analyze the trade variations between China and the other BRICS countries: Russia, India, and South Africa.

Table 7 summarizes the test results. All models were estimated by 2SLS, with fixed state effects, and after underidentification and weak identification tests, we confirmed the validity of the instruments. In Column 1, we have the results of our preferred specification, for comparative purposes, and in the other columns, we have the results using the South American (2), Latin American (3) and BRICS (4) instruments.

Table 7 – Robustness Results: Effects of China Shock on Female Formal Workers by Microregion, with Different Instruments Variables (IV)

	Main Specification	South America Instrument	Latin America Instrument	BRICS Instrument
	(1)	(2)	(3)	(4)
<i>Panel A: $\Delta Women_{participation}$</i>				
IS _{mt}	-0,647*	-0,942***	-0,542	-0,751**
	(0,334)	(0,298)	(0,470)	(0,298)
XD _{mt}	-0,0294	-0,0568	-0,0532	0,0245
	(0,060)	(0,129)	(0,134)	(0,0916)
<i>Panel B: $\Delta \ln Wage_{female/male}$</i>				
IS _{mt}	2,54**	3,45***	2,95***	3,42**
	(1,06)	(1,02)	(1,01)	(1,41)
XD _{mt}	-0,288	2,57e-03	0,0225	-0,326
	(0,222)	(0,344)	(0,350)	(0,251)

Notes: This table displays estimated effects of China Shock (IS_{mt} and XD_{mt}) on changes between 2000 and 2013 in women’s participation in the Brazilian formal labor market (Panel A) and in the gender wage ratio of formal workers (Panel B) by microregion. All models were estimated by 2SLS, using the Frisch-Waugh-Lovell Theorem (FWL) to partialize exogenous regressors (state dummies). In Column (1) we have our main specification, using the IV with all countries (except Brazil). In the others, we use IV with South American countries (2), with Latin American countries (3) and BRICS countries (4). As controls, we use the average age, proportion of workers with at least high school degree or at least college degree, and the average monthly wage of formalized workers and a cubic polynomial of per capita income per microregion in 2000. Standard errors in parentheses, clustered by mesoregions. Coefficients and standard errors are multiplied by 100, so that they roughly represent percentage point changes. *** p <0.01, ** p <0.05, * p <0.1. Sources: Rais microdata and BACI database.

⁶⁵ Costa Rica, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panama, Cuba, Haiti, Dominican Republic.

In general, the signs of the results were the same in most specifications, with some changes in magnitude and significance, when compared with the main estimates. As in the latter, the results suggest that China Shock reduced the participation of women in the formal market (Panel A), while for those who remained employed, it improved their salary relative to that of men (Panel B).

5. CONCLUSIONS

This paper explores the variation of China Shock between Brazilian local labor markets to identify whether Chinese international trade expansion was able to improve the female labor market conditions in Brazil between 2000 and 2013 – measured by the participation of women in the formal market and the wage ratio of female to male workers. Brazil is an interesting case to study because China Shock effects are spread by two channels: the rise of commodities exports to China, and the rise of imports from China. This is the first study to assess how these two channels affected the outcomes of Brazilian women.

Our findings suggest that the China Shock has worsened the entry of women into the formal market in Brazilian microregions most affected, and for those who remained in the formal market, this shock has improved their relative position in terms of their average monthly wages, mostly by the imports channel in both cases. To a certain extent, the exports channel also impacts women in the formal market, but in an adverse way.

EUROPEAN REGIONS, RESILIENCE AND LABOUR DISLOCATION IN THE AGE OF THE FOURTH INDUSTRIAL REVOLUTION.

Fabiano Compagnucci¹, Andrea Gentili², Enzo Valentini³, Mauro Gallegati⁴

¹Gran Sasso Science Institute (GSSI), Social Sciences, Italy. ²Università degli Studi Internazionali di Roma, Faculty of Economics, Italy. ³Università degli Studi di Macerata, Department of Political Science, Communication and International Relations, Italy. ⁴Università Politecnica delle Marche, Department of Management, Italy

ABSTRACT

This paper aims at studying the resilience of the EURO area regions' labour markets to the 2007-2008 crisis from a structural change perspective. Building on the shift-and-share analysis and on the notion of adaptive resilience, and sourcing from the Eurostat regional database data on 150 NUTS 2 EURO regions over the period 1998-2019, we show that both Industrial Mix and Spatial Dependence played a key role in the asymmetric reaction of European regional labour markets to the crisis. Standard and spatial econometric analysis confirms that the pre-crisis structural composition of employment was instrumental in determining the size of the shock at regional level whereas the post-crisis recovery was mainly determined by the kind of structural change each region followed and by competition among regions in hosting Knowledge Intensive Services.

GEOGRAPHIC VARIATIONS IN AUTONOMOUS VEHICLE INTEREST AND PERCEIVED BENEFITS

[Elizabeth Mack](#)

Michigan State University, USA

ABSTRACT

Survey based work has uncovered differences in the willingness to adopt and pay for autonomous vehicles. This body of work finds that men and people with higher incomes are more willing to pay for the features of AVs. Analytical results are less conclusive for people of various ages. In particular, research finds conflicting evidence about older adults' willingness to pay for AVs. Aside from individual characteristics that drive AV adoption, another important, but underexplored aspect of work to this point is how the geographic location of people impacts their propensity to adopt and use AVs. To provide some information about geography and its impact on the perceived utility of and the propensity of people to adopt AVs, this study will leverage survey data from the Michigan State of the State survey to test three hypotheses. One, geography impacts people's interest in AVs. Two, geography impacts people's perception of the importance of using AVs to go places. Three, people's perception that AVs will reduce traffic. Regression models are estimated and policy implications of the results discussed. To provide some information about geography and its impact on the perceived utility of and the propensity of people to adopt AVs, this study will test three hypotheses. One, geography impacts people's interest in AVs. Two, geography impacts people's perception of the importance of using AVs to go places. Three, people's perception that AVs will reduce traffic. Regression models are estimated and policy implications of the results discussed.

**REGIONAL PATTERNS OF 4.0 TECHNOLOGICAL TRANSFORMATION.
CONCEPTUAL REFLECTIONS AND EMPIRICAL EVIDENCE FROM
EUROPEAN REGIONS**

Roberta Capello, Camilla Lenzi

Politecnico di Milano, Italy

ABSTRACT

The creation and adoption of the new 4.0 technologies such as artificial intelligence, intelligent robotics, analytics, just to name a few, are expected to drive pervasive transformations and, potentially, radical impacts on the economy and the society.

Socio-economic changes are particularly affecting the domain of production and application of 4.0 technologies, i.e. sectors and markets that adopt (and under certain conditions co-invent) such technologies.

In particular, three main completely different structural transformations are at place: 1) the automation of industrial production processes (Industry 4.0); 2) the creation of new digital services (servitisation); 3) new service delivery and new traditional industry activities (digitalisation of traditional activities).

The territorial dimension of these phenomena has been so far neglected in the literature. This paper aims at filling this gap from both a conceptual and an empirical perspective. On conceptual grounds, the paper elaborates on the territorial dimension and impact of the three different 4.0 technological transformations. On empirical grounds, the paper documents these transformations in European NUTS-2 region over the period 2008-2016.

HOW CAN COMPLEXITY THEORY AND DATA SCIENCE ASSIST SMART CITY GOVERNANCE? A REVIEW

[Yiqiao Chen, Elisabete Silva](#)

University of Cambridge, United Kingdom

ABSTRACT

'Smart city' is a new label for cities worldwide, aiming to use the information and communications technology and enhance sustainability. Smart cities are adopting 'smart governance' policies in addressing complex social, political, economic issues, with the help of digital means. Data Science plays a key role in transforming a city into digital and smarter systems. As urban issues are nonlinear and dynamic, seeing a city as a complex adaptive system is popular among smart city literature, which requires understanding cities through Complexity Theory. Through the lens of Complexity Theory and Data Science, cities can be better understood, simulated and governed. The transportation sector is the backbone of a city and smarter transportation governance can offer better livability, workability and sustainability in smart cities; therefore, we zoom into smart mobility as an example in smart city governance to illustrate the functions of Complexity Theory and Data Science. This article reviews existing literature on Complexity Theory and Data Science in urban planning, presenting a portfolio of main authors, concepts, theories and their contributions to smart city governance, with a special focus on transportation. The review is aided by bibliometric analysis and key linkages among Complexity Theory, Data Science and Smart City Governance are identified. Complexity theory can provide both the theoretical framework and practical tools for smart city governance. Data science can enhance the management of complex systems in cities through advanced data collecting, processing and modelling techniques. Guided by complexity theory and data science, we conclude that smart city governance requires a theoretical framework of adaptive spatial planning to manage the complex urban systems. This adaptive planning framework can be integrated into dynamic simulation models to better analyze, simulate and ultimately enhance smart city governance. The article also concludes that the integrated framework of adaptive spatial planning and dynamic simulation models has great potential in assisting smart mobility and smart city governance but has rarely been applied in urban practice.

PRIORITIZATION CITIES IN BANGLADESH FOR BUS RAPID TRANSIT (BRT) DEVELOPMENT

Bristi Basak¹, Md Musleh Uddin Hasan²

¹ Transport Planner, Development Design Consultants Ltd. (DDCL), 47 Mohakhali C/A, Dhaka, Bangladesh, Bangladesh, bristibasak0711@gmail.com; ² Professor, Department of Urban and Regional Planning (URP), Bangladesh University of Engineering and Technology (BUET), Dhaka, Bangladesh, Bangladesh, musleh_uddin@urp.buet.ac.bd

ABSTRACT

In Bangladesh 30 district/divisional cities, apart from the capital Dhaka, have population above 100,000. None of these cities have a good, high-capacity public transport system. But considering their socio-economic, demographic and urban characteristics and comparing with other cities in the world having Bus Rapid Transit (BRT) system, it is thought that in some of them BRT should be introduced. But a simple and least data requiring methodology - without going to detailed traffic and transportation surveys - to identify and prioritize cities for BRT development is absent. The study has developed a methodology based on available data. At first 27 criteria, having implications in operation of BRT in different cities of the world, had been identified. In consultation with experts and considering local context the number of criteria was reduced to 15 and they were divided in 5 broad categories. In the 2nd round the same experts were requested to put weightage to each broad category and factors in each category. Using AHP the priority of each category and factors were calculated. The respective priority scores for the five categories and factors within each category are as follows: economy 0.262 (inverse of poverty rate in the district 0.166, no. of non-agricultural establishment 0.096); regional/ surrounding context of the city 0.215 (number of 'A' & 'B' type municipalities 0.091, number of growth centers on or within 500 meter of RHD/upazila road 0.124); major activity center/ land use 0.193 (number of EPZ and economic zone in the district 0.046, number of universities/tertiary education & Vocational centers 0.051, number of specialized hospitals 0.095); transport related factors 0.173 (presence of airport in the district 0.056, number of upazilas/sub-districts having railway station 0.047, motorized passenger traffic volume in the RHD road 0.019, average commercial vehicle per day in the upazila road 0.029, total number of registered motor vehicles in the district for the last 10 years 0.021); and demography 0.157 (average population density of 'A' type municipalities 0.040, share of population engaged in industrial activity 0.074, growth rate of population engaged in non-agricultural activity 0.043). Based on these criteria and weightages composite weighted index for 30 cities were made. It has been found that in one city - Chattogram, BRT is an overdue, while among the rest six cities currently require BRT, 13 cities require in near future and 10 cities yet to require.

KEYWORDS

Analytical Hierarchy Process, Bus Rapid Transit, Developing cities, Prioritization

1. INTRODUCTION

1.1 Background of the Study

Cities in developing countries are growing rapidly and becoming automobile-dominated and less sustainable "Pojani (2015)". By 2030, the world is projected to have 43 megacities with more than 10 million inhabitants, most of them in developing regions "UN (2019)". The urban population in developing countries is set to double from 2010 to 2050 while remaining stable in developed countries "UN (2019), UNDESA (2018)". The fastest-growing urban agglomerations are medium-sized cities with less than one million inhabitants, and will be located in Asia and Africa "UNDESA (2018)". Rapid growth of population causes negative impacts on urban residents especially by creating transport related challenges including pollution, congestion due to not having suitable public transportation system, climate change and lack of accessibility for the poor "Gwilliam (2002)". Now more than 170 cities in the world are using BRT as a Public Transport solution; among them 48 cities are from Asian and developing countries "ITDP (2017), Global BRT database (2019)".

As per Census 2011, currently Bangladesh has 43 cities with population above 100,000. Among them four cities, namely Dhaka, Chittagong, Khulna and Sylhet have population more than 500,000. For Dhaka city RSTP (2015) recommends five Mass Rapid Transit (MRT) Lines (MRT Line 1, 2, 4, 5 & 6) and two Bus Rapid Transit (BRT) Lines (BRT Line 3 & 7) in greater Dhaka city region i.e. area under the jurisdiction of Dhaka Transport Coordination Authority (DTCA). Many other cities of Bangladesh being in the category of medium sized towns from a global perspective and hence having potential to expand in the fastest growing urban agglomeration, do not have any strong public transport system at all. But government of Bangladesh is committed through national and sectoral strategies and plans and international commitments, to provide efficient, accessible and affordable public transport options for the citizens of all the cities in Bangladesh. Considering socio-economic, demographic and urban characteristics of cities, in the world, having BRT there may be scopes for introducing high occupancy public transport system like BRT in other cities in Bangladesh. But question comes which cities should the government consider first. In fact, each year transport sector receives one of the

2. LITERATURE REVIEW

“Levinson (2003)” stated that factors influencing development of BRT systems in a city include (1) the intensity and growth prospects and patterns of the urbanized area; (2) the existing and potential future demand for public transportation; (3) expansion of the urbanized area; (4) street width continuity, capacity, and congestion; (5) opportunities for off-street running ways; (6) bus operating speeds and reliability; (7) locations of major employment centers and residential developments in relation to potential BRT routes; (8) community attitudes; and (9) community resources are important for BRT development.

“Banai (2006)” used Analytic Hierarchy Process (AHP) for multicriteria analysis to assess light rail transit (LRT) corridor and route alternatives. Three broad criteria and nine sub criteria were used to determine the best LRT corridor alternative: (1) mobility to job centers, (2) TOD impact, and (3) operating cost. “Kittelson & Associates (2007)” has provided a general guideline for BRT practitioners for BRT development. They have included some key steps including (a) Establishing need (b) Identifying the Market (c) Selecting Type of Running Way (d) Recognizing Public Preferences (e) Integrating BRT with Existing Bus Services (f) Considering Funding Availability (g) Exploring Development Opportunities etc. for developing and analyzing BRT service alternatives. “MDTA (2011)” has identified four screening criteria including (1) Existing daily bus trips, (2) Percent of corridor within a 1/2-mile radius having BRT-supportive density under future conditions, (3) Presence of major attractors/activity centers and (4) Regional transit connectivity. “Talebian (2014)” distinguished successful cities around the world with respect to transportation and similar city to Isfahan, Iran in his study. He suggested Size of the city, Urban Structure, Operation, Climate, Terrain and Economy as criteria for Sustainable Transportation Policies for Isfahan. “Salavati (2016)” wanted to define appropriate criteria for the systematic approach to evaluate and prioritize multiple candidate corridors for public transport investment in Isfahan, Iran. 12 criteria were described in his paper, such as- alleviating traffic congestion in city streets and highways, traffic safety improvement especially pedestrian safety, and reliability improvement in transportation systems regarding schedule adherence, trip comfortability, accessibility to transportation systems, attractiveness of the transportation system, facilitation of a sense of living in a modern city, mode choice diversity in city trips, efficient response to transportation demand, reducing energy consumption in city transportation sector, reducing travel time, and trip cost. A few studies have been conducted in Bangladesh related to Mass Rapid Transit (MRT). “Ahsan (1990)” studied Mass Transit in Metropolitan Dhaka in which particular attention was given to examine the necessity of a functional and cost effective ‘Mass Transit’ system. “Hoque and Hossain (2003)” suggested to introduce Tramway in Dhaka. They emphasized on the augmentation of mass transit system is a necessity to ensure mobility need, road safety, and liable urban environment for Dhaka city in future. “Mahmud and Anwar (2012)” suggested MRT and BRT will be needed as proposed in STP. But in spite of having huge benefit and large potentials, Insufficient Road Width, Insufficient Space for BRT Station, Uncontrolled and Excessive Access Road are some of the conflicting and constraining issues for implementing BRT in Dhaka. “Nasrin (2015)” combined a mixed qualitative and quantitative methodology to understand potential uptake of BRT by commuters in Dhaka for their work trip in her PhD thesis. “Rahman (2017)” studied Dhaka-Narayanganj and Dhaka-Gazipur these two routes to analyze the mode choice behavior of the commuters who regularly travel to Dhaka from its suburban areas using public transportation. The study found that suburban commuters spend a substantial amount of time for access and egress.

3. METHODOLOGY

Consultation with 10 experts, in transport authority, academia and practice, has been carried out to set criteria and priority matrix. It has been done in two stages. At first a list of 27 potential factors affecting choice (or non-choice) of BRT in a city, identified based on literature, is shared with experts and was requested to identify factors relevant in the context of Bangladesh. Thus, a total of 15 factors were found (Figure 2) Then these factors are categorized in five categories.

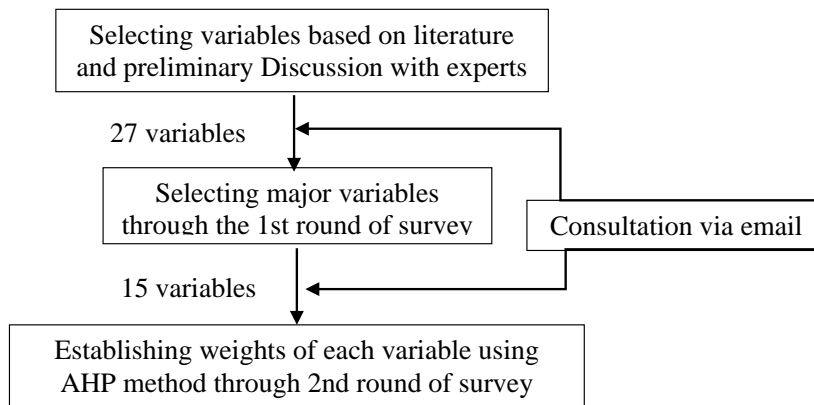

Figure 2: Variable and data collection process with multiple surveys

Using AHP, experts are requested to give priority to each category and sub categories in each category. Table 1 shows the categories and 15 variables, categorized under these 5 categories. Data for studies cities are collected from different census reports published by Bangladesh Bureau of Statistics (BBS), Local Government Engineering Department (LGED), Roads and Highways Department (RHD), Bangladesh Road Transport Authority (BRTA) etc.

Table 1: Fifteen variables were extracted for Analytical Hierarchy Process (AHP) analysis from the survey

Category	Variable	Source of Data
1. Demography	Average Population density of 'A' Category Municipalities	"BBS (2018)"
	Share of population Engaged in industrial activity	"BBS (2016)"
	Annual growth rate of population engaged in non-agricultural activity	"BBS (2016)"
2. Regional/ Surrounding Context	Number of 'A' & 'B' type municipalities	"LGED (2019)"
	Number of Growth Centers on or within 500 meter of RHD/Upazila road	"LGED (2019)"
3. Transport	Presence of Airport in the district	"BBS (2013)"
	No. of Upazilas having Railway station	"BBS (2013)"
	Motorized Passenger Traffic volume in the RHD road	"RHD (2019)"
	Average Commercial Vehicle per day (CVD) in the Upazila road	"LGED (2019)"
	Total No. of Registered motor vehicles in the district	"BRTA (2019)"
4. Major Activity center/ land use	Number of EPZ, Economic Zone in the District	"BBS (2013)"
	Number of Universities, Tertiary education & Vocational centers	"BBS (2013)"
	Number of Specialized Hospitals	"BBS (2013)"
5. Economy	Inverse of Head count ratio (HCR) rate in the district	"BBS (2009)"
	Number of Non-agricultural establishments	"BBS (2016)"

3.1 Priority of categories and weighted index for sub-factors

Overall priority vectors of all the categories of factors have been shown in Table 2 (details can be found in Annex tables).

Table 2: Overall Priority of the Categories of Factors

Category	Overall Priority	Remarks
Economy	0.262	Most significant factor
Regional/ Surrounding Context	0.215	Second most significant factor
Major Activity Center/ Land use	0.193	Third most significant factor
Transport	0.173	Fourth most significant factor
Demography	0.157	Least significant factor
SUM	1	

Ranking of sub factors of Demography, Regional/Surrounding Context, Transport, Major activity center/ Land use and Economy have been done by following the same procedure. Priority vector of the sub factors, i.e. 15 variables selected by the experts in the first phase, are provided in Table 3.

Table 3: Priority vector of the Sub-Factors

Category (Factor)	Sub Factors (variables)	Priority vector of Sub Factors
Demography	Avg. Population density of 'A' Category Municipalities	0.255
	Share of population Engaged in industrial activity	0.474
	Growth rate of population engaged in non-agricultural activity	0.271
	Total	1.0
Regional/ Context	Number of 'A' & 'B' type municipalities	0.424
	Number of Growth Centers on or within 500 meter of RHD/Upazila road	0.576
	Total	1.0
Transport	Presence of Airport in the district	0.327
	No. of Upazilas having Railway station	0.274
	Motorized Passenger Traffic volume in the RHD road	0.110
	Avg. CVD in the Upazila road	0.170
	Total No. of Registered motor vehicles in the dist. (Last 10 years)	0.119
	Total	1.0
Major Activity Center/ Land use	No. of EPZ, Economic Zone in the District	0.240
	No. of Universities, Tertiary education & Vocational centers	0.266
	No. of Specialized Hospitals	0.494
	Total	1.0
Economy	Inverse of Poverty rate in the district	0.632
	No. of Non-agricultural establishment	0.368
	Total	1.0

The variables are in different units. So, weighted index method has been applied in order to convert the values to the same unit. For this, values of each factor have been classified into five equal classes (Table 4). Equal interval method has been used for classification of values. This classification scheme divides the range of attribute values into equal sized sub ranges.

Table 4: Score Classification for each variable or sub-factor

Factor	Subfactors	Score Classification				
		0.2	0.4	0.6	0.8	1.0
Surrounding Demography	Avg. Population density of 'A' Category Municipalities	<2000	2001-4000	4001-6000	6001-8000	>8000
	Share of population Engaged in industrial activity (in %)	<10	10.1-20	20.1-30	30.1-40	>40
	Annual growth rate of population engaged in non-agricultural activity (in %)	<2.50	2.51 to 5.0	5.1 to 7.5	7.51 to 10.0	>10.1
Regional/ Context	Number of 'A' & 'B' type municipalities	<2 or, =2	3-4	5-6	7-8	>8
	Number of Growth Centers on or within 500 meter of RHD/Upazila road	0-15	16-30	31-45	46-60	>60
Transport	Presence of Airport in the district	0	N/A	N/A	N/A	>1 or, =1
	No. of Upazilas having Railway station	<2 or, =2	3 to 4	5 to 6	7 to 8	>9 or, =9
	Motorized Passenger Traffic volume in the RHD road	<100,000 or, =100,000	100,001-200,000	200,001-300,000	300,001-400,000	>400,000
	Avg. CVD in the Upazila road	< 100 or, =100	101-200	201-300	301-400	>400
	Total No. of Registered motor vehicles in the dist. (Last 10 years)	<20,000 or, = 20,000	20,001-40,000	40,001-60,000	60,001-80,000	>80,000
Major Activity Center/ Land use	No. of EPZ, Economic Zone in the District	<2	3-4	5-6	7-8	>8
	No. of Universities, Tertiary education & Vocational centers	0-40	41-80	81-120	121-160	>160
	No. of Specialized Hospitals	0-100	101-200	201-300	301-400	>400
Economy	Inverse of Poverty rate in the district	>40	31 to 40	21 to 30	11 to 20	<10 or, =10
	No. of Non-agricultural establishment	<65,000	65,001-130,000	130,001-195,000	195,001- 260,000	>260,001

After calculating priority vector of each factor (i.e. categories) and subfactors (i.e. variables), they have been multiplied in order to get corresponding weight of the sub-factors (Table 5).

Table 5: Weighted Index of Sub factors

Factors	Priority vector of Factors (i)	Sub Factors	Priority vector of Sub Factors (ii)	Weighted Index (i)×(ii)
Demography	0.157	Avg. Population density of 'A' Category Municipalities	0.255	0.040
		Share of population Engaged in industrial activity	0.474	0.074
		Growth rate of population engaged in non-agricultural activity	0.271	0.043
Regional/ Surrounding Context	0.215	Number of 'A' & 'B' type municipalities	0.424	0.091
		Number of Growth Centers on or within 500 meter of RHD/Upazila road	0.576	0.124
Transport	0.173	Presence of Airport in the district	0.327	0.056
		No. of Upazilas having Railway station	0.274	0.047
		Motorized Passenger Traffic volume in the RHD road	0.110	0.019
		Avg. CVD in the Upazila road	0.170	0.029
		Total No. of Registered motor vehicles in the dist. (Last 10 years)	0.119	0.021
Major Activity Center/ Land use	0.193	No. of EPZ, Economic Zone in the District	0.240	0.046
		No. of Universities, Tertiary education & Vocational centers	0.266	0.051
		No. of Specialized Hospitals	0.494	0.095
Economy	0.262	Inverse of Poverty rate in the district	0.632	0.166
		No. of Non-agricultural establishment	0.368	0.096

4. CALCULATING COMPOSITE INDEX FOR EACH CITY

Corresponding score for each variable has been assigned for each city (Table 6). Calculated weighted index and respective score was then multiplied to get the composite index for each city. Then the multiplication result for each factor has been added up to determine the composite index for each city (Table 7).

Table 6: Score assigned for each city

Sl. No.	City/ District	Demography			Regional/ Surrounding Context			Transport			Major Activity Center			Economy		
		Avg. Population density of 'A' Category Municipalities	Share of population Engaged in industrial activity (in%)	Annual growth rate of population engaged in non-	Number of 'A' & 'B' type municipalities	Number of Growth Centers on or within 500 meter of	Presence of Airport in the district	No. of Upazilas having Railway station	Motorized Passenger Traffic volume in the RHD road	Avg. CVD in the Upazila road	Total No. of Registered motor vehicles in the dist. (Last 10 years)	No. of EPZ, Economic Zone in the District	Number of universities, tertiary education & vocational centers in the district	Number of specialized hospitals or centers higher than upazila	Inverse of Poverty headcount ratio (%)	No. of Non-agricultural establishment

Composite Scores are shown in Figure 3. Chattogram has highest score (0.849) and other cities lie in between 0.336 and 0.614 (i.e. score of Chattogram is like an outlier and it has to be addressed separately). Chattogram has very much potential and developing BRT network has become overdue for the city. Other cities still have potential for BRT development in near future.

Figure 3: Composite Scores of Cities

Composite scores are grouped into three equal distributed range and shown in Table 8 and Figure 4. 10 cities fall under Composite Score range 0.336 to 0.429, 14 cities fall under Composite score range 0.429 to 0.521 and 6 cities fall under Composite score range 0.521 to 0.614.

Table 8: Priority Rank group

City/ District	Composite Score	Categorization as per Score	Remarks
Bogura	0.614	1	Currently Requiring BRT
Cumilla	0.609		
Mymensingh	0.600		
Noakhali	0.556		
Tangail	0.554		
Rajshahi	0.546		
Kushtia	0.512	2	Requiring BRT in near future
Narsingdi	0.499		
Jashore	0.493		
Kishoreganj	0.487		
Pabna	0.486		
Brahmanbaria	0.480		
Sirajganj	0.467		
Cox's Bazar	0.466		
Naogaon	0.465		
Sylhet	0.463		
Dinajpur	0.453		
Barishal	0.435		
Nilphamari	0.431		
Feni	0.414		
Jhenaidah	0.410		
Chapai Nawabganj	0.403		
Faridpur	0.399		
Khulna	0.398		
Jamalpur	0.385		
Chuadanga	0.369		
Rangpur	0.358		
Satkhira	0.349		
Chandpur	0.336		

Priority based map for Potential cities for BRT development has been shown in Figure 4.

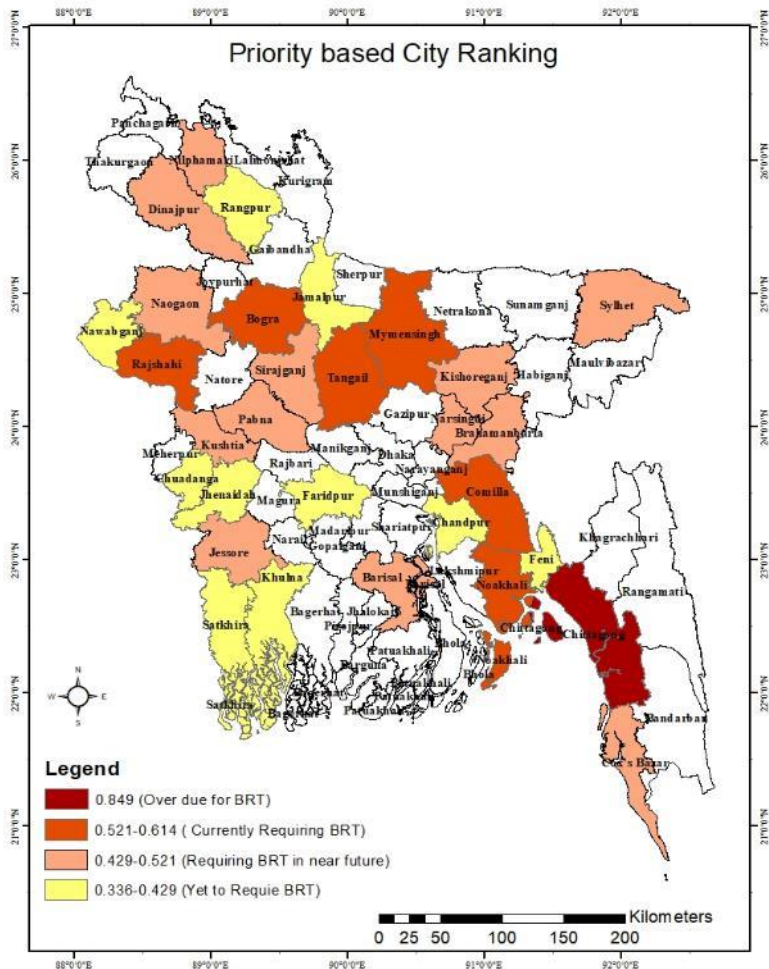

Figure 4: Caetgorization of cities based on the composite scores

5. CONCLUSION

A total number of 30 cities of Bangladesh has been studied. The study has enlisted five major factors, namely, Demography, Regional/Surrounding Context, Transport, Major Activity Center/ Land Use and Economy. Relevant data and information have been collected for the considered factors and their sub factors. Analytic Hierarchy Process (AHP) has been applied for prioritizing the factors. This study shows that, Chattogram has highest composite value (0.849) and it has very much potential but developing BRT network has become overdue for the city. Other cities still have potential for BRT development in near future. As per analysis Bogura, Cumilla, Mymensingh, Noakhali, Tangail and Rajshahi city needs BRT immediately.

ECONOMIC ANALYSIS OF SOLAR IRRIGATION PUMPS: EVIDENCE FROM NORTHERN REGION OF BANGLADESH

Md. Tawhidul Islam¹, Md. Elias Hossain²

¹Department of Economics, Pabna University of Science and Technology, Bangladesh, tawhideco@pust.ac.bd;

²Department of Economics, University of Rajshahi, Bangladesh, eliaseco@ru.ac.bd

ABSTRACT

Bangladesh is heavily dependent on traditional energy sources and imported fossil fuels. Renewable energy technologies are promoted to satisfy the country's rural energy needs mainly as a form of solar home system (SHS) and solar irrigation pump (SIP). As an agriculture-based country, irrigation is vital for ensuring agricultural production sustainability in Bangladesh. Solar irrigation pumps (SIPs) can be a reliable option in this regard. It protects the environment from air and sound pollution as well as water contamination by diesel based fuel. However, there is significant dearth of studies in this regard that provide economic analysis of the solar irrigation pumps. Thus, this study investigates the economic feasibility of the solar irrigation pumps being operated in the northern region of Bangladesh. The study is mainly based on primary data collected from the users of solar irrigation pumps. The data have been collected from four unions under two Upazilas of Dinajpur and Rangpur districts. 30 solar irrigation pumps (SIPs) with different capacities are selected randomly from the study areas after collecting the list of all solar irrigation pumps from the Infrastructure Development Company Ltd (IDCOL). The SIPs are categorized into large, medium, and small pumps. The standard financial indicators and the environmental benefit of different solar pumps are measured in this study. The financial analysis revealed that small SIPs are the most profitable option for investment. Large SIPs are found moderately profitable and their profitability can be improved only when introduced to additional uses. The financial analysis showed that medium SIPs are not a viable option for investment. Thus, 'the fees for ownership model' is found to be more profitable than 'the fees for service model'. The net environmental benefit of SIP is found greater than the given subsidy for installing it. Lastly, it is found that net environmental benefit per kilowatt peak (kWp) is highest for the small SIPs. Therefore, the government should continue giving grants for installing SIPs, especially small SIPs, for their quick spread at the root level.

KEYWORDS

Bangladesh, Environmental Impact, Financial Analysis, Renewable Energy, Solar Irrigation Pumps.

1. INTRODUCTION

Bangladesh is one of the most densely populated countries (1116 persons/km²) in the world, having 162.20 million population as per the 2011 census (Blaauw, 2014). According to the world population prospect of the United Nations, the population of the country will continue to increase up to the year 2050. Thus, it poses a challenge for the country to ensure food security for this vastly growing population. One of the most important solutions in this regard is to increase crop productivity and cropping intensity of the cultivable land. The total cultivable land of the country is 8.52 million hectares, of which the total cropped area is 14.943 million hectares (Ministry of Power, 2008). Out of the 8.52 million hectares of cultivable land, about 7.76 million hectares have already come under irrigation facility (Ministry of Power, 2008) and adoption of irrigation plays a vital role in ensuring efficient use of cultivable land to safeguard food security for the vast population. As the country suffers from scarcity of enough surface water, especially in the dry seasons, underground water has become the primary source of irrigation. The farmers mainly use diesel and grid-connected water pumps for irrigation. Over 1.57 million irrigation pumps are being used in the country for this purpose, of which 80% are diesel engines operated and 20% are electricity operated (BADC, 2020). As the pumps are mostly diesel engines operated, every year Bangladesh has to import about 1.06 million tons of diesel. The government usually provides subsidies in diesel prices to afford irrigation, which creates extra budgetary pressure. Thus, use of solar irrigation pumps can reduce foreign currency expenditure significantly, and a recent report has shown that thirteen hundred solar irrigation pumps can save about \$3.2 million every year by replacing the diesel pumps (BADC, 2020).

On the other hand, the grid-connected irrigation pumps also have some problems in Bangladesh due to low voltage and load shedding. Bangladesh faces an acute shortage of energy, especially in the peak irrigation period and the whole country faces an energy crisis of 1248 MW (BBS, 2018). The total generation capacity of electricity in the country was about 15000 MW in 2018. However, the maximum generation was 10958 MW due to fuel supply constraints (BBS, 2018). The primary source of electricity in Bangladesh is fossil fuels. The contribution of the gas-based power generation is 61.37% (6725 MW), diesel and furnace oil is 24.72% (2708 MW), the coal-based power plant is 2.70% (295 MW), and hydro-electric generation is 1.63% (220 MW) in the total production of electricity in Bangladesh (BBS, 2018). Thus, the primary sources of electricity generation in Bangladesh are natural gas, diesel, and furnace oil-based power plants. Due to the reducing reserve of natural gas of the country and oil price volatility in the international market, these sources have become non-sustainable and vulnerable. To overcome the problem, Bangladesh government has set the vision to

generate 10% of its total power by renewable sources within the year 2021, and it would increase to 20% percent by 2030 (BPDB, 2017). Solar energy can play an essential role in fulfilling the vision because solar radiation is richly available in Bangladesh, with an average variation between 4 and 6.5 kW/m²/day (Hossain et al., 2015). The maximum solar insolation occurs during February–June, and the minimum occurs during October–February in Bangladesh (Rofiqul Islam et al., 2008). The average bright sunshine hours vary from 6 to 9 h/day, which is one of the significant positive indications of solar irrigation pumps' viability.

Besides, diesel and grid based irrigation pumps cause CO₂ emission in Bangladesh's as agricultural activities increase day by day. It rose to 7814 thousand tons in 2012 from 705 thousand tons in 1983, which means about 11 folds increase in CO₂ emission from diesel and electricity run irrigation pumps within 30 years (Al-Masum et al., 2017). It can be checked by introducing solar irrigation pumps instead of conventional pumps. For these purposes, the Bangladesh government has established the Infrastructure Development Company Limited (IDCOL) in 1997. Its purpose was to bridge the financing gap for developing medium to large-scale infrastructure for renewable energy projects. Moreover, IDCOL already has taken a target to replace 50000 diesel pumps with solar irrigation pumps within 2025 (Power Division, 2017). SIPs have almost negligible operational and maintenance cost, and installation of solar irrigation pumps certainly reduces carbon emissions.

Nevertheless, SIP's installation is not free from problems, and the main problem is the high initial capital investment required to install it. Further, the lack of technically trained personnel and supply chains for components and parts of solar photovoltaic (PV) systems in rural areas can lead to low maintenance and delays in repairs (Mahtab & Morshed, 2018). It can affect system lifetime and economic viability as well. Leah C. Kelley et al. (2010) found from a lifecycle cost analysis that solar-powered irrigation is economically viable. However, the PV panels' high costs involve a high initial cash outlay, which needs financing (Kelley et al., 2010). In the developing nations, the capital cost is still the main hindrances to the widespread use of SIPs (Meah et al., 2008). In Bangladesh, Hoque et al. (2016) found that under the current financial scheme for SIPs (20% equity investment, 40% credit support, and the remaining 40% grant), the payback period is 5.43 years, NPV is 13,756 Tk, and IRR is 18%. However, without any support, these projects are not economically attractive. The payback period for this case is about 18 years (Hoque et al., 2016). Thus, solar pumps become financially unviable for farmers without any subsidy than conventional electric and diesel-run pumps. Moreover, solar irrigation pumps are less efficient compared to diesel-operated pumps. A solar pump of 3 horsepower (hp) working for 8 hours a day gives the same water output as a standard 3 hp pump working on grid power or diesel engine for 5 hours a day (Kumar, 2014). Thus, a precise assessment of the economic feasibility of SIPs in Bangladesh is made in this study through providing an economic analysis of the solar irrigation pumps operating in the Northern region of Bangladesh.

The paper is organized as follows: section 2 provides information about the features of solar irrigation pump and its installation; section 3 explains the methodology; section 4 provides the results; and finally, section 5 concludes.

2. KEY FEATURES OF SOLAR IRRIGATION PUMP

Daily water delivery of a solar pump (also known as a photovoltaic pump, PVP) depends on the installed PV panels' number and the water depth. The inter-connected PV panels turn sunlight into direct current (DC), and the electricity is transferred to the solar water pump through a controller. Some solar water pumps use alternating current (AC), so an inverter replaces the controller.

Figure 1: Features of a Solar Irrigation Pump (VEIPL, 2018)

The capacity of a solar pump depends on the number of total installed solar modules. A 1.8 kWp solar pump is equal to the number of solar modules multiplied by each module's capacity ($24 \times 75 \text{ W}_p$) = 1800 Wp. A tracking structure, a submersible pump, controller, installation materials, and pipe are necessary to install a solar irrigation pump (VEIPL, 2018).

Table 1: System Components of a 1.8 kWp Solar Irrigation Pump

Sr. No.	Description	Quantity
1	Solar Modules/panels 75 Wp	24
2	Array tracking structure	1
3	Submersible pump 2 HP	1
4	Motor/pump Controller	1
5	Installation kit	1
6	2" HDPE pipe (meter)	10

Source: Vatio Energy India Private Limited (2018) (VEIPL, 2018).

Solar panel cost is a vital part of the total investment for a SIP, covering about 45% of the total cost. The installation and pump cost account for 18% and 16% of the total cost, respectively.

2.1 Solar Irrigation Pumps in Bangladesh

IDCOL (Infrastructure Development Company Ltd. BD) is a wholly government-owned financial institution, which is implementing the installation of solar irrigation pumps in Bangladesh. Starting its operation in 1997, it is the largest financier and monitoring authority of the renewable energy sector in Bangladesh. IDCOL receives funds from the government of Bangladesh and multiple development partners like the WB (World Bank), KfW ([German government-owned development bank](#)), KOICA (Korea International Cooperation Agency), JICA (Japan International Cooperation Agency), ADB ([Asian Development Bank](#)), USAID (United States Agency for International Development), GPOBA (Global Partnership of Output-Based Aid) and BCCRF (Bangladesh Climate Change Resilience Fund) (IDCOL, 2019). All solar irrigation projects are supported and implemented at the users' level by partner organizations (POs) like Grameen Shakti, Jagorani Energy, ARS Bangladesh, REB, Electro Solar Power Ltd (IDCOL, 2019).

The average bright sunshine hours vary from 6 to 9 hours per day in Bangladesh. Thus, solar energy is richly available in the country with a variation of average solar insolation between 4 and 6.5 kW/m²/day (Tanvir et al., 2017). The insolation rate is one of the essential positive indications of solar irrigation pumps' viability. The northern part of the country has the highest level of average solar insolation rate. That is why 618 out of 832 SIPs have been installed in the region. The total number of approved SIPs in Bangladesh was about 1140. Among them, the number of installed SIPs was 832 up to 2019. The information provided by IDCOL is given in Table 2.

Table 2: Division-wise Number of SIPs up to 2019

Region	Approved	Installed
Rangpur	705	574
Rajshahi	104	44
Khulna	325	211
Chittagong	2	2
Dhaka	4	1
Total	1140	832
Capacity in MW	13.90	8.72

Source: IDCOL (2019) (IDCOL, 2019).

However, the government initially aimed to generate at least 150MW electricity from solar irrigation pumps within 2020 and gradually set to increase the installed capacity of SIPs by projecting irrigation pumps within 2025 to be about 50000 (Ministry of Power, 2008), which would be illustrated year by year in Table 3.

Table 3: Installation Projection of Solar irrigation Pumps

Year	No. of Solar Irrigation Pump (SIPs)
2013	09
2014	80
2015	300
2016	450
2017	661
2018	1013
2019	1519
2020	2278
2021	3417
2022	5126
2023	7689
2024	11533
2025	15925
Total	50000

Source: IDCOL (2019) (IDCOL, 2019).

Thus, the total number of projected solar irrigation pumps will be about 50000 within 2025, is a minimal share of 1.57 million conventional irrigation pumps (Hossain et al., 2015). In 2019, the number of installed SIPs was 832, but the projected number of SIPs was 1519. Thus only about half of the targeted SIPs have been installed up to 2019 (IDCOL, 2019).

2.3 Two Models for Solar Irrigation Pump Program

IDCOL proposed two different models, such as 'fees for service model' and 'fees for ownership model' for installing and managing solar irrigation pumps in the country.

Fees for Service Model

In the 'fees for service model,' partner organizations (POs) collect solar irrigation pumps from suppliers and install them, and farmers purchase water for irrigation from POs. POs receive grants and loans from IDCOL, and IDCOL collects those grants and loans from development organizations and government. This is depicted in Figure 2.

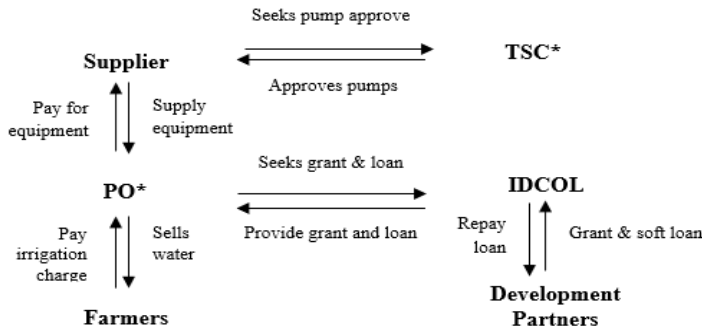

Figure 2: Fees for Service Model of SIP (Rahman, 2015)

Notes: *TSC: Technical Standards Committee of World Bank. PO*= Partner Organization

Fees for Ownership Model

The ownership model is almost the same as the service model. Here POs sell the pump on cash or credit instead of selling irrigation water to the farmers. Also, the farmers pay installments for purchasing the SIP rather than paying irrigation charges to POs. Other functions of the model remain unchanged. The SIP capacity in the ownership model is lower than the service model (For example, the panel capacity for the ownership model would be around 4 kWp, and it would be around 15 kWp for the service model). This model is illustrated in Figure 3.

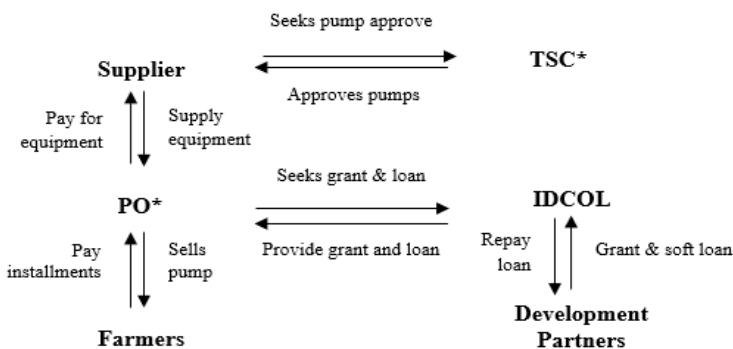

Figure 3: Fees for Ownership Model of SIP (Rahman, 2015)

TSC: Technical Standards Committee of World Bank. PO= Partner Organization

2.4 Financing Structure of Solar Irrigation Pump (SIP)

IDCOL provides up to 40% subsidy and arranging 40% soft loan with the aid of donor agencies. Under this program, POs or individual investors must invest only 20% of the SIP's cost as a down payment (Rahman, 2015). Table 4 shows the financing structure for the implementation of solar irrigation pumps proposed by IDCOL.

Table 4: Financing Structure of Solar Irrigation Pump

Particulars	Percentage
Grant	40%
Debt	40 %
Equity (Down payment)	20%
Total	100%

Source: IDCOL (2019) (IDCOL, 2019).

3. METHODOLOGY

In this study, information about the small, Medium, and large SIPs were collected from the four unions of two Upazilas namely Birganj under Dinajpur district and Badarganj under Rangpur district of Bangladesh. Several partner organizations (POs) such as Gazi, Solargao, and Gram installed the solar irrigation pumps in the visited areas. A total of 30 solar irrigation pumps are selected from the list of total installed solar pumps of IDCOL with different capacities. Secondary information about the SIPs have been collected from IDCOL, SREDA and PO.

3.1 Financial analysis of different solar irrigation pumps

In this study, the standard methods of financial analysis such as **a)** Net Present Value (NPV), **b)** Simple Pay Back Period (PBP), **c)** Internal Rate of Return (IRR), and **d)** Benefit-Cost Ratio (BCR), have been calculated to determine the economic viability of different type of solar irrigation pumps (SIPs) in the study area. The methods are as follows:

3.1.1 Net Present Value (NPV)

NPV is defined as the difference of the present values (PVs) of the total cash inflows (benefits) and the cash outflows (costs). If all future cash flows are incoming and the only outflow of cash is the purchase price (PP), the NPV is simply the present value of future cash inflows minus the purchase price.

$$NPV = \sum_{t=1}^T \frac{CF_t}{(1+d)^t}$$

Where, CF = Cash flow, PP = Purchase price, t = Period of cash flows, d = Discount rate. NPVs is calculated at the discount rates of 6%, 9%, and 12%, which symbolize typical bank interest rates. Thus, we can compare the gains between buying a solar irrigation pump by using money and saving the same amount of money in a scheduled bank.

3.1.2 Payback Period (PBP)

The payback period refers to the period required for the return on an investment to "repay" the sum of the original investment. For example, a \$2000 investment, which returned \$500 per year, will have a four-year payback period.

$$PBP = \frac{II}{NCI/Y}$$

II = Initial Investment NCI/Y= Net cash inflow per year

3.1.3 Internal Rate of Return (IRR)

The internal rate of return (IRR) of a potential investment is the discount rate of interest that makes the net present value equal to zero. If the IRR becomes 15 percent (for buying a SIP with a lifetime of 20 years), buying a SIP brings enough revenue in 20 years to pay its cost and grants a return of 15 percent on the invested capital. Therefore, in this case, borrowing the required capital at less than 15% interest rate and finance it for buying the SIP would be a profitable investment.

Formula of IRR:

$$0 = CF_0 + \frac{CF_1}{(1+IRR)} + \frac{CF_2}{(1+IRR)^2} + \frac{CF_3}{(1+IRR)^3} + \dots + \frac{CF_n}{(1+IRR)^n}$$

$$0 = NPV = \sum_{n=0}^N \frac{CF_n}{(1+IRR)^n}$$

CF₀ = Initial investment CF₁, CF₂, CF₃ . . . CF_n = Cash flows
 n = Each period N = Holding period
 NPV = Net present value IRR = Internal rate of return

3.2 Environmental Impact of Solar Irrigation Pump

The environmental benefits, and the environmental costs of SIPs, are calculated in the study. According to the Intergovernmental Panel on Climate Change (IPCC) guidance, the most common methodological approach to calculate the environmental impact of any investment is to combine information about human activities (called activity data or AD) with coefficients that quantify the emissions per unit activity (Roberta Q, 2006). These are called emission factors (EF). The basic equation is, therefore, is as follows:

$$\text{Emissions} = AD \cdot EF$$

AD= Activity data/ substituted amount of diesel

EF= Emission factors/carbon content

For this study, the activity data (AD) is the substituted amount of diesel by solar irrigation pumps, and emission factors (EF) are the diesel's carbon content. Therefore, CO₂ emissions can be estimated based on the total amount of fuels combusted and the fuels' average carbon content. The environmental benefit of a solar irrigation pump (EBSIP) in terms of CO₂ emission reduction is shown below:

$$EBSIP = TDU \times 2.8 \text{ kg} \quad [1\text{-liter diesel} = 2.8 \text{ kg CO}_2] \text{ (Dev, 2014)}$$

TDU = Total diesel used in 20 years in the liter

The environmental benefit of solar irrigation pump (EBSIP) can be expressed in monetary terms as follows:

$$EBSIP \text{ in Monetary terms} = \frac{EBSIP}{1000} \times CRCO_2$$

Where, EBSIP = Environmental benefit of a solar irrigation pump, CRCO₂ = cost of removal of CO₂ per ton. David W Keith et al. (2018) calculated the cost of removing per ton CO₂ from the atmosphere is about 100 USD in their up-to-date study (Keith et al., 2018). On the other hand, according to the study of Krauter and Ruther (2004), the corresponding emission of CO₂ for the manufacturing of each kWp of PV panels by poly-crystalline silicon is 170 KgCO₂/kWp. This information are used to calculate SIPs' environmental costs. Finally, the solar irrigation pump's net environmental impact has been calculated by subtracting the pump's environmental benefit and degradation.

4. DISCUSSION OF RESULTS

4.1 Financial Feasibility of Large, Medium, and Small Solar Irrigation Pumps (SIPs)

The visited solar irrigation pumps (SIPs) have been categorized equally into three groups such as large, medium, and small SIPs. The capacities of these three groups are as follows:

1. Large solar irrigation pump (with more than 20 kWp solar panels)
2. Medium solar irrigation pump (with 6 to 20 kWp solar panels)
3. Small solar irrigation pump (with 1 to 5 kWp solar panels)

After installation, the partner organizations (POs) own the large and medium SIPs, and the farmers usually possess the small solar irrigation pumps (SIPs). The large and medium SIPs are the example of 'fees for service model' and the small SIP is the example of 'fees for ownership model'. Several POs such as Gazi, Solargao, and Gram installed the solar irrigation pumps in the visited areas. POs appoint an operator for each large and medium solar pump to operate and collect the irrigation fees from farmers. The operator's compensation is TK.3000 per month to ensure the pump's security and 20% of the total collected irrigation fees as commission per year.

The information about costs or *cash outflows* and returns or *cash inflows* of solar pumps has been collected from the installers and farmers. The cash outflows and inflows are the main components for the financial analysis of the pumps.

4.1.1 Basic Information of a Large Solar Irrigation Pump

Large solar irrigation pumps are installed under the 'fees for service model' by partner organizations (PO) at the field level. A large SIP with 30kWp solar panels (120 solar panels each with 250W capacity) and 15kW pump can deliver about 1800000 liter water per day. IDCOL offers 40% of the total price as a grant, the other 40% as a soft loan, and the remaining 20% of the pump's total price has to be paid as a down payment. The total installation cost of the large SIP after receiving a 40% grant becomes about TK.2793840. It can provide irrigation facility to 100 bigha land for Boro cultivation and more than 120 bigha land for other crops cultivation. The irrigation charge for Boro cultivation is TK.3500 per bigha for one season, and for other crops is TK.250 per bigha for one irrigation. The pump provides irrigation facilities on average 200 days in a year. Other days of the year, the pump remains unused. Frequently, this type of large solar irrigation pump without alternative use needs 20 decimal land to install. The necessary information on large solar irrigation pump has given in Table 5.

Table 5: Basic Information of a Large Solar Irrigation Pump

Subject	Information
Panel capacity:	30 kWp (250W×120 panels)
Pump capacity:	15 kW (7.5 kW ×2 Pumps)
Water flow:	1800 m ³ /day or 1800000 Liter/day
Offers:	Irrigation facility to 100 bigha land for Boro and 120 bighas for other crops cultivation
Purchasing pattern:	40% grant, 40% loan and 20% down payment
Total cost:	TK.2793840 (after receiving 40% grant)
Irrigation Charge:	3500Tk/bigha/season for Boro and 250Tk/bigha/irrigation for other crops.
Installed by:	Solargao/ Gazi/ Gram
Facility:	Irrigation only
Number of farmers:	30
Required land:	20 decimal
Operating days:	200/ year
Cultivable crops:	Amon, Boro, mustard, potato, corn, etc.

Source: field survey 2019; (here, 1 bigha=50 decimal).

The main cash outflows are the installation and operating cost, and the main cash inflow is the irrigation fees for this large pump without any alternative use.

4.1.2 Basic Information of a Large Solar Irrigation Pump with Alternative Use

Large solar irrigation pump with alternative use is installed and maintained at the field level by partner organizations (PO). It is also operated under the 'fees for service model.' Generally, alternative provisions like husking and grinding machines have been introduced with the large solar irrigation pump. During off-irrigation time, the solar energy is used for the husking or grinding purpose. The husking machine's power is 10 HP or 7.5 kW, equal to each pump's power. Thus, one pump and the husking machine can run simultaneously by solar electricity. After receiving a 40% grant from IDCOL, the solar irrigation pump's price with the paddy husking facilities became Tk.2903840. About 30 decimal land is

necessary to install this pump with the alternative use. The necessary information on a large solar irrigation pump with a husking machine has given in Table 6.

Table 6: Basic Information of a Large SIP with Alternative Use

Subject	Information
Panel capacity:	30 kWp (250W×120 panels)
Pump capacity:	15 kW (7.5 kW ×2 Pumps)
Water flow:	1800 m ³ /day or 1800000 Liter/day
Offers:	Irrigation facility to 100 bigha land for Boro and 120 bighas for other crops cultivations
Purchasing pattern:	40% grant, 40% loan and 20% down payment
Total cost:	2903840 Tk (after receiving 40% grant)
Irrigation Charge:	Tk.3500/bigha/season for Boro and TK.250/bigha/irrigation for other crops.
Installed by:	Solargao/ Gazi/ Gram
Alternative use:	Paddy husking at the rate of 15Tk/Maund. (1 Maund=40kg)
Facility:	Irrigation and husking
Number of farmers:	30
Required land:	30 decimal
Cultivable crops:	Amon, Boro, mustard, potato, corn, etc.

Source: field survey 2019; (here, 1 bigha=50 decimal).

For this large solar pumps with alternative use, the main cash outflows are the installation and operating cost, without any repairing costs for four years and the main cash inflows are the irrigation and paddy husking fees.

4.1.3 Basic Information of a Medium Solar Irrigation Pump (SIP)

Medium solar irrigation pumps are also installed and maintained by partner organizations (PO) and operated under the 'fees for service model.' A medium SIP with 15kWp solar panels (60 solar panels each with 250W capacity) with a 7.5kW pump can deliver about 1100000 liter water per day. It can provide irrigation facility to 50 bigha land for Boro and more than 70 bigha land for other crops cultivation. IDCOL offers 40% of the total price as a grant, the other 40% as a soft loan and the remaining 20% of the pump's total price has to be paid as a down payment. Thus, the total installation cost of the medium SIP after receiving a 40% grant becomes about 1881948Tk. The pump's irrigation charge for Boro cultivation is TK.3500 per bigha for one season. For the other crop, the charge is TK.250 per bigha per irrigation. The pump is operated on average 200 days a year. On the other days of the year, the pump remains unused. Ten decimal land is necessary to install this type of medium SIP. The summary of the basic information of a medium SIP has given in Table 7.

Table 7: Basic Information of a Medium Solar Irrigation Pump

Subject	Information
Panel capacity:	15 kWp (250W×60 panels)
Pump capacity:	7.5 kW (3.75×2 Pumps)
Water flow:	1100 m ³ /day or 1100000 Liter/day
Offers:	Irrigation facility to 50 bigha for Boro and 70 bigha for other crops cultivation
Purchasing pattern:	40% grant, 40% loan and 20% down payment
Total cost:	1881948 Tk (after receiving 40% grant)
Irrigation Charge:	TK.3500/bigha/season for Boro and TK.250/bigha/irrigation for other crops.
Installed by:	Solargao/ Gazi/ Gram
Facility:	Irrigation only
Number of farmers:	20
Required land:	10 decimal
Operating days:	200/ year
Cultivable crops:	Amon, Boro, mustard, potato, corn, etc.

Source: field survey 2019; (here, 1 bigha=50 decimal).

For this medium solar pump, the main cash outflows are the installation and operating cost; then again, the only cash inflow is the irrigation fees.

4.1.4 Basic Information of a Small Solar Irrigation Pump (SIP)

Small solar irrigation pump's financial structure is designed for 'fees for ownership model.' A typical small SIP with 4kWp solar panels (16 solar panels each with 250W capacity) and 2.5kW pump can deliver about 350000 liter water per day. It can provide irrigation facility to 16 bigha land for Boro cultivation and more than 30 bigha land for other crops cultivation. IDCOL offers 40% of the total price as a grant, the other 40% as a soft loan, and the remaining 20% of the pump's price has to be paid as a down payment. Thus, the small SIP's total cost after receiving a 40% grant becomes about 406128Tk. IDCOL also offers TK.270752 as a loan, and the remaining TK.82000 has to be paid as a down payment. After purchasing, the farmer can save his irrigation cost and rent out the facility to the adjacent farmers. Thus, he can earn from the irrigation charge at 3500Tk per bigha per season for Boro cultivation and TK.250 per bigha per irrigation

for other crop cultivation. Only 2-3 decimal land is necessary for the installation of a small solar irrigation pump. The basic information of a small SIP has been given in Table 8.

Table 8: Basic Information of a Small SIP

Subject	Information
Panel capacity:	4kWp (250W×16 panels)
Pump capacity:	2.5 kW
Water flow:	350 m ³ /day or 350000 Liter/day
Offers:	Irrigation facility to 16 bigha land for Boro and 30 bigha land for other crops cultivation.
Purchasing pattern:	40% grant, 40% loan and 20% down payment
Total cost:	TK.406128 (after receiving 40% grant)
Irrigation Charge:	TK.3500/bigha/season for Boro and TK.250/bigha/irrigation for other crops.
Installed by:	Solargao/ Gazi/ Gram
Facility:	Irrigation only
Number of farmers:	05
Required land:	2-3 decimal
Operating days:	200/ year
Cultivable crops:	Amon, Boro, mustard, potato, corn, etc.

Source: field survey 2019; (here, 1 bigha= 50 decimal).

4.2 Financial Indicators of Different Solar Irrigation Pumps

The information about cash outflows and cash inflows has been utilized to compute the financial indicators such as NPV (net present value), PBP (payback period), and IRR (internal rate of return) of the SIPs. The indicators help to realize which one is the most feasible option for investment. NPVs have been calculated at the discount rates of 6%, 9%, and 12%, which symbolize typical bank interest rates. Therefore, the comparison between the gains of installing the solar irrigation pump and saving the money in a scheduled bank will be possible. IRR helps show the actual return rate at which the net present value of an investment becomes zero. The PBP shows the time required for covering the project's total cost, and after the period, the project starts to earn a profit. The findings of the financial analysis are depicted in Table 9.

Table 9: The Outcomes of the Financial Analysis of Different SIPs

Solar irrigation pump (SIP)	NPV (6%) Tk	NPV (9%) Tk	NPV (12%) Tk	IRR (%)	Payback period (years)
1. a) Large SIP	990167	224460	-316227	10.13	8.10
1. b) Large SIP with alternative use	1135324	320069	-255617	10.54	7.82
2. Medium SIP	-109868	-469166	-722579	5.27	12.91
3. Small SIP	555470	358393	219356	20.1	4.84

Source: Author's calculation based on field survey data, 2019.

In Table 9, large and medium SIPs (1 & 2) represent 'fees for service model' because partner organizations (PO) install, own, and manage these solar irrigation pumps. Under this model, POs sell water to the farmers and collect irrigation fees from them. Besides, small SIP (3) represents the 'fees for ownership model' because an individual farmer can buy the pump from the PO. Table 9 demonstrates the results of all financial indicators of large, medium, and small SIPs. The findings of the financial indicators are as follows:

4.2.1 Large Solar Irrigation Pumps

Without and with alternative use (1a, 1b), the large solar irrigation pumps were found moderately profitable. The NPVs at 6% and 9% were positive, but the values were negative at 12% interest rate. NPVs increased by more than TK.1,00,000 due to the introduction of alternative use of solar panels. The IRRs were 10.13% and 10.54% for large SIPs without and with alternative use. Therefore, after introducing an alternative service, the real return has been increased by about 0.50%. The simple payback period of the large solar irrigation pump with alternative use became 7.82 years. It found 8.10 years without any alternative use. Therefore, the large pump's financial outcome with alternative use seems more viable than the pump without any alternative use. A higher financial gain is possible by introducing more alternative use such as delivering water for fish cultivation, households, and hotel usages, supplying excess solar electricity to the national grid, etc.

4.2.2 Medium Solar Irrigation Pump

The financial indicators of a medium SIP have not seemed attractive. The NPVs at all interest rates were found negative, IRR was at less than 6%, and the simple payback period was more than 12 years of a medium SIP. The causes of the pump's unattractive financial indicators are the high installation cost, operator's salary, and 20% commission on collected irrigation fees. Hence, installing a medium solar irrigation pump would not be a viable option for investment. Though the financial analysis indicates that installing and operating a medium solar irrigation pump is not profitable, POs have installed 186 medium solar irrigation pumps in the Dinajpur and Rangpur districts (IDCOL, 2019). They operate

186 medium solar irrigation pumps as 93 pairs of the pumps. A pair of medium solar irrigation pumps' irrigation coverage, total panel, and pump capacity are the same as a large solar irrigation pump. However, according to the price list of IDCOL, the installation costs of a medium and a large solar irrigation pump are around Tk.3000000 and Tk.5000000, respectively. So, a pair of medium solar irrigation pumps' installation cost is almost TK.6000000, and a large solar irrigation pump's cost is around TK.5000000. The difference in the installation cost of 2 medium and 1 large SIP is more than TK.1000000. Therefore, the installers (POs) received about TK.400000 as a grant (40% of total cost) and another TK.400000 as a soft loan (40% of total cost) from a pair of medium pumps from this excess price. Moreover, from the 93 pairs of medium SIPs, the POs received more than TK.37200000 as a subsidy and the other Tk.37200000 as a soft loan. So, the price structure should be revised to save the given subsidy and soft loan from the medium SIPs. Then, it should be utilized to install the small solar irrigation pump for the farmers' consumption.

4.2.3 Small Solar Irrigation Pump

The small solar irrigation pumps' financial indicators were better than the medium and large solar irrigation pumps. NPVs at all three interest rates for a small SIP were positive. The payback period was less than 5 years, and the IRR was more than 20%. Therefore, the indicators of a small SIP were found attractive. So, it seems that the 'fees for ownership model' is more feasible than the 'fees for service model'. The total installation cost of a small solar irrigation pump (4kWp) offers by IDCOL is TK.676880, which will be about TK.406128 after receiving a 40% subsidy. It still looks expensive for the individual farmer to consume it. Nevertheless, it would be possible to reduce the solar pump's installation cost. As some provisions like underground pipelines, brick-built room are not essential for small SIPs. Besides, a personal solar irrigation pump's total price can be reduced by decreasing the panel and pump capacity. For example, a personal solar pump with 2.50 kWp panels and 1.2 kW pump can provide irrigation facilities to 10 bigha land for Boro cultivation. The market price of this type of small solar pump is about Tk.200000. At present, the solar panel's market price is 40-50 Tk/W. However, the price list of IDCOL shows that the price is about TK.60/W. Thus, by revising the price structure and capacity, small SIP's price can be reduced to around TK.200000. After a 40% subsidy on this price, it would be an attractive investment option for farmers.

4.3 Environmental Impact of Solar Irrigation Pump (SIP)

SIPs have some direct potential to reduce greenhouse gas (GHG) emissions from irrigation activities by replacing fossil fuels with solar energy. At present, solar irrigation pumps substitute diesel-operated irrigation pumps in the country. Thus, diesel consumption is reducing substantially due to the introduction of solar energy. As a result, CO₂ emission is decreased with the reduction of diesel consumption. From the field survey, it was found that on average, 37.5 liter and 3 liter diesel is necessary for Boro and other crops cultivation for one bigha land in a season. The environmental benefit is estimated using the information that 1 liter diesel produces 2.8 kg CO₂ and the cost of removing 1 ton CO₂ from the atmosphere is 100 USD. The calculated environmental benefit of the large, medium and small solar irrigation pumps is shown in Table 10.

Table 10: Environmental Benefit of Large, Medium and Small SIP in 20 Years

Pumps	Coverage for Boro (bigha)	Required diesel (Liter)	CO ₂ emission reduction (Ton)	Cost of CO ₂ reduction (Tk)
Large	100	89400	250.32	2002560
Medium	50	45900	128.52	1028160
Small	16	15600	43.68	349440

Author's calculation based on field survey data, 2019; Here, 1 bigha=50 decimal, 1USD=80Tk.

The tentative total environmental benefits of the large, medium and small solar irrigation pumps in 20 years are about TK.2002560, TK.1028160, and TK.349440, respectively. On the other hand, the solar irrigation pump's main environmental cost is the emitted amount of CO₂ from solar PV panels' production process. Generally, the emitted amount of CO₂ is 170 Kg/kWp in manufacturing poly-crystalline silicon PV panels. Thus, the large, medium, and small solar irrigation pumps produce 5.1 ton, 2.55 ton, and 0.68 ton CO₂; the removal cost of these amounts of CO₂ is about TK.40800, TK.20400, and TK.5440, respectively. Therefore, the large, medium and small solar irrigation pumps' tentative net environmental gains are Tk.1961760, Tk.1007760, and Tk.344000, respectively.

4.4 Comparison of the Subsidy and Environmental Benefit of Solar Irrigation Pump

At present, 40% of a solar irrigation pump's total price is provided as a subsidy. The summary of the comparison between the given subsidies and the net environmental benefits of solar pumps has given in Table 11.

Table 11: Subsidy and Environmental Benefit of Different Solar Irrigation Pumps (Tk)

SIP	Panel capacity (kWp)	Price (Without subsidy)	Price (With subsidy)	Subsidy (40% of price)	Subsidy/kWp	Net Env. benefit in 20 years	Net Env. benefit /kWp
Large	30	4656400	2793840	1862560	62085	1961760	65392
Medium	15	3136580	1881948	1254632	83642	1007760	67184
Small	4	676880	406128	270752	67688	344000	86000

Source: Author's calculation based on field survey data, 2019; PO= Partner Organization, 1USD=80Tk.

Table 11 shows that the given subsidy is almost equal to the pumps' net environmental benefit in 20 years. The net environmental benefit per kWp of the large and medium solar irrigation pumps is almost equal at around TK.65000. However, the small solar irrigation pump's net environmental benefit per kWp is more than TK.85000. So, the calculated net environmental benefit per kWp of small SIP has become the highest. Finally, the environmental benefit has been calculated by considering only the substituted amount of diesel by solar energy. If the reduction of sound pollution and water contamination with diesel were considered, the solar pump's actual gain would be more than the calculated benefit.

5. CONCLUSION

In this study, an economic analysis of solar irrigation pumps' in the Northern region of Bangladesh has been performed. The financial analysis provides that small solar irrigation pumps' economic feasibility was found the most profitable option for investment. Large solar irrigation pumps' economic feasibility is also found moderately profitable, and it has been improved after the introduction of alternative use of the panels. However, the financial indicators do not give viable results in the case of medium SIPs. Therefore, the 'fees for ownership model' found a more profitable option than the 'fees for service model' for the solar irrigation pumps. 'Fees for ownership model' is also more effective in bringing the benefits of given subsidies and soft loans to the farmers. Moreover, the solar irrigation pump's net environmental benefit is greater than the given subsidy to install it. Thus, the provided grant has been justified for this investment. The government should continue providing subsidies for solar irrigation pumps, especially for small pumps, to promote the 'fees for ownership model'. It would ensure the quick dissemination of the solar pump and help to improve the condition of the country's farmers, agriculture, and environment.

ENVIRONMENTAL AMENITY AND RENTAL VALUE OF HOUSES IN RAJSHAHI CITY: A HEDONIC PRICING APPROACH

Md. Abdus Sobhan¹, Md. Elias Hossain²

¹MSS, Department of Economics, University of Rajshahi, Rajshahi-6205. sobhanshuvo2199@gmail.com; ²Professor, Department of Economics, University of Rajshahi, Rajshahi-6205. eliaseco@ru.ac.bd

ABSTRACT

Environmental amenities are great economic resources and important determinants of rental value of houses, because environmental dis-amenities reduces the rental demand for houses. However, measuring the value of environmental amenities is a complex issue and studies on the assessment of the value of environmental amenities (or dis-amenities) in house rental market of Bangladesh are scarce. In the empirical studies, a variety of methods were employed by the environmental economists to measure the value of environmental amenities in the case of house renting. However, the findings of the studies provoked considerable debates over the methods and approaches of measuring such amenities. As environmental amenity in case of house renting is a matter of mental satisfaction, it cannot be measured directly using the conventional methods. Thus, this study is an effort to investigate the determinants of rental value of houses and to measure the value of environmental amenities in connection with renting of houses based on Hedonic Pricing Approach. The study is based on primary data collected from 210 city dwellers who are living in rented houses in various areas of Rajshahi City Corporation in Bangladesh on the basis of random sampling method. The estimation results showed that there are four types of factors- income of tenant, house structure characteristics, neighborhood characteristics and environmental amenities including ventilation, open space proximity, drainage management, waterlogging and landfill by wastes which affect house rent. The disaggregated results show that in the planned housing areas, the influence of proximity to open spaces on house rent is 29.04% higher than that of unplanned housing areas, and the influence of ventilation on house rent in planned residential area is 15% higher than that of unplanned area. The willingness to pay or hedonic valuation for environmental amenities in overall, planned and unplanned areas are estimated as BDT146.16, BDT333.16, and BDT50.69, respectively. Tenants living in planned residential areas are more conscious about environmental amenities and their hedonic valuation for environmental amenities is higher than tenants living in unplanned areas. Finally, this study recommends that improving environmental quality boosts house rent, which in turn fascinates environment-friendly urbanization.

KEYWORDS

Valuation, Environmental Amenity, Hedonic Pricing, House Rental, Bangladesh.

1. INTRODUCTION

Valuation of environmental amenities (dis-amenities) is one of the central issues of study to the environmental economists. Environmental amenities mean the quality of environmental goods and services that reduces the adverse impact on health of the residents, or the environmental attributes that increase their economic welfare. However, the valuation of environmental attributes is a complex task and one cannot estimate market value of environmental attributes directly. Environmental attributes are often designated as environmental amenities or dis-amenities which have non-excludable and non-rival features and these implicitly determine the rental value in the house rent market. If the environmental amenities related to a house increase, the rental value of that house will increase and vice versa (Zoppi et al., 2015). In addition, environmental characteristics are also considered as a normal good which appeals more income generating tenants to choose their houses having much neighborhood and environmental facilities (Carriazo, Ready, & Shortle, 2013). Basic microeconomic theories explain that environmental amenities shift demand curve outward and thus, increases the rental value of houses (Dawkins & Nelson, 2002). Having a house is the basic constitutional right of the people in Bangladesh. Being one of the densely populated country in the world, Bangladesh has been experiencing severe house shortage for its citizens, especially in the urban areas.

Thus, a large portion of the urban residents have to depend on rented houses and there is a huge gap between demand for and supply of housing in the country (Barua, Mridha & Khan, 2010). Due to rapid migration of people in the urban areas creates huge shortage of houses ready for living. There are two types of urbanization where planned urbanization stimulates social and economic expansion through the advancement of physical arrangement, employment generation, enhancement in basic services and standard of living. In contrast, the unplanned urbanization increases urban poverty, joblessness, and environmental degradation (Loton, 2004). Bangladesh has been facing a rapid growth of both planned and unplanned urbanization in the recent years. Planned urbanization improves quality of roads, houses, schools, hospitals, and many other socio-economic structures. On the contrary, unplanned urbanization creates severe pressure on the physical and social infrastructure, deterioration of the urban environment and increase in road-noise, social crime and unrest (Ardeshiri, Radfar, & Shormasty, 2016). The rate of annual urbanization in Bangladesh was 3.17 percent in

2018 (World Bank, 2019). About 38.2 percent of the people of Bangladesh is now living in urban areas and it will be 50 percent by the year 2025 and 56 percent by 2050 (World Bank, 2019). One of the major consequences of rapid urbanization is the increased demand for houses and house rents in the housing market of urban areas.

The rental value of houses generally depends on structural, neighborhood, and environmental attributes (Babalola, Umar, & Sulaiman, 2013; Zoppi, Argiolas, & Lai, 2015). Irfan (2007) and Ooi, Le, & Lee (2014) observed that structural and neighborhood features explicitly determine house rents. Environmental amenities including an improved sewerage system, increases house rent while an environmental dis-amenity like open sewerage condition decreases house rents (Irfan, 2007). Other environmental amenities like parks, urban green spaces and watersheds have positive influence on house rents (Schlapfer, Waltert, Segura, & Kienast, 2015; Poor et al., 2007; Jim & Chen, 2006). Chen (2006) found that the proximity of open space to houses within 1 km increases house rents by 0.08 percent. Similarly, proximity of regional and metropolitan park within 600 meters increases houses rent by 1.9 and 2.9 percent, respectively (Smith, 2010). In contrast, landfilling by wastes decreases value of houses and distance of houses from landfill sites increases house price (Hite, Chern, Hitzhusen, & Randall, 2001).

In the theory of environmental valuation, there are several methods such as Contingent Valuation Method (CVM), Travel Cost Method (TCM), Hedonic Pricing Method (HPM) etc. that can be used to measure the value of environmental amenities. Among them Hedonic Pricing Model is widely used to measure the effects of environmental amenities on the rental value of houses. However, all the studies are mostly concerned with the developed country scenario and there is a dearth of literature on the effects of environmental amenities on house rent in the developing countries like Bangladesh. Rajshahi is one of the largest cities in Bangladesh. Because of rapid urbanization and growing scopes for income earning activities, there is found an increasing inflow of migrant people into the city. Unable to buy a house, most of these people have to rent houses and the payment for houses depends on their valuing of environmental amenities. Therefore, this study aims at estimating the hedonic value of environmental amenity and making comparison of house rents between planned and unplanned residential areas resulting from varying environmental amenity focusing on the house rent market in Rajshahi City Corporation area of Bangladesh. This study uses house rent as proxy variable to estimate the economic value of environmental amenities and dis-amenities.

The rest of the paper is organized as follows: section 2 describes the methodology of the study; section 3 provides the results and their interpretations; section 4 gives concluding remarks.

2. METHODOLOGY

2.1. Study Area and Survey Design

Rajshahi City Corporation is taken as the sample area for this study. It is one of largest city corporations in Bangladesh which is lived by peoples of different occupations, income levels and education. The respondents of the study area are the tenant households who have rented houses for living in different residential areas of the city. Rajshahi city corporation area is a typical area like other areas where income is the most relevant factor that determine the rental value of the respondent residence. However, there are some other factors as well which determine the rental value. For this study, primary data are collected from the respondents living in the study area based on simple random sampling method, and most of them have been living in multistoried buildings in planned and unplanned residential areas. A total of 210 respondents are taken where are 100 from planned residential areas and 110 from unplanned residential areas from five *thanas*: *Boalia, Rajpara, Motihar, Shah makhdum and Chandrima* of Rajshahi City Corporation. The interview is conducted with the household head or any other member who usually participates in the household decision-making process. A semi-structured questionnaire with both open and close-ended questions were used for data collection. Data are collected in a very sensitive way so that they can be fitted for estimation of specified models in this study.

2.2: Theoretical Background

In the hedonic pricing approach, household's willingness to pay for differentiated environmental amenities is computed through maximizing their utility function with respect to budget constraint as follows. The utility function of a household in the hedonic model is:

$$U = U(C, H, N, E) \tag{1}$$

Where, C is a composite good index, H refers to structural attributes of house ($H = H_1, H_2, \dots, H_n$), N refers to the neighborhood attributes ($N = N_1, N_2, \dots, N_n$), and E refers to the environmental attributes ($E = E_1, E_2, \dots, E_n$). We maximize households' utility, reported in equation (1) subject to the following budget constraint.

$$I - CP_c - R = 0 \tag{2}$$

Where, R denotes the prices of consumption goods included into the index and refers to monthly house rents. With the rapid progression of urbanization, renting built houses is quite common in Rajshahi City. Therefore, this study has used rental price instead of sales value by following two recent studies, Van den Berg and Nauges (2012) and Dendup and Tshering (2015). These studies suggest house rent is the function of structural, neighborhood and environmental attributes and thus, rent function is defined as follows.

$$R = R(H, N, E) \tag{3}$$

$$I - CP_c - R(H, N, E) = 0 \tag{4}$$

For maximizing the utility function, we differentiate equation (1) with respect to revised budget constraint as shown in equation (4). From this process, the following implicit price for each environmental attribute can be derived as follows:

$$\frac{dR}{dE} = \frac{dU/dE}{dU/dC} \tag{5}$$

Equation (5) represents the marginal rate of substitution (MRS) between environmental attributes E and a composite good index C , and setting them equal to the rate through which household can exchange E for C in the housing market.

2.3 Econometric Model

This study followed the Dendup and Tshering (2015) approach for choosing appropriate functional forms among the alternatives- linear, logarithmic and semi-logarithmic forms of hedonic models. Since equation (5) shows that house rent depends on environmental attributes E and a composite good index C , we can re-write the equation (5) in the form of population regression function as follows:

$$R_i = X_i\alpha + \varepsilon_i \tag{6}$$

Where, subscripts i specifies households while R_i is the natural log of monthly house rent. Vector X_i denotes a set of independent variables including housing and neighborhood featured as composite goods C and environmental attributes E . Whereas, α is the vector of the coefficient to be estimated and ε_i is the stochastic error term. Simplification of equation (6) can be done as follows:

$$R_i = \alpha_0 + \alpha_1(\text{income}) + \alpha_2H_{ij} + \alpha_3E_{im} + \alpha_4N_{in} + \varepsilon_i \tag{7}$$

where, income represents the monthly income of the head of the households; H represents the structural attributes - age of the building, the numbers of room and garage within the house; E includes the environmental attributes including ventilation, open space, waterlogging and landfills, and N refers to the neighborhood attributes including school and workplace distances. Including these components, the specified form of the hedonic pricing equation which is used in this study is given by Equation (8):

$$\ln Y_i = \alpha_0 + \alpha_1X_{1i} + \alpha_2X_{2i} + \alpha_3X_{3i} + \alpha_4X_{4i} + \alpha_5X_{5i} + \alpha_6X_{6i} + \alpha_7X_{7i} + \alpha_8X_{8i} + \alpha_9X_{9i} + \alpha_{10}X_{10i} + \alpha_{11}X_{11i} + u_i \tag{8}$$

In the above Equation (8) it is specified that $\ln Y_i$ is natural logarithm of monthly house rent; α_0 is the intercept or constant and $\alpha_0 \dots \alpha_{11}$ are the parameters to be estimated; $X_1, X_2, \dots X_{11}$ are the explanatory variables that affect monthly earning of the households and u_i is the stochastic disturbance term. The regression function expressed by the equation (8) is a linear multiple regression model and this equation can be estimated by the Ordinary Least Square (OLS) method. The functional form of the regression model is semi-logarithmic more definitely log-linear.

2.4 The Willingness to Pay Value

Willingness to pay (WTP) is been defined as the maximum amount of money a customer is willing to spend for a product or service (Cameron and James, 1987; Krishna, 1991. Economists refer to WTP as the reservation price (Monroe, 1990). A few studies have tested willingness to pay in relation to product development and market pre-tests (Cameron and James, 1987). Studies of willingness to pay have also been conducted in the food area (Loureiro *et al.*, 2002; Moon and Balasubramanian, 2003). Several approaches can be used to elicit consumers’ willingness to pay for products or services including contingent valuation, experimental auctions, conjoint analysis and hedonic price methods (Lee and Hatcher, 2001). This study has tried to find out the willingness to pay for different environmental attributes as well as other attributes on house rent estimated from equation (8) and a threshold level of environmental (dis)amenities. Following Van den Berg and Nauges (2012) and Yusuf and Koundouri (2005), the WTP is measured as follows:

$$WTP_j = R(e^{\hat{\beta}_j} - 1) \tag{9}$$

Where R is average monthly rent of a house, and $\hat{\beta}_j$ is estimated coefficient of environmental and other attributes (in equation 8).

2.5 Data and Explanation of the Key Variable

The following Table list and defines the dependent and explanatory variables with a unit of measurement used in the interview schedule. The first section introduces the outcome variable and the rest four sections contain explanatory variables of this study. The outcome variable is the monthly house rent. In this study, household income accounts for the accumulated income of all earning members of the households and it is measured in BDT per month. The house rent is expected to be strongly and positively associated with household income. This is because households with higher income usually prefer to rent costlier houses as suggested by basic microeconomic theory.

Table 1: Explanation of the Key Variables

Variable Name	Explanation	Mea.Unit	Expe.Sign
Rent	Monthly house rent	BDT/month	
Income	Household income	BDT/month	+
Structural Characteristics			
Age of the building	Years from building built to date	Years	-
Room numbers	Number of bedrooms	Number	+
Garage	Availabilities of garage within house	Yes/No(1/0)	+
Neighborhood Characteristics			
Workplace distance	Distnce between house and workplace	Kilometers	-
School distance	Distane between house and school	kilometers	-
Environmental characteristics			
Open space	Distance of at least a small play ground	meters	-
Ventilation	Strongly unsatisfactory to srongly satisfactory	5-point scale	+
Waterlogging	Availability of waterlogging	Yes/No(1/0)	-
Landfill	Availability of Landfill	Yes/No(1/0)	-

Drainage/Sewage	Strongly unsatisfactory to strongly satisfactory	5-point scale	+
-----------------	--	---------------	---

For accounting the effect of physical structure on rent, the number of rooms and the presence of garages are expected to impact the house rents positively while age of the house is expected to impact it negatively. On the other hand, the neighborhood characteristics account the distances from houses to the work place and nearest school. In all these cases, the expected signs are negative, implying, the higher the distance to the nearest neighborhood variables is expected to reduce rents. The final section of the Table lists and defines the variables associated with the environmental characteristics including ventilation, proximity to open space, waterlogging, landfill and drainage or sewage system. For constructing 'ventilation' and 'drainage' variable, we take a perception measurement by using 5-point Li-kert scale from the strongly unsatisfactory to strongly satisfactory of ventilation service of air and light flow and drainage condition respectively. In addition, we measured the distance from house to open spaces i.e. park, playground or public garden in meter. We expect a positive association between ventilation and rent and similarly drainage and rent, while increase in distance of open space is expected to reduce rent in the house market. However, variables representing environmental dis-amenities such as waterlogging and landfill are also constructed through category variable where '0' indicates the absence and '1' indicates the presence of these factor. Therefore, house rent is also expected to have inverse association with the increase in waterlogging and landfill degradation level.

3. RESULTS AND DISCUSSIONS

3.1. Summary Statistics

Table 2: Summary Statistics of Key Variables

Variables		Overall Area	Planned area	Unplanned Area
	Measurement	Mean	Mean	Mean
Rent	BDT/Month	10226.19	13940	6850
Income	BDT/Month	61190.48	78650	45954
Age of house	Years	8.63	6.44	10.25
Room number	Number	3.49	4.24	2.70
Garage space	0=No	53.81%	31%	36.36%
	1=Yes	46.19%	69%	63.64%
Work place dis.	Kilometer	2.08	1.12	2.60
School distance	Kilometer	1.53	0.96	2.15
Open space dis.	Meter	138	83	144
Ventilation	1-5 scale	3.19	3.29	2.81
Waterlogging	0=No	57.14%	79%	66.36%
	1=Yes	42.86%	21%	33.64%
Landfill	0=No	59.52%	91%	80%
	1=Yes	40.48%	9%	20%
Drainage/Sewage	1-5 scale	3.22	3.58	2.61

Source: Author's Own Calculation Based on Field Survey, 2020.

The summary statistics of housing attributes in the overall, planned and unplanned residential area in Rajshahi City Corporation are presented in Table 2. In overall residential area, average house rent is around BDT 10226.19 per month varying from BTD 5000 to 18000. The house rent payment in planned residential area is higher than unplanned residential area because higher income earning people live in planned residential area. The monthly household income of overall residential areas is 61190 per month varying from BTD 30000 to 100000. Table 2 depicts that average age of the houses in overall area is around 8 years and varying from 2 to 20 years in overall areas in the Rajshahi City Corporation. The most of the buildings in planned area are newly built while most of the building in unplanned areas are old-aged. In addition, a three-room-flat dominates the housing rent market and there is also difference is observed in this attribute across the planned and unplanned areas. In planned residential areas, most of the neighborhood attributes are closer to access while in unplanned areas are opposite in this regard. For one of the most important sets of attributes is environmental attributes in the housing market. Table 2 reports that the average distance of open space proximity is around 138 meter in overall area and varying from 5 to 300 meter. The average ventilation and drainage system score in overall area is around 3.19 and 3.22 respectively. The average waterlogging and landfill presence in overall area is around 79 and 91 percent respectively. There is a quite difference regarding environmental attributes in planned and unplanned residential areas where comparatively higher ventilation scores, closer proximity to open spaces, improved drainage system, less severity of waterlog and landfill exist in to unplanned residential areas.

3.2 The Determinants of House Rent in Overall Rajshahi City Corporation Area.

The environment of Rajshahi City is quite suitable for living because of its natural beauty and cleanliness. For this reason, this city is known as clean city. As a result, there is a large number of people are migrated from another city to this city. Thus, there is rapid urbanization in the city and growing up housing industry. Besides, there is also a threat of environmental degradation. This study is based on hedonic pricing method to find out the determinants of rental value of houses and valuation for environmental amenities. The results estimated from the hedonic pricing approach of equation (8) are reported in Table 3. It is found that the value of R² is 0.9543. This value of R² indicates that about 95% of variations in the dependent variable are explained by the variations in explanatory variables taken in the model.

Multicollinearity problem is diagnosed by VIF test and partial correlation matrix. The value of VIF is 4.07, which indicates that the regression model is free from multicollinearity problem. From the obtained result it is also revealed that the sum (as its mean=0) of residual is equal to zero and the distribution of residual is normal.

Table 3: Regression Result of the Hedonic Pricing Model of Overall Area

N= 210; F(11,198); = 669.82; Prob.>F= 0.0000 ; R² = 0.9543; VIF=4.07

Note: Significant at: ***p<0.01, **p<0.05, *p<0.1. Source: Author’s Own Calculation, 2020.

In the above table, it is observed that the determinants of house rent are classified by four attributes. We found income is positively and highly significant associated with house rent at 1 percent level of significance, if all other things being constant, as expected. In regarding structural attributes, it depicts that, the age of building, the number of rooms, space for garages are the most relevant factors that determine the extent of house rent. Here, the number of rooms are significant at 5 percent level of significance which implies that, a one additional unit increase in the number of room is associated with rise in house rent by 1 percent, being remain constant other factors. The work place distance is significant at 5% level of significance and negatively influence on house rent. The most important and relevant attribute is the environmental attributes which include distance of open space; at least a small playground from house, the condition of ventilation of house which is measured by 1-5 point scale where 1 indicates the strongly unsatisfactory condition and 5 indicates strongly satisfactory condition, waterlogging and landfill are categorical variable where 0 indicates absence of that factor and 1 indicates presence of that factor, and drainage/sewage system which is also measured by 1-5 point scale where 1 indicates the strongly unsatisfactory condition and 5 indicates strongly satisfactory condition. Here, distance of open space; at least a small playground from house is significant at 10% level of significance and negatively associated with house rent. Truly speaking, tenant are less agreed to pay more for the house if open space distance increases. It implies that a one unit increase in the open space distance is associated with reduce in house rent by 0.5 percent, being remain constant other factors. The ventilation and drainage are measured by 1-5 point scale and it is observed that they are positively significant at 5 and 1 percent level of significance respectively. It implies that a one unit increase in the condition of ventilation and drainage is associated with rise in house rent by 1 and 2 percent respectively, being remain constant other factors. The rest of the factors like waterlogging and landfill are negatively associated with house rents. It implies that a one unit increase in waterlogging and landfill associated with reduce house rent by 1and 1percent respectively, being remain constant other factors. This result is very similar to the results found by earlier studies conducted by previous researchers, (Schlapfer, Waltert, Segura, & Kienast, 2015; Poor at el., 2007; Jim & Chen, 2006).

3.3 Determinants of House Rent in Planned Area, Rajshahi City Corporation

The planned residential area where everything is monitored by central authority.

Table 4: Regression Result of a Hedonic Pricing Model of Planned Area

Explanatory variable	Coefficient	Robust Std. Err.	t-ratio	P-Value
Income	.0000011***	.0000003	3.22	0.002
Age of house	-0.0044***	0.0016	-2.68	0.009
Room number	0.0039**	0.0017	2.23	0.028
Garage	0.0137***	0.0043	3.16	0.002
Work place distance	-0.0100***	0.0030	-3.33	0.001
School distance	-0.0217	0.0165	-1.32	0.192
Open space distance	-0.0117***	0.0038	-5.25	0.000
Ventilation	0.0117***	0.0027	4.27	0.000
Waterlogging	-0.0118*	0.0062	-1.91	0.059
Landfill	-0.0028	0.0041	-0.68	0.497
Drainage/Sewage	0.0046**	0.0022	2.05	0.043
Constant	4.0504	0.0410	98.76	0.000

N= 100; F(11,88); = 196.69; Prob>F= 0.0000 ; R² = 0.9531; Root MSE= 0.01605; VIF=3.52

Note: Significant at: ***p<0.01, **p<0.05, *p<0.1. Source: Author's Own Calculation, 2020.

It is found that income is positively and highly significant associated with house rent at 1 percent level of significance, remaining other factor constant in planned residential area. Among the three structural attributes, the number of rooms are significant at 5 percent level of significance which implies that, a one unit increase in the number of room is associated with rise in house rent by 0.3 percent, being remain constant other factors. The work place distance is significant at 1% level of significance and negatively influence on house rent. Here, distance of open space; at least a small playground from house is significant at 1% level of significance and negatively associated with house rent. It implies that a one unit increase in the open space distance is associated with reduce in house rent by 1.1 percent, being remain constant other factors. The ventilation and drainage are measured by 1-5 point scale and it is observed that only ventilation is positively significant at 1 percent level of significance. It implies that a one unit increase in the condition of ventilation is associated with rise in house rent by 1.1 percent, being remain constant other factors. The drainage is significant at 5 percent level of significance and its sign is positively related to determine the extent of house rent. The rest of the factors like waterlogging and landfill are negatively associated with house rents. This result is very similar to the results found by earlier studies conducted by previous researchers, (Schlapfer, Segura, & Kienast, 2015; Poor at el., 2007).

3.4 Determinants of House Rent in Unplanned area, Rajshahi City Corporation.

The unplanned area can be defined as every socio-economic activities are not governed by a central authority. Here, distance of open space; at least a small playground from house is significant at 5 % level of significance and negatively associated with house rent. The ventilation and drainage are measured by 1-5 point scale and it is observed that only drainage is positively significant at 10 percent level of significance. Unfortunately the ventilation is not significant but its sign is positively related to determine the extent of house rent. The rest of the factors like waterlogging and landfill are negatively significant at 10 and 10 percent level of significance respectively. It implies that a one unit increase in waterlogging and landfill associated with reduce house rent by 1 and 1 percent respectively, being remain constant other factors. This result is very similar to the results found by earlier studies conducted by previous researchers, (Schlapfer, Waltert, Segura, & Kienast, Jim & Chen, 2006).

3.5 The Willingness to Pay for Environmental (Dis) amenities in Overall, Planned and Unplanned Area, Rajshahi City Corporation

In this section, this study shows the tenant's willingness to pay value of environmental (dis)amenities and other attributes from estimated coefficients of equation (8) and (10) and a set of threshold values for these parameters reported in Table 6. In overall area, the tenants are willing to pay more BDT 0.039 from their average rent because of an additional unit increase in income remaining other attributes constant. In case of structural attributes including age of house, the tenants are willing to pay less BDT 60.33 from their average rent associated with an additional unit increase in the age of house. The tenants also willing to pay more for room number, and garage availability are BDT 104.307 and BDT 112.48 respectively from their average rent. In case of neighborhood attributes including workplace and school proximity, the tenants are willing to pay more BDT 61.35 and BDT 30.37 from their average rent because of an additional unit of closer proximity.

Table 6: Results of Willingness to Pay Analysis

Attributes	Overall Area		Planned Area		Unplanned Area	
	WTP(BDT)	HV(BDT)	WTP(BDT)	HV(BDT)	WTP(BDT)	HV(BDT)
Income	0.039	0.039	0.015	0.015	0.007	0.007
Structural Attributes						
Age house	-60.33		-61.33		-0.54	
Room number	104.307	156	54.36	289.94	138.37	192.63
Garage availability	112.48		181.22		54.8	

Neighborhood Attributes						
Work place proximity	61.35	92.02	139.4	168.27	34.25	58.22
School proximity	30.67		29.27		23.97	
Environmental Attributes						
Open space proximity	51.13		306.68		41.1	
Ventilation availability	123.73		163.09		64.39	
Waterlog presence	-153.39	146.16	-164.49	333.16	-68.5	50.69
Landfill presence	-103.28		-27.88		-68.5	
Proper drainage	227.97		055.76		82.5	

Source: Author's Own Calculation, 2020.

The most important environmental attributes including open space proximity, tenants are willing to pay more BDT 51.13 from their average rent with an additional unit of closer proximity. In accordance with ventilation facilities and proper drainage management system, the tenants are willing to pay more BDT 123.73 and BDT 227.97 from their average rent because of an additional unit increase in 5-point scale from strongly unsatisfactory to strongly satisfactory. In contrast, tenants are willingness to pay less BDT 153.39 and BDT 103.28 from their average rent because of an additional unit increase in waterlog and landfill availabilities. Here, the hedonic value of structural, neighborhood and environmental (dis) amenities are BDT 156, BDT92.02, and BDT 146.16 respectively. Since in Bangladesh People are not much conscious of environmental issues, tenants are valuing first structural attributes and then environmental attributes in the study area.

Again, in planned area, the tenants are willing to pay more BDT 0.015 from their average rent because of an additional unit increase in income remaining other attributes constant. In case of structural attributes including age of house, the tenants are willing to pay less BDT 61.33 from their average rent associated with an additional unit increase in the age of house. The tenants also willing to pay more for room number, and garage availability are BDT 54.36 and BDT 181.22 respectively from their average rent.

In case of neighborhood attributes including workplace and school proximity, the tenants are willing to pay more BDT 139.4 and BDT 29.27 from their average rent because of an additional unit of closer proximity. The most important environmental attributes including open space proximity, tenants are willing to pay more BDT 306.68 from their average rent with an additional unit of closer proximity. In accordance with ventilation facilities and proper drainage management system, the tenants are willing to pay more BDT 163.09 and BDT 55.76 from their average rent because of an additional unit increase in 5-point scale from strongly unsatisfactory to strongly satisfactory. In contrast, tenants are willingness to pay less BDT 163.09 and BDT 163.49 from their average rent because of an additional unit increase in waterlog and landfill availabilities. Here, the hedonic value of structural, neighborhood and environmental (dis) amenities are BDT 289.94, BDT 168.27, and BDT 333.16 respectively. Since in planned area tenants are much conscious of environmental issues, tenants are valuing first environmental amenities and then structural attributes in the study area. In unplanned area, the tenants are willing to pay more BDT 0.007 from their average rent because of an additional unit increase in income remaining other attributes constant. In case of structural attributes including age of house, the tenants are willing to pay less BDT 0.54 from their average rent associated with an additional unit increase in the age of house. The tenants also willing to pay more for room number, and garage availability are BDT 138.37 and BDT 54.58 respectively from their average rent. In case of neighborhood attributes including workplace and school proximity, the tenants are willing to pay more BDT 34.25 and BDT 23.97 from their average rent because of an additional unit of closer proximity. The most important environmental attributes including open space proximity, tenants are willing to pay more BDT 41.1 from their average rent with an additional unit of closer proximity. In accordance with ventilation facilities and proper drainage management system, the tenants are willing to pay more BDT 64.39 and BDT 82.5 from their average rent because of an additional unit increase in 5-point scale from strongly unsatisfactory to strongly satisfactory. In contrast, tenants are willingness to pay less BDT 68.5 and BDT 68.5 from their average rent because of an additional unit increase in waterlog and landfill availabilities. Here, the hedonic value of structural, neighborhood and environmental (dis) amenities are BDT 192.63, BDT 58.22, and BDT 50.69 respectively. Since in unplanned area, tenants are not much conscious of environmental issues, tenants are valuing first structural attributes and neighborhood attributes and then environmental attributes in the study area. This result is very similar to the results found by earlier studies conducted by previous researchers, such as *Md. S. Islam, et al. (2017), Smith (2010) and Van den Berg, C., & Nauges, C. I. (2012).*

4. CONCLUSION

In the planned areas, tenants are much conscious of environmental issues, tenants are valuing first environmental amenities and then structural attributes in the study area. In contrast in unplanned area, tenants are not much conscious of environmental issues, tenants are valuing first structural attributes and neighborhood attributes and then environmental attributes in the study area. This study has found the determinants of house rents and the value of environmental (dis)amenities in the housing area of Rajshahi city. In this regard, I have adopted a widely used hedonic pricing approach. To my best knowledge, this is the first attempt to investigate the determinants of house rents and the value of environmental (dis)amenities in the housing market of Rajshahi city. On the basis, these findings, some policies can be suggested on these issues like policy maker of the urban area and developers may be conscious about the importance and necessity of the residential structures, location and environmental quality. In the contrary, policy makers, government and non- government authorities may take necessary steps to improve urban residential environment and

ensures the better living standard for the people living in the Rajshahi City. However, there may be common mistakes in case of measurement. It is expected that, future researchers would pay proper attention to the limitations of this study.

SPATIAL AGGLOMERATION AND FIRM PRODUCTIVITY: DOES TRADE STATUS MATTER?

Jian Wang^{1,2}, Qing Liu³

¹Shanghai University, China. ²University of Technology Sydney, Australia. ³Hefei University of Technology, China

ABSTRACT

This study uses micro-level panel data from Chinese manufacturing firms to investigate the impact of urban agglomeration on firm productivity taking a firm's engagement in international trade into consideration. Embracing firm heterogeneity in trade status, we find that non-exporters benefit from urban agglomeration through manufacturing specialisation whereas little effect of local specialisation on productivity is found among exporters. The findings mainly are driven by processing exporters involved in straightforward assembly. These findings increase the understanding of heterogeneous productivity gains from urban agglomeration and the spatial economy in China.

RESEARCH ON THE EFFICIENCY OF TECHNOLOGICAL INNOVATION IN CHINESE INDUSTRIAL ENTERPRISES

ABSTRACT

This paper mainly studies the technological innovation efficiency of Chinese industrial enterprises. First, use the SBM-DEA model to measure and analyze the two-stage and comprehensive technological innovation efficiency of industrial enterprises from 2011 to 2019; secondly, use the method of spatial statistics to analyze the spatial correlation of the comprehensive technological innovation efficiency; finally, use the tobit measurement model to empirically analyze the influencing factors of the comprehensive technological innovation efficiency. Through analysis, it is concluded that the overall level of comprehensive innovation efficiency of Chinese industrial enterprises is not high, the gap between regions and provinces is obvious, and the efficiency of technological innovation in the two stages is not coordinated. The comprehensive technological innovation efficiency level is highest in the eastern region, and the lowest in the northeast. From the perspective of spatial statistical analysis, the comprehensive technological innovation efficiency of inter-provincial industrial enterprises has obvious spatial agglomeration. From the perspective of factors affecting the efficiency of technological innovation, the eastern region is mainly affected by R&D capital investment; the central region is mainly affected by the investment of R&D personnel, high-speed rail density, enterprise scale and economic development level; the western region is mainly affected by government intervention and R&D capital investment and R&D personnel; Northeast China is mainly affected by the density of high-speed rail, the scale of enterprises and the level of regional economic development.

KEYWORDS

Industrial enterprise; technological innovation efficiency; spatial statistical analysis

1. INTRODUCTION

At present, China's economic development is facing a new normal, and the driving force of economic development is changing from factor-driven and investment-driven to innovation-driven (Xiao Renqiao, Wang Zongjun, Qian Li, 2015:190-201). Industrial enterprises are the most important industrial carriers of technological innovation, and their technological innovation efficiency level not only determines the technological innovation level of the industry in which they are located, but to a large extent also determines the efficiency of technological innovation in the entire country. In the context of increasing investment in technological innovation of industrial enterprises, what is the efficiency of technological innovation? How is it distributed in space, and what is the relationship? Analyzing the status quo of technological innovation efficiency of industrial enterprises and finding out the existing problems are of great significance to the transformation and upgrading of industrial enterprises. Based on this, this paper selects inter-provincial industrial enterprises above designated size (from 2011, industrial enterprises above designated size whose main business income is 20 million yuan and above) as the research object, analyze their technological innovation efficiency, and try to find out Factors that affect the efficiency of technological innovation of industrial enterprises, so as to better promote the high-quality development of industrial enterprises.

2. LITERATURE REVIEW

The research on the efficiency of technological innovation has always been a hot topic in the academic circles. The research on the efficiency of technological innovation of industrial enterprises mainly focuses on the following aspects: ①Evaluation of the innovation efficiency of industrial enterprises in different regions. Chen Wei et al. (2017:66-71) took large and medium-sized industrial enterprises in Northeast China as the research object, and used the Malmquist index method to analyze the dynamic trend of technological innovation efficiency and its influencing factors. Xu Min and Xie Lingling (2012:74-76) analyzed the efficiency of technological innovation by taking Chinese large and medium-sized industrial enterprises as the research object. ②The measurement of technological innovation efficiency of industries and industrial enterprises of different ownerships. Feng Genfu (2006:46-51) selected 35 industries from 1996 to 2004 as samples, and used SFA methods to conduct empirical research on the R&D efficiency and influencing factors of Chinese industrial enterprises. Xiao Renqiao (2015:190-201), etc., based on the perspective of two-stage value chain, constructed a two-stage association network DEA model and index system, and used panel data to calculate the staged and overall efficiency value of technological innovation of different industrial enterprises in China. ③Study on the influencing factors

of technological innovation efficiency of industrial enterprises. Du Kang et al. (2019:41-48), taking Anhui industrial enterprises as an example, used Malmquist productivity index method to empirically analyze its total factor productivity and its influencing factors. Wu Shijian et al. (2018:181-189) empirically analyzed the technological innovation efficiency of industrial enterprises and its influencing factors based on the two-stage DEA model.

The existing literature enriches the research results of technological innovation efficiency of industrial enterprises, but it also has some shortcomings: ①In the research content, it basically focuses on the input-output single-stage mode, which usually regards the innovation process of enterprises as a "black box". Although some literatures begin to study from the perspective of R&D-transformation, quantitative analysis methods need to be further supplemented in this field. ②From the perspective of time and space, existing research focuses on the time dimension, ignoring the spatial changes of the research objects. Therefore, this paper uses the two-stage network DEA model to divide the innovation process into two stages: technological research and development and technological achievements transformation, which opens the "black box" of enterprise innovation activities to a certain extent and provides help for finding the lack of efficiency in the process of technological innovation; And use the method of spatial statistics to analyze its spatial characteristics to understand its spatial relevance.

3. EFFICIENCY EVALUATION METHOD AND TWO-STAGE MODEL

3.1. Network SBM-DEA model

The traditional DEA model regards the decision-making unit as a "black box", and the input is transformed into output through the "black box", without considering the operation and integration of internal resources in the "black box", which is not suitable for processes involving multiple subsystems; In addition, the traditional DEA model is a radial model, and the improvement of input-output must be equal, without considering the influence of input and output relaxation variables. The network SBM-DEA model proposed by Tone and Tsutsui (2009:243-252) is used to evaluate the efficiency of the whole decision-making unit and its constituent departments. This model has the characteristics of non-radial, and overcomes the limitation of "input-output" and other proportions (non-equal proportions), thus making the efficiency measurement more accurate and reasonable.

3.2. Construction of two-stage model

3.2.1. *The division of two stages in the process of technological innovation*

Because of the different perspectives and contents of the research on technological innovation, there is no uniform standard to divide the technological innovation process in academic circles. Based on the research of Dou Chao, Xiong Xi et al. (2019:77-85) and Du Debin, Liu Shufeng et al. (2019:173-182), this article believes that the innovation process of industrial enterprises is based on the existing innovation knowledge, and develops new knowledge, technology, etc., and then apply the new technology to the company's own services and products, so as to bring profits to the company. Therefore, this article divides the technological innovation process of industrial enterprises into two stages: technological research and development and technological achievement transformation. By measuring the efficiency value of each stage, find the specific links that lead to inefficiency.

3.2.2. *Selection of lag period*

Most studies have found that the impact of R&D investment on R&D output generally has a time lag of 1-2 years. This paper summarizes the principle analysis and time lag setting of innovation activities by scholars such as Nasierowski (2003: 215-234), Yu Yongze (2013:6-20) and Xiao Renqiao (2015:190-201). Combined with the characteristics of technological innovation in industrial enterprises, the time lag period of both stages is set to 1 year, and the lag period of the whole innovation process is 2 years. That is to say, the data of 2011-2017 are used for investment in technology R&D stage, 2012-2018 for output in technology R&D stage and 2013-2019 for output in technology transformation stage. In this way, the entire research period (2011-2019) of this article is divided into 7 periods: the first period (2011-2013), the second period (2012-2014), the third period (2013-2015), the fourth period (2014-2016), the fifth period (2015-2017), the sixth period (2016-2018), and the seventh period (2017-2019).

3.3. Selection of indicator system

3.3.1. *Investment indicators for technology research and development stage*

The investment in technology R&D stage mainly includes manpower and capital elements, and manpower elements mainly refer to the input of R&D personnel in this stage. In this paper, the full-time equivalent of R&D personnel, which is commonly used in the world, is used to measure the input of R&D personnel. As for the investment of capital elements, most scholars at home and abroad choose the internal expenditure of R&D funds as the index to measure the capital investment, and this general practice is followed in this paper.

3.3.2. *Output index of technology research and development stage*

The output index of the technology research and development stage is both the output variable of the first stage and the input variable of the second stage. Scholars (Chen H, Xu R, Feng Z, 2013: 3169-3173; Zhang Baichun, Fan Decheng, Sheng Nan, 2018: 901-912) mostly choose the number of patent applications or the number of patent grants as a measure of

output at this stage. Taking into account that patents are easily affected by other factors from application to grant, they cannot show the true results of enterprise technological innovation activities in a timely manner, and the number of patent applications can better reflect the company's R&D results, so the number of patent applications is selected as the output indicator at this stage.

3.3.3. Input indicators in the transformation stage of technological achievements

In the transformation stage, besides the output of the previous stage as input, it also needs the input of manpower and capital.

Generally speaking, the exploratory and professional aspects of the achievements transformation stage are relatively lower than those of the R&D stage, and more personnel input is needed. Referring to the research of Liu Hui, Huang Fen and others (2015:19-33), the number of personnel in R&D institutions is selected to represent the personnel input at this stage.

The technology transformation stage is mainly to use new technologies to develop new products, so it requires investment in new product development funds. In addition, the core technologies of some industries and fields need to be purchased to make up for their deficiencies. In addition, the transformation from technology to products still requires digestion, absorption, and transformation to promote the practical application of scientific and technological achievements (Zhang B, Luo Y, Chiu Y H, 2018). In this paper, the four items of industrial enterprise technology introduction, digestion and absorption, domestic purchase and transformation expenditures are summed into technical expenditures as another aspect of this stage of expenditures. Therefore, the funding for this stage includes new product development funding and technical funding.

3.3.4. Output indicators in the transformation stage of technological achievements

The stage of technological transformation is the process that enterprises transform technological innovation value into product innovation value and realize commercialization. The new products produced by industrial enterprises reflect the innovative value of technology application and commercialization through technological innovation (Chen K, Kou, Fu X, 2018).

3.4. Data sources and processing

3.4.1. Data sources

In this paper, the data of industrial enterprises above designated size in 27 provinces of Chinese mainland from 2011 to 2019 are taken as research samples (excluding Xinjiang, Tibet, Qinghai and Hainan). The data used in the efficiency evaluation part comes from China Science and Technology Statistical Yearbook and China Statistical Yearbook from 2012 to 2020. If there is any missing data in the intermediate years, it should be filled by interpolation. If the data of boundary year is missing, it will be filled by extrapolation.

3.4.2. Data processing

In order to avoid the impact of price fluctuations on the analysis results, using 2011 as the base period, the nominal variables were deflated using the price indices of the corresponding years in each province. The sales income of new products is deflated using the ex-factory price index of industrial products; the internal expenditure of R&D expenditure is deflated using the R&D expenditure price index. For the R&D expenditure price index, this article refers to Lobe, P., and V.lin (1997: 272-278), Zhu Pingfang and The research of Xu Weimin (2003(6)) et al, structured it according to the detailed composition ratio of internal R&D expenditures.

According to the use of internal R&D expenditures in the "China Science and Technology Statistical Yearbook", the R&D expenditures are divided into two categories: daily expenditures and asset expenditures. Since the internal expenditures of R&D expenditures use data from 2011-2017, the calculation of 2011- In 2017, these two types of expenditures accounted for the proportion of internal R&D expenditures, and finally got the R&D expenditure price index=0.89*consumer price index+0.11*fixed asset investment price index; technical expenditures and new product development expenditures were also deflated according to this method.

4. MEASUREMENT OF TECHNOLOGICAL INNOVATION EFFICIENCY OF INDUSTRIAL ENTERPRISES

Based on the evaluation index system of technological innovation efficiency established above, this paper measures and analyzes the technological innovation efficiency of China's industrial enterprises as a whole, four major regions and provinces by using the network SBM-DEA model. The efficiency values of the four regions are obtained by averaging the efficiency values of the provinces in each region, and the national efficiency values are obtained by averaging the efficiency values of the 27 provinces in China. The four major regions are East, Central, West and Northeast China, among which the eastern region includes Beijing, Tianjin, Hebei, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong and Guangdong; The central region includes Shanxi, Anhui, Jiangxi, Henan, Hubei and Hunan; The western region includes Inner Mongolia, Guangxi, Chongqing, Sichuan, Guizhou, Yunnan, Shaanxi, Gansu and Ningxia; Northeast China includes Liaoning, Jilin and Heilongjiang. The software used in the analysis is dea-solver pro13.

This part first analyzes the two-stage technological innovation efficiency, and then takes the technological innovation process as a whole and analyzes the comprehensive technological innovation efficiency. In order to reflect the change trend and overall characteristics of the efficiency value of the country and each region, a line chart of the efficiency value

of the country and the four major regions has been drawn. In order to understand the average level of technological innovation efficiency of each province during the study period, the average value of technological innovation efficiency of each province was calculated, and with reference to the research of related scholars (He Yingwei,2019), the technological innovation efficiency was divided into five levels: relatively effective (efficiency value is 1), high level [0.8,1], medium level [0.6,0.8], medium level [0.4,0.6] and medium level. Specific analysis is as follows:

4.1. Analysis of the efficiency of technological innovation in the technological research and development stage

It can be seen from Table 1 that the overall level of technological innovation efficiency in the R&D stage from 2011 to 2019 is 0.535, 46.5% of the innovation resource input has not been effectively used, the overall level of efficiency is not high, and there is still greater development potential. The overall national technological innovation efficiency is on a downward trend, but its fluctuations are relatively stable, with efficiency values varying between 0.5 and 0.6.

Table1 Value of technological innovation efficiency in technological research and development stage of Chinese industrial enterprises

area	the first period (2011-2013)	the second period (2012-2014)	the third period (2013-2015)	the fourth period (2014-2016)	the fifth period (2015-2017)	the sixth period (2016-2018)	the seventh period (2017-2019)	average value	rank

Source: The original data comes from the "China Science and Technology Statistical Yearbook" (2012-2019), calculated by dea-solver pro 13 software, and finally compiled according to the calculation results.

4.1.1. Analysis of the efficiency value of technological innovation in the four major regions

It can be seen from Table1 that the average efficiencies of the east, middle, west and northeast regions are 0.594, 0.524, 0.563, and 0.301, respectively, decreasing in order. The overall level of efficiency in each region is low and there are certain differences; the highest value of the four regions in the first period there is a difference of 0.334 from the lowest value, and a difference of 0.284 for the seventh period. The difference between regions shows a shrinking trend. It can be seen from Figure 1 that during the study period, the efficiency values of the eastern and northeastern regions continued

to decline from the first period to the sixth period, and only increased slightly in the last period; the western region was in a fluctuating downward trend; the central region's efficiency values were from the first period to the first period. The fourth period is in a fluctuating downward trend, but since the fourth period, there has been a significant increase, and after the fifth period, it surpassed other regions and became the region with the highest efficiency value in the country. Generally speaking, the initial value of the efficiency value of the eastern region is the highest, but the decline is the fastest. The initial value of the efficiency value of the central region is low, but the rise is the fastest. The efficiency value of the northeast region has been at the lowest level in the country. The efficiency values of the four regions range from "Eastern>West>Central>Northeast" in the first period to "Central>Eastern>West>Northeast" in the seventh period.

Figure 1 Technical Innovation Efficiency of Chinese Industrial Enterprises in Technology R&D Stage

4.1.2. Analysis of the Efficiency Value of Inter-provincial Technological Innovation

From the provincial level, it can be seen from Table 1 that the number of provinces with effective efficiency value in each period remains at 2-5, and only Anhui and Ningxia are at the forefront of efficiency in each period of the whole study period; The minimum value is 0.266, and the difference between the maximum value and the minimum value is 0.734. The average efficiency value of 17 provinces is below the national average level, accounting for 63% of the total samples, which indicates that the technology R&D resources in most provinces have not been effectively utilized and there is a serious waste of resources.

From the average point of view, the provinces distributed in the middle and low levels are the most, with 9 in each, accounting for 66.7% of all provinces; there are 3 and 4 provinces with high and medium-high levels respectively; only two DEA are effective. On the whole, the average level of innovation efficiency in the stage of technology research and development is mainly concentrated in the middle and low levels.

4.2. Analysis of the Efficiency of Technological Innovation in the Stage of Technological Transformation

From a national perspective, the overall efficiency level in the stage of technology transformation is 0.743, which is at a medium-to-high level, which is higher than the average efficiency value of 0.535 in the technology research and development stage, indicating that the efficiency of the combination of technology and economy in industrial enterprises is relatively good, but overall there is a slight decline trend, from 0.750 in the first period to 0.721 in the seventh period.

Table 2 Value of technological innovation efficiency in the stage of technological transformation of Chinese industrial enterprises

area	the first period (2011-2013)	the second period (2012-2014)	the third period (2013-2015)	the fourth period (2014-2016)	the fifth period (2015-2017)	the sixth period (2016-2018)	the seventh period (2017-2019)	average value	rank
Beijing	1.000	1.000	0.770	1.000	1.000	1.000	1.000	0.967	12

4.2.1. Analysis of the efficiency value of technological innovation in the four major regions

It can be seen from Table2 that the efficiency values of the eastern and western regions are 0.890 and 0.788, respectively, which are higher than the overall level of the country; the efficiency values of the central and northeastern regions are 0.605 and 0.622 respectively, which are lower than the overall level of the country, and the development of each region is uneven. The difference between the highest and lowest values in the first period of the four major regions was 0.251, and the difference in the seventh period was 0.383. The differences between regions showed an expanding trend.

Figure 2 Technological innovation efficiency of Chinese industrial enterprises in the stage of technological transformation

During the study period, the changes in the efficiency values of the eastern and northeastern regions were relatively stable; the central region saw a significant increase in the third period, and then fell significantly in the fourth period, and then remained in a stable state of development; the western region has the largest fluctuation range, except for the increase in the sixth period, the other periods all declined. The efficiency values of the four regions range from "Eastern>Central>West>Northeast" in the first period to "Eastern>Central>Northeast>West" in the seventh period. The efficiency value of the eastern region has always been at the highest level, and the efficiency value of the western region has declined the fastest, and by the seventh period it became the region with the lowest efficiency value in the country.

4.2.2. Analysis of the efficiency value of inter-provincial technological innovation

At the provincial level, 9 provinces, including Shanghai, Zhejiang, Shandong, and Guangdong, were all in a valid state during the study period, and the number of valid provinces in each period remained at 12-15. The minimum value of the average efficiency is 0.221, and there is a large gap between the maximum value and the minimum value. The average efficiency value of 15 provinces is higher than the national average, accounting for 55.6% of the total number of samples, indicating that more than half of the provinces can well convert knowledge output into economic output. From the perspective of the average value of efficiency, the provinces with efficiency values at the effective level are the most, with 9; provinces with high, medium-high, medium, and low-level levels are 6, 3, 4, and 5 respectively. Among them, provinces with effective DEA and high-level levels account for 55.6% of all provinces, and the overall level is relatively high, which is better than the average level of the technology research and development stage.

4.3. Comprehensive technological innovation efficiency

It can be seen from Table3 that the average efficiency of comprehensive technological innovation in China is 0.634, and 36% of the investment in innovation resources has not been effectively utilized. The efficiency value decreased from 0.657 in the first period to 0.613 in the seventh period, showing a downward trend as a whole, and the efficiency value varied between 0.6 and 0.7, with stable fluctuation.

4.3.1. Analysis of efficiency values in the four major regions

It can be seen from Table3 that the average efficiency values of the east, middle, west and northeast regions are 0.734, 0.657, 0.568, and 0.453, respectively, decreasing in order. The eastern and central regions are higher than the national average, and the western and northeastern regions are lower than the national average. Regional development is not balanced. The difference between the highest and lowest values in the first period of the four major regions is 0.303, and the difference in the seventh period is 0.265. The differences between regions show a shrinking trend. During the study period, the eastern region has been at the highest level in China, and its change trend is similar to that of the whole country, showing a downward trend on the whole. The central region as a whole showed an obvious upward trend, exceeding the national average efficiency value after the second period, and had a tendency to catch up with the eastern region. The western region fluctuated greatly and showed a downward trend as a whole. Northeast China has always been at the lowest level in China.

Figure 3 Comprehensive technological innovation efficiency of Chinese industrial enterprises

4.3.2. Analysis of inter-provincial efficiency value

At the provincial level, the number of provinces that are valid in each period remains at 3-5, and only Anhui and Ningxia are in the DEA effective state in each period. The minimum value of the mean value of efficiency is 0.232, and there is a large gap between the maximum value and the minimum value. From the average point of view, there are the most provinces in the middle and high level, with 9; the provinces at the high level and the middle level are both 5, and there are 6 provinces at the low level. There are 16 provinces at middle and high level and above, accounting for 59.26% of all provinces. The average value of 15 provinces is above the national overall level, while the remaining 12 provinces are below the national overall level, indicating that some provinces still face many problems in the transformation and upgrading of industrial enterprises, and there is still a certain gap from the innovative growth mode.

Table 3 Comprehensive technological innovation efficiency value of Chinese industrial enterprises

4.4. Comparative analysis of national two-stage and comprehensive technological innovation efficiency

It can be seen from Figure4 that the development of technological innovation efficiency at different stages is unbalanced. Compared with the technological research and development stage, the efficiency value of the technological achievement transformation stage is higher, and the efficiency of the technological research and development stage shows a downward trend as a whole. The difference between the efficiency values of technology transformation stage and technology research and development stage is 0.170 from the first stage (2011-2013) to 0.204 from the seventh stage (2017-2019), showing an expanding trend. Affected by the efficiency value of the technology research and development stage, the comprehensive technological innovation efficiency value is also relatively low. The overall efficiency and the change trend of the transformation efficiency of technological achievements are basically the same. It shows that in the joint effect of technology research and development efficiency and achievement transformation efficiency on overall efficiency, technology transformation efficiency is dominant. Therefore, if comprehensive efficiency is to be improved, achievement transformation efficiency must be improved, but the improvement of efficiency value in technology research and development stage cannot be ignored.

Figure 4 Two-stage and comprehensive technological innovation efficiency value of Chinese industrial enterprises

5. SPATIAL CORRELATION ANALYSIS

The above has carried out calculation and analysis on the technological innovation efficiency of industrial enterprises. This part will use the spatial statistical methods of global autocorrelation and local autocorrelation to study its spatial correlation characteristics in depth. The global space autocorrelation reflects the characteristics of a certain attribute in the global space, which is generally represented by the global Moran index (Golbal Moran, s I). The range of Golbal Moran, s I is [-1,1]. The closer to 1 at a given significance level, the higher the degree of agglomeration; the closer to -1, the greater the degree of dispersion and the more obvious the difference; When it is 0, it indicates that there is no spatial correlation.

Local spatial autocorrelation is usually used to study the similarity between a certain area and its surrounding areas. In this paper, local Moran index is used to analyze local spatial autocorrelation. LISA aggregation graph is a visual expression of Local Moran, s I, which can clearly express the local aggregation characteristics of technological innovation efficiency. The spatial weight matrix used in this part of the analysis is based on Queen's first-order spatial weight matrix, and the software used is ArcGIS 10.4 and GeoDa. The specific analysis is as follows:

5.1. Global spatial autocorrelation analysis

Golbal Moran, s I of comprehensive technological innovation efficiency of inter-provincial industrial enterprises is calculated. As shown in Figure 5, Moran, s I are both positive, and each period has passed 1% or 5% significance test, indicating that the spatial distribution of comprehensive technological innovation efficiency is not random, and there is obvious spatial agglomeration and spatial dependence. High efficiency provinces are adjacent to high efficiency provinces, while low efficiency provinces are adjacent to low efficiency provinces. From the trend of change, Moran, s I showed an "M"-shaped fluctuation, rising from 0.195 in the first period (2011-2013) to 0.336 in the third period (2013-2015), then falling to 0.242 in the fourth period (2014-2016) , Then rose to 0.355 in the sixth period (2016-2018), and finally fell to 0.311 in the seventh period (2017-2019), showing a volatile upward trend as a whole. It shows that although the spatial agglomeration of comprehensive technological innovation efficiency has certain volatility, it shows a trend of strengthening as a whole.

Fig. 5 Global Moran index change chart of comprehensive technological innovation efficiency of China's inter-provincial industrial enterprises

5.2. Local spatial autocorrelation analysis

In order to further analyze the local spatial characteristics, the first, third, fifth and seventh periods of LISA agglomeration maps were made (Figure 6). There are four types of agglomeration States in LISA agglomeration diagram: ① high-high: agglomeration area with high efficiency value; ② High-low: the high-efficiency area is surrounded by the low-value area; ③ Low-high: the low efficiency area is surrounded by the high efficiency area; ④ Low-low: low-value agglomeration area. The spatial agglomeration feature shown in Figure 7 passed the significance test of 1% or 5%.

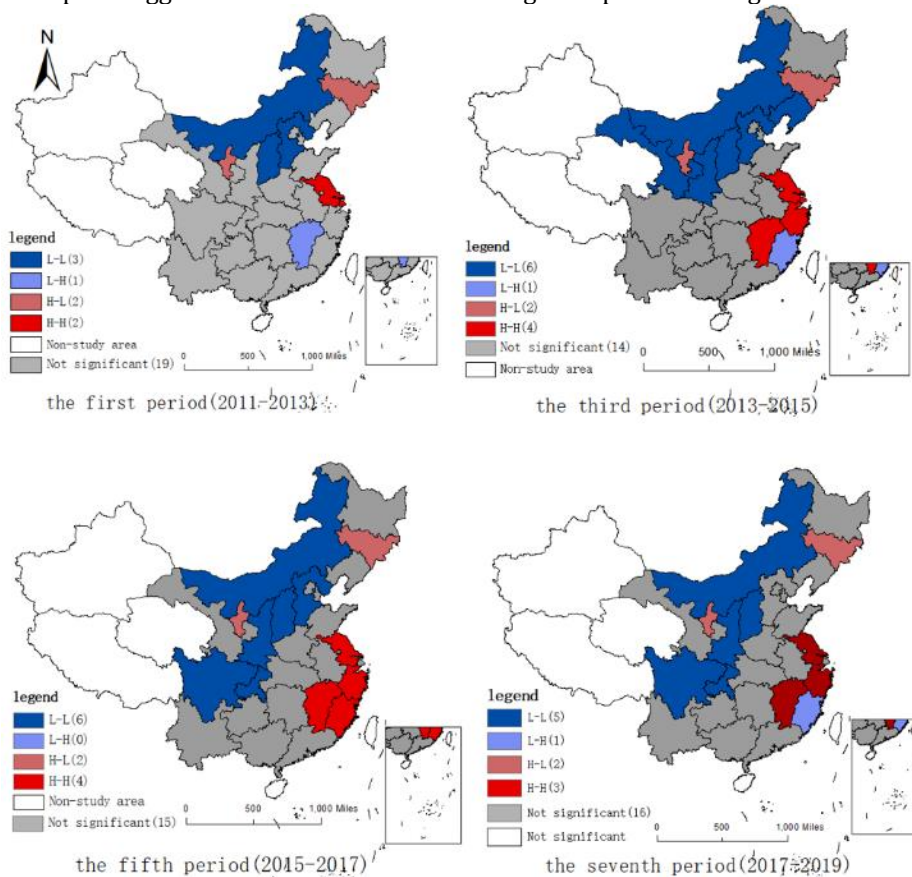

Figure 6 LISA cluster diagram of comprehensive technological innovation efficiency of Chinese industrial enterprises

It can be seen from Figure 6 that the high-growth agglomeration mainly consists of Jiangsu, Shanghai, Zhejiang and other provinces. Among them, Jiangsu Province has always been the high-growth agglomeration area. These provinces are mainly located in the eastern coastal area. This area has a developed economy, convenient transportation, and agglomeration of innovative resources. Provides certain advantages for innovation and development; low and low agglomerations are mainly located in the remote inland areas of the central and western regions. These provinces have relatively weak economic foundations, relatively scarce high-quality innovation elements such as R&D funds, technology, and talents, and the level of technological innovation efficiency of industrial enterprises Lower. Jilin and Ningxia have been high-low agglomeration during the entire study period. The efficiency values of these two regions are higher than the surrounding areas, but the spatial diffusion effect is limited and the radiation driving ability is weak, which cannot effectively promote the improvement of the efficiency value of the surrounding areas.

From an overall point of view, the agglomeration mode is mainly high-high agglomeration and low-low agglomeration, and the number of provinces belonging to these two agglomeration states is on the rise, indicating that the inter-provincial inter-regional linkage correlation is obviously strengthened. Provinces located in the middle of low-low agglomeration and high-high agglomeration regions performed insignificantly.

6. ANALYSIS THE INFLUENCING FACTORS

According to the previous evaluation and analysis of efficiency, it can be seen that there are obvious differences in different regions. In order to clearly understand the factors that affect the efficiency of technological innovation in each region, this section will regress the 27 provinces across the country as a whole, and then regress the four regions separately.

6.1. Construction of indicators

6.1.1. Dependent variable

Select the inter-provincial comprehensive technological innovation efficiency as the dependent variable and record it as *inn*.

6.1.2. Independent variables

Technological innovation efficiency is affected by many factors. This paper selects relevant indicators from the internal and external aspects of the enterprise. Within the enterprise, we mainly select three indicators: the input of R&D funds, the input of R&D personnel and the scale of industrial enterprises; the external selection of high-speed rail density, government support for innovation, the degree of government intervention in the economy and the level of regional economic development.

6.1.2.1. Investment of R & D funds

R & D funding is an important part of R & D activities and the basis for the smooth development of technological innovation activities. In this paper, the R & D internal expenditure divided by the sales revenue of new products is used to express the R & D investment, which is recorded as *cap*.

6.1.2.2. Investment of R & D personnel

R & D personnel are the human input of enterprises in R & D activities and the main participants in technological innovation activities(Liu Chunjiao, 2019: 147-149), which is of great significance to the development of technological innovation activities. The number of R & D personnel of industrial enterprises in various regions is selected to measure the index. In order to reduce the impact of heteroscedasticity, the logarithm is taken and recorded as *lnper*.

6.1.2.3. Scale of industrial enterprises

The influence of enterprise scale on enterprise innovation efficiency has always been the research focus of domestic and foreign scholars. Different enterprise scales have different effects on enterprise innovation efficiency. This article refers to the research of Li Peng (2013), and uses the ratio of the total assets of industrial enterprises to the number of industrial enterprises in each region to represent the average size of industrial enterprises in each region, which is recorded as *sca*.

6.1.2.4. High-speed rail density

The construction of transportation infrastructure is an important driving force for regional economic growth (Zhang Xueliang, 2012:60-77). As a new type of transportation, high-speed rail has greatly shortened the railway operation time between cities, promoted the flow of resources, and expanded the scope of knowledge spillover. As an important market entity, any changes in the macro environment will have an important impact on enterprises. The opening and construction of high-speed rail will also affect the behavior of enterprises to a certain extent. This article divides the number of high-speed rail mileage in each region by the total population of each region at the end of the year to express the density of high-speed rail in each region, denoted as *hsr*.

6.1.2.5. The government's support for innovation

Although enterprises are the mainstay of innovation, the government can influence the innovation activities of industrial enterprises through fiscal and tax policies. With reference to the research of Zhang Hong and Wang Yulei (2016:118-189), the proportion of government funds in the internal expenditure of R&D expenditures of industrial enterprises in each region is used to express the funding of various regions' governments for innovation, which is recorded as gov.

6.1.2.6. *The degree of government intervention in the economy*

Economic development requires moderate government intervention, but if the government intervenes too much, it will affect the effective play of the market mechanism. The increase in fiscal expenditure will squeeze enterprises to use their own resources to invest, and have a negative impact on the improvement of technological innovation efficiency. This article uses the proportion of regional public fiscal expenditures in each region's GDP to express the degree of regional government intervention in the economy, denoted as *inter*.

6.1.2.7. *Regional economic development level*

The development of innovative activities requires certain financial support, and needs to rely on the good economic development level of the region. The per capita GDP of each region is used to express the regional economic development level. In order to reduce the impact of heteroscedasticity, the logarithm is taken and recorded as *lngdp*.

6.1.3. *Data source and processing*

Since this paper sets a two-year lag period, the overall efficiency of each period is affected by the combined effect of the influencing factors of the first two years of each period, and is the sum of the influencing factors of the first two years of each period. The influencing factors use data from 2011-2018, and the statistical caliber is industrial enterprises above designated size. The mileage of high-speed rail comes from online searches, and the rest of the data comes from the "China Statistical Yearbook" and "China Science and Technology Statistical Yearbook" (2012-2019) of the corresponding year. The missing part of the data is filled in according to the method mentioned above. In order to eliminate the impact of prices, the regional GDP per capita index is used as the base period to deflate the regional per capita GDP, the number of R&D personnel input is the actual variable, and other indicators are proportional data, and no deflation will be carried out.

6.1.4. *Selection of regression model*

When performing regression analysis in this part, the dependent variable is the comprehensive technological innovation efficiency value, and its efficiency value cannot be greater than 1, and all values greater than 1 are compressed at the point 1. In this case, using OLS regression directly, the results obtained are biased. This is because after the dependent variable is blocked, its probability density will also change accordingly. When the dependent variable is intercepted data, although there are all observation data, some observation data are compressed at one point. At this time, the probability distribution of the dependent variable is a "joint distribution" composed of a discrete point and a continuous distribution. Constitute. In this case, no matter whether the entire sample is used or the sub-samples of discrete points are eliminated, it is impossible to obtain a consistent estimate for the OLS estimation, and the Tobit model can overcome this problem. The Tobit model is also called a restricted dependent variable model, which is a model that takes values when the dependent variable satisfies certain constraints. It is applicable when the value of the dependent variable is partly continuous and partly discretely distributed data. The Tobit model is divided into three forms: left limited, right limited and bilateral limited according to the setting of the interception point. The comprehensive technical efficiency value of this article belongs to the right limited situation. The specific form of the Tobit model used in this article for:

$$Y_{it}^* = \alpha + \beta X_{it} + \varepsilon_{it} \tag{1}$$

$$Y_{it} = \begin{cases} Y_{it}^*, & Y_{it}^* < 1 \\ 1, & Y_{it}^* \geq 1 \end{cases} \tag{2}$$

Among them, Y_{it}^* is the latent variable, Y_{it} is the actual dependent variable, β is the parameter to be estimated, ε_{it} is the random error term, α is the constant term. The dependent variables and independent variables are substituted into the Tobit model. This article constructs the measurement model as shown below:

$$inn_{it}^* = \alpha_i + \beta_1 cap_{it} + \beta_2 ln per_{it} + \beta_3 sca_{it} + \beta_4 sr_{it} + \beta_5 int er_{it} + \beta_6 gov_{it} + \beta_7 lng dp_{it} + \varepsilon_{it} \tag{3}$$

In this paper, we first establish the individual random effect model, and then conduct LR test to determine whether to use the mixed panel model or the individual random effect model.

Table 4 Tobit regression results of influencing factors of technological innovation efficiency of industrial enterprises in China as a whole and in various regions

	The whole country	Eastern region	Central region	Western region	Northeast region

6.1.5. Regression results

The software used in this section is stata16, which estimates five individual random effect models. According to the models established in the whole country and the eastern, central and western regions, the LR tests are respectively "Prob >= chibar2 = 0.000, Prob >= chibar2 = 0.000, Prob >= chibar2 = 0.000, Prob >= chibar2 = 0.000", both rejected the null hypothesis that there is no individual effect at the 1% significance level; according to the model established in the Northeast region, the LR test is "Prob >= chibar2 = 1.000", does not reject the null hypothesis that there is no individual effect. Therefore, the country as a whole and the eastern, central and western regions established the individual random effect Tobit model, and the northeastern region established the mixed Tobit model. These five models have passed the test and are all valid as a whole. The regression results are shown in Table 4:

- (1) The technological innovation efficiency of national industrial enterprises is significantly positively correlated with the investment of R&D personnel and government intervention in the economy; there is also a positive correlation with government support for innovation, but the effect is not obvious; the size of the enterprise has a significant effect on the improvement of technological innovation efficiency. Significant negative impact.

- (2) The technological innovation efficiency of industrial enterprises in the eastern region is significantly positively correlated with R&D capital investment, and there is also a positive correlation with the investment of R&D personnel, high-speed rail density, government intervention in the economy, and government support for innovation, but the effect is not significant; and The level of regional economic development is significantly negatively correlated.
- (3) The technological innovation efficiency of industrial enterprises in the central region is significantly positively correlated with the investment of R&D personnel and the density of high-speed rail. It is also positively correlated with government intervention in the economy and government support for innovation, but the effect is not obvious; it is related to the scale of the company significantly negatively correlated with the level of regional economic development.
- (4) The technological innovation efficiency of industrial enterprises in the western region is significantly positively correlated with government intervention in the economy, and is also positively correlated with government support for innovation and the level of regional economic development, but the effect is not significant. It is related to R&D capital investment and R&D personnel. Significantly negatively related to investment.
- (5) The technological innovation efficiency of industrial enterprises in Northeast China is significantly positively correlated with high-speed rail density, and significantly negatively correlated with the scale of enterprises and the level of regional economic development.

7. SUMMARY

7.1. Conclusion

This paper measures and analyzes the technological innovation efficiency of Chinese industrial enterprises, and tests their spatial relevance, and finally empirically analyzes the factors that affect technological innovation efficiency. The main conclusions are as follows:

7.1.1 From the perspective of technological innovation efficiency of industrial enterprises

In terms of the two-stage efficiency value: the average efficiency of the technology research and development stage is 0.535, the average efficiency of the technology transformation stage is 0.743, the average efficiency of the technology transformation stage during the research period is always higher than the average efficiency of the technology research and development stage, and the two-stage efficiency value exists Gap, and the gap is expanding. The efficiency value of the technology research and development stage shows a downward trend as a whole; there are gaps in different regions. The average efficiency of the eastern region is the highest, the northeast region is the lowest, and the central region has the fastest rise; only Anhui and Ningxia are effective in each period; from the average value It can be seen that the provinces that are distributed in the middle and low levels are the most, and the average value of 17 provinces is below the national average. The overall level of efficiency in the transformation stage of technological achievements is relatively high, but it shows a slight downward trend; there are 9 provinces where the efficiency values in each stage have reached the effective state, more than in the R&D stage.

In terms of comprehensive technological innovation efficiency: the national average is 0.634, the overall level is not high; from the perspective of different regions, the eastern region has the highest efficiency value, and the northeast region has the lowest efficiency value; from the provincial level, only the two provinces of Anhui and Ningxia Periods are in the state of DEA effective. From the average of the provinces, 15 provinces are above the overall level of the country, and most of these provinces are from the eastern and central regions. In short, the overall level of comprehensive technological innovation efficiency of Chinese industrial enterprises is not high, the gap between regions and provinces is obvious, and there is obvious incoordination in the efficiency of two-stage technological innovation. Compared with the efficiency value of the technological research and development stage, the efficiency value of the technological achievement transformation stage Higher, the comprehensive technological innovation efficiency value and the change trend of the efficiency value in the transformation stage of technological achievements are basically the same, that is, the comprehensive technological innovation efficiency is mainly affected by the efficiency of the technological transformation stage.

7.1.2. From the perspective of the spatial relevance of technological innovation of industrial enterprises

The technological innovation efficiency of Chinese industrial enterprises has obvious characteristics of spatial agglomeration. High-high agglomerations are mainly distributed in the eastern coastal areas, and low-low agglomerations are mainly distributed in the central and western inland areas. Although the spatial agglomeration of technological innovation efficiency has certain fluctuations, The overall trend is increasing.

7.1.3 From the perspective of influencing factors of technological innovation efficiency of industrial enterprises

Due to the different development stages and development methods of industrial enterprises in various regions, there are also differences in the factors affecting the efficiency of technological innovation in various regions.

The technological innovation efficiency of national industrial enterprises is significantly positively correlated with the investment of R&D personnel and government intervention in the economy; it is significantly negatively correlated with the investment of R&D capital and the size of the company, indicating that the overall R&D investment in the country is redundant and the R&D expenditure has increased extensively. It has not effectively promoted the improvement of

efficiency. The size of the enterprise has a significant negative impact on the improvement of technological innovation efficiency. It may be because the larger the enterprise, the less conducive to the effective allocation of resources and the improvement of efficiency.

The eastern region is mainly affected by the investment in research and development funds, which has significantly promoted the efficiency of industrial enterprises in the eastern region.

The central region is mainly affected by the investment of R&D personnel, the density of high-speed rail, the scale of enterprises and the level of economic development.

The western region has a significant positive correlation with government intervention in the economy, and a significant negative correlation with R&D capital investment and R&D personnel investment; it shows that moderate government intervention in the economy has effectively promoted efficiency improvement, but government investment in enterprise innovation funds inhibited innovation. The improvement of efficiency may be due to the "crowding out effect" of the government's excessive capital investment on the technological innovation input of industrial enterprises (Liu Ruiyu, 2016:277-283).

Northeast China is mainly affected by the density of high-speed rail, the scale of enterprises and the level of regional economic development. The construction of high-speed rail has effectively promoted the increase in efficiency in the Northeast; the unreasonable enterprise scale has inhibited the increase in efficiency.

7.2. Policy recommendations

7.2.1. Different regions should adopt different policies according to local conditions

The eastern region should give full play to its capital advantages, increase investment in research and development, increase research and development efforts, cultivate independent brands of enterprises, and improve core competitiveness; the central region should appropriately increase the investment of research and development personnel, enhance the independent research and development capabilities of enterprises, and increase the transportation infrastructure such as high-speed rail. The construction of facilities, speed up the flow of various resources and elements, and improve efficiency; the western region should give full play to the government's role in economic regulation, create a good innovation environment, and appropriately control the input of R&D elements to avoid waste of resources and improve R&D resources. Utilization efficiency: The Northeast region should increase the construction of high-speed rail and other transportation infrastructure, promote the rapid flow of various elements, improve efficiency, and appropriately adjust the scale of enterprises, control the scale of production within a reasonable range, and give full play to the positive role of economies of scale.

7.2.2. Promote the coordinated development of two-stage technological innovation efficiency

The low level of efficiency in the current technology research and development stage hinders the further improvement of the overall technological innovation efficiency level. All regions should focus on increasing investment in technology research and development, increasing research and development efforts, and promoting both on the basis of maintaining relatively high efficiency in the technology transformation stage. Stage the coordinated development of technological innovation efficiency, thereby improving the level of comprehensive technological innovation efficiency.

7.2.3. Strengthen regional cooperation and promote coordinated development of various regions

There are obvious regional differences and spatial correlations in the technological innovation efficiency of industrial enterprises. Each region should make full use of its spatial correlation, strengthen regional cooperation, and promote the coordinated development of various regions, so as to promote the improvement of comprehensive technological innovation efficiency. The eastern region should actively play the leading role of innovation on the basis of maintaining its own relatively high level of efficiency; the central region, linking the east to the west, must give full play to its location advantages, and actively take over the eastern region under the strategic background of "the rise of the central region." The industrial transfer of China should absorb its advanced technology to promote its own efficiency. At the same time, it should also play a radiating role to drive the efficiency of the western region. The western region should strengthen communication and exchanges with the eastern and central regions in terms of technology and talents, and introduce advanced technology and management experience improve innovation efficiency; as an old industrial base, the Northeast region is in the transitional stage of industrial transformation and upgrading. System reform and structural adjustment should be accelerated, exchanges and cooperation with other regions should be strengthened, and independent innovation capabilities should be comprehensively improved.

DOES SOCIAL-DISTANCING SAVE LIVES?: THE IMPACT OF SOCIAL DISTANCING MEASURES ON PEOPLE MOBILITY AND COVID-19 CASES IN INDONESIA

Bondi Arifin, Eko Wicaksono, Nugraheni Kusumaningsih

Fiscal Policy Agency, Indonesia

ABSTRACT

As unprecedented event, Covid-19 pandemic has forced government across the world to rely more on non-pharmaceutical intervention since no specific medication nor vaccine were ready to counter the spread of this particular disease. Both social and mobility restriction were among the chosen policies implemented. Indonesian government took two substantial interventions at the onset of Covid-19 pandemic. Those interventions are school closure and voluntary social distancing which then was followed by Large Scale Social Restriction (PSBB). Voluntary social distancing encourages businesses and worship places to implement health protocol and there were legal punishment given to those who neglected the advice. On the other hand, PSBB had stricter measures in its implementation since only essential businesses could remain open during its period. It also required worship places closure and limited activities on public facilities as well as transportation. In addition, the government provided the legal basis in its implementation so that any disobedience would lead to legal consequences.

We evaluated the impact of these interventions on people mobility and the growth rate of confirmed COVID-19 cases. People mobility data were obtained from Google Mobility Report. Meanwhile, the cases growth rate data were obtained from official case counts which cover 34 provinces across Indonesia in between February 16, 2020 and May 7, 2020. We employ both synthetic control design and an event-study design adapted for continuous treatment to determine the impact of these non-pharmaceutical intervention on people mobility and cases growth rate.

We find that both interventions could reduce 30 % of average workplace mobility, and on the other hand, increased 15 % of average residential mobility. Using synthetic control method, we found that PSBB alone in DKI Jakarta decrease further its workplace mobility by 10%, but the impacts are more subtle in both West Sumatera and Gorontalo. Both school closure-voluntary social distancing and PSBB interventions have significant impact towards the growth of positive COVID-19 cases. During school closure-voluntary social distancing period, 1% increase in residential activity leads to decrease of COVID-19 cases growth by 1.03 percentage point in the first week and stagnant at 1.48 percentage point for the following periods. Holding residential mobility at pre-COVID-19 period, COVID-19 positive cases in Indonesia would have reached 17.450 cases instead of the actual observed cases at 12.754 or correspond to 37% higher on May 7, 2020. Furthermore, with a stricter social distancing that is PSBB, our simulation displays that the observed cases could further be reduced. These findings imply that containment policy at the early onset of Covid-19 outbreak is very important to flatten the curve and save more lives.

NEGATIVE EXTERNALITIES FROM PORT DEVELOPMENT: EVIDENCE FROM MARINE POLLUTION IN INDONESIA

Muhammad Halley Yudhistira^{1,2}, [Indra Degree Karimah](#)³, Nadya Rahmi Maghfira^{1,2}

¹Institute for Economic and Social Research, Faculty of Economics and Business, Universitas Indonesia, Indonesia.

²Cluster of Urban and Transportation Economics, Department of Economics, Universitas Indonesia, Indonesia. ³Ministry of Transportation, Republic of Indonesia, Indonesia

ABSTRACT

Developing transport infrastructure must involve a comprehensive cost-benefit analysis, and accounting for environmental quality changes associated with such infrastructure is one important aspect that can help complete this picture. In this study, we used difference-in-difference to estimate the marine pollution changes related to port development in Indonesia over the last decade. Using unique MODIS-derived monthly data of marine pollution, we found that local port presence causes a 1.7% increase in chlorophyll-a in coastal areas within 6 kilometers of the port. The effects are concentrated in the first two months of operation, and there is evidence for anticipation effects associated with the construction period. We found a greater effect in Indonesia's eastern regions, which rely on small ports for their local activities. Nevertheless, we argue that the effect can be substantial and potentially capable of creating an algal bloom in a larger port.

Regular Session: RS11.1 - Rural development

09:30 - 10:45 Wednesday, 26th May, 2021

Chair Charles Kofi Owusu

RENEWABLE MINIGRIDS FOR RURAL ELECTRIFICATION IN GHANA: ANALYSIS OF HOUSEHOLDS' WILLINGNESS TO PAY

Artem Korzhenevych^{1,2}, Charles Kofi Owusu^{2,3}

¹Leibniz Institute of Ecological Urban and Regional Development, Germany. ²Technische Universität Dresden, Faculty of Business and Economics, Germany. ³Kumasi Institute of Technology, Energy and Environment, Ghana

ABSTRACT

Renewable energy minigrids hold enormous prospects for the African energy sector in terms of enhancing clean energy access, while fostering sustainable low carbon development. The government of Ghana has established pilot renewable minigrids in 5 rural offgrid communities to provide mastery and learning for the electrification of over 600 existing rural communities that cannot be electrified via the national grid. Although, there is evidence on willingness to pay (WTP) for renewable-generated electricity in some developing countries, little is known about households' WTP for renewable-based electricity in Ghana and in particular renewable minigrids for rural electrification. The study sought to provide one of the first WTP estimates for renewable-based electricity for rural electrification in a developing economy context such as Ghana, setting the stage on how to de-carbonize the rural energy sector and spur low-carbon rural development. A Contingent Valuation (CV) survey was undertaken using structured questionnaires in all 5 pilot renewable minigrid project communities in Ghana, located in 3 of the 16 regions of Ghana. Two hundred households were interviewed adopting a combination of cluster and simple random sampling approaches.

We established that rural households are willing to pay an average of GHC29 (≈\$5)/month for renewable-powered electricity services, which is twice the amount they are currently paying based on the Uniform National Tariffs. Households in the rural areas are willing to pay between 9% and 11% of their discretionary incomes to cover the cost of accessing renewable-powered electricity in the rural, offgrid communities in Ghana. The findings suggest a positive attitude by households regarding their preparedness to pay for the cost of renewable-powered electricity services in the hope of contributing to a sustainable electricity service delivery and enhanced access in the communities. We call for a closer view at these estimates in the development of tariff regulations and frameworks by the government for renewable minigrid development in the rural areas.

LIVELIHOOD RESILIENCE AND COPING STRATEGIES OF SELECTED RURAL HOUSEHOLDS IN BANGLADESH DURING THE COVID-19 PANDEMIC

ABSTRACT

The paper intends to explore the impact of COVID-19 on the livelihood of different types of rural households in Bangladesh and their livelihood resilience by employing the Resilience Index Measurement and Analysis II (RIMA-II) model. It has also explored the coping strategies that are adapted by the rural households during the pandemic. Data were collected through telephone surveys using the structured questionnaire and checklist. Convenience sampling was used to select 157 rural households from 102 sub-districts in eight divisions of Bangladesh. The study reveals that mixed (having both agricultural and non-agricultural livelihood capitals) households are the most resilient, and non-agricultural households are the least resilient during the pandemic. This study also reveals that COVID-19 has not affected employment status that much in rural areas. However, business activities have been affected the most compared to farming and service activities. In general, all rural households have low livelihood resilience, which indicates that rural households are not capable enough to cope with the adverse effects of the COVID-19 pandemic. To minimize livelihood risk agricultural households mostly rely on external coping strategies, whereas non-agricultural and mixed households depend on internal coping strategies. The main drivers of resilience capacity include having basic education and skills to shift livelihood strategy, a stable income source, and access to financial help when needed.

KEYWORDS

Bangladesh, Coping Strategies, COVID-19 Pandemic, Livelihood Resilience, Rural Households.

1. INTRODUCTION

The unprecedented COVID-19 pandemic has led to a worldwide disruption of lives and livelihoods “Rashid et al. (2020); Walsh (2020); Zabaniotou (2020)”. Being an impoverished and densely populated country, Bangladesh is highly vulnerable to the COVID-19 pandemic “Genoni et al. (2020); Sakamoto et al. (2020)”. In March 2020, the government of Bangladesh declared a countrywide lockdown to limit community transmission of COVID-19 “Sakamoto et al. (2020)”. However, this lockdown has reduced the income opportunities of rural people, which makes the livelihood of rural people more stressful and vulnerable “Hasnin (2020); Rashid et al. (2020)”.

A livelihood comprises capabilities, assets, and activities that are needed to sustain a living “Rudiarto et al. (2019)”. Sudden exposure to shocks and stress that creates adverse effects on livelihood makes people vulnerable “Sarker et al. (2020); Endris et al. (2017)”. COVID-19 pandemic is a systemic shock as it affects the broader community at the same time or same place “Endris et al. (2017)”. To assess the vulnerability and to cope with unforeseen external disruptions and shocks, the concept of resilience has emerged “Steenbergen et al. (2020); Alam et al. (2018)”. Households will be resilient if they could anticipate, resist, cope with, and recover from shocks “Alam et al. (2018); Barua et al. (2014); Fan et al. (2014)”. Resilience is a multidimensional concept which refers to the ability of the individuals, households, communities, group, or organizations to cope with and adapt to shocks “Sarkar et al. (2020); Convertino & Valverde (2019); Roberts et al. (2019); Rudiarto et al. (2019); Alam et al. (2018); Tanner et al. (2015)”. Livelihood resilience is “the capacity of all people across generations to sustain and improve their livelihood opportunities and well-being despite environmental, economic, social, and political disturbances” “Tanner et al. (2015: 1)”. Resilience capacity is the combination of three interrelated capacities: adaptive capacity, absorptive capacity, and transformative capacity “TANGO International (2018); Vaughan (2018)”. Coping strategies increase livelihood resilience and decrease vulnerability to shocks “Farzana et al. (2017)”. These are the strategies or mechanisms that vulnerable people adapt in times of sudden shock to minimize risks such as selling assets, borrowing money, reducing household food consumption, and migrating to other areas “Sultana & Rayhan (2012)”. Several studies have focused on the livelihood resilience of rural people in Bangladesh. However, only a few of them have measured livelihood resilience. Moreover, the livelihood resilience of

various occupational households during the COVID-19 pandemic has not been addressed yet. Therefore, this study addresses this gap and intends to answer the following research questions:

- Based on the occupational status of the households, which household is more resilient during the COVID-19 pandemic in rural areas of Bangladesh? What factors influence the resilience capacity of these households in Bangladesh during the COVID-19 pandemic?
- What is the impact of COVID-19 on the employment status of earning members in rural households of Bangladesh?
- What are the coping strategies of different types of rural households during the COVID-19 pandemic?

It is expected that this study will help the policymakers and planners to address the factors that expose people to vulnerability and the factors which make the rural household more resilient during any systemic shocks.

2. RELEVANT RESEARCH

Several studies have been found on the resilience of rural people in Bangladesh during natural shocks such as disasters, for example, livelihood resilience of riverine island dwellers “Sarker et al. (2020)”, community resilience to cyclone and storm “Uddin et al. (2020)”, climate change resilience “Alam et al. (2018)”. Many studies have explored the coping strategies of rural people in times of natural disasters “Islam et al. (2018); Fakhruddin & Rahman (2015); Masud-All-Kamal (2013); Sultana & Rayhan (2012)”. As natural disasters and pandemics both are systemic shocks, these studies are also helpful for the livelihood resilience study of rural people during the pandemic “Endris et al. (2017)”. Few recent research studies have addressed the vulnerability issue of Bangladesh during pandemic “Rahman et al. (2020); Sakamoto et al. (2020)”. However, the livelihood resilience of rural households in Bangladesh during the pandemic has not been explored yet. Few previous studies have measured the livelihood resilience of rural people during natural disasters. Measuring livelihood resilience is a very challenging task “Sarker et al. (2020); Quandt (2018)”. Among the measurement approach, composite indicator-based assessment is widely used to measure resilience “Sarker et al. (2020); Alam et al. (2018); Weldegebriel & Amphune (2017); Béné et al. (2016); FAO (2016); Alfani et al. (2015). So, this approach is followed in the study to measure the livelihood resilience of rural households, and to identify the factors that influence their resilience capacity during the COVID-19 pandemic.

3. STUDY AREA AND SAMPLE HOUSEHOLDS

As whole Bangladesh has been going through widespread community transmission of COVID-19 pandemic and is largely affected by it, 157 villages from 102 upazilas, from 48 different districts under all 8 divisions are selected as study area to represent the complete COVID-19 situation of rural areas. A telephone survey with a structured questionnaire was done in the period of October and November 2020. Information regarding 157 households and their villages was collected. Based on the responses, it has been found that from March to August 2020, when the transmission of COVID-19 was at its peak in Bangladesh, lockdown was declared in about 90% of these studied upazilas by the government. It was also found that lockdown was declared either by local administration or national government. Among the selected upazilas 82% are agriculture dominant, and 18% are non-agriculture dominant “BBS (2015)”. Studied households are divided into three categories: Agricultural households, Non-agricultural households, and mixed households. “A household is considered to be an agricultural household when at least one member of the household is operating a holding (farming household) or when the household head or main income earner is economically active in agriculture” “DESA (1984: 157)” Rural households that do not engage in agricultural activities are non-agricultural, and the households whose members are engaged in both agricultural and non-agricultural activities are mixed households “Videnovic & Arandjelovic (2020)”.

4. MEASURING LIVELIHOOD RESILIENCE

Several studies used the composite indicator-based assessment to measure the livelihood resilience of vulnerable people during shocks "Sarker et al. (2020); Alam et al. (2018); Weldegebriel & Amphune (2017); Béné et al. (2016); FAO (2016); Alfani et al. (2015)". COVID-19 pandemic is a systemic shock that has disrupted rural people's livelihood to a great extent "Hasnin (2020); Rashid et al. (2020); Endris et al. (2017)". Resilience Index Measurement and Analysis II (RIMA-II) developed by "FAO (2016)" was followed in this study to measure the livelihood resilience of rural households during the COVID-19 pandemic. RIMA-II has been chosen as it covers all the livelihood aspects of households "Sarker et al. (2020); Weldegebriel & Amphune (2017)". The model and the selected indicators have been customized in this study following relevant research "Sarker et al. (2020); Alam et al. (2018); Weldegebriel & Amphune (2017); FAO (2016); Qasim et al. (2016); Hahn et al. (2009)".

Resilience is a function of three interrelated capacities: adaptive, absorptive, and transformative capacity "Sarker et al. (2020); Rudiarto et al. (2019); FAO (2016)".

$$\text{Resilience} = f(\text{Adaptive, Absorptive, Transformative}) \quad (1)$$

These capacities are comprising some indicators. Five major indicators of the capacities were selected from "FAO (2016)". Equal weights were applied to the indicators and then aggregated to obtain a multidimensional livelihood resilience index (LRI) for agricultural, non-agricultural, and mixed households of the study area.

Thus, LRI measurement is expressed as:

$$LRI_b = f(AC_b, ABC_b, TC_b) \quad (2)$$

Where, LRI_b is the livelihood resilience index for b-type households; AC_b is the adaptive capacity for b-type households; ABC_b is the absorptive capacity for b-type households; TC_b is the transformative capacity for b-type households.

Adaptive capacity is the ability of a household to cope with the risks, stresses, and shocks of livelihood "Sarker et al. (2020)". Absorptive capacity is the ability of a household to absorb the harmful effects of shocks "Sarker et al. (2020)". Transformative capacity is the ability of a household to transform livelihood from the adverse effects of shocks "Sarker et al. (2020)". Considering the major three components, FAO's RIMA model is contextualized in this study. Therefore, households' livelihood resilience index can be expressed as:

$$LRI_i = f(IFA_i, NA_i, AC_i, SSN_i, S_i) \quad (3)$$

Where, LRI = livelihood resilience index; IFA = household's income and food access; NA = household's non-agricultural assets; AC = household's adaptive capacity; SSN = household's social safety nets availing facility; S = household's sensitivity. Household's adaptive capacity, non-agricultural assets, income and food access are the main elements of adaptive capacity "Sarker et al. (2020)". Sensitivity is one of the major components of absorptive capacity, which indicates the extent to which shocks affect a household's livelihood "FAO (2016)". The social safety net is taken as a part of transformative capacity "Sarker et al. (2020)".

Each major indicators are comprising some sub-indicators. The sub-indicators were selected and customized from different literature based on the research topic. Each of the sub-indicators contributes equally to the corresponding major indicator's index value. A score ranges from 0.00 to 1.00 was applied to the indicators. The highest score of 1.00 indicates the most resilient, and the lowest score of 0.00 indicates the least resilient.

At first, the index value of each sub-indicator was calculated using the following equation:

$$Index_{S_b} = \frac{\sum_{i=1}^n SS_{bi}}{n} \tag{4}$$

Where, S_b is one of the sub-indicators for b-type households; $\sum_{i=1}^n SS_{bi}$ represents the total score of that sub-indicator, indexed by i , for b-type households. This can be obtained by adding all the b-type household's scores for that sub-indicator; n indicates the total number of b-type households.

After that, the index value of each major indicator was calculated using the following equation:

$$M_{bj} = \frac{\sum_{i=1}^n Index_{S_b}}{n} \tag{5}$$

Where, M_{bj} is the value of major indicator j for b-type households; $\sum_{i=1}^n Index_{S_b}$ indicates the total score of all sub-indicators of major indicator j , indexed by i for b-type households. This can be obtained by adding scores of all the sub-indicators of major indicator j for b-type households; n represents the number of sub-indicators in major indicator j .

After calculating the index value of five major indicators, the values were directly used in Eq. (3) to obtain the livelihood resilience of b-type household:

$$LRI_b = \frac{w_{IFA}IFA_b + w_{NA}NA_b + w_{AC}AC_b + w_{SSN}SSN_b + w_S S_b}{w_{IFA} + w_{NA} + w_{AC} + w_{SSN} + w_S} \tag{6}$$

Where, LRI_b is the livelihood resilience index for b-type households which is equal to the weighted average of five major components. $w_{IFA}, w_{NA}, w_{AC}, w_{SSN}, w_S$ indicates the weightage of household's income and food access, household's non-agricultural assets, household's adaptive capacity, household's social safety nets, household's sensitivity respectively. The number of sub-indicators that comprise each major indicator is the weight of that major indicator. Thus all sub-indicators have equal contribution to the total LRI "Weldegebriel & Amphune (2017); Hahn et al. (2009)". $IFA_b, NA_b, AC_b, SSN_b, S_b$ is the index value of household's income and food access, household's non-agricultural assets, household's adaptive capacity, household's social safety nets, and household's sensitivity respectively. The interpretation of the calculated value of LRI is shown in table 1.

Table 1: The Interpretation of Livelihood Resilience Index

Index Score	Interpretation of Livelihood Resilience
0.81 - 1.00	Very high
0.61 - 0.80	High
0.41 - 0.60	Medium
0.21 - 0.40	Low
0.00 - 0.20	Very low

Source: "Rudiarto et al. (2019)".

5. Results and Discussion

5.1 Socio-Economic Profile

In this study, around 53% are nuclear families having less than five members. Majority households (53%) has semi-pucca house (brick/concrete-walled house with a tin roof), 34% has pucca houses (brick/concrete house), and 13% has kutcha houses (mud/bamboo walled house with tin or thatched roof). Only a few household heads are illiterate (7%) in the study area, and 39% are graduates. Illiterate household heads are relatively higher in agricultural households, whereas graduate household heads are comparatively higher in non-agricultural and mixed households. Farming, service, and business activity are the major occupation of the respondents. Most households (69%) are engaged in non-agricultural activities. About 22% of households are engaged in agricultural activity, whereas only 10% of households are engaged in both agricultural and non-agricultural activities. Most of the households' (47%) monthly income are within 20001 to 40000 BDT, 34% within 10001-20000 BDT, 3% up to 10000 BDT, and only 16% of households' income are above 40000 BDT.

5.2 Livelihood Resilience Index

LRI of agricultural (0.326), non-agricultural (0.287), and mixed households (0.373) are low (Table 2). The LRI value of mixed households is slightly higher, which infers that mixed households are more resilient than agricultural and non-agricultural households during the COVID-19 pandemic (Table 2). The low LRI value of the households indicates that the households are not capable to cope with the adverse impacts of the pandemic which disrupts their livelihood to a large extent. Household's adaptive capacity, income and food access, and social safety net are the major factors that help the households to be more resilient during the pandemic (Table 2).

Table 2: The index value of major indicators comprising the livelihood resilience index

Major indicators of livelihood resilience	Index value of each indicator		
	Agricultural Household	Non-agricultural Household	Mixed Household
Household's adaptive capacity	0.616	0.638	0.704
Income and food access	0.372	0.332	0.402
Social safety net	0.324	0.166	0.253
Non-agricultural asset	0.151	0.129	0.226
Sensitivity	0.030	0.084	0.241
Livelihood Resilience Index (LRI)	0.326	0.287	0.373

Source: Authors' own construction from telephone survey, 2020.

5.3 Major Indicators of Livelihood Resilience

The livelihood resilience index (LRI) is a function of adaptive, absorptive, and transformative capacity “Sarker et al. (2020); Rudiarto et al. (2019)”. The combination of these three capacities represents the resilience capacity of the households “TANGO International (2018); Vaughan (2018)”. All the households of the study area have low LRI scores. The study also finds some variation between the index values of major indicators, which indicates that the resilience capacity of rural households varies both at an overall level and in particular indicators.

5.3.1. Household’s Adaptive Capacity

The major components of household’s adaptive capacity are household’s dependency ratio, education level of household head, having skills to shift livelihood, having training to cope with pandemic and household’s awareness level regarding pandemic “Sarker et al. (2020); Alam et al. (2018); Weldegebriel & Amphune (2017); FAO (2016); Qasim et al. (2016); Hahn et al. (2009)”. Mixed households have a very high score (0.704) in household’s adaptive capacity than agricultural (0.616) and non-agricultural households (0.638), which is the major reason behind their higher resilience during the pandemic (Table 2). The index value for skills to shift livelihood is also very high for mixed households than the other two households (Figure 2). Thus mixed households have a high capacity to cope with the sudden livelihood shocks during the pandemic. The education level of the household head also contributes highly to enhance the resilience capacity of rural households (Figure 2).

Figure 2: Indicators of household’s adaptive capacity index

Source: Authors’ own construction from telephone survey, 2020.

5.3.2. Income and Food Access

The components of income and food access include lending money to other people, borrowing money from neighbors, borrowing goods from local shops and neighbors, taking loans from the bank, no change in income source, decrease in monthly income, and having less food or low-cost food during pandemic “Sarker et al. (2020); Alam et al. (2018); FAO (2016)”. The overall index value for income and food access is much higher for mixed households (0.402) compare to agricultural (0.372) and non-agricultural households (0.332) (Table 2). The index value of “No change in income source” is comparatively higher than other factors, which indicates that a stable income source is one of the most significant factors to enhance the resilience capacity of households during the COVID-19 pandemic (Figure 3).

Figure 3: Indicators of income and food access index

Source: Authors’ own construction from telephone survey, 2020.

5.3.3. Social Safety Net

The major components of the social safety net include help or support from samiti or social welfare organizations, NGOs, government, cooperatives, and wealthy relatives or neighbors from the village “Sarker et al. (2020); Hahn et al. (2009)”. Several studies have found that the social safety net has a significant influence to increase the livelihood resilience of rural people during shocks “Awal et al. (2013); Davies et al. (2013)”. In this study, agricultural households have comparatively a high index value (0.324) for the social safety net, which indicates that these households receive the highest help and support from the community, government, and other organizations than the other two households (Figure 4). However, non-agricultural households have a very low index value (0.166) of the social safety net, which makes them less resilient during the COVID-19 pandemic (Table 2).

Figure 4: Indicators of social safety net index

Source: Authors’ own construction from telephone survey, 2020.

5.3.4. Non-agricultural Asset

Ownership of durable assets indicates resilience to COVID-19, as these items can be sold when necessary to cope with the adverse situation “Sarker et al. (2020)”. In this study, ownership of motorbike, van, bicycle, CNG, rickshaw, boat, sewing machine are considered as some major components of non-agricultural assets “Sarker et al. (2020); Alam et al. (2018); FAO (2016)”. The score of non-agricultural asset availability is very low for agricultural (0.151) and non-agricultural (0.129) households, which is comparatively higher for mixed households (0.226) (Table 2). Therefore, non-agricultural asset availability also makes mixed households more resilient than the other two households to some extent (Figure 5).

Figure 5: Indicators of non-agricultural asset index

Source: Authors’ own construction from telephone survey, 2020.

5.3.5. Sensitivity

The term sensitivity indicates the extent to which shocks affect a household’s livelihood (FAO, 2016). The components of sensitivity include being infected by COVID 19 pandemic and became unemployed due to losing jobs during the pandemic “Sarker et al. (2020); Alam et al. (2018); FAO (2016)”. Households’ sensitivity score is much higher for mixed households (0.241) compare to agricultural (0.030) and non-agricultural households (0.084) (Table 2). The study findings show that no respondent from agricultural households was infected by the COVID-19 pandemic, whereas mixed households were infected most by the COVID-19 pandemic in the study area (Figure 6). Again, the number of people who became unemployed during the pandemic was least in the agricultural households and most in the mixed households (Figure 6). Although the mixed household has a higher sensitivity score, in this study mixed household is most resilient (Table 2).

As mixed households have comparatively a high score in household’s adaptive capacity (0.704) and income and food access (0.402), they can cope with shocks (Table 2).

Figure 6: Indicators of sensitivity index

Source: Authors’ own construction from telephone survey, 2020.

5.3 Impact of COVID-19 on Employment Status

Major employment activities of these villages are farming, business, and service activities. In general, the COVID-19 pandemic has not affected employment status that much in rural areas. However, business activities have been affected the most compared to farming and service activities (Figure 7).

Figure 7: Impact of COVID-19 on employment status in rural area

Source: Authors’ own construction from telephone survey, 2020.

5.5 Coping Strategies

Several studies found that household’s spending reduction, migration, savings, asset depletion, borrowing money from family/ community, taking loans from the bank, borrowing food items from shops/ community, taking help and support from government and NGO are some strategies that vulnerable people adapt in times of sudden shocks to minimize risks “Paumgarten et al. (2020); Endris et al. (2017); Farzana et al. (2017); FAO (2016); Sultana & Rayhan (2012)”. According to “Paumgarten et al. (2020)”, these strategies can be categorized as external and internal strategies. Households seeking help and assistance from family, community, government, and other non-government organizations (NGOs) are external coping strategies while household’s internal adjustments, such as household spending reduction, migration, savings, and asset depletion are internal coping strategies “Paumgarten et al. (2020)”.

5.5.1. External Coping Strategies

The finding of this research shows that most of the agricultural households (31%) of the study area adapt external coping strategies during the pandemic, which indicates that agricultural households mostly rely on external help or assistance to cope with the adverse impacts of the COVID-19 pandemic. This finding is also consistent with the score of the major indicators of livelihood resilience. Agricultural households have a low score in household adaptive capacity and a high score in social safety net than the other two households (Table 2). For this reason, the percentage of agricultural households that depend on external support is also higher, which is comparatively lower for non-agricultural (15%) and mixed households (18%).

Figure 8: Percentage of households of the study area adapt external coping strategies

Source: Authors’ own construction from telephone survey, 2020.

The external strategies which are mostly adapted by the households of the study area are borrowing goods, taking help & support from samiti, government, and wealthy relatives/ neighbors of the village during the pandemic (Figure 8). Help from samiti and the government are found as top external coping strategies in all households of the study area (Figure 8). A notable percentage of agricultural (53%) and non-agricultural households (19%) borrow goods during the pandemic, whereas a small percentage of mixed households (7%) borrow goods during the pandemic (Figure 8).

5.5.2. Internal Coping Strategies

Most of the mixed households (30%) rely on internal adjustment during the COVID-19 pandemic. The percentage of households that adapt internal coping strategies is lower for agricultural (22%) and non-agricultural households (17%) than mixed households. Among the top internal coping strategies adapted by the households, migration and spending reduction are common for all types of households in the study area (Figure 9). All the migration was temporary except for one permanent migration. Asset depletion is the third important internal coping strategy for mixed and non-agricultural households, whereas the change in employment status is the third important coping strategy for agricultural households (Figure 9).

Figure 9: Percentage of households of the study area adapt internal coping strategies

Source: Authors’ own construction from telephone survey, 2020.

6. CONCLUSION

This study measured the livelihood resilience of different occupational rural households in Bangladesh and explored the factors affecting their resilience capacity during the COVID-19 pandemic by developing a composite indicator-based index. All these households of the study area have low LRI values, which indicates that the rural households are not resilient during the COVID-19 pandemic. Among the rural households whose members are engaged with both agricultural and non-agricultural activity are more resilient than agricultural and non-agricultural households. Mixed households have a high score in adaptive capacity, which makes them more resilient during the pandemic. The key factors that enhance the resilience capacity of rural households include having basic education, having skills to shift livelihood strategy, a stable income source, and access to financial help when needed. More improvement and interventions are needed in these sectors to make vulnerable rural households more resilient. At present, most agricultural households rely on external coping strategies, while non-agricultural and mixed households mostly adapt internal strategies to minimize livelihood risk during the COVID-19 pandemic. All the findings of the study will assist in better planning of resources and will guide resilience-building projects and programs in rural areas during any systemic shocks.

A STUDY OF PROMOTING MOBILE BROADBAND ADOPTION IN AFRICAN DEVELOPING COUNTRIES FOR ACHIEVING SDGS.

Sobee Shinohara

KDDI Research, Inc., Japan

ABSTRACT

Objective

This paper makes a study for achieving SDGs in promoting mobile broadband (=3G+4G+5G) adoption, by employing the granger causality test in African Developing Countries.

Motivation

United Nations advocates the SDGs, which categorizes 17 Goals such as “No Poverty (Goal 1),” “Quality Education (Goal 4),” and “Partnerships (Goal 17)” by 2030 (United Nations, 2019). The 17 Goals are all interconnected and particularly “Partnership (Goals 17)” directly describes the importance of “information and communications technologies (ICTs).” United Nations also pointed out that The Internet is important for Goal 17 but “Almost half of the world’s population is not connected to the internet, particularly in poor countries” (United Nations, 2019). We must find out the ways to promote The Internet adoption especially for those countries.

The Internet consists of fixed broadband and mobile broadband, and this paper focuses on the latter.

Previous studies

Shinohara, Morikawa and Tsuji (2015) examined factors promoting mobile broadband adoption by OECD 34 countries data, and obtained the following factors: (i) the launch of Android and iPhone handsets; (ii) network externality; (iii) availability of trunk lines between mobile base stations; and (iv) competition of mobile carriers. Policy cannot directly handle (i) and (ii), and regarding (iii) policy does not either provide enough budget to build up trunk lines between mobile base stations. But policy can handle “(iv) competition of mobile carriers,” by allowing licenses to new entrants, for example, implying it is important to study the role of competition.

Methodologies and Expected Results

This paper estimates mobile broadband adoption in African countries and more than 200 countries. The dataset of this study contains the following characteristics: (i) quarterly data from 2000 to 2018; (ii) more than 200 countries; (iii) adoption ratios of mobile broadband; and (iv) market shares of mobile carriers.

This paper tests Granger causality between mobile broadband adoption and HHI. HHI is the reverse proxy of the competition of mobile broadband, calculated by the market shares of mobile carriers. The tentative result obtained is such that the null hypothesis “low HHI has no Granger causality for mobile broadband adoption ratio” is rejected (the number of countries: 219, the number of observations: 6705, F-Statistic: 5.428, Prob: 0.03%). In other words, this result indicates “low HHI promotes mobile broadband adoption.”

This paper will attempt to conduct the same estimation, focusing on developing countries in Africa.

The results of this paper suggest important theoretical basis of national broadband policy in each country for Achieving SDGs.

KEYWORDS

SDGs, Mobile Broadband, Diffusion of Innovation, HHI, Granger Causality Test

USE OF TECHNOLOGY IN THE RURAL HOUSEHOLDS OF BANGLADESH HAVING MIGRANT MEMBERS

Tasnuva Zaman¹, Md. Musleh Uddin Hasan², Neelopal Adri³, Nawshin Tabassum⁴

¹ Graduate, Bangladesh University of Engineering and Technology, Dhaka, Bangladesh, tasnuvazaman@ug.urp.buet.ac.bd; ² Professor, Bangladesh University of Engineering and Technology, Dhaka, Bangladesh, musleh_uddin@urp.buet.ac.bd; ³ Assistant Professor, Bangladesh University of Engineering and Technology, Dhaka, Bangladesh, neelopal@urp.buet.ac.bd; ⁴ Lecturer, Bangladesh University of Engineering and Technology, Dhaka, Bangladesh, nawshin@urp.buet.ac.bd

ABSTRACT

A good number of rural households in Bangladesh have at least one migrant family member – either in the cities of Bangladesh or abroad. These migrants contribute to the technology diffusion in rural households. The remittance sent by these migrants increases the household income, thus increases the affordability of rural households to buy modern technological items. Based on the survey of 276 rural households of 8 sub-districts, this study finds that though the indirect impact of migration by sending remittance on technologies is quite significant, the direct flow of technology in the country is lagging behind. Almost 60-80% of the technological instruments are self-purchased rather than sent by migrant members. However, the presence of migrant members in a family has statistically significant impact on the family income. Thus, this study shows that the effect of migration is low on the technological advancement of rural households in Bangladesh.

KEYWORDS

Migration, Technology, Rural

1. INTRODUCTION

Bangladesh is a developing country with almost 62.8% of the total of population belonging to rural area “Worldometers (2019)”. Given this large rural region, technological advancement in rural areas is very important for achieving overall development in Bangladesh. A popular speculation of technological advancement in origin countries is through migration “Global Economic Prospects (2006)”. This paper explores the effects of technological progression in Bangladesh by the migrant members of the rural households.

Migration is the movement of people either across international border (International migration) or within the state (Internal migration) for different purposes like employment, education, family reunification etc. “IOM (2019)”. Both international and internal migrants may contribute in transferring technology and related information back to their families living in rural areas as discussed in this paper “Global Economic Prospects (2006)”. Though technology is a vast term, this paper considers mainly money transfer technologies and information communication-based technologies like TV, mobile, internet and computer etc.

Migrants can directly send technology and technological information from developed destination countries or big cities to the rural areas. The remittance they send to their families in the rural areas can also increase the affordability of technologies “Global Economic Prospects (2006)”. This paper analyses the migration and technology related data collected from field survey from different rural areas of Bangladesh to understand the technological effect of migration on rural households. The overall the migration situation in the surveyed rural areas of Bangladesh has been explored, followed by whether the presence of migrant family members positively influences technological advancement, both directly by sending technology and indirectly by sending remittances to buy technology in the rural areas of Bangladesh. 276 respondents from 276 households in 24 villages of seven upazilas (sub districts) of Bangladesh were selected for structured questionnaire survey (Figure 1). Different variables such as socio-economic background, presence of migrant member, sources of different technological gadgets, use of money transfer technology etc. were tested for each respondent. six (07) Focus Group Discussions (FGDs) were also arranged in five upazilas, out of the seven upazilas (Annex Table 1).

Figure 1: Number of respondents from each upazila

Source: Field Survey, 2018.

2. LITERATURE REVIEW

It is stated that migrants from technologically developed countries can transfer various technological goods and knowledge in developing countries “Ivus & Naghavi (2014)”. Diasporas are known to connect high technology countries with low ones promoting the local acceptance of new technologies “Valette (2016)”. One study indicated that a one percent increase in migration to the developed countries from developing countries quickens the growth rate of technology usage of the origin country by 0.3% “Lebesmuehlbacher (2015)”. When migrants return to their home countries, they bring technologies and knowledge about adaptation with them. Even if they do not return, they may send those stuff in other ways which contribute to the development of the origin countries “Linard (2006)”.

Other than the physical transfer of technologies, money sent back to home helps to buy new technologies or fund related projects. A study on Mexico found remittance sent by migrants had significant effect on flourishing the technology in agriculture sector “Quinn (2009)”.

Though comparatively well-off families can migrate abroad and the poorer are more engaged in domestic migration, both phenomena have positive impact on the adaptation of technology in rural households of Bangladesh “Mendola (2004).” As the rural to urban migrations cause local development of villages by remittance and knowledge flow, there are policies to promote such migrations in China to ensure equal development in all parts of the country “Ping & Shaohua (2005)”

3. MIGRATION SITUATION OF STUDIED RURAL AREAS

About 6.1% of total households of Bangladesh have migrant family members, among which about 81% are from rural area according to the Population and Household Census 2011 of Bangladesh “BBS (2015)”.

Figure 2 shows that there is considerable variation in number of migrants (to different destinations –upazila sadar/headquarter, zila sadar/district headquarter, big city, abroad from studied villages in each upazila.

Figure 2: Destination and distribution of migrants from studied upazilas

Source: Field Survey, 2018.

Migration is extremely low from Pirganj and Shaghata area (Figure 2). From Focus Group Discussion (FGD) it is found that there is only seasonal migration to big cities like Dhaka from Pirganj. It has also been revealed that ever since the river erosion problems of Shaghata upazila have been resolved, migration has reduced drastically. From FGDs, it is found that almost every family in Meghna and Sreenagar have migrant members who choose to migrate abroad rather than completing their education (FGD number 1 and 6 in Annex Table 1).

According to the Population and Household Census 2011, Feni and Noakhali Sadar districts are supposed to have the highest migration rate “BBS (2015)”. Though this data matches for Noakhali Sadar (Figure 2), FGD in Noakhali revealed that migration rate has reduced significantly from before as people are now keener to complete proper education and settle in the country rather migrating abroad (FGD number 4 in Annex Table 1).

4. IMPACT OF MIGRATION ON TECHNOLOGY DIFFUSION IN RURAL BANGLADESH

“Lebesmuehlbacher (2015)” suggests that the destination of migration is more important than the skill level of the migrants in technology diffusion. So, this study only focuses on the destination places of migrants.

Studies “Docquier & Marfouk (2004)”, “Clemens & Pritchett (2016)” and “Gelb (2016)” show that migrants transfer technology and information mainly in 3 ways: (1) Directly by technological and knowledge transfers; (2) Investment and remittances contribute to the economic growth and transformation of migrants’ place of origin; and (3) Supporting entrepreneurship development in origin. This paper addresses the impact of first two ways and categorize them as direct impact and indirect impact.

4.1 Direct Impact

Migrants can induce technology use directly by either sending them to villages or by communicating using technologies with families at home.

4.1.1 Technology Inflow

The most basic way migrants contribute to the technology diffusion is by transferring technology to their home country directly. This is also reported in FGD 7 (Annex Table 1). During survey, it has been found that ICT gadgets and devices such as phone, computer, laptop and TV were sent by migrants to their families in the villages. Migrants from abroad seem to send more technologies than the migrants of big cities within the country. As phones, computers and laptops are smaller than TV, they are more often sent from abroad. However, figure 3 shows that most technological devices are self-purchased by the respondents.

Figure 3: Percentage of different ICT from different sources

Source: Field Survey, 2018.

As migration rate is highest in Noakhali, Feni and Sreenagar, transfer of phones from abroad is also high in these areas. Transfer of phones from big cities in the country is low except in Noakhali (Figure 4).

Figure 4: Percentage of sources of phones from different upazilas

Source: Field survey, 2018.

Computer is one of the least popular technologies used in the rural areas of Bangladesh. From figure 5 it is seen that among the very few computers in these areas, transfer from abroad is high in high migration areas like Noakhali, Sreenagar and Feni. Though migration is not high in Ghior, relatives in abroad are the major source of computers there. Some computers are sent from cities to Pirganj as internal migration is dominating there. A good portion of computers are transferred from cities to Meghna too as it is located quite close to Dhaka.

Figure 5: Percentage of sources of computers from different upazilas

Source: Field survey, 2018.

Overall transfer of TV from abroad is lower than other technologies except in Noakhali and Sreenagar. There is also some transfer of TV from big cities of the country to Noakhali as internal migration is also quite significant there (Figure 6). However, there is no inflow of televisions in Saghata as the rate of migration is extremely low there.

Figure 6: Percentage of sources of TV from different upazilas

Source: Field survey, 2018.

4.1.2 Technologies for Communication

In high migration areas, different technologies like mobile phone, computers and internet can be used to communicate with the migrant family members. During FGD (FGD number 6 in Annex, Table 1) in Munshiganj it has been found that the migrants of different countries communicate with their families living here using internet, especially the app "Imo". Besides people also communicate with family members living in abroad, via apps like Skype, if better internet connection is available via mobile phone. Lots of rural respondents informed that communication is one of the key reasons for using phones, computers and internet. This way, technology is bringing the migrants closer to their home and families.

4.2 Indirect Impact

Bangladesh is one of the top 10 remittance receiving countries in the world. In 2013, share of remittance was 9.24% in the total GDP of Bangladesh "BBS (2015)." Remittance and investments sent by migrants can affect technology diffusion in two ways- by increasing income and thus increasing the affordability of families to buy technologies or by using money transfer technologies.

4.2.1 Impact on Income

A significant relation between income and presence of migrant family member is seen in Chi-square test. Here Pearson chi-square= 40.896 (df=4) and p= 0.000. As the creamers V value is 0.387(>3), the impact is quite strong.

Figure 7: Impact of migrant family member on household income

Source: Filed Survey, 2018.

Figure 7 indicates that relation is quite positive as the presence of migrants increases in the higher income families. So, it can be assumed that migrants of these families send remittance which increase the household income. Another Chi-square test shows a significant relation between income and the number of migrants present in a family. Here the Pearson chi-square= 89.480 (df=20) and p= 0.000. As the creamers value is 0.287(2<0.287<3), the impact is moderate.

Figure 8: Effect of number of migrant members on family income

Source: Filed Survey, 2018.

Figure 8 shows that families with multiple migrant members generally belong to higher income groups indicating that the higher migrant numbers in a family may yield higher the amount of remittance and income. FGD in Sreenagar revealed that, new technologies are mostly used by the solvent people (about 80% of total users) of the area. Higher income increases the possibility of buying different technologies to upgrade the living standards of households.

4.2.2 Technologies Used in Money Transfer

For receiving foreign remittance, banks are the main channel. However, different local money transfer technologies are being used by the internal migrants as they are cheaper, quick and user friendly. A money transfer app named Bkash is more popular in every upazila (Figure 9).

Figure 9: Use of money transfer technologies in different upazilas

Source: Filed Survey, 2018.

5. CONCLUSION

Though different studies show high impact of migration on technology diffusion, this study concludes that effect is not so big in Bangladesh. Specially in the case of technology transfer, only some of the high migration areas have some inflow. Indirect impact of remittance and investment on technologies and communication technologies are more dominant than the direct technology flow in the country. As the migration rate is quite high in different rural areas of this country, there is ample potential to use that to enhance the technology use in rural areas. Different policies can be taken to encourage technology inflow in the country.

ANNEX

Table 1: Information from Focus Group Discussions (FGDs) of the study

FGD No.	Upazila	Place	No. of participants	Age & gender of participants	Occupation of participants	Relevant information
1	Meghna	Local tea stall, Chandanpur	Six	Two elderly (70+ years) and four middle aged (34-45 years). All male	One was the owner of the tea stall and rest were local farmers	<ul style="list-style-type: none"> • High international migration rate • Most male members migrate abroad passing secondary school • Migrants send high remittance. • Every house has TV, Fridges and phones, mostly bought from remittance money.
2	Shaghata, Gaibandha	Local tea stall, Bharatkhalai bazar	Six	25- 90 years, All male	Worker at rice mill, a businessman, a teacher, a van driver and two unemployed	<ul style="list-style-type: none"> • High internal migration rate due to severe river erosion problem in the past • Migrated for better living conditions and job • Drastically reduced migration rate for past few years due to reduced river erosion problem.
3	Pirganj, Rangpur	House of the village head, Panial village	Six	Five male (25-60 years), one female (38 years)	One ward member, two farmers, a lecturer, a housewife and the village head	<ul style="list-style-type: none"> • No international migration • All seasonal migrants to Dhaka city • Many male villagers stay at home only during cultivation season and migrate to Dhaka for rest of the year to work at garments
4	Feni	Shorishadi Bazar	Four	30-60 years, three male, one female	Two assistant teachers at Shorishadi High School and two business men	<ul style="list-style-type: none"> • Very high international migration rate in the past, when people favored working abroad over completing school • Recent decrease in migration as villagers are keener to complete their education and settle in the country • Yet, most of the well-off families in the village have at least one earning member working abroad
5	Sreenagar, Munshiganj	Crockery shop, Birata Village	Four	(26-50 years), all male	Two shopkeepers and two local businessmen	<ul style="list-style-type: none"> • Reduced migration rate due to several incidents of human trafficking • People are more careful and only migrate abroad through reliable sources • Low rates of internal migration
6	Sreenagar, Munshiganj	Tea stall, Hashara Village	Eight	25-65+ years, all male	Two van driver, three local businessmen, one fish-selling businessman and one unemployed elderly person	<ul style="list-style-type: none"> • International migrant member in almost every family of the village • Usual destination are Singapore and UAE • Preference of migrating before completing education is the cause of low literacy rate • People having family members living in abroad easily communicate via apps like Skype, Imo due to availability of internet
7	Sreenagar, Munshiganj	Tea stall, Hashara Village	Seven	Two were 60+ years, four were 30-50 years and one was 20, all male	Tea stall owner, one van driver, two businessmen, one carpenter and two farmers	<ul style="list-style-type: none"> • High international migration rate, though less than before • Migrants send both technologies and high amount of remittance • Many of the household technologies are sent from abroad to families having migrant members

COMMUNITY GARDENS AND URBAN RESIDENTS' QUALITY OF LIFE (QOL): A CASE STUDY FROM SHANGHAI, CHINA

Yingjie Ge¹, Lily Kiminami², Shinichi Furuzawa²

¹ Graduate School of Science and Technology, Niigata University, Japan, f21m002f@mail.cc.niigata-u.ac.jp; ² Institute of Science and Technology, Niigata University, Japan, kiminami@agr.niigata-u.ac.jp, furuzawa@agr.niigata-u.ac.jp

ABSTRACT

In general, a high productivity due to the effect of agglomeration and economic growth has been realized along with urbanization in China. However, the accelerated urbanization has brought about environmental problems due to human activities, such as the reduction of green spaces, air and water pollution, noise and waste disposal problems in the country. Moreover, as urbanization progresses, the resources of available land in megacities are becoming more and more scarce, the lifestyles of residents have been influenced by a less communication among each other and the problems of community dilution are emerging (Zhang, 2017). On the other hand, in China, the middle class has been expanding in recent years, and they are increasingly concerned about the quality of life (World Bank & PRC, 2013). Therefore, to provide its local residents with a "better city, better life" (SHANGHAI MASTER PLAN, 2017-2035) has become an urgent challenge for urban planning.

On the other hand, existing studies have shown that urban residents' participation in community gardens can improve public health in cities (Armstrong, 2010). It is also pointed out that there is a positive correlation between the social capital of local residents and their interactions in community gardens (Alaimo et al. 2010). Furthermore, a study on community gardens and social sustainability showed that trust and stewardship contributed significantly to social sustainability through community gardens (Rogge et al. 2018).

Therefore, the purpose of this study is to explore the role of community gardens in improving the quality of life (QOL) of urban residents through multi-functionality of community gardens in Shanghai, China. We conduct a web-based questionnaire survey on Shanghai residents (including users and non-users of community gardens) and introduce structural equation modeling to clarify the following hypotheses: "The multi-functionality of community gardens can enhance the utility and life satisfaction of urban residents (H1)", "People with higher levels of social capital also have higher levels of community gardens participation and evaluation (H1-1)", and "People with higher community gardens participation and evaluation are more satisfied with local life (H1-2). Based on the analytical results, it concluded that a development strategy for urban agriculture is required in line with the vision of sustainable development of the city that meets the diverse needs of the residents.

KEYWORDS

Quality of life (QOL), Community gardens, urban agriculture, Multi-functionality, Life satisfaction

1. INTRODUCTION

After reforming and opening up for the decades, the economy in China has grown rapidly and its level of urbanization has also highly progressed. According to a survey by the National Bureau of Statistics, China, in 2016, China's urbanization rate has already reached 57.35%, with a urban resident population of 792.98 million. And by 2030, the urbanization rate is expected to reach 70% (World Bank and PRC 2014).

In general, a high productivity due to the effect of agglomeration and economic growth has been realized along with urbanization in China. However, the accelerated urbanization has brought about environmental problems due to human activities, such as the reduction of green spaces, air and water pollution, noise and waste disposal problems in the country. Moreover, as urbanization progresses, the resources of available land in megacities are becoming more and more scarce, the lifestyles of residents have been influenced by a less communication among each other and the problems of community dilution are emerging (Zhang, 2017). On the other hand, in China, the middle class has been expanding in recent years, and they are increasingly concerned about the quality of life (World Bank & PRC, 2013). Therefore, to provide its local residents with a "better city, better life" (SHANGHAI MASTER PLAN, 2017-2035) has become an urgent challenge for urban planning.

On the other hand, existing studies have shown that urban residents' participation in community gardens (CGs) can improve public health in cities (Armstrong, 2010). It is also pointed out that there is a positive correlation between the social capital of local residents and their interactions in CGs (Katherine et al. 2010). Furthermore, a study on CGs and social sustainability showed that trust and stewardship contributed significantly to social sustainability through CGs (Rogge et al. 2018). On the other hand, according to a study that evaluated the external economic effects of parks, playgrounds, etc. and woodlands using a land value function, it is known that parks with green spaces have a positive external effect on land value (Kobayashi et al. 2009). Therefore, it is also supposed that CGs have a positive external effect on land value.

Therefore, the purpose of this study is to clarify the role that CGs in meeting the needs of urban residents for “better city, better life” in Shanghai, China, one of the largest cities of the country and the earliest beginning of community garden projects.

2. LITERATURE REVIEW

2.1. Urban residents' Quality of life (QOL) and the Role of Urban Agriculture

2.1.1 Urban residents' Quality of life (QOL)

In recent years, the seriousness of the problems caused by the traditional approach to urban development has been recognized, and the need has arisen to seek sustainable development that can reconcile the natural environment with social development. The concept of “development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (“Our Common Future”) was proposed in 1987. And in 2015, the United Nations published the internationally agreed 17 Sustainable Development Goals (SDGs), in which the sustainable developments of cities and communities (Make cities and human settlements inclusive, safe, resilient, and sustainable) are included.

In addition, sustainable urbanization in China is defined as providing people with the required quality of urban life, while making it compatible with the environment (land, air and water) and natural resources (World Bank & PRC, 2014). It is characterized by a greater focus on the quality of life of urban residents or urban amenities. And the quality of life of urban residents is a composite indicator about people’s mental and physical health (Marans 2015). On the other hand, the development of urban green infrastructure in cities to re-establish the relationship between nature and the built environment (Building Green Cities) helps to create attractive urban landscapes and a better quality of life (Breuste 2020). By providing blue and green infrastructure in the city, cultural ecosystem services can also be provided to the city, creating a multidimensional connection between people and their living environment (Andersson et al., 2015). In addition, some researchers have pointed out that urban agriculture can contribute to improving the quality of urban life by performing multi-functionality and providing local public goods (Kiminami & Kiminami, 2007).

2.1.2 Urban Agriculture and its role

Urban agriculture is an important part of sustainable urban development (Zeeuw & Dubbeling 2011). The growing of plants and the raising of animals within and around cities. According to the Food and Agriculture Organization of the United Nations (FAO), urban and peri-urban agriculture (UPA) is defined as the growing of plants and the raising of animals within and around cities. And according to the Ministry of Agriculture and Rural Affairs of the China (2012), urban agriculture is modern agriculture that has developed along with urban modernization in, near and within large cities. These are the most straightforward definitions of urban agriculture geographically, limiting it to cities and their surroundings, while China’s definition of urban agriculture, in its own context, emphasizes the modernization of agriculture. However, these definitions of urban agriculture do not explicitly refer to the multi-functionality of urban agriculture.

On the other hand, regarding the multi-functionality of agriculture, the WTO (glossary) defines agriculture has many functions in addition to producing food and fiber, e.g. environmental protection, landscape preservation, rural employment, food security, etc. It has also been pointed out that urban agriculture, in addition to its obvious locational characteristics (in and around cities), has a variety of functions such as providing environmental services and social services in addition to food production, and supports the local economy through direct access to urban markets (Sanyé-Mengual 2015). Kiminami et al. (2018) mention that urban agriculture has multi-functionality such as promoting communication, welfare, education, recycling, environmental protection, forming beauty, disaster prevention, and experiencing agriculture, in addition to its production function. The multi-functionality of urban agriculture can therefore be divided into three categories: environmental, social and economic functions.

Firstly, in terms of environmental protection functions, according to Artmann & Sartison (2018), urban agriculture has the function of providing ecosystem services and the function of conserving biodiversity. And civic farms in cities can have the same importance as parks by providing ecosystem services, among other roles, (Breuste & Artmann, 2014). In addition, it has been argued that urban agriculture can contribute to low carbon cities and sustainable urban development by reducing greenhouse gases through lower food miles (mainly vegetables) (Lee et al., 2015).

In terms of social functions, urban agriculture can make use of various areas in the city, such as open spaces, residential areas and rooftops, to farm and supply the city with fresh produce produced (Saha & Eckelman, 2017). Urban agriculture has also been found to improve dietary diversity by providing calories (Zezza & Tasciotti, 2010). In addition, urban agriculture can re-establish the relationship between those involved and nature, increase awareness of environmental protection and satisfy participants’ own need to belong (Chan et al. 2016), and it also plays a more important role for socially disadvantaged groups such as the unemployed and the poor (Cabannes & Raposo 2013).

Regarding the economic functions of urban agriculture, Kiminami & Kiminami (2007) use Tokyo as a case study to point out that urban agriculture also has high economic functions through the production of high quality, high value agricultural products. On the other hand, they argue that the multi-functionality of urban agriculture can attract the creative class, which is a source of urban creativity, and that these people can contribute to the sustainable development of cities by actively participating in social business that address urban social problems (Kiminami et al. 2019). On the other hand, urban horticulture has many other uses besides food production and there are some differences between

urban horticulture and urban agriculture (Appendix 1), but urban horticulture and urban agriculture cannot be separated, especially at the small-scale production level (Breuste 2020).

2.2. Urban Agriculture and Community Gardens

2.2.1 Definition of Community and Community Gardens

CGs can be found in many parts of the world, but it is not easy to find a strict definition for them, and According to Guittart et al. (2012), around 63% or more of the papers on CGs do not define them strictly. The reason for this is that it is difficult to identify a fitting and uniform community garden based on different national or regional circumstances. In the United States, for example, attention has been paid to the ability of CGs to meet the diverse needs of the people who use them (McKelvey 2015), and to the social function of CGs in providing needed support to vulnerable groups, especially young people among them (e.g. drug users) (Ferris et al. 2002). On the other hand, China also emphasizes the multi-functionality of CGs, particularly the function of facilitating communication between residents, but the functions and roles of CGs differ between China and America due to the differences in their national circumstances.

In addition, the definition of community is closely related to society and culture, which means that CGs have different meanings in different countries and regions, which makes it difficult to define them. In general, a community is socially constructed through collaboration for a common purpose (Firth et al., 2011). In contrast, traditional Chinese communities (Shequ or Xiaoqu) are places where residents live (blocks are similar to Chinese streets or sub-district), with a greater focus on local and neighborhood relationships. However, since the reforming and opening up, communities have become fragmented (fragmentation of the socio-spatial structure, fragmentation of the profit structure, fragmentation of the power structure) with the transformation of traditional institutions (Li & Ge 2013). Therefore, nurturing communities through grassroots social organizations (Residents committee, Owners committees, Property management committee) can help build a harmonious society and develop civil society (Qiu, 2018).

In the case of China, CGs are gardening areas within residential areas that are operated collaboratively by residents and provide a place and opportunity for local residents to interact (Liu & Wei, 2018). Therefore, when discussing CGs in China, it is necessary to take into account the characteristics that each area has. Therefore in this study, CGs can be defined as a horticultural area closely related to urban agriculture that fulfils multi-functionality, including environmental, social and economic functions, through the active participation and management of the local residents, and can meet the diverse needs of them.

2.2.2 Multi-functionality of Community Gardens

CGs can be divided into three categories: environmental and ecological functions, social functions and economic functions. A case study conducted by Clarke & Jenerette (2015) in America found that CGs contribute to urban ecosystems and biodiversity and also provide valuable ecosystem services to communities with food security issues. Whereas allotment gardens and CGs, while providing important ecosystem services to urban communities, such as local climate and water regulation and habitat for diverse organisms, their contribution depends largely on the intensity of management and to some extent on their location in the city, and it has also been noted that CGs, in contrast to allotment gardens, are characterized by the cultivation of native plant species (Cabral et al., 2017). In addition, the trend in urban redevelopment policy is to increasingly include community participatory green space planning (Ferris et al., 2002). On the other hand, CGs provide environmental or ecological benefits as well as social functions. For example, CGs have been found to help promote public health and civic pride in cities (Armstrong 2000, Twiss et al. 2003). In addition, the trust among community residents is largely due to the high level of interaction and close relationships, and the cultural activities of community residents enhance the sense of community and indirectly contribute to the autonomy of the community (Qiu 2018). In addition, increasing the interaction and closeness of local residents to nature through the construction and management of CGs can promote neighbourhood harmony, community cohesion and the psychological well-being of residents, as well as increase residents' enthusiasm for public affairs and enhance their sense of community (Kou et al. 2019). These studies suggest that when local residents use CGs for communication, and cooperation, trust is deepened through the formation of networks among residents, which may enhance social capital (e.g. Firth et al., 2011; Alaimo et al., 2010). On the other hand, Glover et al. (2005) show that residents' activities in CGs promote citizenship and play a role in the democratic governance of the city.

And many researchers in Europe and America have pointed out that the construction of CGs contributes to food security in cities (e.g. Ferris et al., 2002). Specifically, CGs can provide cities with fresh or organic produce. However, the role of CGs in promoting food security and food safety is currently not much talked about in China. Therefore, the food security function of CGs may become one of the future research topics in China.

2.3 History of the building of Community Gardens in China (Shanghai)

In developed countries or regions such as Europe, America and Japan, CGs have a relatively long history of development and construction (Liu & Wei, 2018). On the other hand, in China, CGs are still in their infancy and are being built on an experimental work in megacities such as Beijing and Shanghai. In 2008, the concept of CSA was first introduced, with Renmin University of China and the Haidian District Government as the main builders, to build the "XiaoMaoLú" civic farm in Haidian District, Beijing (Fan 2013).

Previously, urban agriculture in Shanghai gradually moved from the city center to the suburbs due to urban development plans (Kiminami et al., 2006). On the other hand, with the development of the city, in 2015 the Shanghai government

launched “Shanghai Urban Renewal Implementation Measures”, which introduced the concepts of “organic urban renewal” and “people first reconfiguration of space and activation of communities”. In addition, the Shanghai Greening Bureau advocates “residents’ greening autonomy”. In this context, between 2014 and early 2018, four green autonomous patterns had been formed in Shanghai, with more than 340 CGs of different sizes built (Shanghai Manual 2018). participation by urban residents (Liu 2020). On the other hand, despite they have temporality and short-term issues, current CGs provide a better living environment for local residents by overcoming urban social problems and providing nature education sites for children through cooperation between stakeholders, among other functions (Yin 2017). Furthermore, the World Bank and PRC (2014) report that as China’s urbanization grows, urban density is increasing, making urban land and space resources increasingly valuable. Therefore, there will be scope for further development of community gardens that can make effective use of urban micro land and space. However, there is a lack of research that discusses the role of CGs as a form of urban agriculture in terms of understanding the relationship between the quality of life of urban residents, as well as sustainable urban development.

3. ANALYSIS FRAMEWORK AND HYPOTHESES

Based on the above survey of existing studies, Figure 1 shows the analytical framework of this study. In other words, we argue that urban residents’ utility is enhanced and their quality of life is also improved through participation in CGs. We also believe that the multi-functionality of community gardens would be further enhanced if the way in which they are operated could be improved to meet the potential demand for community gardens (feedback).

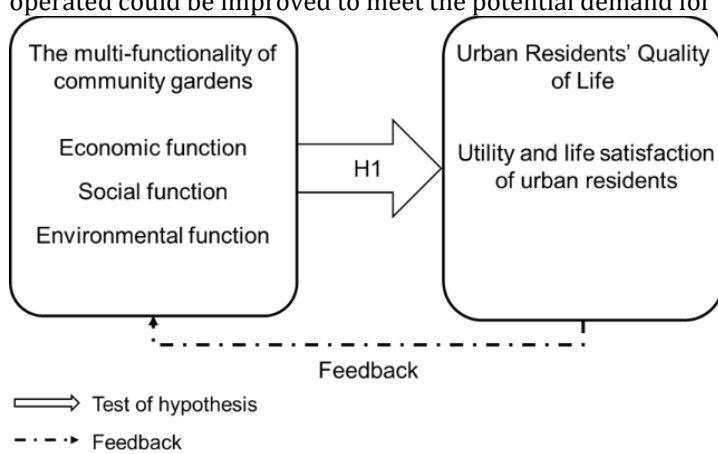

Figure 1: Analytical framework

Therefore, in order to achieve the objectives of this study, the following hypotheses have been formulated.

Hypothesis 1: The multi-functionality of CGs can enhance the utility and life satisfaction of urban residents.

1-1: People with higher levels of social capital also have higher levels of CGs participation and evaluation.

1-2: People with higher CGs participation and evaluation are more satisfied with their local life.

4. ANALYSIS METHODS

Structural equation modeling (SEM) is a statistical analysis method that reveals the relationships between elements with complex structures. To clarify hypothesis 1, this study will conduct a web-based questionnaire survey of Shanghai residents (including users of CGs). In addition, the results of the web-based questionnaire will be used to introduce SEM analysis to clarify urban residents’ participation in CGs and their evaluation of social capital.

Figure 2 shows the conceptual model for the structural equation modeling in this study. A study by Zhang et al. (2017) explored the importance of social relationship capital in building online communities. For this reason, it is assumed that the social relationship capital of local residents positively influences their participation in the construction and operation of the CGs (H1-1). Furthermore, it can be assumed that through participation in the CGs, can meet the diverse needs of local residents and their satisfaction with local life will increase (H1-2).

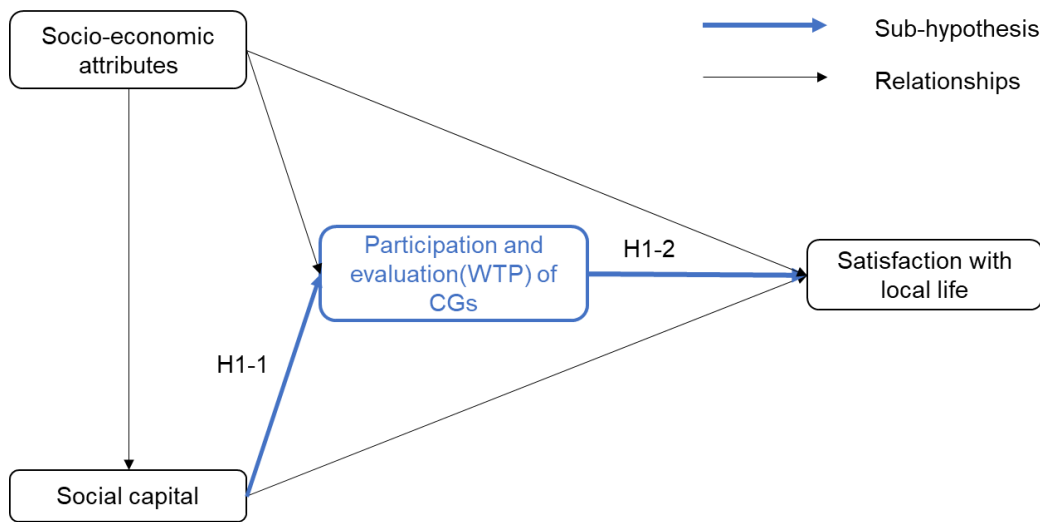

Figure 2: Conceptual model of SEM

5. ANALYSIS RESULTS

5.1. An overview of Shanghai and the reality of CGs operation

Located at the mouth of the Yangtze River in eastern China and facing the Pacific Ocean, Shanghai covers an area of 6,340.5 km² and consists of 16 districts with a resident population of 24.18 million at the end of 2017. In addition, the regional GDP reached RMB 306,329 million in 2017, with a per capita regional GDP of 18,450 Dollars.

In order to preserve Shanghai’s urban environment, create a beautiful landscape and build a harmonious society, the Shanghai government is promoting the construction of CGs. According to the “Shanghai Manual 2017”, there were 28 CGs distributed in the central area with high population density and house price and its adjacent areas by 2017.

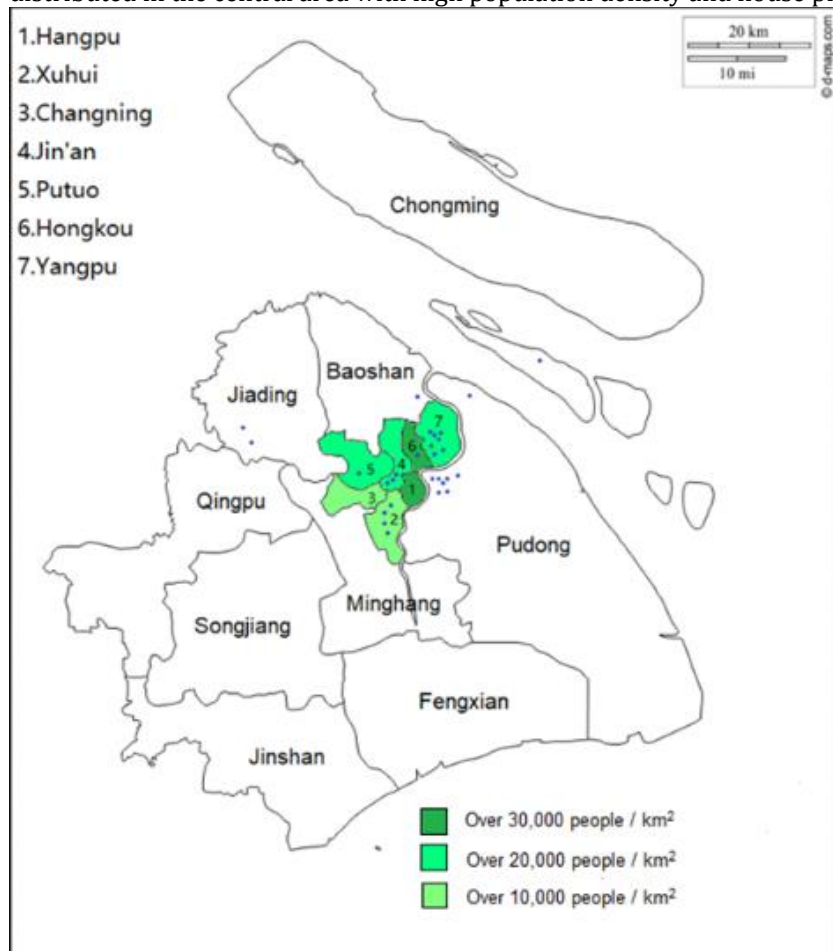

Figure 3: Community gardens and population density

Shanghai Statistical Yearbook 2018, Shanghai Manual 2017

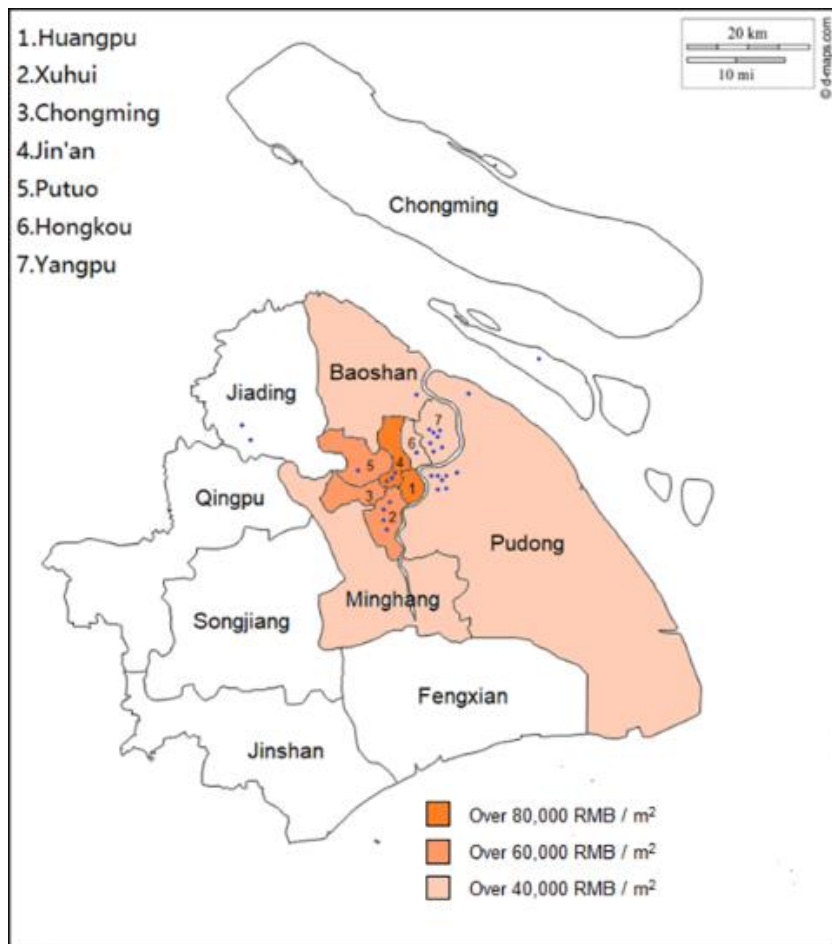

Figure 4: Community gardens and Community gardens and house price

Shanghai Statistical Yearbook 2018, Shanghai Manual 2017

And according to Kou et al. (2019), as the management system of the CGs (including the construction and management entities), local residents are actively participated in all stages of the construction of the CGs. The CGs project is supported by companies or the government (funding, materials, etc.), and a team of experts designs and implements the CGs. NPOs, NGOs and other civil society organizations, as well as local community organizations and street residents’ committees are also participated in the project. The construction and operation of CGs can therefore be found to be characterized by a large number of stakeholders. On the other hand, based on practical experience in the construction and management of CGs, the researchers make the suggestion that, as residents are likely to lack awareness and capacity in the early stages of community participation, external interventions are to be initiated, with capacity training by experts.

5.2. Basic overview of the web-based questionnaire

We commissioned NTT Com-Online Marketing Solutions to conduct a web-based questionnaire of local residents, including users of CGs in Shanghai. The survey was run from 25 August 2020 to 28 August 2020. The valid sample size is 536. In addition to examining the socio-economic attributes and social capital of residents, and how their participate in CGs affects how they evaluate CGs (satisfaction with CGs and willingness to pay (WTP)) and their satisfaction with local life. To examine whether this was the case, respondents were assigned a proportion of “Still in use or Used to use”, “knew but never use” and “did not know”.

Table 1 shows the profile of the respondents to the questionnaire. In terms of the sex of the survey respondents, males (45.9%) are slightly lower than females (54.1%). In terms of where respondents live, no one lives outside of Shanghai, with over 90% of respondents living in the central of Shanghai (Old Town) or Pudong New Area. In terms of having children, over 60% of respondents answered that they have children. In terms of monthly household income, over 60% of respondents had a monthly income between “RMB10,000 and RMB30,000”, 25% of less than “RMB10,000” and 13.81% of more than “RMB30,000”. And more than half of the respondents were aware of the existence of farmland (urban agriculture) around their homes. On the other hand, in terms of the age structure of the respondents, “30-39 years old” was the most represented age group (46.9%), followed by “19-29 years old” (35.8%).

Table 1: Summary of respondents to the questionnaire

	Rate						
Sex ¹	Male 45.9%	Female 54.1%	Total 100%				
Residential areas	central district ² 61.8%	Pudong New Area 29.9%	Other districts in Shanghai 8.4%	Outside of Shanghai 0%	Total 100%		
Children	With children 61.6%	No children 38.4%	Total 100%				
Monthly household income	RMB10,000 25%	RMB10,000~30,000 61.2%	RMB30,000 13.8%	Total 100%			
Farmland (urban agriculture)	There is a lot 19.8%	There is a little 47.2%	here is not much 21.1%	There is not any 11.9%	Total 100%		
Age ¹	Below 18 1.5%	19~29 35.8%	30~39 46.8%	40~49 9.5%	50~59 4.1%	Over 60 2.2%	Total 100%

1: According to the 2019 Shanghai Statistical Yearbook, by the end of 2018, Shanghai’s registered population (14.623 million) consisted of 7.241 million males (49.5%) and 7.382 million females (50.5%). In terms of the age structure of Shanghai’s registered population, 1,765,000 (12.1%) are aged 17 and below, 2,474,300 (16.9%) are aged 18-34, 5,364,200 (36.9%) are aged 35-59, and 5,502,300 (34.3%) are aged 60 and over. 2: Central District means Huangpu District, Xuhui District, Changning District, Jing’an District, Putuo District, Hongkou District and Yangpu District in the center of Shanghai.

Table 2 shows the social capital of the respondents and their level of participation in the community garden and their evaluation of the CGs. And more than half of these respondents are involved in civil society organizations and social groups. And among the organizations and groups involved, residential community organizations (e.g. owners’ committees) had the highest proportion (17.7%), followed by charitable organizations (16.2%) and social service organizations (e.g. environmental protection organizations) in third place (16%). In addition, over 70% of respondents said that they had a very good relationship with their community. Regarding participation in CGs, about 60% of the respondents have been participated in CGs and 32.7% were still participating in CGs. On the other hand, using WTP as an evaluation of CGs, more than 80% of the respondents were willing to pay for the maintenance of CGs, while about 20% are not willing to pay.

Table 2: Social capital, and community garden participation and evaluation

	Rate							
Relationships with the community	Very good 20.9%	Good 55.6%	Cannot be sure 20.7%	Not very good 2.6%	Very bad 0.2%	Total 100%		
Participation in social organizations	Trade organizations 9.7%	Charitable organizations 16.2%	Academic groups 12.1%	political organizations 11%	Community organizations 17.7%	Social service organizations 16%	civic mutual aid organizations 8.2%	Peer organizations 14.7%
	Religious groups 2.4%	Regional activity groups 3%	Other NPO organizations 0.2%	Not involved 43.3%				
Participation in CGs	Still in use 32.7%	Used to use 26.3%	Knew but never used 24.8%	Did not know 16.2%	Total 100%			
Satisfaction with CGs	Very satisfied 24.4%	Satisfied 58.9%	Cannot be sure 12.9%	Not very satisfied 4.4%	Very dissatisfied 0.3%	Total 100%		
Evaluation (WTP) of CGs	Below 50 RMB/month 9%	51~100 RMB/month 19.4%	101~150 RMB/month 19.2%	151~200 RMB/month 21.1%	201~250 RMB/month 9.3%	Over 251 RMB/month 4.3%	Don not want to pay 17.5%	Total 100%

Table 3 shows the suggestions for CGs. The most popular concern was “rational planning of land layout” (42.9%), followed by “location of CGs” (37.1%), “openness of the range of users” (36.6%) and “greater participation in management” (36.4%).

Table 3: Suggestions for CGs

	Number	Rate
Openness for users of CGs	196	36.6%
Standard size of land available for use	134	25.0%
Rational planning of land layout	230	42.9%
Increasing participation in the operation of CGs	195	36.4%
Set reasonable fees and rules	187	34.9%
Matching with the city's development plan	161	30.0%
Location of CGs	199	37.1%
Increase the proportion of edible plants cultivated	174	32.5%
Improve the facilities and equipment attached to the CGs	150	28.0%
Other	0	0%
Cannot be sure	39	7.3%
Total	536	100%

Regarding the reasons for using CGs (multiple choice question), only a small proportion (2.2%) of respondents indicated that they were invited by others, indicating that most community garden users participate in the gardens voluntarily. The most common reason was “love plants and want to be close to nature” (56.0%), followed by “to experience farming activities” (39.6%) and “to exercise the body” (33.9%) (Table 4).

Table 4: Reasons for using CGs

	Number	Rate
For mental health	82	26.0%
To exercise the body	107	33.9%
Love plants and want to be close to nature	177	56.0%
To experience farming activities	125	39.6%
To make use of the produce obtained through farming	67	21.2%
Want to participate in activities held in the community garden	76	24.1%
To interact with other users	68	21.5%
To use the community garden as a place to rest	100	31.7%
To have a view of the neighborhood	70	22.6%
To improve the natural environment of the neighborhood	76	24.1%
To increase the vitality of the community	56	17.7%
To be invited by others	7	2.2%
Other	0	0%
Total	316	100%

In contrast, the most common reason for not using CGs was “ don't have a lot of free time “, followed by “don't know about community gardens” and “No community gardens near home” (Table 5 (collated from responses to free-response questions)). This implies that at this stage there is not enough publicity about CGs, residents do not have a comprehensive understanding of CGs, the range of services that existing CGs can provide does not fully meet the needs of residents, and there is room for the development and evolution of CGs.

Table 5: Reasons for not using CGs

	Number
Don't have a lot of free time	68
Don't know anything about Community gardens	46
No community gardens near home	56
Too many people or consider it ineffective for socializing	6
Not interested in CGs	36
Community gardens are not well run	7
Other	12
Total	220

This is a free-response question from the respondent. We have collated and summarized the answers. On the other hand, as shown in Table 6, when community garden users were asked how satisfied they were with their local life (“Are you satisfied or dissatisfied with the local you currently live in?”) Approximately 80% of the respondents answered that they were satisfied with their local life. Also, in response to the question “Please select the city that best fits your vision of the future of the city you currently live in from the following city types”. “Sustainable city, eco-city or green city” had the highest response rate of over 50% (Table 7).

Table 6: Users' satisfaction with local life

	Number	Rate
Very satisfied	107	20.0%
Satisfied	315	58.8%
Cannot be sure	78	14.6%
Not very satisfied	32	6.0%
Very dissatisfied	4	0.8%
Total	536	100%

Table 7: Users' vision of the city future

	Number	Rate
Sustainable cities, eco-cities, green cities	277	51.7%
Global cities	61	11.4%
Smart Cities	106	19.8%
Creative Cities	60	11.2%
Megacities	18	3.4%
Inclusive Cities	14	2.6%
Other	0	0%
Total	536	100%

In addition, Table 8 shows the respondents' perception of the role of urban agriculture (multiple choice question). As can be seen from the results, only 1.9% of the respondents did not consider urban agriculture to play an important role. And among the roles considered important, the most chosen were the roles of "conservation of the green and environment" (58.6%) and "supply of fresh and safe agricultural and livestock products" (42.2%). This was followed by the role of "formation of good scenery" (38.2%), "education functions such as farming experience and food education" (35.3%) and "making a life tasteful and peaceful" (32.3%).

Table 8: Awareness of the role of urban agriculture

	Number	Rate
Supply of fresh and safe agricultural and livestock products	226	42.2%
Providing the employment	146	27.2%
Conservation of the green and environment	314	58.6%
Education functions such as farming experience and food education	189	35.3%
Revitalization of regional industry	148	27.6%
Disaster prevention function such as evacuation place in case of disaster	105	19.6%
Making a life tasteful and peaceful	173	32.3%
Succession of local tradition and culture	121	22.6%
Formation of good scenery	205	38.2%
Place for local community	121	22.6%
Medical and welfare functions such as horticulture therapy	122	22.8%
Place of familiar recreation	83	15.5%
Other	0	0.0%
Not considered important	10	1.9%
Total	536	100.0%

5.3 Results of the SEM analysis

The SEM analysis is introduced for the results obtained from the above questionnaire. Tables 9 and 10 summaries' the variable settings and basic statistics used in the SEM analysis.

Table 9: Variable settings

Classification	Variable	Setting
Socio-economic attributes	Sex	Male (1); Female (0)
	Monthly household income	Over RMB30,000 (2); RMB10,000~30,000 (1); Less than RMB10,000 (0)
	Children	With children (1); No children (0)
	Residential areas	Huangpu District, etc. (3); Pudong New Area (2); Other districts in Shanghai (1); Outside of Shanghai (0)
	Farmland (urban agriculture)	There is a lot (3); There is a little (2); There is not much (1); There is not any (0)
Social capital	Participation in social organizations	It was set up with 12 steps, such as 0 for no participation, 1 for participation in one organization, and 2 for participation in two organizations.
	Relationships with the community	Very good (4); Good (3); Cannot be sure (2); Not very good (1); Very bad (0)
Participation and evaluation(WTP) of CGs	Participation in CGs	Still in use (3); Used to use (2); Knew but never used (1); Did not know (0)
	Evaluation (WTP) of CGs	Below \$50 (6); 51-100 RMB/month (5); 101-150/month (4); 151-200 RMB/month (3); 201-250/month (2); Over \$251 (1); Don not want to pay (0)
Satisfaction with local life	Satisfaction with local life	Very satisfied (4); satisfied (3); Cannot be sure (2); Not very satisfied (1); Very dissatisfied (0)

Table 10: Statistics of SEM variables

Variables	No.	Mean.	SD.	Min.	Max.	
Socio-economic attributes	Sex	536	0.46	0.50	0	1
	Monthly household income	536	0.89	0.61	0	2
	Children	536	0.62	0.49	0	1
	Residential areas	536	2.53	0.65	0	1
	Farmland (urban agriculture)	536	1.75	0.91	0	3
Social capital	Participation in social organizations	536	1.11	1.37	0	11
	Relationships with the community	536	2.94	0.74	0	4
Participation and evaluation(WTP) of CGs	Participation in CGs	536	1.75	1.08	0	3
	Evaluation (WTP) of CGs	536	2.62	1.72	0	6
Satisfaction with local life	536	2.91	0.80	0	4	

And the path coefficients and path diagrams obtained from the SEM analysis using Stata/SE software are shown in Figure 4 and Table 11. The goodness-of-fit index was RMSEA = 0.051 and CFI = 0.991, which was a good result. The results of the analysis revealed the following.

Firstly, the presence or absence of children and the farmland around the homes had a strong positive effect on the relationship with the community, and the presence or absence of children, residential areas and farmland around the homes had a strong positive effect on participation in social organizations. The socio-economic attributes that are particularly effective for participation in CGs are residential areas, farmland and social capital (participation in social organizations and relationships with the community). On the other hand, the socio-economic attributes that are particularly effective in evaluating (with WTP) CGs are monthly household income, farmland and social capital. This suggests that people with higher levels of social capital are more enthusiastic about participating in CGs and evaluate it more positively. Furthermore, there was a positive relationship between participation in CGs and evaluation of CGs (WTP). In other words, it is clear that people with high engagement rate CGs highly, because they enjoy the utility it brings. In addition, satisfaction with local life was positively correlated with the evaluation of the CGs (WTP) and its relationship with the community. This suggests that residents who are often participated in social organizations and have good relationships with their communities are more likely to be participated in CGs, and that the utility they derive from CGs increases their satisfaction with local life.

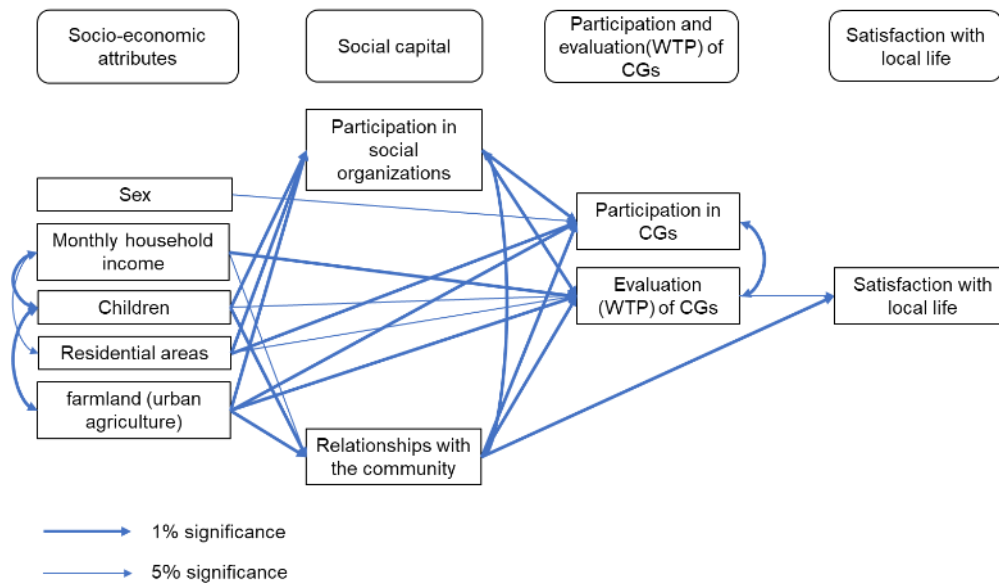

Figure 3: Path diagram of the results of the SEM

6. CONCLUSION

The results of the above analysis support out hypothesis “The multi-functionality of CGs can enhance the utility and life satisfaction of urban residents” (H1). In other words, people with higher levels of social capital are more actively participate in CGs and also enjoy the benefits of CGs more, and are more satisfied with their local life. As traditional urbanization in China has left many challenges, so Chinese policy makers are seeking “people first” sustainable urbanization (OECD, 2015). In this context, CGs, as one of the means of urban renovation, not only beautify the environment, but also play an important role in promoting neighborhood relationships and building a harmonious society (Kou et al., 2019). This study considers CGs as a form of urban agriculture and clarifies their role in improving the quality of life (QOL) of urban residents through their multi-functionality. This means that there is room for further development of CGs, because they make effective use of fragmented urban land and space, improve the social capital of residents and increase their satisfaction with local life. In addition, CGs are not the only urban agriculture form that makes use of the small amount of land and space available in a large city; rooftop agriculture is also attracting attention. The development strategy of urban agriculture must therefore be in line with the current situation and development vision of each city, which is one of the challenges for sustainable urban development in the future.

On the other hand, CGs are still in their infancy in China, and even in Shanghai they are still in the pilot stage. As this questionnaire is biased towards people who know or participate in CGs, further research is needed to reach out to urban residents who are not yet aware of CGs, and this will be an issue for our future research agenda.

DEVELOPING RENEWABLE ELECTRICITY WITH CARBON TAX RECYCLING MECHANISMS IN THE EAST ASIA REGION

[Yuventus Effendi, Budy Resosudarmo](#)

Arndt Corden Department of Economics, Australia

ABSTRACT

The East Asia region has become more important in terms of economy and population. Nonetheless, the region also has a significant increase in carbon emissions. One way to reduce carbon emission while ensuring economic development in the region is to develop more renewable electricity by using a carbon tax recycling mechanism. Nonetheless, there has been limited study on the impacts of the carbon tax recycling mechanism on renewable electricity development. Therefore, this paper analyses the socioeconomic and environmental impacts of the carbon tax recycling mechanisms to develop renewable electricity in the East Asia region. To achieve the objectives of this paper, this paper uses a multi-country computable general equilibrium for East Asia to conduct the analysis. There are three specific recycling mechanisms in this paper through additional investment in renewable electricity, indirect tax reduction for renewable electricity sectors, and subsidies for renewable electricity consumption by households. This paper finds that depending on the type of recycling mechanism and economy structure, a country could achieve double dividend or environmental benefits only. Regarding the best policy to develop renewable electricity, this paper finds that in terms of the economic objective, investing in renewable electricity to renewable electricity development would mostly benefit all East Asian countries except for Singapore. Providing indirect tax reduction is only economically beneficial for China. Further, subsidizing renewable electricity prices for households would mostly benefit India and South Korea. Regarding environment objectives, this paper finds that investing in renewable electricity or providing indirect subsidies for renewable electricity is beneficial for all East Asian countries while subsidizing renewable electricity prices for households would not benefit Australia, Indonesia, and rest of ASEAN. This paper also finds that recycling mechanisms could alter the distribution pattern across countries in the East Asia region and some countries could reduce poverty incidences. Also, only a few countries have a reduction in poverty incidence. Investing in renewable electricity or providing indirect subsidies to renewable electricity reduces poverty incidence in Indonesia and the rest of ASEAN. On the other hand, China and India could achieve a reduction in poverty incidence by subsidizing renewable electricity prices for households.

THE ROLE OF NGO'S IN SHAPING INDONESIA'S CLIMATE CHANGE POLICIES

Rakhmindyarto Rakhmindyarto

Fiscal Policy Agency-Ministry of Finance of the Republic of Indonesia, Indonesia. rakhmindyarto@gmail.com

ABSTRACT

This paper explores the involvement of Non-Government Organisations (NGOs) in the development of Indonesia's climate mitigation policies. It analyses how NGOs both domestic and international influence and shape the national climate change landscape. Further, it also analyses the influence of international institutions and international norms in Indonesia's climate change policies. This paper uses grounded theory method as a research approach, based on in-depth interviews with 29 Indonesia's key stakeholders between August 2016-July 2018. This paper finds that both domestic and international NGOs play a significant role in shaping Indonesia's climate change policies. It also finds that international organisations are influential in the development of climate policies in Indonesia. Overall, this paper contributes to academic knowledge especially the influence of NGOs in the policy process in Indonesia.

1. INTRODUCTION

Indonesia is one of the top 10 largest greenhouse gas (GHG) emissions producers in the world. The data from the World Resource Institute Climate Analysis Interactive Tool (CAIT)⁶⁶ shows that Indonesia ranks 6th with 1.98 gigatons of GHG emissions in total (China is 1st and the US is 2nd) (WRI, 2015). This contributes 4.16% of total global GHG emissions. With an average emissions growth rate of 3.7% a year for the decade from 2001 to 2012 (WRI, 2015), and a population of close to 260 million, reducing GHG emissions in Indonesia will have a significant impact on slowing global emissions growth. Indonesia is determined to reduce its GHG emissions through a significant reductions target. To achieve such a target, Indonesia needs to maintain economic growth for the prosperity of the population. Efforts to reduce nationwide GHG emissions requires significant funding. Indonesia is the largest archipelagic country worldwide, with extensive tropical rainforests. It also has significant energy and mineral resources such as coal, oil, and gas. With major GHG emissions arising from forestry and energy sectors, climate mitigation policies will be very costly because of the need to reduce activity in major economic sectors. Therefore, policymakers need to formulate an effective carbon mitigation policy at the lowest cost.

The policy process in Indonesia involves multiple stakeholders and the government which are not necessarily steering in the same direction. A wide range of organisations engage in the policy process such as government agencies, business stakeholders, politicians, and non-government organisations. All of the stakeholders play an important role in shaping the policy making process.

This paper explores the involvement of Non-Government Organisations (NGOs) in the development of Indonesia's climate mitigation policies. It analyses how NGOs, both domestic and international, influence and shape the national climate change landscape. Further, it also analyses the influence of international institutions and international norms in Indonesia's climate change policies. It aims to understand how NGOs involve in the policy making process in terms of Indonesia's climate change governance. This paper contributes to the literature by giving new insights of the roles of NGOs in the climate change policy making in Indonesia by exploring the perspectives of Indonesian key stakeholders. This contribution is significant given the fact that the study about the role of NGOs in the climate policy process in Indonesia is still limited.

2. REVIEW OF LITERATURE

Domestic non-government organisations and international organisations play an important role in the policy process in some policy sectors. Through the formulation process of regulatory frameworks, laws, and other implementing regulations, donor agencies have had an influence on public policy development (Pramusinto, 2016, p. 125). For example, recent research by Datta et al (2018) showed the influence of the World Bank on higher education policy development (Datta et al., 2018, p. 11). According to this study, the World Bank has been the most dominant actor in shaping and involving higher education policy. For example, the World Bank has promoted the enhancement of higher education autonomy; promoted greater competition between higher education institutions; and promoted the improvement of accountability and transparency of higher education institutions in the use of public funding (p. 11). Rosser (2015) also pointed out that NGOs, parents, and teachers have been engaged in demonstration, lobbying, and strategic use of the court system to influence the education policymaking process (Rosser, 2015, p. 72).

Since the fall of Soeharto in 1998, a large number of civil society organisations, environmental advocates, female activists, and human rights activists, have also influenced the policy development process by entering politics (Mietzner, 2013, p.

⁶⁶ <http://cait.wri.org>

29). For example, NGO leaders have official positions in political parties, journalists enter parliamentary commissions, and labour activists join the bureaucracy. This enables NGOs provide policy insights to control environmental policies. NGOs play a significant role in addressing environmental issues. For example, World Wildlife Fund-Indonesia involved in establishing a transboundary agreement to promote sustainable forest management in Kalimantan Island among Indonesia, Malaysia and Brunei (Nugraha, 2016, p. 3). According to Nugraha, in 2007, WWF-Indonesia reached a large-scale conservation agreement with Malaysia and Brunei to protect forests of Borneo and put the whole of Borneo as an internationally significant conservation area. To follow up this commitment, in collaboration with international agencies such as UNESCO, UNICEF, and UNEP, WWF developed partnerships and coalitions with Indigenous People's Alliance (AMAN) to support its advocacy efforts.

NGOs also play an important role in framing environmental problems. Framing process is an effort to convince various targets and general public to support a policy change (Benford & Snow, 2000, p. 615). For example, in 2009 Greenpeace succeeded to frame forest fires as a problem in Indonesia caused by large palm oil companies (Ardhian, Adiwibowo, & Wahyuni, 2016, p. 214). They used public campaigns to accuse the Sinar Mas group of burning forests to expand their palm oil plantations. Greenpeace prevailed to stop supply chains, where large companies such as Nestle and Unilever ceased purchase contracts of palm oil products with the Sinar Mas (Ardhian et al., 2016, p. 214; Greenpeace South East Asia, 2010, p. 10). In the case of forest fires in 2015/2016, issue framings were more broadened and various. While WALHI and WWF-Indonesia developed their framings that forest fires were corporate crimes by palm oil industries, some Indonesian NGOs established an advocacy network (*ResponsiBank*) which framed that banks involved in Indonesia's forest fires by providing financial assistance to palm oil industries (Herlan, 2017, p. 125).

3. METHODOLOGY

This study uses grounded theory as the research strategy to address the research questions. Grounded theory enables an in-depth analysis of a social phenomenon based on dialogue with the participants to obtain data from their experiences (Charmaz, 2014; Francis, Chapman & Whitehead, 2016). This approach has been used to analyse the data from 29 Indonesian key stakeholders from interviews conducted between August 2016 and July 2018, along with a number of relevant documents. Grounded theory was selected because it allows for the exploration of the perspectives of Indonesian key stakeholders regarding the roles of NGOs in shaping Indonesia's climate change policies. This paper is a part of my doctoral thesis which addresses the opportunities and challenges of introduction a carbon tax in Indonesia.

Interviews have been chosen as the data collection method in this research to achieve in-depth insights and responses about the roles of NGOs in influencing the climate change governance in Indonesia. The interviews involved civil society groups or NGOs. In the current Indonesian context, NGOs play a significant role in addressing political issues, including environmental issues. There are at least three influential civil society groups or NGOs related to climate change issues in Indonesia: Greenpeace, *Wahana Lingkungan Hidup Indonesia (WALHI)*, and World Wildlife Fund (WWF) Indonesia. These organisations are actively involved in determining Indonesian positions in both domestic and international climate change negotiations. For example, they were part of the Indonesian negotiation team at COP 24 in Katowice, Poland 2018. They were also actively involved in the creation of the First Nationally Determined Contributions (NDCs) document submitted to the UNFCCC in 2016. Therefore, they have an influential position in lobbying the government and the private sector in response to cross-cutting agendas. Their focus is on efforts to shift government policy towards a low-carbon development path. Therefore, in this study, these NGOs are key stakeholders that have an important influence on government programs, systems, and policies. However, during the data collection process, the researcher could not contact the participant from World Wildlife Fund Indonesia. The reason for their refusal was that their schedule was very tight, so they did not have time to be interviewed. As a replacement, a participant from Friends of the Earth Indonesia was interviewed.

4. RESULTS AND DISCUSSIONS

4.1. The importance of stakeholders engagement

The interviews with the key Indonesian stakeholders revealed that one of the most influential factors in achieving an effective policymaking process for introducing a carbon tax is for the government to engage with all stakeholders in the policymaking process. The literature shows that the importance of integrating multiple stakeholders with different perspectives and interests into the environmental policymaking process is increasingly being recognised at all levels of government (se e.g. Koontz, 2005, p. 459; Mangun et al., 2007, p. 157; Watson & Foster-Fishman, 2013, p. 151). The absence of engagement between policymakers and stakeholders is a key factor in policy failure. Conversely, stakeholder collaboration mechanisms could facilitate the policy process and improve policy outcomes (Marsh & McConnell, 2010, p. 572).

All relevant stakeholders should be involved by the government since the beginning of the policymaking process. A good communication must be established among the executives, legislatives, and civil society to introduce a carbon tax (NGO-02).

The participants mentioned that it is important to engage all stakeholders from the beginning of the policymaking process. As stated by Marsh and McConnell (2010, p. 572), bringing together all the stakeholders with their different interests in the policy process can lead to an understanding being reached, and ultimately, to a successful policy process. A successful policymaking process can lead to successful policy implementation. Therefore, to produce a successful multi-stakeholder initiative, dialogue between stakeholders is required (Bartley 2007, p. 300; Mena & Palazzo 2012, p. 536).

The regulation is comprised of rewards and punishment which will be effective if all the stakeholders have a shared commitment to the goals. Therefore, a common perspective among all the stakeholders will play a crucial role in the effectiveness of the introduction of a carbon tax. The goal is to achieve carbon emissions reduction target with this policy (NGO-04).

A policy succeeds when it can manage a complex and multi-stakeholder approval process to create an implementable policy (Howlett 2012, pp. 545-546). Engaging policy participants with diverse interests and opinions is the key element in developing a legitimate sustainable initiative (Balzarova & Castka 2012, p. 266), especially in relation to a complex issue such as climate change (Tompkins, Few, & Brown 2008, p. 1583). On the contrary, failure to involve stakeholders in an effective way can lead to failure to achieve the ultimate objectives of a policy (Hoque, Clarke, & Huang 2016, p. 369). Close collaboration between government and stakeholders from the beginning of the policymaking process is important. This is because in order to start the policy process, the policy participants inside and outside of government need a *problem* to become a policy issue in order for it to be addressed. According to Kingdon's theory of the policymaking process, whether a problem is recognised by the government as an important issue to be addressed also depends on the stakeholders outside of government that make the government pay attention to a problem and bring it onto the policy agenda (Herweg et al., 2018, p. 19). Therefore, framing an issue as a problem that reaches the attention of government is important. This implies that the role of the stakeholders in framing a problem in a particular way to gain the attention of the government is significant. As part of Kingdon's multiple streams approach, in the *problem stream*, policy participants inside of government and stakeholders outside of government are almost equally important in bringing a problem onto the policy agenda (Kingdon, 2011, p. 21).

4.2. The importance of stakeholders engagement

An example of the important role of stakeholders in framing an issue to become a problem which reaches the attention of government is the policy process of the ratification of the Paris Agreement. Stakeholders from Non-Government Organisations explained that NGOs played a crucial role in the process of ratifying the Paris Climate Agreement. Collective action by NGOs and other environmental activists in Indonesia, such as Greenpeace and Friends of the Earth became a major consideration for Indonesian policymakers in the ratification of the Paris Climate Agreement. Pressure applied to government by NGOs and the Indigenous communities reflected their awareness of environmental sustainability.

The NGOs and environmental activists started to frame the issue of Indonesian tropical forests and the role of the Indigenous communities to protect the forests to mitigate climate change. As many as 32 environmental and civil society organisations gathered before the signing of the Paris Agreement on 22 April 2016 in New York. They formed the *Climate Justice Now!* network and intensified their actions to urge the government to ratify the Paris Agreement. Meetings and negotiations between the network and the government occurred to discuss the importance of the ratification of the Paris Agreement for Indonesia as a commitment to protect Indonesian people from the adverse impacts of climate change.

NGOs play an important role in advocating environmental issues in Indonesia. For example, in 2007 World Wildlife Fund (WWF) initiated the establishment of declaration of the Heart of Borneo (HoB), a forest conservation and sustainable development program in Indonesia-Malaysia-Brunei Darussalam border (Nugraha, 2016). The objective of the HoB is to manage primary forests and cross-border area, manage sustainable natural resources, develop eco-tourism, and increase human resource capacity under sustainable development (Nugraha, 2016, p. 5). The HoB is a commitment by three countries (Indonesia, Malaysia, and Brunei Darussalam) to protect Kalimantan forests for the benefit of next generations based on the mutual respect of each country.

NGOs also play an important role in the development process of Indonesia's timber legality verification system. This is a government-rule standard to address illegal loggings as the most significant problems in the forestry sector in Indonesia. The policy process of timber legality verification has heavily involved environmental non-government organisations (NGOs) led by the Nature Conservancy (Maryudi, 2016, p. 103). In the earlier process, NGOs worked with government agencies to create and develop legality rules. The process took place between 2006 and 2008 involving broader stakeholders such as the government agencies, timber industries, universities, and research organisations (Maryudi, 2016, p. 103).

WALHI is a leading NGO in Indonesia that promotes environmental protection activities. While they urge the government to mainstream climate change in the national development plan, in the field they create a system of forest management system together with indigenous people. This concept is a counter activity for extractive industries which create deforestation and forest degradation through land use change activities. Together with indigenous people, WALHI has created a coalition which protect primary forest are from converting to oil palm plantations (www.walhi.co.id, accessed 2 April 2020).

The actions of the NGOs and civil society organisations in framing the issue succeeded in reaching the attention of the government in their considerations of the ratification of the Paris Agreement. They used citizen's *perceptions* to frame the issue as a problem to be brought to the attention of the government (Kingdon, 2011, p. 110). Their perceptions were that the Paris Agreement was important for demonstrating the government's commitment to protecting Indonesian people from the impacts of climate change.

The role of NGOs and environmental activists is not only to frame and bring a problem to government attention (*problem broker*). They move further beyond the problem stream and find solutions in the *policy stream*. In the multiple streams approach, NGOs and other activists are known as *policy entrepreneurs*. The difference between the two is that problem brokers only frame a problem and argue that action must be taken to address the problem without offering policy solutions, while policy entrepreneurs suggest solutions to problems.

The NGOs also played an important role as *policy entrepreneurs* because they facilitated the government process by drafting an academic paper and the Law. The academic paper, which is a prerequisite of the policy process, was prepared by the government and brought to the parliament with a draft of the bill. In *the policy stream*, the government and the NGOs worked together to prepare the academic paper. Focus group discussions and a consultative process with the policy community consisting of experts, analysts, bureaucrats, and academics, were then undertaken. In the *political stream*, the stakeholders influenced the political dynamics of the political process through advocacy campaigns. In this process, the problem, policy, and political streams were coupled, and thus converged to open the policy window of opportunity for policy change (Kingdon, 2011, p. 202). This coupling resulted in the Law of the Ratification of the Paris Agreement. In this case, the role of government in bringing a problem onto the policy agenda is crucial. As Kingdon said, in the problem stream, when a problem is not perceived by the policymaker as an issue that requires attention, it will not go onto the policy agenda. In such a situation, stakeholders need to frame the issue as one that requires government attention. For example, researchers and/or academics could create focus group discussions with government agencies throughout Indonesia to discuss the research findings and the potential for bringing it onto the government agenda, while NGOs could frame the importance of introducing a carbon tax in Indonesia through mass media campaigns. For example, WALHI-Friends of the earth Indonesia engaged in the global March for Climate, urging global leaders to rise an awareness of addressing climate change impacts. WALHI also established the School of Ecology in Malang, East Java as one of their initiatives to raise people awareness of climate change and environment.

4.3. The role of NGOs in the climate change policy process

The role of NGOs (both domestic and international) is important in the formulation of climate mitigation policy in Indonesia. In Kingdon's multiple streams framework (in the *problem stream*), these stakeholders have framed the issues as a problem which then enabled them to bring the problem onto the government agenda. They framed the importance of the forestry sector in Indonesia as the major source of emissions. To do so, they leveraged international organisations, international NGO networks, transnational alliances, and Indonesia's foreign policy goals. Framing a particular situation and bringing it to the government's attention is important because the government only has limited time to pay attention to all the problems they have to deal with (Herweg et al., 2015, p. 437; Kingdon, 2011, p. 184). In the aforementioned example, the NGOs and CSOs in the policy process of the ratification of the Paris Agreement in Indonesia became *policy entrepreneurs*. Policy entrepreneurs play an important role in framing problems to generate attention, prepare solutions, and create opportunities to act (Cairney, 2018, p. 202). According to Kingdon (2011), they are stakeholders of policy change who have the skills and knowledge to be able to exploit opportunities (Kingdon, 2011).

The Indonesian policy to ratify the Paris Agreement is a continuation of the Indonesian commitment to international laws and treaties to address global climate change issues. As the stakeholders explained in the interviews, *image building* for Indonesia is important in the global political arena. Having a good international reputation will help Indonesia gain international assistance for achieving its emissions reduction target (Wuryandari, 2015, p. 125). Beyond this, Indonesia will lead developing countries in combatting global climate change problems. The ratification of the Paris Agreement also showed that Indonesia complies with international principles and responsibilities as part of the global community to preserve the quality of life (Windyswara, 2018, p. 1433). Through the ratification of the Paris Agreement, Indonesia has gained a number of advantages such as access to international funding, human resource development, environmental protection technology, and the necessary cooperation and coordination to assist with the implementation of the Paris Agreement. Nevertheless, the most important objective of the ratification of the Paris Agreement is for the international community to have a positive impression about the awareness of the Indonesian government towards environmental protection at both the national and global levels.

The results of this paper show that most Indonesian stakeholders agree with government efforts to reduce GHG emissions according to global norms and international organisations. However, there is also a growing influence of the business stakeholder coalition in the parliament. The ACF is a useful framework to explain this. Jenkins-Smith et al. (2014) has argued that according to the ACF, organisations which aim to influence the policy-making process form competing advocacy coalitions based on shared core beliefs, including value priorities, elemental causes, and preferred solutions (Jenkins-Smith et al., 2014, p. 189).

This is useful to mention here because there is a strong coalition that connects climate goals to foreign policy goals, but there is also a growing domestic coalition of business stakeholders and corrupt officials. Transnational NGOs have formed a strong coalition with domestic NGOs. They believe that it is important for the Indonesian government to produce climate policies to reduce GHG emissions that are connected to global norms and international organisations. However, the economic coalition represented by business stakeholders believes that climate policies could harm the economy. They propagate the idea to the government that a carbon tax will create additional costs which will harm their business activities.

The findings of this paper also show that there is no clear indication of opposition in these coalitions to global norms and international organisations. All the stakeholders (except for the business stakeholders) are in agreement about the global norms on anthropogenic climate change and about the adverse impacts of global climate change and agree that there is a need for collective action to address global climate change problems. There is also a much less polarised debate between stakeholders regarding the global norms and the influence of international organisations in Indonesia's climate change policy-making process. This is important because less opposition motivates the government to create domestic policy change.

The lower level of opposition from Indonesian stakeholders to global climate change norms and international organisations can probably be understood through two factors. First, international organisations have provided financial assistance for the government of Indonesia in relation to climate change mitigation programs. According to data from the Ministry of Finance, in 2011, 22 international donors contributed an estimated US\$3.851 billion to public finance flows in Indonesia in the form of climate change program loans and grants (Ministry of Finance, 2012). Most climate change program loans flow to state-owned enterprises as a form of low-cost project debt. Grants flow to private consultancies, NGOs, and other organisations involved in capacity building. Even though the funding disbursements are significantly lower than the commitments, international financial assistance helps the government of Indonesia achieve its ambitious emissions reduction goals. Second, it seems that global norms are less demanding for lower-income countries (non-annex 1) in terms of emissions reduction targets. According to the Paris Agreement, even though each country needs to submit their Nationally Determined Contributions (NDCs) to the UNFCCC after ratifying the Paris Agreement, there is still less opposition from lower-income countries, including Indonesia, because the emissions reduction targets are voluntary and there are no penalties if Indonesia does not achieve its emissions reduction target. Nevertheless, Indonesian stakeholders perceive that aligning with global climate change norms and international organisations provides strategic political advantages and aligns with the government's foreign policy goals (based on the interviews for this project).

5. CONCLUSION

The lofty international ambitions to reduce GHG emissions have motivated the government to produce domestic climate mitigation efforts that are linked to global norms. For example, a transnational advocacy coalition represented by international NGOs has created a transboundary climate network with domestic NGOs, which has motivated the Indonesian government to make an international commitment, and this has created pressure for domestic policy change. The ratification of the Paris Agreement followed by the submission of Indonesia's First Nationally Determined Contributions exemplifies this, showing that Indonesia has committed to serious efforts to combat global climate change under international principles and norms. However, this has also created internal and external pressure to align with domestic policy commitments. As one of the biggest GHG emitters in the world, Indonesia has a commitment to reduce its GHG emissions while at the same time, as a developing country, Indonesia has to maintain its economic growth. In practice, the commitments to reduce GHG emissions to the international community are in conflict with current domestic policy goals. Current economic development policy goals are focused on sectors and activities that are contrary to the GHGs reduction target. Instead of transforming carbon-intensive development towards a low-carbon trajectory, the Indonesian government has promoted sectoral policies which will produce more emissions. Domestic commitment to these policies has been significantly influenced by business stakeholders working in favour of their own interests.

CONTRIBUTION OF URBAN FACILITIES FOR REGIONAL SUSTAINABILITY THROUGH MUSEUM-LIKE FUNCTIONS

Noriko Horie¹, Kiyoko Hagihara², Fumiko Kimura³, Chisato Asahi²

¹Bukkyo University, Japan. ²Tokyo Metropolitan University, Japan. ³Soka University, Japan

ABSTRACT

Regional sustainability is an urgent issue in Japan, where population decline is rapidly progressing. An area cannot be maintained without urban facilities that support various activities. It is very difficult for an area with a population decline to maintain urban facilities because of the insufficient budget. However, needless to say, a budget is required to maintain urban facilities, but citizens' understanding and cooperation are also important. For example, in order to maintain a waste disposal system, it is necessary for people to properly separate garbage and make efforts to reduce waste. Furthermore, it is necessary to provide a budget for maintaining the system from waste collection to the final disposal. These are maintained by the understanding and cooperation of citizens who are the waste generators, taxpayers, voters involved in decision-making, and finally as residents accepting facility locations that are often regarded as so-called nuisance facilities. Urban facilities have multi-functions. They have not only their original functions but also wider functions, which are significantly important for the community, such as symbolizing the wisdom and hardship of the ancestors, cultural assets and local characteristic features. They make up the local landscape and convey the local memories. We think that urban facilities have museum-like functions. And we have been working on grasping the current situation through questionnaire surveys of water treatment facilities and waste treatment facilities. As a result, it was shown that many urban facilities have museum-like functions centering on exhibition education and they play an educational role in the area. There is a significant correlation between these functions and the amount of effort and the number of collaborations. The sustainability of the region, including population migration, population composition, and socio-economic activities, depends on "people". Urban facilities contribute to the sustainability of the community through efforts to work on "people" in addition to their original functions. Urban facilities serve as a base for raising interest in the region. And can nurture human resources which can deal with regional issues and contribute to improving the sustainability of the region. The significance of the museum-like functions of city facilities is as follows. The first is the role of disaster prevention education and environmental education for a wide range of citizens. The second is to convey local memories and lessons learned from ancestors and history. The third role is to provide a place for communication between citizens and city facility managers. For sustainability assessment, indicators such as the SDGs are presented. Education is emphasized in the SDGs, but the evaluation index is based only on school education. The contribution of urban facilities to local sustainability should be appropriately assessed by sustainability indicators. We need to consider assessing the contribution of urban facilities to local sustainability through museum-like functions.

ON THE WORKING OF THE SOULFULIAN ON RISK SOCIETY: AN EMPIRICAL ANALYSIS OF THE KARAHORIAN, OSAKA, JAPAN

Kazuyoshi Hayama

Japan

ABSTRACT

“SOULFULIAN” means people who survived the predicament. In this case, the predicament is about COVID-19. Because the current crisis is unprecedented. According to WHO(2020), On 31 December 2019, the WHO China Country Office was informed of cases of pneumonia unknown etiology (unknown cause) detected in Wuhan City, Hubei Province of China, and on May 3, 2020, The United States suspected that the source of the COVID-19 is China. However, the initial source of 2019-nCoV still remains unknown. So (first) wave and (first) silent wave and after first silent wave of COVID-19 is an academic area that is not well, completely, understood even among experts.

Digitization of information in all of its forms is one of the most developed things of the twentieth century.

This paper is about the COVID-19 for a sustainable clean region.

In the midst of the birth, after billions of years, the planet called Earth was formed. At the end of the twenty-first century, it will have been only a quarter of a millennium since computation emerged on Earth, which is a blink of an eye on an evolutionary scale—it's not even very long on the scale of human history.

But KARAHORIAN values human connections and the KARAHORI area continues to evolve sustainably from the end of the at least Muromachi (between 1336–1573) era period to this day of KARAHORIAN as the “SOULFULIAN” at the time of Corona (COVID-19) crisis.

For that reason, this paper investigated two things based on the historical perspective from the end of the Muromachi era period to the current of KARAHORIAN as the “SOULFULIAN” at the time of Corona (COVID-19) crisis, One is behavioral characteristics, and the others are about not masks-wearing people. The purpose is to discuss for the sustainable clean region, so discuss the effects of the first wave, first silent wave, second wave, second silent wave, third wave, third silent wave, and after these of COVID-19 in KARAHORI streets, Osaka, in Japan. This paper presents indicative the after Covid-19 data. The significance of this paper is the study of improves the environment and based to makes it a clean environment by preventing in the future and prevention.

This paper presents the transport data and not wear face masks data in times of crisis and concludes that there are no major prospects for an environmentally friendly recovery from the COVID-19 crisis unless there are adequate policies.

The order of life takes place amid great chaos. It is significant to study the possibility of the future of a sustainable region based on the current data. It will become the assets to be studied in the future.

PLACE-BASED SME FINANCE POLICY AND LOCAL INDUSTRIAL REVIVALS: AN EMPIRICAL ANALYSIS OF A DIRECTED CREDIT PROGRAM AFTER WW2

Keisuke Takano¹, Hiroyuki Okamuro²

¹University of Tsukuba, Japan. ²Hitotsubashi University, Japan

ABSTRACT

This paper examined the effects on the performance of local SMEs of a modernization fund program for small business enterprises implemented by Osaka Prefecture in the early 1950s. Utilizing firm-level panel data based on business credit reports, we empirically evaluated the effects of the program. We found an improvement in production levels among the recipients. In addition, recipients in sectors related to munitions production or in industrial agglomerations specialized in these sectors achieved additional or larger improvements in their production levels.

'JUGAAD' AND SOCIAL NETWORK OF BENGALI-SPEAKING MUSLIM MIGRANT WORKERS IN MUMBAI

Debangana Baruah

Tata Institute of Social Sciences, Mumbai, India

ABSTRACT

The paper explores how a poor-landless Muslim community of Bengali-speaking migrant workers, who are originally from the state of Assam, migrate to the financial capital city of Mumbai. At home, they face hostility and communal persecution from the mainstream Assamese-speaking Hindu community based on the suspicion that this poor landless Bengali-speaking Muslim community is of Bangladeshi origin, and that they are illegal immigrants in the state of Assam. In reality, this community lives near the riverine areas of Brahmaputra. In Mumbai, most of these migrant workers' work in the informal sector as contractual labourers.

The paper investigates how the network mediates via the use of technology with the private/public agents to provide jobs by determining the demand and supply of information in the labour market. This information, which is provided via mobile phones, helps migrants to make alternative arrangements—jugaad—for themselves and their kin, thus making it possible for other potential labourers to also migrate. The peculiar kind of jugaad is embedded in the network, and it creates social capital for the members within it.

This new form of technology mediation has further their mobility by lending these urban spaces for them to practice the everyday urban experiences of the marginalized migrant workers who make efforts to claim the city amidst their precarious existence at its fringes. The network functions as the reservoir of their cultural identity and memory and compensates for the loss of social capital in the present climate of heightened xenophobia. Based on Bourdieu's social capital theory, the significance of social capital shapes migrants' agency to use, maintain, and reproduce their network. The essence of jugaad is to manifest their bargaining power to resist the powerful bureaucratic institutions and reclaim their right to the city.

Borrowing insights from the African context, De Sardan's idea of 'corruption complex' fits in the study. Engaging with the context of brokerage among Dalits in North India, the concept of technological mediation into state falls in the purview of my study, and it is important to look at how the moral economy of corruption takes place due to the struggle over state's resources.

Methodologically, the paper will adopt a bottom-up framework to understand the hierarchies within the migrant networks located in two Muslim neighbourhoods in South Mumbai, namely- Crawford Market and Masjid Bandar.

An ethnographic analysis will be conducted to understand the process of mobility in the city. These methods will be helpful in exploring migrant networks how they have been seen to expand over the years.

To this end, the paper investigates how the city creates a space for them, wherein the reproduction of networks is symbolic of their identity and is vital for the existence of their community.

THE TRAJECTORY OF PLANNED URBAN DEVELOPMENT: A CASE STUDY ON RAJARHAT- NEWTOWN, KOLKATA

Angana Banerjee

India

ABSTRACT

This article tries to figure out the how the co production of formal and informal place within the planned boundary of a metropolis has stimulated a mixed kind of place. Rajarhat-Newtown, a planned township located at the periphery of Kolkata, is an outcome of unwitting plan by the government of West Bengal in mind 1990s. The west Bengal government has denied its status of being a 'smart' city and declared it as a planned green city. Interestingly the place fragmented into formal city places with contradiction of unplanned village pockets within its planned boundary. This research will try to find out what factor has prompted the existence of village pocket within the planned area and the interaction between them. To understand the dilemma related to the existing village pockets urban ethnography was used as a method. To unfold about the existence of village pockets; historical narratives from the villagers, interview from the HIDCO officials, and the published secondary documents analyzed. This analysis helps to understand about whether those existing village pockets are example of neglect of planning or it is a legacy of planning? It also tries to answer "informality from the very heart of state and as an integral part of territorial practice of state power" (Roy, 2009). Therefore, this paper tries to reflect about the place is neither "smart" nor "planned". The transformation of rural place due to declaration of a planned township and the associated consequences will help to figure out the tyranny of planning and the trajectories of urban governance. Is this kind of urban development expands the city, transform rural places and generates a kind of mixed places (both urban and rural character) along the periphery of metropolis? It raises question in terms of planning, governance and sustainability. Thus it will help to understand the irony of planning, mapping-unmapping of a region and will try to figure out the actors and its interaction between how planned illegalities have reshaped a region and it helps to understand urban planning for India should be understood with the help of management of resources.

TRANSCULTURATION AND COLLECTIVE IDENTITY IN SUBALTERN SPACES: URBAN DYNAMICS OF THE ETHNIC ENCLAVES OF CHITPUR ROAD FORMED BY MULTI-ETHNIC DIASPORA.

Pritam Dey¹, Paridhi Kedia²

¹Urban Designer, Academic Co-ordinator, Jindal School of Art and Architecture, India. pritam0025@gmail.com;

²Anthropologist (Pursuing Majors), Independent Researcher, paridhi.arch@gmail.com

ABSTRACT

City's today are agglomeration of multi-ethnic communities. Heterogeneity of sociocultural attributes, activities and everyday life differentiates old city from the more contemporary quarters which possess a higher degree of homogeneity. Older neighbourhoods of the city display a complex special semiotics where people appropriate the social space through active participation and asserting their presence in the socio-spatial domain. Diaspora shift is not a contemporary phenomenon but happened extensively in the past, as a result *glocalised*¹ spaces are formed. Humans are territorial, through cultural and social attributes they define the practical limit of physical territory and social meanings of existence. It creates an important process of self-definition and by differentiating the sense of self and non self they tend to claim agency in the physical environment. Streets, shops, pavements, living quarters are often customized acquiring an informal expression and social meaning, due to assemblage of people from diverse ethnic background and exercising a plethora of socio-economic processes creating ethnographic neighbourhoods. Thus, we realise there is a simultaneous negotiation between human activities and space that creates the phenomenology of the urban environment. Globalization in an old city like Calcutta has brought in diverse communities from across the globe who migrated along with their culture and occupational choice and settled within a distinct political boundary, thereby creating a diverse spatial semiotics in the everyday life on streets, shops, public spaces. Dynamics of capitalistic and neo-liberal urban aspirations are potentially posing as threats to the old quarters of cities of Global South.

India's extensive economic and demographic growth queries what the old city cores (foundation cities, pre-industrial cities, precolonial cities) can become in the future? These cores with their remarkable diversified urbanity are today under a double transformation: abandoned by the middle class and subject to brutal physical change by capitalist transformations.

2 anthropological perceptions of city could be understood in this kind of situation:

The interactional role studies behaviour lines that tie the social setting to the city and determine its evolution within a larger society. It would also reveal the performers of socio-cultural roles within an overall social organization.

The ideological ties, eg. *pattern of values that bind this sub altern society to the city*. Here, rules would be studied, those composed the cultural roles of ethnic enclaves and its diffusion from the smaller cultural society to the city.

The paper tries to **analyse the transcultural effect of the subaltern communities, their collective identity and attempts of legitimising presence in the city**. The conative, expressive, and phatic (Jacobson, 1960) expressions of spatial semiotics will be read along one of oldest streets of Calcutta-chitpur road.

The research uses an ethnographic method through direct observation and participation observation method. (A)

The next step would be to understand the symbiotic relation between and space and communities through interview.

The next step would be to understand **how collective identity and a hybrid socio-cultural perspective played an important role in shaping up the urban environment embodying a localized set of everyday practices, social customs, interactional relationships, and cultural meanings?**

*Glocalised*¹ - *Glocalization, first appeared in a late 1980s publication of the Harvard Business Review* At a 1997 conference on "Globalization and Indigenous Culture", sociologist [Roland Robertson](#) stated that glocalization "means the simultaneity – the co-presence – of both universalizing and particularizing tendencies.

1. INTRODUCTION

People makes place. It is the multi-layered activity and manifestation of everyday life processes that create a phenomenology of an urban space.

Globalization in an old city like Calcutta has brought in diverse communities from across the globe who migrated along with their culture and occupational choice and settled within a distinct political boundary, thereby creating a diverse spatial semiotics in the everyday life on streets, shops, public spaces. Dynamics of capitalistic and neo-liberal urban aspirations are potentially posing as threats to the old quarters of cities of Global South.

India's extensive economic and demographic growth queries what the old city cores (foundation cities, pre-industrial cities, precolonial cities) can become in the future? These cores with their remarkable diversified urbanity are today under a double transformation: abandoned by the middle class and subject to brutal physical change by capitalist transformations.

Kolkata (Calcutta till 2001) is indeed not such an old city, It was relatively a newly built city, founded during the colonial time by the British Raj in the XVII century (1690), constituting three villages Sutanati, Kalikata, and Gobindapur on the East bank of the Hooghly river. Chitpur Road is part of the native settlement, which grew, around the colonial town, Fort William. This native town was majorly occupied and appropriated by **merchants and craftsmen** coming from East Bengal but also from other provinces and countries. These two towns also received names: the colonial city, the 'White Town', opposed to the native town, the 'Black Town'. Nevertheless, the Indians researchers have criticized this distinction reminding the number important of interrelationships existing between the two societies (business, constructions, weddings, etc.). It leads to another concept for naming this urban situation: the 'Grey Town'.

Chitpur Road has been for 3 centuries the place to be for the merchants, craftsmen (business, vocations), middle class Bengali residents.

2. DIVERSITY OF CHITPUR ROAD IN TERMS OF SPACE, AGENCY AND SOCIETY

Chitpur road is characterized by successive urban enclaves organised around distinguished vocations and different kinds of bazars: merchants (textile and others products), craftsmen (blacksmiths, sculptors of marble, sculptors of idols, woodworkers), fruits and vegetable sellers (markets), printers (theatre posters, books), etc. All these occupations (or vocations) were originally based on communities from the same region and similar caste. Thus numerous ethnically diverse, cultural enclaves were formed along the stretch of the street. These communities produced a specific urban fabric called 'para' in Bengali - conceptually like the 'pol' of Ahmedabad or 'mohalla' in Varanasi, but practically they seem to be quite different. These 'para' - and for the smaller neighbourhoods '-tuli-' or '-tola' were organised socially and culturally, but they have been changing with time since post-independence era. However, the physical structure of 'para' around massive mansions of the then urban elites and bourgeoisie upper middle class still struggles to exist reminding an eclectic past.

So, these two aspects, which are even two main dynamics, have been structuring the Chitpur Road since the foundation:

- **The occupation:** Chitpur has always been the place to be for merchants and craftsmen (business, vocations).

The multi-ethnic diaspora: various ethnic groups of merchants and craftsmen, traders from across the globe (China, Israel, Persia, Afghanistan, Bangladesh, England) migrated and settled in Chitpur road creating a socio-culturally hybrid urbanity.

3. TENTATIVE METHODOLOGY

A

The First step: learning from Chitpur Road by making drawings on 'occupations (vocations)' attempting to express the physical space (architecture) as well as the activities (people working, living, etc.).

Identifying 7 distinctive diverse (socio-culturally and occupation wise) neighbourhoods along chitpur road. Identify type of activities existing (occupations, vocations), expressions of identity and both of these are juxtaposed in which kind of space (architecture) in the following scales.

- **the doorstep of a shop (occupations and architecture)**

- **from the doorstep to the façade of the building**

- **from the doorstep to the section of the building.**

In other words:

- **from the shop to the road, from the shop to the back storage, from street to courtyard, from ground floor to roof top.**

The Second step: A critical ethnographic analysis of the data and inferences revealed from the **First step** through a cross cultural frame of reference.

THE GEOGRAPHY OF DISCONTENT OR THE DISCONTENT OF THE PEOPLE. EVIDENCE FROM INDIVIDUAL DATA FOR SOME EUROPEAN COUNTRIES.

Enrique López-Bazo

AQR–University of Barcelona, Spain

ABSTRACT

At present, the world is going through rapid urbanization, which greatly affects the climatic condition of a particular area and human life within this region. The rapid growth of the urban population of developing countries in south-east Asia like China, India, Pakistan, Bangladesh, Indonesia, Malaysia, etc., heading towards unplanned and haphazard growth of urbanization, which altered the urban microclimate greatly. Urban areas face intensified heatwave conditions due to the Urban Heat Island (UHI) effect, which results from anthropogenic changes on both surface and atmospheric temperature patterns relative to the natural environment. (Arnfield, A. J., 2003). Asansol, the second-largest city in West Bengal after Kolkata, is experiencing a rapid urban growth rate. This rapid urbanization is negatively affecting the environmental condition, especially on the microclimatic condition of the city. Urbanization, Industrialization, the growing transportation sector, and coal mining activities uniformly produce greenhouse gases like CO₂, CO, SO₂, NO₂, CH₄, and CFC, dust particles leading to the greenhouse effect and rising temperature. Built-up areas and industrialization have increased the impervious land surface and emit poisonous gases for the greenhouse effect, which changed the micro climatic condition. This present study will bring out the relationship and effect of Land Use Land Cover changes spatiotemporally and relationship with Land Surface Temperature change. Land Use Land Cover map is prepared through Landsat satellite images of 1990 and 2020, and corresponding Land Surface Temperature is also calculated using thermal bands. Correlation of Land Surface Temperature (LST) with various spatial indices like Normalized Difference Vegetation Index (NDVI), Normalized Difference Water Index (NDWI), Normalized Difference Built-up Index (NDBI) have been measured, and it shows there is a significant and strong correlation with each other. Temperature patterns indicate a direct association with changing LULC patterns of the study area. The maximum and minimum temperature of 1990 were 37.37°C, and 16.25 °C respectively, which increased to 39.27 °C and 26.05 °C in 2020. This change is indicating a continuous increase in LST.

On the other hand, the built-up area has also increased from 8.86 to 22.87 percent, respectively, from 1990 to 2020, signifying natural land conversion to the built-up area. The average temperature increased to 5.85 °C during this period, indicating a significant change in temperature in the city. Nearly 22 %, i.e., 71.84 km² was under green cover in 2000, which has reduced to 17.05 %, i.e., 55.66 km² in 2010; so green space has lost 4.5 % only in 10 years (Siddique et al., 2020) which validate the impact of human on environmental change.

THE URBAN-RURAL DIVIDE IN ANTI-EU VOTE: SOCIAL, DEMOGRAPHIC AND ECONOMIC FACTORS AFFECTING THE VOTE FOR PARTIES OPPOSED TO EUROPEAN INTEGRATION

ABSTRACT

In recent years, protest voting, voting for populist parties and, specifically for Europe, votes for parties opposed to European integration, have increased substantially. This has focussed the attention of researchers and policy makers on the causes behind this trend. Most of the existing research looked at voters' characteristics, mainly values, education and age, or economic insecurity, such as rising unemployment or a declining economy more in general. This paper focuses instead on the urban-rural divide in anti-EU sentiment, and tries to explain why cities – and urban areas in general - in Europe tend to vote less for Eurosceptic parties. Using electoral data for national elections at the electoral district level for the years 2013-2018 and political parties' orientation as assessed by the Chapel Hill Expert Survey, we find robust statistical evidence of a lower anti-EU vote in cities, towns and suburbs than in rural areas. We also find that drivers of voting for anti-EU parties differ significantly between urban and rural areas in the EU and UK, despite some similarities. We show that three factors are associated to a higher anti-EU vote in all areas: growth in unemployment, a low turnout and a higher share of people born outside the EU. A sluggish economy is associated to a higher anti-EU sentiment in rural areas, but not in cities and towns and suburbs. Higher shares of university graduates, people aged 20-64, and of people born in a different EU country reduce anti-EU voting in rural areas and towns and suburbs, but have no impact in cities.

KEYWORDS

Euroscepticism; anti-system voting; urban-rural divide; economic insecurity; voters' socio-demographic characteristics

1. INTRODUCTION

In recent years, anti-EU voting has emerged as an electoral force in Europe. Lack of trust in the European Union (EU) passed from around 25% in the mid-2000s, to around 45% in the late 2010s (source: Eurobarometer Survey; see also Dijkstra et al., 2020). This growing lack of trust in the EU can also be seen in the growing votes for parties that were against EU integration. Between 2013 and 2018, around 13% of voters in EU national elections cast their votes for parties strongly opposed or opposed to European integration. This figures increased to around 27% if we consider also parties moderately opposed to European integration (Dijkstra et al., 2020). Against this background, a large body of research has rapidly emerged in Europe trying to explain this phenomenon, whether analysing country specific voting, as in the case of the Brexit referendum to leave the EU (Alabrese et al., 2019; Abreu and Öner, 2020) or looking at the EU as whole (Lechler, 2019; Dijkstra et al., 2020). In particular, we can distinguish between two approaches. A first approach highlights that individual characteristics, such as income, education and age, or cultural factors such as political orientation and tolerance towards immigrants, drive anti-EU sentiment (Schoene, 2019; Schraff, 2019). A more recent strand of the literature, initiated by Dijkstra et al. (2020), extends previous research by including geography as an additional driver of anti-EU sentiment, originating what is well-known as the Geography of EU discontent.

In the present work, we go one step further by trying to explain the causes behind a potential urban-rural divide in anti-EU voting in Europe, a phenomena widely studied in the context of rising populism in the United States (see for example Rodden, 2019), but which received little attention so far in Europe.⁶⁷ Recent studies, mainly in the field of political science, and often based on country-specific analyses, have suggested that rural, suburban and peripheral areas are more likely to be influenced by populist parties (Scoones *et al.* 2018; Mamonova and Franquesa, 2020). Particularly after the great crisis, the socio-economic urban-rural divide in the EU became a focus of debate. The 2019 Eurostat Statistical Yearbook (European Commission, 2019), for instance, reports that rural areas, as well as towns and suburbs, if compared to cities, show a considerable digital skills divide. An urban-rural split is observable also in population trends, with the majority of urban regions reporting population growth, and many peripheral, rural and post-industrial regions a decline. A gap is noticeable also on health perception, with a higher proportion of people living in cities that perceive their own health as good or very good. Finally, in at least half of EU Member States self-employed persons in rural areas are not satisfied with their job, possibly because they are self-employed due to lack of other options. For the case of the United States, research has focussed on the concept of “great inversion”, referring to once prosperous rural regions and middle-to-small

⁶⁷ See for instance Schoene (2019) for the EU, and Marcinwiewicz (2018) for Poland.

metropolitan areas that suffered a (relative) economic and/or employment decline, (see Moretti 2012; Rodden, 2019). It has also been linked to a “populist explosion” (Judis, 2016), with small towns in rural and peripheral regions becoming reservoirs of populist resentment (Cramer, 2016). For Europe, Dijkstra et al. (2020) show that rural areas and small towns are more Eurosceptic than bigger cities, while Gordon (2018) identifies a greater support for populist parties in non-urban areas (countryside or village). On the other hand, the results of Schoene (2019) support the position of Essletzbichler et al. (2018), who posit that the geographies of the electoral rise of anti-system parties are more complex than the rural-urban differences in populist vote shares.

In what follows, we try to answer to three questions: [i] do urban areas in the EU and UK vote more or less than rural areas for parties that are opposed or strongly opposed to European integration? [ii] what are the territorial roots of anti-EU voting? and [iii] do they differ between urban and rural areas?

The paper is organized as follows. Section 2 shows that the vote share of anti-EU changes according to the place where people live, and tend to increase when we move from cities, to towns and suburbs, to rural areas. Section 3 explains the methodology and data used to analyses the drivers of anti-EU votes. Section 4 presents the econometric specification and describes the results. Section 5 concludes.

2. ANTI-EU VOTING BY DEGREE OF URBANIZATION

Firstly, we look at whether in Europe we can talk of an urban-rural divide when it comes to voting preferences for parties that are opposed to European integration. To do so, we first classify all 63,231 electoral districts in the EU and the UK into three categories (Dijkstra and Poelman, 2014): i) cities or large urban areas (for a total of 2,172 electoral districts), ii) towns and suburbs (9,452 electoral districts), and iii) rural areas (51,607 electoral districts).⁶⁸ When referring to urban areas, we refer to cities plus towns and suburbs. Voting data in our analyses cover all national elections that had taken place in the EU and UK between 2013 and 2018. Party positioning on European integration comes from the assessment made in 2014 and 2017 by the Chapel Hill Expert Survey. In the survey, political parties received a score between 0 (European integration not at all important) and 10 (European integration extremely important) with respect to their position with respect to European integration. Following Dijkstra et al. (2020), we consider as anti-EU vote the share of votes obtained by parties opposed and strongly opposed to European integration (i.e parties receiving a score below 2.5).

Figure 1 shows, for example, that votes for anti-EU parties in the EU and UK are consistently lower in cities, with the exception of few countries.

Figure 1: Vote share of parties opposed or strongly opposed to EU-integration in national election, 2013-2018

When considering all electoral districts, without referring to the country where the elections have taken place, we observe that in cities, and in towns and suburbs, people tend to vote less for anti-EU parties than in rural areas. The median vote for parties opposed and strongly opposed to the EU decreases with the degree of urbanization of the electoral district. The median vote for Eurosceptic parties is 23.4% in rural areas; it declines to 20.5% in towns and suburbs, and further decreases to 15% in cities (Figure 2).

⁶⁸ Cities or large urban areas if at least 50% of the population lives in high-density clusters. Towns and suburbs if less than 50% of the population lives in rural grid cells and less than 50% lives in high-density clusters. Rural areas, if more than 50% of the population lives in rural grid cells. The classification considers as basic units of classification 1 km² grid cells. Rural grid cells are the grid cells outside urban clusters. Urban clusters are those clusters of contiguous grid cells of 1 km² with a density of at least 300 inhabitants per km² and a minimum population of 5,000. High-density cluster are contiguous grid cells of 1 km² with a density of at least 1,500 inhabitants per km² and a minimum population of 50,000.

Figure 2: Boxplot of the share of the vote for parties opposed or strongly opposed to European integration (2013-2018) by degree of urbanisation

We also check whether there are statistically significant differences between the mean values of anti-EU votes in the three types of areas, using an Analysis of variance (ANOVA) methodology. Our (null) hypothesis is that the average vote for Eurosceptic parties is equal in urban and rural areas, meaning that there is no relationship between the type of territory (whether it is urban or rural) and the propensity of voters to support Eurosceptic parties. The alternative hypothesis is that not all the means for the three area types are equal, and that there is a relationship between the type of area and the propensity to vote for Eurosceptic parties. Results in Table 1 confirm that the variation of the share of votes for parties opposed and strongly opposed to European integration among different areas is much larger than the variation within each type of territory. This finding corroborates our initial hypothesis of a significant relationship between votes for Eurosceptic parties and whether an electoral district can be identified as rural or urban.

Table 1: ANOVA for votes for parties opposing and strong opposing European integration and degree of urbanisation

	Degrees of freedom	Sum of Squares	Mean Squares	F-test
Degree of Urbanisation	2	71,67	35,83	183***
Residuals	63,23	12,377,573	196	

Notes: *** p-value<0.01, ** p-value <0.05, p-value *<0.10.

One limit of the previous analysis based on a standard ANOVA is that, however, it does not show which typologies of electoral districts are different from the others. To overcome this, a Tukey test is used (Table 2). The test performs multiple pairwise-comparisons between the means of the three groups and shows significant difference in Eurosceptic vote between each pair of type of areas. Results show that the vote for Eurosceptic parties is significantly higher in rural areas than in towns and suburbs and cities, and that in towns and suburbs it is higher than in cities. In cities, the support for anti-EU parties is around 5.5 percentage points lower than in rural areas. In towns and suburbs, the support for anti-EU parties is around 1.3 percentage points lower than in rural areas. The difference between cities and towns and suburbs corresponds to 4.1 percentage points.

Table 2: Tukey test: votes for parties opposing and strong opposing European integration by Degree of Urbanisation

	Percentage points difference	Lower	Upper
Towns and suburbs areas vs. Rural areas	-1.3	-1.7	-1.0***
Cities vs. Rural areas	-5.5	-6.2	-4.7***
Cities vs. Towns and suburbs	-4.1	-4.9	-3.4***

Notes: *** p-value<0.01, ** p-value <0.05, p-value *<0.10.

3. DRIVERS OF ANTI_EU VOTING: METHODOLOGY AND DATA

As a second step, we empirically investigate the drivers of anti-EU voting, with a focus on whether there are similarities or differences across cities, towns and suburbs, and rural areas. We correlate the share of votes for anti-EU parties, at the electoral district level, with a set of potential explanatory variables. We perform the analyses for the full sample, and by looking separately at cities, towns and suburbs and rural areas. Following Dijkstra et al. (2020), we estimate the following equation:

$$AEV_{r,2013-2018} = \alpha + \beta X_{r,t} + \nu_c + \varepsilon_{r,t} \quad (1)$$

where $AEV_{r,2013-2018}$ is the share of the vote for parties opposed and strongly opposed to European integration in national legislative election that took place between 2013 and 2018. The terms r and t denote *constituency* (i.e. electoral district) and *time*, respectively. The vector $X_{r,t}$ contains a set of explanatory variables identified by the literature as potential drivers of populist vote. Finally, $\varepsilon_{r,t}$ denotes the error term.

Due to data limitation, our explanatory variables on the right-hand side of equation (1) are observed at different levels of territorial aggregation (i.e. electoral districts, NUTS3 regions and for a few indicators NUTS2 regions⁶⁹). We estimate our model via Ordinary Least Square (OLS), and we cluster the standard errors at the NUTS 3 level of territorial aggregation, to correct for the fact that variables are observed at different territorial scales.⁷⁰ In order to capture country dynamics, we include country specific effects, ν_c . In addition, a Chow test is performed to check whether the coefficients calculated for each type of area (namely, cities, towns and suburbs, and rural areas) are significantly different from the estimates for the full sample.

Based on the existing empirical literature on anti-system and populist vote, we identify four groups of drivers of Euroscepticism: *Regional economic variables*, *regional socio-demographic variables*, *electoral district characteristics* and *electoral variables*.

Recent studies based either on microdata (Jennings et al., 2016; Ramiro, 2016) or data aggregated at electoral district or regional level (Algan et al., 2017; Nicoli, 2017; Gordon, 2018; Essletzbichler et al., 2018; Dijkstra et al. 2020, Lechler, 2019; Schraff, 2019; Guiso et al., 2018) show that economic and socio-demographic factors, such as age, education, unemployment and wealth drive anti-system and anti-EU voting. Therefore, we control for:

Regional economic variables

- *GDP per capita* and *GDP per capita growth*. These two variables approximate the local economic conditions and the dynamics over time, respectively. The role of GDP per capita has been highlighted by Schraff (2017) who, combining European Social Survey data (ESS) with regional level data, finds that disadvantaged poor regions and middle-income regions show significantly higher probabilities of Eurosceptic voting, a result confirmed more recently by Dijkstra et al. (2020). In addition, wealth can also be associated to a higher propensity to cast votes for anti-EU parties, in those countries or regions where voters, for instance, may believe they do not need the EU, as their national governments are able to provide them what they need (Dijkstra et al., 2020). Average GDP per capita and GDP per capita growth are calculated over the years 2002-2014 and are defined at NUTS3 territorial level (Source: Eurostat).
- *Unemployment rate* and *change in unemployment rate*. The inclusion of this variable finds justification on the fact that rising unemployment is one of the main factors behind recent populist votes in Europe (Emmenegger et al, 2015; Nicoli, 2017; Guiso et al., 2018 and 2020; Algan et al., 2019). Using data from the European Social Survey (ESS), Lechler (2019) finds that regional employment growth is a causal factor for forming attitudes towards the European Union and reduces voting for Eurosceptic parties.

The two variables are calculated as the average over the period 2002-2014 and are defined at NUTS2 level of territorial aggregation (Source: Eurostat).

Regional socio-demographic variables

- *Age structure* is proxied by including the share of the population by age group 20-39, 40-64 and 65 and over in the total population, observed in 2017, and is defined at NUTS3 level. In the empirical literature on factors driving populist vote, age is often used as a control variable, but not often by looking at different age-groups of the population. In our case, similarly to Jennings et al. (2016), we aim at checking not only for the Euroscepticism of the different cohorts, but also for the differences according to the degree of urbanisation. To avoid multicollinearity issues, as there is very strong correlation between age groups, we include each one at the time. This serves also as a robustness check with respect to the other variables.
- *Education* consists in the share of adults (25-64) with a tertiary education, observed in 2017, at the NUTS2 level. Following the recent literature (see Dijkstra et al. 2020; Lechler, 2019; Schraff, 2019, among others), highly educated voters are expected to support less anti-EU parties, as they have on average better jobs and a more

⁶⁹ The nomenclature of territorial units for statistics (NUTS) is a classification for the EU and the UK providing a harmonised hierarchy of regions. The NUTS classification subdivides each Member State into regions at three different levels, covering NUTS 1, 2 and 3 from larger to smaller areas. For more details, see: <https://ec.europa.eu/eurostat/web/nuts/background>

⁷⁰ As Moulton (1986) shows, when the nesting of observations within geographical units is not considered, the unobserved characteristics that individuals share within this unit are not accounted for, leading to an underestimation of the standard errors of the dependent variables, due to the within-group (intra-class) correlation across individual units.

cosmopolitan view, in opposition to lower educated voters that, according to Gordon (2018), are more likely to support more localist and anti-establishment parties.

- *Share of population born in a different EU Country and share of population born outside EU.* The two variables are defined at NUTS 3 level of territorial aggregation (reference year 2011). Barone et al. (2016) find that immigrants have a causal effect on increasing votes for the centre-right coalition and on the rising of protest votes in Italy, in particular in smaller municipalities. Hartevelde et al. (2018) demonstrate that the number of asylum applications in EU Member States did affect Euroscepticism in countries where it had increased. The relevant channels are cultural diversity, native-immigrant competition in the labour market and in the access to public services (Norris and Inglehart, 2019). Nicoli and Reinl (2020) confirm the result for European regions. In our empirical setting, instead of using a single variable regarding immigration, like in Barone et al. (2016), we distinguish migrants according to their place of origin. Population born in a different EU country has a different profile than those born outside the EU. For example, people born in another EU country are more likely to be employed than those born in that country, while people born outside the EU are less likely to be employed. Countries such as Portugal, Spain, France and Italy have seen an inflow of affluent retirees from colder Western European countries. The freedom of movement within the EU also means that people can easily move back to their country of birth or to another EU country, if the economic situation changes. This is much more complicated and costly for immigrants from more distant countries or countries experiencing conflict. Given the higher economic integration of the population born in another EU country, we expect that it will reduce voting for anti-EU parties. Compared to people born in another EU country, people born outside the EU may also stand out more because a higher share of them may have a different skin colour and may adhere to a religion with a distinct dress code. In several EU countries, Muslims and/or Jews have been cast in a negative light by populist parties. As a result, a high *share of population born outside EU* could be linked to a higher vote share for anti-EU parties.

Electoral districts characteristics

We follow Rodríguez-Pose (2018) and Dijkstra et al. (2020) and control for:

- *Neighbourhood density*, calculated for each electoral district using the density (reference year 2011) of 1 km² grid cells. For each cell, density is multiplied by the population count. The products are summed by electoral district and divided by the total population of the district, providing a measure of spatial concentration. The advantage of using this methodology compared with the simple ratio between population and area is that this measure of density is not affected by the size of the geographic units for which it is calculated and approximates the average density of neighbourhood where residents live. Indeed, given the way in which population-weighted density is constructed, two constituencies with the same size and population where the first has very sparse population and the second very concentrated, will have very different population densities: very high the first, and very low the second. This also adds a differentiation within the three Degrees of Urbanisation. It will distinguish large from small cities, towns from suburbs, and villages from other rural areas. This variable has been rescaled (the original value has been divided by 100) to make the magnitude of the estimated coefficients interpretable.
- *Road performance* is measured using the indicator recently introduced by Dijkstra et al., (2019), which combines accessibility and proximity into an overall metrics of road performance. Thanks to the high spatial resolution at which it can be computed, this measure allows to analyse and compare road performance among different types of settlements (cities, rural areas and towns and suburbs). As for GDP, road performance can be a proxy of the stage of development of an economy. It may also contribute to a higher confidence in national than EU institutions, which has been shown to contribute to anti-EU votes (De Vries 2018).⁷¹

Electoral variables

The last group of variables includes *turnout*, defined as the number of valid votes expressed as a percentage of the total number of eligible voters, and conceived as another way to express dismay or approval of the EU (Guiso et al. 2018) and the share of votes going to parties not included in the waves 2014 and 2017 of the Chapel Hill Expert Survey (CHES).

4. RESULTS

Results based on the full sample show that a combination of socio-demographic and economic factors are the main drivers of anti-EU votes in the EU and UK, which is in line with the literature (Goodwin et al. 2016). On average, electoral districts with a more educated workforce and a higher share of population aged 20 to 39 vote less for anti-EU parties in all three OLS regressions (see Table 3). In contrast, a higher share of population aged 40 to 64 increases the anti-EU vote, which suggests that the generational divide happens at an early age than retirement age. Growing unemployment rates has a highly significant link to a higher share of vote for anti-EU parties in all three regressions. A relative economic decline is also linked to a higher share of anti-EU voting, but it is not significant in one regression and less significant than changes in unemployment in the other two regressions. The level of unemployment and the level of GDP per capita both have no significant impact. Higher weighted population density (or neighbourhood density) reduces anti-EU voting and efficient, well-functioning road network increases it.

⁷¹ For more details on the methodology, see Dijkstra et al. (2019)

A recent study finds that the inflow of asylum seekers into the EU has increased Euroscepticism (Harteveld et al., 2018), while a number of studies conclude that concerns about immigration are the main drivers of support for radical right parties, for which a common factor is a strong aversion toward the EU (Evans and Mellon, 2016 and 2019; Hobolt and Tilley, 2016). Our results show that the presence of migrants is associated to a higher anti-EU vote, but only for migrants from outside the EU. In contrast, the presence of migrants from other EU countries leads to a lower support for anti-EU parties.

Higher neighbourhood densities lead to lower anti-EU voting in all three regressions, which fits with the significant differences found between cities, towns and suburbs, and rural areas. Better road performance, on the other hand, is linked to more anti-EU voting in all three regressions. As in other studies, higher turnout leads to a lower share of anti-EU votes.

The Chow-White test rejects the joint null hypothesis of structural stability among areas, further corroborating our initial hypothesis that it is meaningful to analyse drivers of anti-EU voting separately for urban (cities, towns and suburbs) and rural areas. Table 4 examines how differences in the degree of urbanisation across European territories shape the level of anti-European voting at electoral district level in national elections.⁷² It shows that, among the economic factors, GDP per capita level has no effects on anti-EU vote, while its growth decreases anti-EU vote in rural areas. As expected, unemployment growth is positively and significantly correlated to the share of Eurosceptic vote, and this happens regardless of the type of area. On the other hand, high unemployment levels are significantly linked to lower anti-EU voting in cities and in towns and suburbs. This puzzling result is not new in literature and the possible causes are well-explained by Nicoli (2017). The author observes that “*although several northern countries have enjoyed low levels of*

⁷² Our data has a hierarchical structure, due to data availability, with variables measured at different levels of territorial aggregation. To check for the robustness of our results, we performed additional estimates using a multilevel model (Hox, 2001). We estimated three alternative specifications of a multilevel model: [i] the first model includes country random effects, [ii] the second model is estimated at the NUTS3 level of territorial aggregation (i.e. electoral districts are aggregated at a larger territorial scale, the NUTS3) and country random effects, and [iii] a third model has NUTS3 nested within NUTS2 and controls for country random effects. Independently from the estimation technique used, the coefficients are found to be robust both in term of sign, magnitude and significance. For a discussion, see McNeish et al. (2017) and Primo et al. (2007). Results are available upon request.

unemployment, they have nonetheless developed strong Eurosceptic parties in opposition to bailout programmes for southern states (for example, the case of Finland's True Finns). In contrast, Southern European countries with very high levels of unemployment have seen the electoral emergence of Eurosceptic forces only some years after the beginning of the crisis (Italy after 2013; Spain in 2014). The results seem to suggest that voters attribute the responsibility in failing to address the crisis to the EU rather than blaming it for the crisis itself." (Nicoli, 2017: page 324). Furthermore, given that he finds a positive correlation between the unemployment rate and non-zero net contributions to the financial support measures, he hypothesizes the existence of a domestic effect of economic governance.

Lechler (2019) shows that the share of EU migrants significantly and positively shapes individuals' attitudes toward the EU, while the share of non-EU migrants does not have any significant effects. Our results show that the presence of immigrants has a significant impact in towns and suburbs and in rural areas, but not in cities. The impact in those areas is in line with our expectations. Areas with a higher share of population born in a different EU country have lower votes for Eurosceptic parties, which may be because they are more likely to have a job than the native born and tend to stand out less. Areas with a higher share of people born outside EU have higher share of anti-EU votes, which may be related to their lower employment rates and/or their visible differences.

Cities have a much higher share of people born in another country (17% of the population of 15 and older in 2019 in the EU28) than other areas do (12% in towns and suburbs, and 6% in rural areas). As a result, people in cities may be more accustomed to living with people born in other countries. This may explain why the share of population born in another EU country has no significant impact and the share of population born outside the EU has a weak and less significant impact. If the link between the share of people born outside the EU and anti-EU voting is primarily driven by economic concerns, then boosting employment growth and increasing the economic integration of people born outside the EU could lead to less anti-EU voting both directly, by reducing unemployment, and indirectly, by addressing economic concerns linked to immigration. If this link is primarily driven by a discomfort with visibly different populations, a purely economic policy will not address this problem.

As is the case in other research, we also found that a higher share of younger people (20-39 years old) implies a lower vote share for anti-EU parties, but only in town and suburbs and in rural areas. On the other side, the share of people aged 40-64 has significant and positive impact at 5% level in towns and suburbs, and at 10% in rural areas. Only in cities does the share of people 65 and older have a significant positive affect on anti-EU voting. We draw from these results that in cities what matters is the share of older people, while in town and suburbs and in rural areas it is the share of younger and the middle aged. In the first case, it is possible that older age people feel uncomfortable with the rapid changes in cities and react by voting against further EU integration. On the other hand, in town and suburbs and in rural areas, youngers tend to vote pro EU, as they may perceive more directly the advantages of EU integration (for instance, in terms of travel opportunities, and study exchange programs). Population aged 40 to 64 in town and suburbs may be concerned about their income and employment prospects as technological change and trade affects some areas and industries more than others.

Following the same logic, tertiary education reduces Euroscepticism in such areas by increasing people's chances to secure a good job or find a new one. Cities have the highest share of tertiary educated (42% in 2019 as a share of people aged 25-64), compared to towns and suburbs (29%) and rural areas (24%). Since 2012, the share of tertiary educated has been increasing in all three areas, but faster in cities. This lower growth in tertiary educated outside cities may lead to a wider gap in the perceived benefits of the EU or in the capacity to benefit from the opportunities offered by EU membership. This may explain why education has not impact on anti-EU voting in cities, but reduces it in towns, suburbs and rural areas. Significance levels are slightly lower than for other variables, but this may due to low spatial resolution of that data (NUTS-2).

High population-weighted or neighbourhood density reduces anti-EU voting for all three types of areas, except in cities when controlling for the share of population aged 65 and over. This means that villages are less likely to vote anti-EU than other rural areas, that towns are less anti-EU than suburbs and that large cities are less anti-EU than smaller cities. It is striking that not only does anti-EU voting in general decreases as densities rise, but this pattern is also found within each type of area.

Road performance is also positively and highly significantly linked to anti-EU voting. This road performance indicator compares the population that can be reached in a 90 minute drive to the population within a 120 km radius. The combination of a concentrated population with a dense road network including highways will the higher the road performance. The positive impact of the road performance on anti-EU voting shows that it is not the lack of road infrastructure that leads to anti-EU voting. On the contrary, within each degree of urbanisation the lack of a performant road network is linked to less anti-EU voting. People in areas with a poor road performance may think that their area needs more public investment, which may make them more supportive to the EU and the transport investments it funds. It may also be related to a pattern found in recent papers where higher GDP is associated to higher anti-EU sentiment (see Dijkstra et al., 2020). As for GDP, road performance can be a proxy of the stage of development of an economy and may contribute to a higher confidence in national than EU institutions, which has been shown to contribute to anti-EU votes (De Vries 2018).

Finally, in contrast with Lecher (2019), turnout has a significant and negative impact on anti-EU vote shares. In other words, the higher the turnout, the lower the vote for anti-EU parties. Our finding is more in line with but in line with Guiso et al. (2018), who find that a higher turnout translates into less votes for populist parties.

Table 4 reports the complete set of results, while Table 5 summarises the main findings.

	↑	Increases	Anti-EU vote								
	↓	Decreases									

Variable importance is a useful concept in econometric modelling. After estimating a linear regression model, quantifying the importance of each variable is often looked-for, not only for academic purposes but also to design the most effective interventions. This normally involves decomposing the variance, or, equivalently, its R-squared (Grömping, 2006 and 2015). Consequently, as a final step, we look at the relative contribution of each variable in the right hand side of equation (1) to the model's total explanatory power (that is on the total R-squared).⁷³ See Figure 3. Overall, we observe that the highest contribution (around 50%) derives from country fixed effects, meaning that a large share of the variability is due to country-specific characteristics. Economic variables (*GDP per capita level and growth*, and *unemployment share level and growth*) have the second highest contribution, corroborating previous findings on the drivers of anti-EU voting (Dijkstra et al., 2020), followed by socio-demographic characteristics (*age, education, migrants born within and outside the EU*). Without considering country fixed effects, economic variables seem to explain most of the variability in towns and suburbs and rural areas, due to significant impact of *GDP change* and *unemployment change* in rural areas and *unemployment levels* and *change* in towns and suburbs. Socio-demographic variables (*education, age, share of migrants*) have a significant impact in towns and suburb and rural areas, and especially in towns and suburbs, they explain a relevant share of variability. In cities only, electoral variables (*turnout and share of no-CHES votes*), in particular *turnout*, contribute substantially to the overall explanatory power of the model.

Figure 3: Relative contribution of the explanatory variables, based on results in columns (1), (4), (7), and (10)

5. CONCLUSIONS

This work shows that the people in rural areas are significantly more likely to vote for anti-EU parties, also after taking into account many economic, socio-demographic and local characteristics.

The issues linked to higher anti-EU voting also differ by degree of urbanisation. Economic decline leads to more anti-EU voting in rural areas, but not elsewhere. More tertiary educated reduces anti-EU voting in rural areas, towns and suburbs, but not in cities. This underlines the importance of promoting economic growth in rural areas. Increasing the share of tertiary educated outside cities depends not only on access to this type of education, but also on the employment opportunities for people with more qualifications. More remote education and employment opportunities could help to reduce this gap. The current pandemic is likely to accelerate the trend to more online learning and working remotely.

The impact of the age structure also depends on the degree of urbanisation. In rural areas, towns and suburbs a low share of people aged 20-39 and a high share of people aged 40-64 are both linked to more anti-EU voting, but not in cities. In cities, a high share of population aged 65 and over is linked to more anti-EU voting, but not elsewhere. Most studies have focussed on the elderly and the young, while this study highlights that Euroscepticism starts at middle age. More research is needed to understand how the perception of the EU changes across different age groups in the three different types of areas.

The impact of migrants depends on their country of birth and on the type of area. Migrants born outside the EU increase anti-EU voting, but not in cities. Migrants born in other EU countries reduce anti-EU voting, but this impact is smaller and less significant in cities. The right to free movement of people within the Union is an important achievement and tends to make people more supportive of the EU as well. The economic integration of people born outside the EU would benefit these migrants and the communities they live in. It may also reduce EU discontent especially in rural areas, towns and suburbs.

⁷³ See Annex I for more details on the methodology and a full description of the results, broken down by variable. Note that the relative importance of the regressors is independent from the statistical significance of the explanatory variables. This means that we could have some regressors that explain a high share of the overall R² in spite being not-significant, and the *vice-versa*. Therefore, in commenting the contribution of each variable to overall R², we stress the results only for variables that are found statistically different from zero.

The biggest impact on anti-EU voting, after the country effect, comes from the regional economic and socio-demographic variables. This implies that boosting economic growth, reducing unemployment, increasing education and supporting the economic integration of migrants born outside the EU have the most potential to reduce EU discontent, especially in rural areas.

The key challenge is to understand what is driving this rural EU discontent. This paper provides a first indication of which factors contribute to anti-EU voting, but more research both quantitative and qualitative is needed. The public consultation launched by the European Commission in the context of the long-term vision for rural areas may provide additional insights into rural EU discontent.

ELECTORAL EARTHQUAKE: NATURAL DISASTERS AND THE GEOGRAPHY OF DISCONTENT

Augusto Cerqua, Chiara Ferrante, Marco Letta

Sapienza University of Rome, Italy

ABSTRACT

The recent literature on the determinants of populism has highlighted the role of long-term gradual trends of progressive isolation and prolonged economic stagnation in engendering discontent and, in turn, demand for radical political change. We investigate, instead, the potential of unanticipated local shocks in shaping the 'geography of discontent'. Using comprehensive data at a fine spatial scale and a quasi-experimental method, we document that the occurrence of two destructive earthquakes in Italy resulted in sharply diverging electoral outcomes: while the Emilia 2012 seism did not alter voting behaviour, L'Aquila 2009 earthquake paved the way for an impressive and persistent surge in right-wing populism in the most affected areas. Such heterogeneous patterns mainly originate from a stark contrast in the post-disaster reconstruction process. Our findings are consistent with the idea that not just "places that don't matter", but also "places that don't recover", can become populist hotbeds. This makes the evolution of the geography of discontent more unstable and, thus, unpredictable, and places an additional burden on the role played by institutions in managing local recovery and ensuring territorial resilience.

INCLUSIVE ATTITUDES TOWARDS IMMIGRANTS IN EUROPE: THE ROLE OF PREFERENCES, SPACE, AND ECONOMIC OUTCOMES

Riccardo Borgoni, Dario Casamassima, Caterina Liberati, [Alessandra Michelangeli](#)

DEMS – University of Milan-Bicocca, Piazza dell’Ateneo Nuovo 1, 20126 Milan (Italy), riccardo.borgoni@unimib.it, caterina.liberati@unimib.it, caterina.liberati@unimib.it, alessandra.michelangeli@unimib.it

ABSTRACT

In this paper, we analyze the extent of inclusive attitudes towards immigrants within European countries. To this purpose, we use data from the European Social Survey Round 1 and 7, collected in 2002 and 2014, respectively. The two waves contain a module of questions exploring different aspects of public opinion about immigration. We distinguish between variables identifying the kind of migrants Europeans wish from those variables providing information about the extent of contact with members of migrant communities and the perceived costs and benefits of immigrants on the economy, cultural context, welfare system of host countries. The survey data are merged with data from Eurostat providing information on socio-economic conditions.

Natives’ attitudes are measured by an index reflecting the overall level of support for immigration. The advantage of such a measure is that it can be broken down into specific areas of investigation reflecting people’s perceptions of the effects of migration on the economic, cultural and welfare system. This allows to identify the role and the importance of different issues in determining the level of inclusive attitudes towards migrants. A similar measure is developed to cardinalize natives’ preferences for the kind of immigrants they wish. We explore the correlation between our measure of natives’ attitudes and the measure of natives’ preferences plus an array of aggregate economic and social indicators.

We obtain a comprehensive picture of natives’ attitudes towards immigrants that is broken down into specific areas such as rural/urban locations, as well as into groups identified, for example, by gender or country. We also show that different patterns of inclusive attitudes across European countries are in general positively related to economic activity and social capital while are negatively related to inequality.

THE ROMANIAN RESPONSE TO THE COVID-19 CRISIS: LOCAL, COUNTY OR REGIONAL EFFORT? A PERSPECTIVE ON VACCINATION CAMPAIGN

Elena Grad-Rusu¹, Antoanela-Paula Mureşan²

¹ Faculty of European Studies, Babeş-Bolyai University, Cluj-Napoca, Romania, elena.rusu@ubbcluj.ro; ² Faculty of European Studies, Babeş-Bolyai University, Cluj-Napoca, Romania, paula.muresan@ubbcluj.ro

ABSTRACT

Against the backdrop of a continuously changing situation, Romania, as many other countries, has adapted on the go to the pandemic situation. On 27 December, 2020, the national vaccination campaign started. The existing literature shows that such an effort requires coordination and a clear strategy that must include all the administrative levels. But in this Covid-19 situation it is still unclear what role can be played by the territorial units (local, county and regional level) in unitary states. To address this gap in the literature this article tries to analyse the Romania's strategy in managing a national vaccination campaign and what is the involvement of local, county and regional authorities in pursuing this aspect. From the methodological point of view, this research is based on a comparative approach, by using also quantitative (statistics) and qualitative data. The analysis is done through primary data, obtained from government official websites, public declarations and other official documents issued by national and county authorities. The documents analysed were selected on the basis that they represent the official vaccination programmes and campaign materials published on the most widely-used platforms. This filtering of the material was based on the initial research, which showed that such terminological association on vaccination campaign was a common and important feature of the official programmes. According to the procedures, each hospital within which a vaccination centre is organized establishes its vaccine requirement for three days, based on the schedules made, and sends it to the county public health directorates. They, in turn, centralize the vaccine requirements from all the rounded vaccination centres and send it, by 1 pm the day before the actual vaccination, to the Regional Storage Centre where they are rounded up. The regional storage centre prepares, for distribution, the necessary quantity of vaccines, according to the requests / schedules received and distributes them, accordingly, to the public health directorates, respectively the vaccination centres. Therefore, the Regional Centres are not independent entities, they are based on the national structure, on units subordinated to the Ministry of Defence or the Ministry of Health. However, the preliminary findings of our study show that the use of existing regional structures might increase the efficiency and the level of coordination between the national and local authorities.

1. INTRODUCTION

Vaccine hesitancy is an old story which happened multiple times in different contexts. But this time, due to the Covid-19 pandemic, with the widespread mortality and economic disruption, a well-informed campaign should be organized in order to improve the trust of the people.

The new global context of this pandemic saw governments and health authorities in the way to develop new laws and public communication strategies to inform people about their actions. From the beginning of this pandemic, along with official messages from the authorities, an unusually wide range of disinformation and conspiracy theories about the origins and severity of Covid-19 spread online and on personal messaging platforms (Freeman et al., 2020; Chadwick et al., 2021). This may have been also influenced by official authorities' missteps, delays, and mixed messages, along with an unknown virus and unknown ways how to deal with it.

The same pattern happened when the first available vaccine was approved. We might agree that vaccine hesitancy, in this context, is also a social information situation. If people decide to get the vaccine or not depends on the level of information about the safety and efficacy. When official authorities develop a well-organized strategy and provide access to the vaccines, the success is easier to be achieved.

Previous vaccination campaigns have shown that multiple factors might influence the success of this. For example, not only sociodemographic factors have played a role in adult vaccination acceptance (Head et al., 2020), but also the way in which the vaccination strategy was organized – controlled only by the centre or with a regional or local initiative. In a pandemic time, in order to deliver efficient immunization services, it takes a proactive approach of all political, economic or health bodies from national, regional or subregional / local levels (WHO Regional Office for Africa, 2015). Thus, the development of the vaccination campaign will need to be managed by experts of local, regional and national bodies and this also determines the strengthening of national capacity and regional infrastructure.

Also, as a vehicle of promotion and communication, mobilizing leaders or public figures to be a voice for immunization might increase the number of people who will accept the vaccine. But this requires continuous updating of their

knowledge through highly condensed, relevant briefings with talking points (WHO Regional Office for Africa, 2015). In conclusion, country and regional communication, research and development innovations maximize the benefits of immunization campaigns.

1.1. How are vaccination campaigns going in other European countries?

The United Kingdom was one of the most affected countries by the COVID-19 pandemic. So, excepting the fact that their national specialists were involved in developing a proper vaccine, when the first one was developed, this was seen as an opportunity to limit the impact of the disease and to reduce the number of deaths in any third wave.

The vaccination campaign in the UK involved from the beginning the Local Clinical Commissioning Groups who supported and coordinated the arrival of vaccines to practices. The government also developed mass vaccination centres in local hospitals, pharmacies and community centres (Harnden, Earnshaw, 2021). Thus the UK government approved three types of vaccination site:

- vaccination centres, using large-scale venues, such as football stadiums and accessed by a national booking service;
- hospital hubs, using NHS trusts across the country;
- local vaccination services, made up of sites led by general practice teams working together in already established primary care networks and pharmacy teams through community pharmacies⁷⁴.

Italy, the country with the oldest population in Europe and the first one severely affected by the COVID-19 pandemic, planned its vaccination campaign including cooperation between the national and regional health agencies. The vaccination plan in Italy was centred around 8 axes. The sixth axis concerns the governance of the vaccination plan, which will be ensured through a constant coordination between the Ministry of Health, the Extraordinary Commissioner, the Regions and Autonomous Provinces⁷⁵. This partnership between the national and regional health authorities speaks to the unified and centralized response to the country's vaccination strategy⁷⁶.

Spain, another European country with a high percentage of old people, was strongly affected by the current pandemic. The Ministry of Health in Spain worked at the creation of a COVID-19 State Vaccination Register in collaboration with the autonomous communities and cities, which were fed with information from the vaccine registers and information systems, or any other system with information of interest on the autonomous communities and cities⁷⁷. In developing a vaccination campaign, Spain's regions prepared mass vaccination sites, as a complement to, and aimed at avoiding congestions of, health centres, which are also a key part of the immunization campaign (El País, 2021).

Sweden, known from its different perspective in considering a lockdown during the pandemic, developed a well-organised vaccination strategy. There was approved a national coordinator, but, specifically, certain responsibilities have been assigned to the regions for carrying out COVID-19 vaccinations. This included:

- Distributing vaccines within the respective region;
- Making plans for staffing, premises and successfully carrying out vaccinations;
- Offering COVID-19 vaccination to residents, as decided in the region on the basis of the Public Health Agency of Sweden's recommendation⁷⁸.

Also, the county administrative boards continue to be responsible and involved in coordinating regional crisis and supporting regions, municipalities and civil society in their vaccination process.

1.2. Methodological approach

In this article, we mainly focus on the “where”—the vaccination campaign was coordinated from the Romania's perspective. The “how”—the specific thematic messages—is crucial as well but is not our main focus here.

H1. Enhancing local, county and regional structures in the vaccination strategy will create mutual benefits for all the actors involved (authorities in managing the campaign and people as beneficiaries of the vaccines as soon as possible).

In demonstrating this hypothesis, the actual research is based on a comparative approach, by using also quantitative (statistics) and qualitative data. The main research question of our study is: are regional centres individual entities in developing a strategy and implementing a strategy?

In order to assess the role and contribution of each Romanian region in implementing the vaccination strategy, our study employs document analysis from the national, regional and local authorities involved in this regard. The analysis is done through primary data, obtained from government official websites, public declarations and other official documents issued by national and county authorities. The documents analysed were selected on the basis that they represent the official vaccination programmes and campaign materials published on the most widely-used platforms.

2. ROMANIA'S STRATEGY OF COVID-19 VACCINATION

The main document for the vaccination campaign against COVID-19 in Romania is the Government's strategy which establishes the vision, principles and way of action for the administration of the vaccines authorized by the European Medicines Agency. The document is formulated in accordance with the European legislation and medical protocols. The strategy, called *Vaccination Strategy of 27 November 2020 against COVID-19 in Romania*, was published in the Official Gazette no. 1171 of 3 December, 2020, Strategy of November 27, 2020, Issuer - The Government of Romania.

Through this strategy, Romania aims to ensure access to vaccination against COVID 19 in terms of safety, efficacy and equity to prevent infection and to limit the spread of COVID-19 pandemic in the country.

The strategy includes information about the entire process and national chain of vaccination, as: storage of vaccines, maintenance of the cold chain, monitoring safety and efficiency and waste management. In the context in which other local and regional key actors will be involved in the process, the strategy proposes the underlying guidelines of the vaccination campaign against COVID-19 in Romania.

At the time of elaboration of this strategy, 19 November 2020, 393,851 cases of infection with the new Coronavirus were confirmed; of those infected - 269,590 were declared cured. At the same time, the number of deaths caused by the virus infection was amount to 9,596 people⁷⁹.

The general purpose of the vaccination strategy is to ensure access to vaccination against COVID-19 under conditions of safety, efficacy and equity for the prevention of SARSCoV-2 infection and the limitation of the COVID-19 pandemic in Romania.

To achieve this goal, a management structure of the vaccination campaign was established. The organization and coordination of activities is carried out by a National Committee for the Coordination of Activities on Vaccination against COVID 19, which is an inter-ministerial body, without legal personality, subordinated to the General Secretariat of the Government and in coordination of the Prime Minister.

To this national level, other central structures were involved with responsibilities in ensuring the proper functioning of the vaccination program against COVID-19. Those were and are still functioning by this time:

- The Ministry of Health with all subordinated institutions, in coordination and under the authority of the Ministry, with a role in public health;
- The Ministry of National Defence with its subordinate institutions;
- The Ministry of Internal Affairs with the subordinate and coordinated institutions;
- Special Telecommunications Service;
- Other ministries and institutions with their own health networks;
- Other ministries.

After presenting the responsibilities of each of these national institution, the Romanian Vaccination Strategy continues with the presentation of the local structures with responsibilities in ensuring the proper functioning of the vaccination campaign against COVID-19. As we can see, the regional level is left beside.

So the local structures involved were:

- The institution of the prefect;
- County Centre for Coordination and Management of Intervention (CJCCI);
- The Public Health Directorate of the Municipality of Bucharest and the county public health directorates;
- Territorial administrative units - county, municipality, city and commune;
- Other governmental and non-governmental institutions and organizations;
- Public and private providers of medical services;

As we can see, at the local level are mentioned and involved in the vaccination strategy only institutions and authorities from the county, municipality, city and commune structures. Again, the regional level is not mentioned at the national structures, neither at the local ones.

Chapter eleven of the *Strategy* is dedicated to the organization and conduct of vaccination against COVID 19 campaign, being focused on the following pillars:

- How to implement the vaccination campaign;
- Description of population groups for vaccination against COVID 19;
- Vaccination stages;
- Storage and distribution network: cold chain;
- Stock and loss management;

Thus, at national level a module dedicated to vaccination will be developed against COVID 19 within the National Electronic Vaccination Register (NEVR), which will constitute electronic vaccination database. Each person will receive a certificate of vaccination from the NERV with specific vaccination data.

For the description of population groups for vaccination against COVID 19, one important criterion made reference to *epidemiological criteria* to allow flexibility in vaccine allocation at the regional level and local - depending on the evolution of the infection in the territory, such as: the rapid, exponential growth of the number of cases above a certain threshold value (definition of an incidence threshold) at the level of a region will allow, depending on the characteristics of the population, the priority distribution of vaccines in that population to limit the spread of the virus.

⁷⁹ The Government of Romania, *Vaccination Strategy against COVID-19 in Romania*, available at https://vaccinare-covid.gov.ro/wp-content/uploads/2020/12/Strategia-vaccinare-02-12-2020-CL-FINAL-cu-COVID-19-tabel-2_CUPRINS-UPDATE-1.pdf

The document also exemplifies the population categories (stage I - health and social workers - public and private system, stage II - population at risk, workers carrying out activities in key areas and stage III - all the population).

As for the vaccination stages, these are assumed as follows: for stage I, vaccination will be organized at the workplace and through fixed and mobile vaccination centres and for stages II and III vaccination will be made through fixed and mobile vaccination centres, mobile teams, family medicine network and drive-through centres.

The storage and distribution network bring into discussion the existence of a central storage and regional storages. The number or the location of regional storages are not mentioned in the Strategy. It is stipulated that all have to fulfill the requirements of storage according to the vaccines (for vaccines with long-term storage at -80-degree Celsius, for vaccines with long-term storage at -20 - degree Celsius, for vaccines with long-term storage at 2-8 degree Celsius). The distribution to the local, fixed and mobile vaccination centers will be made from the central and regional storages.

As for the stock and loss management, all vaccination centers should monitor the use and loss of vaccine doses on a monthly basis. This activity is extremely important being a way of scheduling and self-control.

*The National Institute of Public Health*⁸⁰ based on the Ministry of Health distribution order, will upload to NEVR the vaccine stocks distributed to regional storage centers, and the centers, based on the record of the number of people, will distribute the vaccine to users in the territory at the level of local vaccination centers and at the level of family medicine practitioners. The vaccine coverage will be available at county and national level.

Because the health of the population is very important, the Strategy, in the last chapter makes also reference to the possible side-effects reactions after the vaccination which will be monitor for a period of 30 days through an individual electronic reporting system and to the vaccination waste management.

3. REGIONAL INVOLVMENT

The regional implication of the regional centers, in terms of receiving and storing the vaccines, was presented by the coordinator of the vaccination campaign in Romania, dr. Valeriu Gheorghiu. In November 2020, before the starting of the campaign, he declared that : *In addition to the Cantacuzino Institute, which will be the main storage center for the anti-COVID-19 vaccine, 6 regional centers will be organized in military hospitals, which have the capacity to keep the vaccine at a temperature of minus 80 degree Celsius*⁸¹.

Accordingly, 6 military hospitals have the role of Regional Storage Centers, as it is mentioned on the site of Ministry of Defense, as follows:

- Military Emergency Clinical Hospital "Dr. Iacob Czihaç" Iași;
- Military Emergency Clinical Hospital "Dr. Constantin Papilian Cluj-Napoca;
- Military Emergency Hospital "Dr. Alexandru Gafencu" Constanța;
- Military Emergency Clinical Hospital "Dr. Ștefan Odobleja" Craiova;
- Military Emergency Hospital "Regina Maria" Brașov;
- Military Emergency Clinical Hospital "Dr. Victor Popescu" Timișoara⁸².

⁸⁰ National Institute of Public Health, *Organizational Structure*, available at <https://insp.gov.ro/>.

The activity of the Institute at territorial level is realized through 4 national centers and 6 regional centers of public health, organized in its structure, without legal personality.

The national centers, which ensure the specific professional coordination at national level of the Institute, are:

- a) The National Center for Surveillance and Control of Communicable Diseases (NCSCCD);
- b) The National Center for Monitoring the Risks in the Community Environment (NCMRCE);
- c) National Center for Health Assessment and Promotion (NCHAP).
- d) National Center for Statistics and Informatics in Public Health (NCSIPH)

The regional centers of public health, which ensure the coordination and professional execution at regional level of the Institute, are:

- a) Bucharest Regional Center for Public Health (BRCPH);
- b) Cluj Regional Center for Public Health (CRCPH);
- c) Iasi Regional Center for Public Health (IRCPH);
- d) Timisoara Regional Public Health Center (CRSPT);
- e) Targu Mures Regional Public Health Center (TGRPHC);
- f) Sibiu Regional Public Health Center (SRPHC).

⁸¹ Hotnews.ro, *Vor fi 6 centre regionale în spitale militare pentru depozitarea vaccinului anti-COVID în România / Medici școlari și studenți, în echipele care vor vaccina populația - coordonatorul campaniei de vaccinare*, available at <https://m.hotnews.ro/stire/24435238>.

⁸² Ministry of National Defense, The Medical Directorate of the Ministry of National Defense, available at <https://directiamedicala.mapn.ro/pages/view/191>.

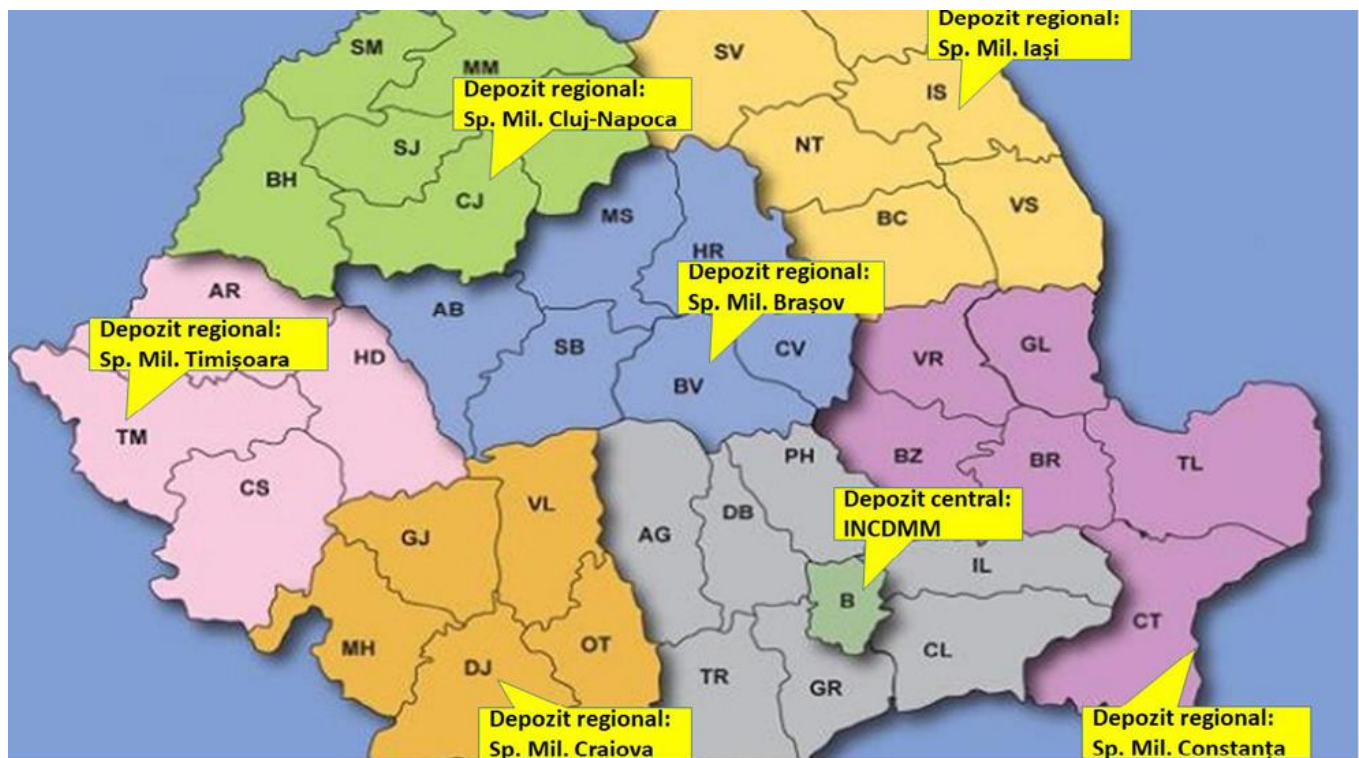

Figure 1. Regional Storage Centers⁸³

In fact, they overlap with the Romanian development regions, excepting South Muntenia which is also served by the *Cantacuzino Institute* (including Bucharest and Ilfov county, too).

Due to its involvement in ensuring the transport of vaccine doses by land and air, from their arrival in the country to the regional storage centers and by supporting the distribution to the vaccination centers in the country and the vaccination teams with qualified human resources, the Ministry of National Defense has a very important role in supporting the inter-institutional effort in the anti-COVID-19 vaccination campaign.

In Romania, as concern the regional development, there are eight regions related to NUTS 2 level in the European Union. The law no. 315/2004 establishes the institutional framework, objectives, competencies and instruments specific to the regional development policy in Romania⁸⁴ and is considered to be the fundamental law of regional development in Romania. For each region was also constituted eight different Councils for Regional Development, which analyse and decide the regional development strategy and programs. Coordinated by the Councils, were also established eight Regional Development Agencies, non-governmental bodies, of public utility, with legal personality and not seeking to make a profit.

In what concern the regional approach for the COVID-19 vaccination campaign, these regional entities were not involved in any particular aspect and did not have any responsibilities.

At the county level, only the public health directorates were involved in reporting on the incidence of illness per thousand inhabitants. Depending on this report, vaccine doses are distributed to the vaccination centers. Also, the public health directorates offer authorizations for vaccination centres and involved personnel in the county were they are functioning. The evidence from quarantine / decarantine of the people is also in their role. In this regard, it is important to mention that the county public health directorates in Romania are deconcentrated public services under the authority of the Ministry of Health⁸⁵.

4. CONCLUSION

In conclusion, the general purpose of the vaccination strategy in Romania was to ensure access to vaccination against COVID-19 under conditions of safety, efficacy and equity for the prevention of SARSCoV-2 infection and the limitation of the COVID-19 pandemic in the country. To achieve this goal, national and local authorities and institutions were involved and as concerns the regional level, the existing entities like the regional as Regional Councils or Regional Development Agencies from each one of the eight regions had no responsibility.

The regional approach is missing and the only implications were developed through the regional centers, in terms of receiving and storing the vaccines. Those regional centers are also military hospitals, one for each region, excepting South-Muntenia which was grouped with Bucharest-Ilfov regions to one single hospital. To conclude, were established

⁸³ Source. Ministry of National Defense, available at <https://directiamedicala.mapn.ro/pages/view/191>.

⁸⁴ Lau no. 315 of June 28, 2004 (* updated *) on regional development in Romania, available at <http://legislatie.just.ro/Public/DetaliiDocument/53040>.

⁸⁵ Ministry of Health, List comprising the units with legal personality subordinated, under the authority or under the coordination of the Ministry of Health, available at <http://old.ms.ro/?pag=8>.

only seven regions to implement the vaccination strategy in Romania. In these regions were functioning military hospitals used for receiving and storing vaccines. In the same time, at the county level, the public health directorates were involved in reporting on the incidence of illness per thousand inhabitants. Through this reporting, the doses were sent to the vaccination centers.

We can observe that the regional approach in Romania is still in an incipient phase, and it was ignored in the writing and implementation of the vaccination strategy, differently that it was in other European countries where the regions and regional authorities had a stronger voice and implications.

REMOTE WORKING AS DRIVER FOR INDIVIDUAL AND ORGANIZATIONAL RESILIENCE IN PANDEMIC CONTEXT

Alina Georgiana Profiroiu, Maria-Roxana Briscariu

Bucharest University of Economic Studies, Romania

ABSTRACT

Global pandemic is exerting extreme pressure on the economy, and on our view of life by bringing to the fore goals that we did not choose but simply we had to adhere to. An important change was felt at the labor market, at the individual and organizational level. Resilience and work adaptability are increasingly relevant for employees and employers, in the context in which the working frame has moved from a clearly defined place and with a specific structure, as a program and as a set of actions, to working from home, remote, (teleworking).

In this paper, we analyzed the ability of employees to adapt to pandemic context, by identifying the drivers of individual resiliency. We explored their capacity of coping with adversity or opportunity through the condition of remote working. In addition, part of research is focus on shocks and risks as disrupts the proper functioning of certain production processes in labor market.

The study was conducted using the quantitative research method. The research method consist in questioner based survey for collecting empirical data. The questionnaire was applied online among employees with full-time jobs in private and public organizations, using a non-probabilistic sample.

A more resilient employees and organization have to shift to sustainable practices and to adapt to the context. We argued that remote working process helps achieving goals, prioritizing activities, get the target results, cope with change, maintain a work-life balance, and ensure individual and organizational resilience.

ACKNOWLEDGEMENT

This work was supported by a grant of the Ministry of Research and Innovation, CNCS - UEFISCDI, project number PN-III-P4-ID-PCCF-2016-0166, within the PNCDI III project "ReGrowEU - Advancing ground-breaking research in regional growth and development theories, through a resilience approach: towards a convergent, balanced and sustainable European Union".

MAKING COMMUNITIES RESILIENT DURING THE COVID-19 PANDEMIC. WHO COMPLIES WITH SOCIAL-DISTANCING RULES? AN ANALYSIS ON THE METROPOLITAN AREA OF CLUJ-NAPOCA

[Alina Pavelea, Alexandru Pavel](#)

Babeş-Bolyai University, Romania

ABSTRACT

During the COVID-19 pandemic authorities have relied on the adherence of citizens to the social-distancing and mask wearing rules in order to limit the spread of the virus. Nevertheless, it was soon evident that not all citizens are willing to comply with the rules imposed by authorities. It is highly important to identify the factors that influence the extent to which people adhere to the social-distancing rules, as it can make the difference between resilient and non-resilient communities during the pandemic. However, only a limited number of studies examined these factors. As such, the present paper seeks to identify the factors that predict the extent to which people comply with the social-distancing rules in the metropolitan area of Cluj-Napoca. In doing so we make use of a representative survey conducted in December 2019 on a sample of 705. More specifically, we investigate the extent to which the following factors predict the declared level of compliance with the social-distancing rules: trust in authorities, perception regarding the way authorities communicated with the public, the media sources individuals used to keep informed, and other socio-demographic variables.

THE INTRIGUING CONNECTIONS BETWEEN REGIONAL TOURISM AND ECONOMIC RESILIENCE

Bogdan-Constantin Ibanescu¹, Gabriela Carmen Pascariu¹, Peter Nijkamp², Karima Kourtit²

¹Centre for Interdisciplinary Research in European Studies, Faculty of Law, Alexandru Ioan Cuza University of Iasi, Romania. ²Open University, Heerlen, Netherlands

ABSTRACT

Tourism is an important key sector in regional and national economies which appears to have often a favorable recovery potential after a shock, leading to the notion of resilience capacity of regions. In the context of a tourism-led growth mechanism, the concept of tourism-led resilience capacity is introduced (constituted of sustained tourism resilience and speed of recovery). The analytical framework is tested for the 2008-2012 financial crisis in European Union by examining relevant data from European NUTS 2 regions. The research is unfolded on two complementary axes: a) assessing the resilience of the tourism sector, and b) estimating the weight of tourism in the overall resilience performance of EU regions. Finally, several implications for regional and European policies are addressed as well, particularly related to the role of innovation and diversification in increasing the recovery speed following a disruption.

SMART CITIES FROM LOW COST TO EXPENSIVE SOLUTIONS. AN OPTIMAL ANALYSIS

Romeo-Victor Ionescu¹, Monica Laura Zlati², Valentin-Marian Antohi³

¹ Dunarea de Jos University, 111th, Domneasca Street, Galati, Romania, romeo.ionescu@ugal.ro; ² Stefan cel Mare University, Suceava, Romania, sorici_monica@yahoo.com; ³ Dunarea de Jos University, 111th, Domneasca Street, Galati, Romania, valentin_antohi@yahoo.com

ABSTRACT

Each region contains at least one urban agglomeration which becomes a growth pole over time. During pandemics, such as COVID-19, the negative effects on growth poles are exacerbated by the accumulation of aggravating health and economic factors. In this context, the concept of smart city has acquired a new nuance and has aroused both theoretically and practically the interest of the researchers.

The objective of this scientific approach is represented by a critical analysis starting from the current state of scientific knowledge in the area, the development of the smart city / smart community concept in order to objectively evaluate the progress of these organization forms in relation to other classical / traditional forms of the cities' organization.

The empirical approaches are supplemented by a pertinent statistical analysis of the socio-demographic and economic indicators reported through the Eurostat platform by the first 10 European smart cities, to which is added the city of Bucharest, as an anti-pole of smart city development.

The statistical data processed in dynamics allowed the consolidation of smart indicators at the level of the selected sample (local GDP, internet users, R&D&I, Internet of Things, internet banking, general motor rate, green vehicle motor rate and polluting vehicle motor rate).

The elaborated model allowed the construction of the dashboard of the access actions in the smart city / smart community category on two levels of financial effort correlated with the impact on the sustainable development of the smart cities. We have to specify that this model is absolutely new. It is not a copy or an adaptation of another existing model. This model was transposed by pivoting the hypotheses into a minimal and extended dashboard with pivoting links on each branch of the table in order to facilitate the step by step implementation of this form of superior organization of urban populations. We started from simple solutions, implementable on short term, but we arrived at extensive solutions with high efficiency and high added value on the inhabitants' life of the applicant cities.

The statistical analysis covers 2009-2020, the period representative as duration and which includes the impact of COVID-19 on the urban society.

The validity of the proposed model and our approach are supported by the complex statistical analysis performed in this scientific article.

The results of the study are useful for all administrations ready for change which want the rapid implementation of the measures with beneficial effects on the community or which through a strategic vision aim to connect to the European objectives of sustainable growth and social welfare for citizens.

The entire analysis is based on the latest official statistics, which are processed in the form of diagrams, tables and relevant mathematical equations and functions.

KEYWORDS

IoT, smart city, smart economy, sustainability, urban development.

1. INTRODUCTION

The urban overpopulation and urban growth poles impose significant differences in social and economic development for these communities' members compared to other forms of population aggregation and bring direct benefits to the residents by sustainably increasing of the life quality and adaptability of the population to permanent societal challenges. On the contrary, this urban agglomeration produces amplified effects during the pandemic period through the accumulation of aggravating health and economic factors, but also during general periods, through the environment pollution. In relation to the European strategic development objectives, the limitation in time of these effects is seen as a side of the sustainable development, the practices of limiting the adverse effects being supported by long-term financing by the European and global organisms.

In this context, the concept of smart city has acquired a nuance and has aroused the interest of researchers both theoretically and practically, currently existing top cities on all indicators that have approached the concepts of smart city or smart community in order to manage the negative aspects of the growth urban agglomeration.

In this sense, a combination of scientific approaches have shown that the smart management's implementation in communities can generate viable solutions to specific problems, but an integrated approach is needed to achieve the status of smart city or smart community.

The objective of this scientific approach is represented by a critical analysis starting from the current state of the scientific knowledge in the field, the development of the smart city / smart community concept, in order to objectively evaluate the progress of these forms of organization in relation to other classical / traditional forms of towns' organization. The transposition of this model by pivoting the hypotheses into a minimal and extended dashboard with pivoting links on each branch of the table facilitates the step by step implementation of this form of superior organization of the urban populations, starting from simple solutions, implementable on the short term, to extensive solutions with high efficiency and high value-added contribution on the life of the applicant cities' inhabitants.

The methods used in carrying out this scientific approach are prospective for analysing the achievements in the smart city field for urban localities included in the top of the European smart cities and around the world, as they have been transposed in the literature by the international experts. The empirical approaches are supplemented by a pertinent statistical analysis of the socio-demographic and economic indicators reported through the Eurostat platform by the first 10 European smart cities, to which is added the city of Bucharest, as an anti- pole of the smart city development.

The statistical data processed in dynamics allowed the consolidation of the smart indicators at the level of the selected sample (local GDP, internet users, R & D & I, Internet of Things, internet banking, general motor rate, green vehicle motor rate and polluting vehicle motor rate). These indicators were structured according to the average evolutions on the selected sample during 2009-2020. The main observations of the core of indicators allowed the elaboration of a smart economic model, which analyses the impact at the sample level of the adaptation of the smart city / smart community policies.

The elaborated model allowed the construction of the dashboard of the access actions in the smart city / smart community category on two levels of financial effort correlated with the impact on the smart cities' sustainable development. The results of the study are useful to all administrations ready for change which want the rapid implementation of the measures with beneficial effects on the community or which through a strategic vision aim to connect to the European objectives of sustainable growth and social welfare for citizens.

2. LITERATURE REVIEW

The interest for the scientific research related to the smart urban development is huge. According to an analysis conducted by Google Scholar, were published a number of over 930,000 scientific articles, some with over 800 to 2400 citations, during 2010-2020. In the last year, 2019-2020, approximately 140,000 articles have been published, some of them with over 150 citations. The Figure 1 below shows these.

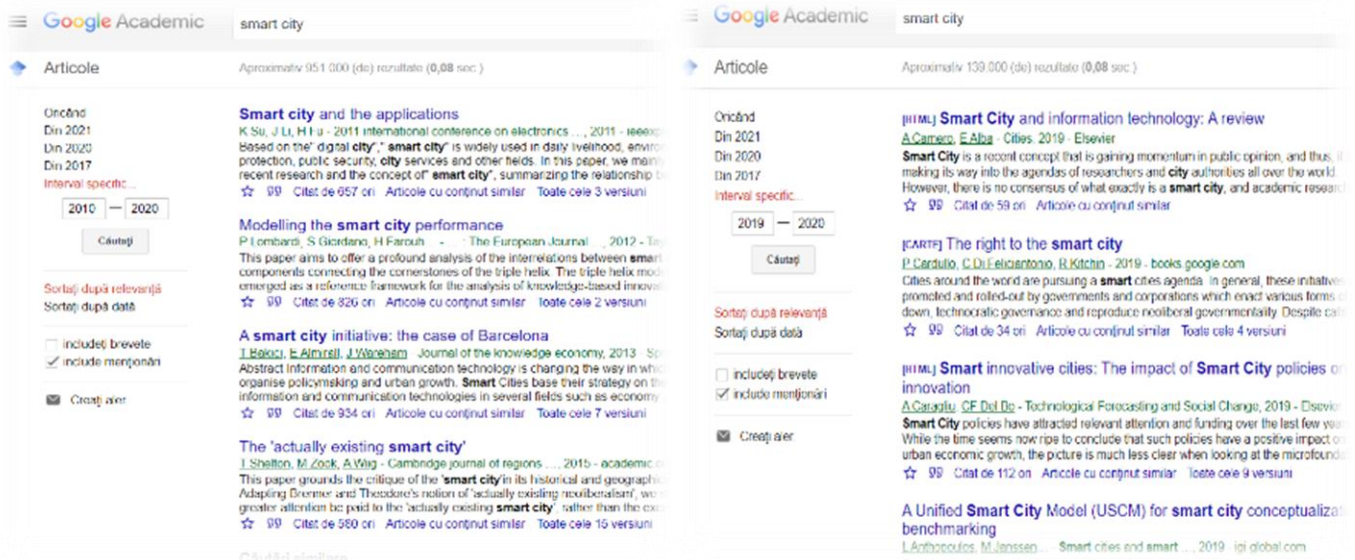

Figure 1: Literature focused on smart city concept

Source Google Scholar platform.

In order to quantify smart city capacity, different models were developed. One of them, a quadruple-helix model for smart city capacity measurement, directly connects the city and the innovation capacity of the companies based in it. As a result, the concept of smart city is defined and analysed using relevant phrases such as: smart governance, smart economy, smart living, smart environment, smart mobility and smart human capital. These concepts are derived from the smart use of: strategy and planning, marketing, quality management, technological processes, logistics and human resources (Lombardi, Giordano, Farouh, & Yousef, 2012).

The smart urban development must be carried out in conditions of environmental protection and reduction of energy consumption. The urban demographic dynamics is another important element. In this sense, there is already a European regulatory framework (directives and technical norms). The concrete way of applying these regulations in the case of the large Mediterranean city in Italy (Palermo) is analysed in detail in the case of this research. The entire analysis is supported by The Urban and Environmental Building Code as Implementation Tool. This Code covers 4 Areas and 20

Articles. The Areas are: Environmental sustainability and context appraisal; Energy performance of building envelope; Energy performance of technical systems; and Renewable energy systems. The result of this approach was a smart planning protocol able to create an instrument between cloud governance and smart tools for local urban administration (Riva Sanseverino, Riva Sanseverino, R., Vaccaro, & Zizzo, 2014).

The smart city services are treated in an aggregate manner and cover: “Initiatives for communities with special needs like jobless, elderly, female and disabled; Vocational training services; Heritage provision and protection services and economic support (e.g., loan provision for settlement); Several types of consulting services (e.g., training and new business registration); Volunteer and cultural activities; Metro-WiFi infrastructure and pet related services since they both are consider to be related with local quality of life (L. G. Anthopoulos & Reddick, 2016).

From the economic and the quality of urban life point of views, another paper is focused on the costs of implementing the smart city concept, on their efficiency seen from the perspective of energy savings, production value, ease of implementation, improving quality of life, etc. The authors of this paper discuss complex concepts such as improving urban economic development and social acceptance (L. Anthopoulos & Giannakidis, 2017).

An interesting concept of smart development is the energy dimension of a smart city. It allows a new understanding of the urban systems and progress towards a new style of urban management. The new urban management is based on energy and technology (Lai, Leone, & Zoppi, 2016).

The engine able to move the urban system in its spatial and temporal development is the technological dimension of the smart city. It must be completed by energy, because the cities represent the greatest energy consumers. As a result, a new approach in the planning of a smart city has to be based on the energy dimension. This approach was implemented in Italy, where the concern about cities’ energy is real. The international researchers used three dimensions in order to analyse the smart city concept: ECOware: natural capital; Water/energy; and SMART environment. The concept of ECOware: natural capital covers: hand-made capital, economic and financial capital, institutional capital, human capital and social capital. Water/energy is focused on: transport, business, city services, citizens and communications. Finally, SMART environment deals with: SMART mobility, SMART economy, SMART governance, Smart people and SMART living (Lai et al., 2016).

An interesting analysis is that which connects the accessibility by collective transit and the availability of space for parking vehicles under a smart approach. This accessibility takes into account two elements: the individual motorized transport accessibility and the collective and non-motorized transport accessibility (Gerundo, Fasolino, & Grimaldi, 2016).

The concept of smart city was defined in connection to the urban innovation and e-government and human welfare. This connection represents the base of defining and implementing new planning and management principles and ideas for smart urban governance (L. Anthopoulos, 2017b).

The theoretical approach of the smart city concept and its evolution is made in a reference work that aims to find answers to questions related to the type of technologies used by the smart city, the types of services offered by the smart city approach, the solutions offered by the smart city approach and the differences between theory and practice in the case of smart cities. Moreover, the paper analyses the processes that synthesize a smart city project, how to mobilize resources and the life cycle of the smart project (L. Anthopoulos, 2017a).

The contemporary economic approach cannot be done without internet platforms. If we can talk about an Industry 4.0, we can also talk about the Internet of Things (IoT), which connects with digital productive capacities. The main global economic actors already have industrial platforms 4.0: Germany has the “Industry 4.0 Platform”, China the “Made in China 2025” and the USA the “Industrial Internet Consortium”. The Industry 4.0 platform is connected to industrial manufacturing and IoT applications for healthcare management, transportation, energy and smart cities (Sendler, 2017).

An interesting component of the smart city is education, respectively smart learning as a key element for the innovative and sustainable urban development. Education is able to promote creativity and innovation. Moreover, based on education, new concepts have been developed such as: smart technology, smart teaching, smart education, smart e-learning, smart classrooms, smart universities, and smart society. In this approach, the smart learning covers both traditional learning and informal learning, as well (Liu, Huang, & Wosinski, 2017).

The Netherlands is one of the main promoters of the smart approach. In this sense, the Netherlands has advantages compared to other states. At the urban level, there is a good collaboration between the local administration, the private sector and the academic environment. In addition, smart solutions are already being implemented in society on a large scale. This process is also supported by the presence of some important multinational companies in this country. The Netherlands also has an extremely high-performance physical and digital infrastructure, functional test stands and a strong civil society (Bamwesigye & Hlavackova, 2019)

In Romania, large companies such as ENEL, have launched smart programs at the level of urban communities. This company’s smart approaches target multiple connections between underground infrastructure, energy and transportation infrastructure, urban energy flows, personal urban flows, buildings and green and public areas. The company’s smart solutions, included in the ENEL X project, allow the urban administrations to use a single interface, to process interconnected and integrated services (EnelX-SRL, 2021).

An interesting approach is that starting from the impact of the urban development on the environment. This approach was able to support the building of the ISUT Model. The model defines a Composite Index able to quantify the sustainability of the urban development using a vector cartography the urban land and building an alpha-numerical database. This database prepares the model’s inputs regarding the green spaces and the built-up area (Gerundo et al., 2016).

Other interesting approach defines the smart city as a building based on 6 concepts like the following: smart city economy; smart people; smart mobility; smart environment; smart living; smart governance (Vinod Kumar & Dahiya, 2017).

The smart city development has to be realised under sustainability. This approach started from the idea that the smart city represents an application of IoT (Internet of Things). Moreover, the city development has to improve the environment, the citizen lifestyle and the governance's performance. The basic approach is that the development of the smart technologies has to be achieved with minimal human interaction (Silva, Khan, & Han, 2018).

A more optimistic approach considers the smart city as the solution for rapid urbanisation. The classic urban development is limited and face harder to the new challenges. As a result, the smart city development is able to face to all new challenges, including the pandemic (Okai, Feng, & Sant, 2018).

The real advantages of the smart city are related to the citizens' life standards, the local economy development, transport and traffic management, environment and better connection to the public administration. Under the new challenges, a smart city has to be analysed under its specific aspects: smart mobility, smart living, smart environment, smart citizens, smart government and smart architecture in their connections to technologies and concepts (Ismagilova, Hughes, Dwivedi, & Raman, 2019).

A new approach is interesting by introducing the concept of smart ecosystem as a complex connection between governance/administration, transportation, agriculture, logistics, maintenance, education and healthcare. Such a smart city has to be connected to the Information Communication Technology (ICT) which is able to improve even the traditional urban infrastructure (Ahad, Paiva, Tripathi, & Feroz, 2020).

The goals of the urban sustainable development are analysed in order to quantify the quality of life. In order to realise this, the authors combine public resources, human and social capital, information and communication technologies. The analysis is based on a survey implemented in Brazil and uses the application of the Structural Equation Modelling (SEM) methodology. The authors of the paper points out that they succeeded in improving the governance of the smart cities in order to increase the quality of urban life (De Guimarães, Severo, Felix Júnior, Da Costa, & Salmoria, 2020).

The Chinese experience in developing smart cities is presented in a study which covers 35 smart cities, using the principal component analysis and back propagation neural network techniques. Such a neural network takes into consideration six dimensional factors and 22 operating indices. According to the analysis' results, the main element in development of the smart cities is the development of a smart economy through sustainable productivity in innovative companies and in high-tech industries (Li, Fong, Dai, & Li, 2019).

A real link between the smart city's components seems to be the sustainable transport. Nowadays, almost all urban transport systems are unsustainable. As a result, the sustainable transport, including cycling, and the greater implication of the women in this industry are analysed starting from the good practices in Netherlands and Germany. The same analysis is implemented in Kenya and Uganda (Bamwesigye & Hlavackova, 2019)

A review of the literature on smart governance and its implication on supporting the active cooperation between citizen and public administrations in developing smart cities was realised in 2019. The authors considered that the smart development is more theoretical than practical. As a result, they propose new way of cooperation and an agenda able to improve the active partnership between citizens and public administration for smart development (Tomor, Meijer, Michels, & Geertman, 2019).

According to the above literature review, it results that, in dynamics, the concept of smart city has gained consistency since the '00s, when against the background of increasingly obvious climate change, complemented by changes in demographic trends (in the sense of their accentuation) and marked economic fluctuations deep crises, which destabilized the global economy) was the problem of organizing large cities in the sense of fruitful technological and digital development.

Thus, monitoring components of the main elements of the local economic development were created in accordance with the increasingly stringent objectives of the environment and resources' protecting. The core of monitoring of the smart city development is composed of capitals, energy and water resources and environment with applicative purpose at the level of local economic development on smart components. The synthesis of this desideratum is the increase in the urban population's quality of life and the normalization of the risk factors associated with the demographic growth at global, national and local level.

On this structure, the opportunity of the study proposed by the authors in this paper is demonstrated. It aims to create a tool for evaluation and gradual implementation of the smart concept starting from socio-economic indicators related to the monitoring core and the top 10 cities in Europe which have made significant progress in the smart city area.

3. METHODOLOGY

According to the Eurostat data, the top ten European smart cities are those in Figure 2.

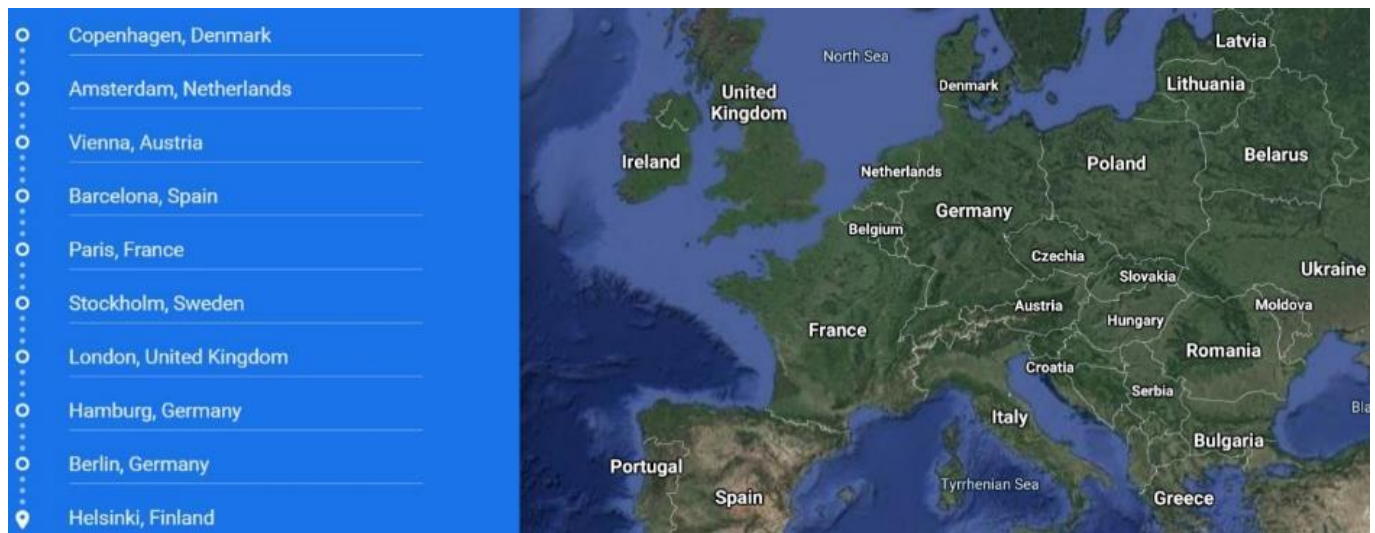

Figure 2: Top ten European smart cities in 2020

Source Author`s contributions.

To these was added as an anti-pole the city of Bucharest, which stands out with similar demographic characteristics (2583460 inhabitants) in relation to the general average of the population of the 10 smart cities (2265876 inhabitants). Instead, the rest of the economic indicators are significantly lower than those of the evaluated smart cities in Bucharest. For example, GDP / capita is 0.02 million Euro / inhabitant in Bucharest compared to the average of smart cities of 0.04 million Euro / inhabitant.

In the analysis of this scientific approach, we sought to use atypical "new" indicators compared to dedicated classical studies, but with a significant impact on urban smart development. These indicators refer to:

- **local GDP** - reflects the economic development of cities classified in terms of smart development and certified by the international top rankings made by the Eden Strategy Institute and Ong & Ong (OXD)'s research report;
- **internet users** - the urban consumption of internet communications that attests the possibilities of implementing intelligent communications among the population and its opening up to the assimilation of new technologies in the field;
- **R & D & I** - the level of innovation reached / implemented at local level as a factor of economic development associated with the acceptance of new technologies and the integration of these technologies in daily activity. This indicator is in line with the European objectives promoted through the competitiveness axis, through technological R&D and innovation;
- **Internet of Things (IoT)** - smart city specific indicator that involves the use of the Internet to interconnect devices and services through network devices. In dynamics, the use of IoT started with the expansion of the logistics chains in order to make them more efficient (2000s), reaching in 2010 the interconnection of security networks and supervision of the food transports and administrative services. Currently, it has reached the stage of monitoring and control of remote objects through teleoperation and manipulation of services (tele school, tele work, tele health);
- **internet banking** - indicator of financial capacity of the local market that evaluates the flexibility of the financial system used by the inhabitants and its capacity to connect to the global financial flows in a safe and secure environment;
- **the general motorization rate** - seen from the point of view of the contribution to the local pollution. This indicator measures the urban transport capacity related to the sustainable dimension of this service. As the taxonomy of the ecological transport service is recent, this general indicator is able to measure the sustainable dynamics only in relation to the following two indicators;
- **motor vehicle rate of green vehicles** - calculated on the basis of registrations of new ecological vehicles less than two years old;
- **motorization rate of polluting vehicles** - calculated on the basis of registrations of polluting vehicles older than 10 years.

In order to test the homogeneity of the data series collected from the Eurostat platform, non-parametric Kolmogorov-Smirnov were used, which demonstrated, by rejecting the null hypothesis and rejecting the alternative hypothesis, the homogeneity of the sample as follows:

Table 1: Statistical analysis of the Null Hypothesis

Hypothesis Test Summary				
Null Hypothesis	Test		Sig.	Decision
The distribution of Official population is normal with mean 2.294.747 and standard deviation 2202215.786	One-Sample Smirnov Test	Kolmogorov-	.029 ¹	Reject the null hypothesis.
The distribution of INTERNET - 2016 is normal with mean 87 and standard deviation 7.148.	One-Sample Smirnov Test	Kolmogorov-	.047 ¹	Reject the null hypothesis.
The distribution of INTERNET - 2018 is normal with mean 89 and standard deviation 5.047.	One-Sample Smirnov Test	Kolmogorov-	.041 ¹	Reject the null hypothesis.
The distribution of INTERNET - 2019 is normal with mean 91 and standard deviation 6.235.	One-Sample Smirnov Test	Kolmogorov-	.011 ¹	Reject the null hypothesis.
The distribution of IOT - 2013 is normal with mean 73 and standard deviation 15.312.	One-Sample Smirnov Test	Kolmogorov-	.047 ¹	Reject the null hypothesis.
The distribution of IOT - 2014 is normal with mean 74 and standard deviation 14.588.	One-Sample Smirnov Test	Kolmogorov-	.036 ¹	Reject the null hypothesis.
The distribution of Banking - 2020 is normal with mean 74 and standard deviation 20.323.	One-Sample Smirnov Test	Kolmogorov-	.035 ¹	Reject the null hypothesis.
The distribution of CAR - 2009 is normal with mean 17.334.825 and standard deviation 16037305.994.	One-Sample Smirnov Test	Kolmogorov-	.021 ¹	Reject the null hypothesis.
The distribution of CAR - 2010 is normal with mean 17.528.774 and standard deviation 16217332.357.	One-Sample Smirnov Test	Kolmogorov-	.022 ¹	Reject the null hypothesis.
The distribution of CAR - 2011 is normal with mean 17.701.606 and standard deviation 16395452.280.	One-Sample Smirnov Test	Kolmogorov-	.023 ¹	Reject the null hypothesis.
The distribution of CAR - 2012 is normal with mean 17.882.952 and standard deviation 16568308.953.	One-Sample Smirnov Test	Kolmogorov-	.023 ¹	Reject the null hypothesis.
The distribution of CAR - 2013 is normal with mean 18.180.288 and standard deviation 16826907.303.	One-Sample Smirnov Test	Kolmogorov-	.020 ¹	Reject the null hypothesis.
The distribution of CAR - 2014 is normal with mean 18.298.673 and standard deviation 16.926156.882.	One-Sample Smirnov Test	Kolmogorov-	.020 ¹	Reject the null hypothesis.
The distribution of CAR - 2015 is normal with mean 18.488.342 and standard deviation 17074308.925.	One-Sample Smirnov Test	Kolmogorov-	.021 ¹	Reject the null hypothesis.
The distribution of CAR - 2016 is normal with mean 18.771.165 and standard deviation 17276098.823.	One-Sample Smirnov Test	Kolmogorov-	.020 ¹	Reject the null hypothesis.
The distribution of CAR - 2017 is normal with mean 19.063.598 and standard deviation 17446381.917.	One-Sample Smirnov Test	Kolmogorov-	.019 ¹	Reject the null hypothesis.
The distribution of CAR - 2018 is normal with mean 19.337.658 and standard deviation 17616522.414.	One-Sample Smirnov Test	Kolmogorov-	.019 ¹	Reject the null hypothesis.
The distribution of CAR - 2019 is normal with mean 19.588.177 and standard deviation 17792833.690.	One-Sample Smirnov Test	Kolmogorov-	.019 ¹	Reject the null hypothesis.
The distribution of CAR - 2020 is normal with mean 19.866.565 and standard deviation 17981294.029.	One-Sample Smirnov Test	Kolmogorov-	.019 ¹	Reject the null hypothesis.
The distribution of NEW CAR - 2009 is normal with mean 2.647.154 and standard deviation 2444367.156.	One-Sample Smirnov Test	Kolmogorov-	.004 ¹	Reject the null hypothesis.
The distribution of NEW CAR - 2010 is normal with mean 2.519.893 and standard deviation 2341374.842.	One-Sample Smirnov Test	Kolmogorov-	.005 ¹	Reject the null hypothesis.
The distribution of NEW CAR - 2011 is normal with mean 2.320.708 and standard deviation 2154252.829.	One-Sample Smirnov Test	Kolmogorov-	.024 ¹	Reject the null hypothesis.
The distribution of NEW CAR - 2012 is normal with mean 2.303.830 and standard deviation 2173046.909.	One-Sample Smirnov Test	Kolmogorov-	.031 ¹	Reject the null hypothesis.
The distribution of NEW CAR - 2014 is normal with mean 2.251.151 and standard deviation 2172256.564.	One-Sample Smirnov Test	Kolmogorov-	.018 ¹	Reject the null hypothesis.
The distribution of NEW CAR - 2019 is normal with mean 19.600.384 and standard deviation 17802107.469.	One-Sample Smirnov Test	Kolmogorov-	.019 ¹	Reject the null hypothesis.
The distribution of NEW CAR - 2020 is normal with mean 19.875.697 and standard deviation 17988234.697.	One-Sample Smirnov Test	Kolmogorov-	.019 ¹	Reject the null hypothesis.
The distribution of OLD CAR - 2009 is normal with mean 5891278.808 and standard deviation 5406678.465.	One-Sample Smirnov Test	Kolmogorov-	.011 ¹	Reject the null hypothesis.
The distribution of OLD CAR - 2010 is normal with mean 6022711.647 and standard deviation 5452717.427.	One-Sample Smirnov Test	Kolmogorov-	.012 ¹	Reject the null hypothesis.
The distribution of OLD CAR - 2011 is normal with mean 6072948.025 and standard deviation 5471075.665.	One-Sample Smirnov Test	Kolmogorov-	.013 ¹	Reject the null hypothesis.
The distribution of OLD CAR - 2012 is normal with mean 6240598.701 and standard deviation 5555250.104.	One-Sample Smirnov Test	Kolmogorov-	.030 ¹	Reject the null hypothesis.
The distribution of OLD CAR - 2013 is normal with mean 6.191.282 and standard deviation 5512597.718.	One-Sample Smirnov Test	Kolmogorov-	.014 ¹	Reject the null hypothesis.
The distribution of OLD CAR - 2014 is normal with mean 6.303.108 and standard deviation 5571509.819.	One-Sample Smirnov Test	Kolmogorov-	.026 ¹	Reject the null hypothesis.

Notes: Asymptotic significances are displayed. The significance level is .05. ¹Lilliefors Corrected Source Author`s contributions.

In order to elaborate the new proposed model, the following **working hypotheses** are used:

H1: The rate of urban economic development is significantly and directly proportionally influenced by the efforts to implement the R & D & I results and by the openness of the inhabitants in the use of the IT infrastructure for the management of financial flows.

H2: Urban economic development does not significantly influence the pro-ecological attitude of the inhabitants. In order to activate it, administrative steps are required in terms of infrastructure and service networks.

H3: The development of IoT is directly related to the openness of the inhabitants in the use of IT infrastructure for the management of financial flows.

H4: The smart maximization function is valid and adequate if and only if there is a minimum level α_i of each of the above indicators for an urban population correctly dimensioned according to the urban endowments and the minimum level of economic capacity measured by the rate of the urban economic development.

Based on the above hypotheses, we developed a **smart economic model**, which analyses the impact at the sample level of adapting smart city / smart community policies. The model was developed using the least squares method (OLS), by simple linear regression and is of the form:

$$\begin{cases} \widehat{SMART}_{GDP} = \alpha_1 * NEW_CAR + \alpha_2 * IoT + \alpha_3 * RDI + \alpha_4 * Banking \\ \forall i \in N, i \neq 0, \exists i, \text{ so that } \max_{i \rightarrow 1}(SMART_{GDP_i}) \gg GDP_i \cup \alpha_i > 0 \end{cases} \quad (1)$$

where: $SMART_{GDP}$ - the smart function of the cities` economic development based on the transformation of the administrative flows into smart flows using IoT; NEW_CAR, RDI, Banking.

4. RESULTS AND DISCUSSIONS

The model ensures the evaluation of the smart policies` applicability / efficiency at the level of smart city / smart community, starting from the development core of the first 10 European smart cities published in the specialized tops in contrast to the smart development anti-poles. Following the modelling, the model equation becomes:

$$\begin{cases} SMART_{GDP} = -6,858E^{-6} * NEW_{CAR} - 127.897 * IoT + \\ + 53.74 * RDI - 75.988 * Banking \\ \max_{i \rightarrow 1}(SMART_{GDP_i}) \gg GDP_i \cup \alpha_i > 0 \end{cases} \quad (2)$$

The sample for which the model was applied concerns information related to the following smart cities: Copenhagen, Amsterdam, Vienna, Barcelona, Paris, Stockholm, London, Hamburg, Berlin, and Helsinki. The anti-pole of smart development Bucharest was used for comparison.

From the distribution averages point of view, after applying the evaluation procedure on the frequency series pivoted after each evaluated smart city, we found that the anti-pole (Bucharest) is from the smart development point of view at a distance of 43% from the average evaluated sample, with differences from the sample (see Figure 3).

Figure 3: Presentation of the smart development at the evaluation date for the anti-pole of the model: the city of Bucharest

Source Author`s contributions.

It can be seen from Figure 3 that, in terms of the smart development`s main components, the city of Bucharest is deficient in most key development points: RDI, IoT, banking, new cars, but well represented by the use of the Internet and the engine rate of polluting vehicles. This aspect demonstrates the model`s usefulness and opportunity, which in the first step

allows the evaluation of the development in order to identify later the vulnerable points that need improvement strategies in order to maximize the smart function of the city.

From the Pearson correlation table, it results that, at the level of the analysed sample regarding the concept of smart city integrated on modelled components (GDP, Internet, RDI, IoT, internet banking, motorization rates), the weakest correlation is found at the level of motorization of green vehicles, which is an active component of the pollution reduction with a lower resilience to implementation, while the internet banking and the RDI component generate the most significant correlations on the Pearson correlation coefficient with sigma value tending to 0 (see Table 2).

Table 2: Pearson Correlation

Indicators		GDP mill. euros	RDI	IOT	Banking	NEW CAR
Pearson Correlation	GDP mill. euros	1.000	.994	.958	.990	.652
	RDI	.994	1.000	.973	.998	.656
	IOT	.958	.973	1.000	.975	.584
	Banking	.990	.998	.975	1.000	.663
	NEW CAR	.652	.656	.584	.663	1.000
Sig. (1-tailed)	GDP mill. euros	.	.000	.000	.000	.011
	RDI	.000	.	.000	.000	.010
	IOT	.000	.000	.	.000	.023
	Banking	.000	.000	.000	.	.009
	NEW CAR	.011	.010	.023	.009	.

Source Author`s contributions.

By using the Entered method in the linear regression model (using the least squares method), model in which the regression variable is local / regional GDP, as a implementation of the smart city concept's favouring factor, all regression variables were included (NEW CAR , IOT, RDI, Banking). As a result, no variables were excluded in the modelling.

The proposed model proved to have a coefficient of determination of over 98% and a standard estimator error of 384.96%. The model is valid, with a sigma value of the change factor tending to 0, according to the summary of the model presented in Table 3.

Table 3: Model Summary

Model ^b	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics	
					R Square Change	F Change
1	.995 ^a	.989	.983	384.96550	.989	159.245
Model	Change Statistics					
	df1	df2	Sig. F Change		Durbin- Watson	
1	4	7	.000		1.665	

Note: b. Dependent Variable: GDP mill. Euros.

Source Author`s contributions.

From the normal distribution of the dependent variable's point of view, the histogram diagram reflects a homogeneous distribution with accumulation on the ascending slope (afferent to the anti-pole in the model) and on the descending slope. This demonstrates that there are significant differences between the distribution of the dependent variable for the analysed smart city core in relation to the Bucharest anti-pole, which demonstrates that the evaluation is relevant and captures the differentiated smart development dynamics of the anti-pole from the rest of the smart city core in the sample (see Figure 4).

Figure 4: Normal distribution of the dependent variable

Source Author`s contributions.

Following the ANOVA test, it is found that the dependent variable in relation to the regressor variables is mainly characterized (98.91%) by the regression function, the influence of the residual factor being only 1.09%. The number of degrees of freedom on the regression function is 4 and on the residual function is 7. The value of the F test is 159.24 with sigma tending to 0 (see Table 4).

Table 4: ANOVA method

Model ^a		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	94399485.842	4	23599871.460	159.245	.000 ^b
	Residual	1037389.064	7	148198.438		
	Total	95436874.906	11			

Notes: a. Dependent Variable: GDP mill. Euros; b.Predictors: (Constant), NEW CAR, IOT, RDI, Banking.
Source Author`s contributions.

P-P plot diagram for the presentation of the standardized residual regression for the dependent variable GDP reflects the fact that the years 2013, 2015 and 2011 are best represented for smart development according to the model, while the distance from the regression line that measures the average deviation of the observed values the probabilistic evolution is maximized for the years 2010, 2016 and 2012. The years 2019 and 2020 show an average deviation from the forecasted evolution, which means that the development over time (in dynamics) of the cities and their transformation into cities with smart management is variable, with sinusoidal development function and significant external influences induced by the macroeconomic context and the strategic development directions adopted by the EU associated with their financing (see Figure 5).

Figure 5: Normal P-P Plot of Regression Standardized Residual for Dependent Variable (GDP)

Source Author’s contributions.

It is found that in relation to the model variable, the R&D function plays a significant role and is in direct proportionality with the dependent variable of the model, which demonstrates the H1 hypothesis of the model, namely: **H1:** *The rate of urban economic development is significantly and directly proportionally influenced by the efforts to implement the R & D & I results and by the openness of the inhabitants in the use of the IT infrastructure for the management of financial flows.*

From the variable rate of motorization rate of green vehicles’ point of view, there is an inversely proportional evolution of the variable in relation to the dependent variable at the level of representation of non-standard beta coefficients (-6,858E-6) and at the level of correlation coefficients on the covariance matrix, which proves the H2 hypothesis of the model: **H2:** *Urban economic development does not significantly influence the pro-ecological attitude of the inhabitants. In order to activate it, administrative steps are required in terms of infrastructure and service networks.*

Regarding the use of IoT, it has an inversely proportional correlation with the dependent variable, which means that it is a managerial component with significant resource consumption, which has long-term performance in smart function and is dependent on openness to the use of non-polluting means and with the concept of R&D. According to the correlation of the coefficients, the IoT concept varies inversely with the internet banking flows, this aspect being a decelerator of the IoT development, which is demonstrated by the H3 hypothesis: **H3:** *The development of IoT is directly related to the openness of the inhabitants in the use of IT infrastructure for the management of financial flows.*

The proposed model is homogeneous, well represented and significant for evaluating the smart development of cities in relation to a core of development poles in Europe and demonstrates the H4 hypothesis by comparing it with the Bucharest anti-pole, as follows: **H4:** *The smart maximization function is valid and adequate if and only if there is a minimum level α_i of each of the above indicators for an urban population correctly dimensioned according to the urban endowments and the minimum level of economic capacity measured by the rate of the urban economic development.*

The correlation coefficients used in the argumentation of the hypotheses and in their validation are presented in Table 5.

Table 5: Coefficient Correlations

Model ^a			NEW CAR	IOT	RDI	Banking
1	Correlations	NEW CAR	1.000	.371	.117	-.262
		IOT	.371	1.000	.021	-.303
		RDI	.117	.021	1.000	-.956
		Banking	-.262	-.303	-.956	1.000
	Covariances	NEW CAR	6.219E-10	.001	7.558E-5	-.002
		IOT	.001	17293.651	71.962	-10640.291
		RDI	7.558E-5	71.962	669.097	-6604.536
		Banking	-.002	-10640.291	-6604.536	71294.709

Source Author’s contributions.

At the level of partial regression on the regressive variables of the model, the aim was to evaluate the development of these components as part of the smart policies in dynamics (by years) at the level of the study sample. Regarding RDI, it

is found that there is a unified practice regarding the coherent application of policies to approximate RDI policies as a smart part, excepting 2014, 2017 and 2018. This evolution represents a logical consequence of the economic recovery processes at EU level after the global economic contractions due to the crisis. In addition, for 2017-2018, the initiation of Brexit was a difficult test for the European economy, a fact reflected in the table above by the presence of the city of London (see Figure 6).

Figure 6: R&D&I regression analysis

Source Author`s contributions.

At the IoT development's level, there is a core focused on the entire period, excepting 2015-2017, years in which the incidents caused by the Mirai malware (Munro, 2021) caused infections of DVR devices, materialized in DDOS type attacks (in 2016, the KrebsOnSecurity block (Goodin, 2016) was attacked with a 600Gb stream, and in 2017, the Hajime worm infected many devices, blocking access to their ports), (see Figure 7).

Figure 7: IoT regression analysis

Source Author`s contributions.

As the financial crisis evolved into the euro area debt crisis it became clear that deeper integration of the banking system. Initially, mechanisms were introduced: single supervisory mechanism (SSM) (European Commission, 2021b) and single resolution mechanism (SRM) (European Commission, 2021a), which directly influenced the development of the internet banking. In October 2017, the above two mechanisms became fully operational, leading to a significant increase in the unionist banking architecture in the EU, including the explosion of banking operations (see Figure 8). The evolution of the demand for new vehicles at EU level was constantly high, but the coordinates of the new production of green cars were not felt in 2009. The demand for such vehicles has grown exponentially during 2017-2019. In 2020, the restrictions imposed by the COVID-19 pandemic changed the structure of transport options to personal ones, increasing the choice of consumers for green vehicles in accordance with the strategy of their promotion applied by all major car manufacturers (PricewaterhouseCoopers, 2020), (see Figure 9).

Figure 9: New car regression analysis

Source Author's contributions.

From the presented analysis, the following smart development strategies applicable to cities whose goal is to reduce administrative costs and ensure integrated urban functionality by using alternative means generated by the implementation of new technologies and integrated financial flows are as follows (see Table 6):

Table 6: Low cost vs expensive costs/solutions

Indicator	Type	Solutions	Impact	Comments
Local GDP	Low cost Implementation	<ul style="list-style-type: none"> - Differentiated charging system; - Progressive system of fines for environmental pollution applied to the local agents; - Differentiated taxation of the locations which promote R & D & I. 	<ul style="list-style-type: none"> - Increasing the collection in the interest of the local community; - Financing subsequent smart city development projects; - Development of smart infrastructure projects. 	<ul style="list-style-type: none"> - Both options are desirable and allow local / regional GDP growth; - Sustainable development; - Increasing the quality of life; - Smart city development.
	Expensive solution	<ul style="list-style-type: none"> - Implementation of new technologies in local administration; - Digitization; - Development of local research for the introduction of new technologies. 	<ul style="list-style-type: none"> - Resource economy; - Increasing the income of the urban population; - Increasing the taxpayer satisfaction. 	
Internet users	Low cost implementation	<ul style="list-style-type: none"> - Supporting the educational policies for access to the new technologies and communications in schools; - Creating an open society for the implementation of the new technologies. 	<ul style="list-style-type: none"> - By increasing the number of users on long term; - Obtaining an educated local population, open to the new. 	<ul style="list-style-type: none"> - Both options are desirable and allow the sustainability of the process, especially by inserting the new technologies in the school and give the process a high character of sustainable development.
R&D&I	Expensive solution	<ul style="list-style-type: none"> - Creation of urban networking centres; - Activation of counselling and guidance cells led by specialists / experts; - Creating IT clusters and developing solutions within them to local problems. 	<ul style="list-style-type: none"> - Immediate accessibility on short and medium term; - Increasing the degree of adaptation to information technologies for the mature population; - High possibilities to reduce unemployment and increase the quality of life through information. 	<ul style="list-style-type: none"> - Both options are desirable and allow the sustainability of the innovation process and the use of the solutions for the smart city development with an effect in reducing the development costs and immediate operationalization of the measures (also benefiting from the technical support of the specialists who produced the innovation).
	Low cost implementation	<ul style="list-style-type: none"> - Implementation of the 9 stages of technology readiness level in innovation; (Comes, Bunduchi, Vasile, & Stefan, 2018) - Implementation of the benchmark in innovation. 	<ul style="list-style-type: none"> - Increasing the applicability of innovation on medium term; - Connecting theory with practice. 	
Internet of Things (IoT)	Low cost implementation	<ul style="list-style-type: none"> - Implementation of IoT at the level of surveillance processes (traffic, waste collection) in the second wave of applications; - Creating integrated and electronically coordinated flows; - Ensuring an integrated operational system at the level of local administration for the maintenance of the created flows. 	<ul style="list-style-type: none"> - On the medium term, these flows will be operationalized, resulting in a saving of human and material resources at the level of local administration that will exceed the value of the investment during a time period assimilated to a discount rate of 8%. 	<ul style="list-style-type: none"> - Both variants are desirable; they allow the sustainability of the monitoring process and the implementation of IoT, with effect on the consumption of resources and on the increase of the quality of the local administrative act. (Prince & David, 2018)
	Expensive solution	<ul style="list-style-type: none"> - Introduction of teleoperation and telepresence systems with remote object monitoring and control; - Development of risk sensor detection agent software for IoT's efficiency and operationalization. 	<ul style="list-style-type: none"> - On the medium and long term, it will be possible to manage with a very low cost and a maximum limitation of the risks the entire administrative flow at the locality level, which will lead to a maximization of the smart city rate. 	

Indicator	Type	Solutions	Impact	Comments
Internet banking	Low cost implementation	<ul style="list-style-type: none"> - Multiplication of internet applications for accessing bank accounts and products; - Stimulating the use of internet banking through various incentives granted to the customers. 	<ul style="list-style-type: none"> - The increase of internet banking activities on short term; - The increase of the number of banking internet users on medium and long term; - Increasing security of the banking operations on short, medium and long term. 	<ul style="list-style-type: none"> - Both variants are desirable and allow the operational financing of the activities, current economic development, increasing the smart level of local development (smart city).
	Expensive solution	<ul style="list-style-type: none"> - Generalization of the internet banking access through single supervisory mechanism (SSM) and single resolution mechanism (SRM). 	<ul style="list-style-type: none"> - Increasing the financial security on long term; - Increasing the speed of accessing funds by shortening the analysis time; - Supporting the sustainable development. 	
The overall rate of motorization	Low cost implementation	<ul style="list-style-type: none"> - Creation of the networks for alternative traffic of cyclists and mopeds; - Expansion of parks and green spaces. 	<ul style="list-style-type: none"> - Reducing pollution on short term; - Traffic reduction; - Increasing the quality of life. 	<ul style="list-style-type: none"> - Both variants are desirable, they allow the decrease of pollution, achieving the objectives of sustainable development (environment component) and activating the urban quality indicators related to the smart city.
	Expensive solution	<ul style="list-style-type: none"> - Creation of an operational infrastructure and an adequate capacity related to the urban traffic, which should limit the general motorization rate applied in the locality; - Ensuring optimal power supplies for vehicles. 	<ul style="list-style-type: none"> - Reducing pollution on short term; - Traffic decongestion; - Reducing the carbon footprint of the locality; - Increasing the quality of life of smart city residents. 	
The rate of green motorized vehicles	Low cost implementation	<ul style="list-style-type: none"> - Providing power supplies for green vehicles; - Application of the differentiated taxation system on the vehicles. 	<ul style="list-style-type: none"> - Increasing the motorization rate of the green vehicles on short term. 	<ul style="list-style-type: none"> - Both variants are desirable; they allow the achievement of the sustainability objectives on the environment component; - Reduction of urban pollution, with long-term effect on increasing the quality of life; - Important pillar for smart city development.
	Expensive solution	<ul style="list-style-type: none"> - Offering facilities for the construction of services dedicated to green vehicles; - Replacement of the local transport fleet with green vehicles. 	<ul style="list-style-type: none"> - Increasing the motorization rate of the green vehicles on long term; - Reducing pollution; - Increasing the quality of life. 	
The rate of polluting vehicles	Low cost implementation	<ul style="list-style-type: none"> - Application of the differentiated taxation system on the vehicles; - Establishment of areas with access restrictions for polluting vehicles. 	<ul style="list-style-type: none"> - Decrease in the engine rate of polluting vehicles on short term; - Reducing pollution; - Increasing the quality of life. 	<ul style="list-style-type: none"> - Both variants are desirable; they allow monitoring the city's fleet of polluting vehicles and limiting it in time; - Increasing sustainability; - Increasing the degree of smart city development.
	Expensive solution	<ul style="list-style-type: none"> - Establishment of pilot programs to stimulate the replacement of the polluting vehicles (providing facilities); - Establishment of a monitoring system of CO₂ emissions produced by polluting vehicles whose effect should be manifested in strict monitoring of the city's car fleet. 	<ul style="list-style-type: none"> - Decrease in the engine rate of polluting vehicles on medium term; - Reducing pollution; - Increasing the quality of life. 	

Source Author's contributions.

According to the two-phase smart implementation table (Table 6) which covers the proposed objective of piloting a concept implementation tool from accessible to complete, from low cost to expensive solutions, it results that the concept is affordable and implementable not only by cities that know a top economic development, but also by cities that due to the large urban agglomeration should carefully monitor the core of indicators whose combined risk affects the quality of life and for which the smart solution is at least a desirable alternative.

5. CONCLUSIONS

The paper addresses a topic of maximum interest for the current economy, drawing attention to the need to monitor those indicators of vulnerability that trigger risks in large urban areas and the solution to reduce these risks by developing smart cities.

The components of the monitoring core were selected after careful monitoring of the literature, which presents a multitude of approaches to smart development, but which undoubtedly links this development to environmental issues, improving the quality of life and sustainable economic growth.

We drafted, based on a vector cluster of monitoring indicators studied at the level of European smart city cities (Top 10) and a smart development anti-pole (Bucharest), a model for evaluating the staging of smart city development in relation to the cluster average, highlighting, at the level of the selected indicators, the vulnerabilities which prevent the anti-pole from aligning with the smart development desideratum.

The main shortcoming of the model consists in the relatively limited number of indicators, the authors proposing to extend the model in a future study, including the implementing of questionnaires at the local administration level of this anti-pole of smart development.

The study can be extended to any other large urban agglomeration without translation problems of the model, based on known statistical methods and consolidation principles detailed in this study and valid demonstrated working hypotheses.

The second post-evaluation stage consists in identifying the possible smart development alternatives for each variable in the monitoring core by building a biphasic picture from accessible to complete, which would give the local administration the effective chance to implement the concept at the locality level.

The authors state that there are no conflicts of interest.

HOW DIFFERENT PATTERNS OF URBANIZATION AFFECT REGIONAL INNOVATION? EVIDENCE FROM RUSSIA

Sabyasachi Tripathi, [Evgeniy Kutsenko](#), Victoria Boos

National Research University Higher School of Economics, Russian Federation

ABSTRACT

The present paper assesses the impact of general urbanization and urbanization patterns (the number of cities of a certain size in the region) on different phases of the regional innovation process: knowledge creation, implementation, and production of innovation production. Knowledge creation is measured by patent statistics, knowledge implementation – by the share of innovative organisations, innovation production – by the volume of innovation production produced by industrial organisations.

We apply the dynamic panel data model technique by using data from the period of 1998 to 2016. Our results suggest that general urbanization has a positive influence on every stage of the innovation process, while the impact of different urbanization patterns varies depending on its stage. Million plus cities affect knowledge creation in the region but have no considerable impact on knowledge implementation and innovation production. At the same time, the presence of cities with a population from 500 000 to 1 000 000 people in the region positively influences more mature stages of the innovation process: knowledge implementation and manufacturing of innovation production.

So far as the effective innovation development demands complete innovation cycle, not only million plus cities should be considered as the main drivers of innovation, but cities of lower size (at least with population from 5 000 000 to 1 000 000 people) as well should attend the innovation agenda.

RADICAL INNOVATIONS AND INDUSTRIAL STRUCTURE OF REGIONS: INSIGHTS FROM RUSSIA

Evgeniy Kutsenko, Kirill Tyurchev, Vasily Abashkin, Ekaterina Ivanova

National research university Higher School of Economics, Russian Federation

ABSTRACT

Radical innovations as a key driving force for long-term socio-economic progress are one of the vivid topics in regional science. The paper aims to shed light on the structure-specific factors of regional economies that favor the increase of a firm's radical innovations, considering the case of Russia. We use data from national innovation survey and measure radical innovations as the sales of new-to-the-market and new-to-the-firm innovative goods and services. The ordinal regression is applied to quantify the effects of independent variables on radical innovations. These indicators reflect how much the industrial structure of a firm's home region is diversified or specialized, and the shares of knowledge-intensive business services (KIBS) and creative & cultural industries (CCI) in a region's economy. We control regional market size, expenditures on technological innovations, and a firm's location in a region with a city of over 1 million population. The results show that, apart from expenditures, the industrial structure of regional economies affected the likelihood of higher sales of radical market novelties introduced by the firms located therein. More sales were detected in the firms, operating in the specialization industries of their home regions that were identified with cluster mapping of related industries. The shares of KIBS in the industrial structure of regions had greater impact on radical innovations, while the influence of CCI was not significant.

THE IMPACT OF INTERNATIONAL SKILLED MIGRATION ON INNOVATION RESILIENCE OF RUSSIAN COASTAL REGIONS

[Andrey Mikhaylov](#)^{1,2}, [Anna Lialina](#)¹, [Daniil Maksimenko](#)³

¹Immanuel Kant Baltic Federal University, Russian Federation. ²Institute of Geography RAS, Russian Federation.

³Higher School of Economics, Russian Federation

ABSTRACT

The highly dynamic and progressive regions around the globe all share certain commonalities – competitive industries, advanced infrastructure, and the inflow of talents. Despite being somewhat elusive and implicit, the competencies, ideas and creativity are continuously regarded as the drivers of regional growth. The processes of knowledge spillovers, innovation diffusion, and regional learning are all related to interpersonal communication. The development of coastal regions is particularly defined by the coastalization phenomenon, which stands for the attraction of human resources, economic activity and financial capital to the coasts. The aim of the study is to test the interdependence of international skilled migration with innovation development in the coastal regions of Russia. The research design is based on quantitative statistical data of the Federal Service for Labor and Employment (Rostrud), the SPARK-Interfax database on industry performance, and the Scopus database on research output. The sourced dataset is geotagged and processed in QGIS for identifying the spatial patterns. The incoming flows of migrant workers from abroad analyzed in the article mainly represent countries with a visa regime for entry and are characterized by a high level of qualifications or a profession that is in short supply on the Russian labor market. Despite the numerical reduction of this cohort of workers in recent years, their concentration in the most economically developed coastal regions of Russia contributes to the human capital of the receiving territories. This effect is most noticeable at the level of individual regions, where the share of such workers in the labor market is most significant. At the same time, not only traditional centers of attraction in the most economically developed regions of the country (North-West and South of Russia) but also new local centers of attraction that have developed within the regions of population outflow (North and Far East of Russia) are attractive to international skilled migration. Highly educated migrants are concentrated in economically developed coastal regions with a high level of development of international relations (e.g. Kaliningrad region), while in the periphery, workers with secondary general, secondary, or primary vocational education are in demand. The study suggests that coastal regions attract skilled migrants giving an extra impulse for the regional innovation systems taking into consideration local specifics.

INNOVATION FOR SUSTAINABLE DEVELOPMENT IN POOR COUNTRIES- LESSONS FROM ETHIOPIA

Raphael Bar-El^{1,2}, Dafna Schwartz³, Jennifer Shkabatur³

¹Ben-Gurion University, Israel. ²Sapir Academic College, Israel. ³Interdisciplinary Center (IDC), Herzliya, Israel

ABSTRACT

Innovation is generally considered as knowledge creation (e.g., patents), R&D activities, and technological advancement. It typically benefits highly-developed regions, increasing their gaps with poorer regions. The integration of innovation in poorer countries can thus significantly contribute to their integration in the global economy. However, the common innovation policy concepts are inappropriate for poor countries.

We devise a conceptual approach for innovation in poor countries, design and test a simplified methodology for its implementation, and employ the case of Ethiopia for its demonstration. Our approach is summarized in four steps:

- Innovation is not a goal in itself, but rather an instrument for the achievement of distinct national development goals (e.g., economic growth, employment, improved wellbeing).
- Distinct types of innovation contribute to different development goals.
- The innovation ecosystem factors should be adapted to the specific innovation needs and conditions of poor countries.
- Innovation priorities should be adapted to the country's exogenous macro-economic conditions (development level, economic regime, economic structure, and development priorities).

The methodology employed to test the innovation needs and priorities of Ethiopia was as follows: key-informant interviews, focus group discussions, and questionnaires involving all ecosystem actors: government, academic and research institutions, business leaders (n= 49). Seven main ecosystem factors were tested (finance, human capital, infrastructures, information, academy, government services, culture) and evaluated through a total of 91 variables. Two aspects were evaluated for each variable, on a 1-5 scale: the variable's perceived importance for the advance of innovation, and the variable's current availability in the Ethiopian reality. The gap between the two scores indicates respondents' "frustration" level. The robustness of the findings is further corroborated by specific questionnaires for students (n=55), researchers (n=67), unemployed (n=53), and small enterprises (n=71). Secondary data on the national economy and the innovation situation in the country (drawing on the Global Innovation Index) complemented our primary data.

Findings indicate a gloomy economic situation and low innovation level, but at the same time high potential for growth based on a growing market, and considerable government commitment and efforts. The ecosystem analysis reveals frustration with the low availability of each of the factors, as well as their weak interaction within the ecosystem: lack of coordination between government, industry and academy; lack of coordination within government departments; and lack of interaction among businesses.

Several directions for innovation policy guidelines are derived from the analysis.

- *Adaptation.* At given exogenous conditions, innovation efforts should focus on a broad-base adaptation of existing technologies to more traditional activities.
- *Impact innovation.* Priority should be given to innovation types that can have major economic impacts and boost productivity and employment—e.g., in agriculture, industrialization, and SMEs.
- *Focus on market needs.* Rather than encouraging technology push, the innovation policy should focus on the market pull, respond to people's unmet needs, and support privatization.
- *A governmental coordination platform* is needed to set up the development priorities of innovation activities, strengthen coordination and collaboration among all ecosystem factors, and provide appropriate services and infrastructures.

KEY ENABLING TECHNOLOGIES AND THE COMPLEXITY OF JOBS, TASKS, AND SKILLS IN EMILIA-ROMAGNA

ABSTRACT

During the last decade, the economic literature has depicted different scenarios with respect to the effects of the "fourth industrial revolution" on employment (Brynjolfsson and McAfee, 2014). Within this framework, one interesting field of investigation concerns the effects of Key Enabling Technologies (KETs) on regional occupational structures and the related implications for skills development. It is widely argued that KETs will lead to a major shift in skill demand due to both the change in the occupational composition of the labour force (between-occupation effect) and the need for new skills or a change in the relative skill composition in certain job categories (within-occupation effect).

Focusing on between-occupation effects, this paper investigates whether a more intense use of KETs corresponds to a higher demand for more complex jobs, tasks, and skills in the manufacturing industry of Emilia-Romagna region, Italy, between 2008 and 2017. The empirical analysis relies on three data sources. Employment data come from the Sistema Informativo Lavoro - Emilia-Romagna (SILER), consisting in administrative linked employers-employees microdata collected by Italian regions. Such a system encompasses all occurrences concerning a job position (hiring, firing, conversion and fixed-term contract prolonged duration) at the firm-level. These data are merged with information provided by the INAPP-ISTAT national survey on jobs, tasks, skills, and work attitudes for all the occupational profiles in Italy. With this information we compute two dependent variables: (i) following Autor et al. (2003), the routine task index (RTI), defined as the share of local employees accomplishing high-, or low-, routine tasks; (ii) following Hidalgo and Hausmann (2009), three indicators of complexity, based on the diversity and exclusivity of jobs, tasks, and skills respectively. While the former aims to measure routine-biased technological change at the intensive margin, the latter is more suited for measuring it at the extensive margin. Data on regional KETs endowment come from OECD-REGPAT. KETs-related patents are identified as those labelled with at least one International Patent Class (IPC) and/or Cooperative Patent Classification (CPC) identified by the European Commission feasibility study on KETs (EC, 2012). Specifically, we use NUTS-3 regional patent applications to the following six classes of patents that we redistribute to local labour market areas (LLMA) in the region: advanced manufacturing technology, advanced materials, industrial biotechnology, nanotechnology, micro-, and nanoelectronics, and photonics. Our fixed-effects estimates show that a higher share of KETs in an LLMA corresponds to a higher level of task and skill complexity, but not of job complexity. Using an instrumental variable approach, we find that this result is robust to endogeneity. The general-purpose, and enabling, nature of KETs stimulates a higher demand for a more diversified, and exclusive, portfolio of tasks and skills while keeping job profiles unchanged. We also find that such a relationship is particularly strong for advanced manufacturing technologies.

THE FORMATION MECHANISM OF SPATIAL AGGLOMERATION OF URBAN CULTURAL INDUSTRY—CASE STUDY ON CHENGDU CITY

[Mingxia He](#)

ABSTRACT

Based on the theory of professional division of labor, spatial location theory and Marshall externality theory, this paper studies the spatial agglomeration of cultural industry, and measures the location entropy of the spatial agglomeration of cultural industry in Chengdu. From three aspects of economic factors, cultural factors and location factors, combined with the policy factors of the government, this paper constructs a mathematical model of the influencing factors of cultural industry spatial agglomeration. The empirical test of spatial econometrics is carried out. Research practice has proved that the cultural industry spatial agglomeration is the result of the interaction of cultural factors, location factors and economic factors, and the government's policy support and financial investment play a direct role in promoting and stimulating the spatial agglomeration of cultural industry. Finally, based on the research results, the corresponding policy recommendations have been given.

KEYWORD

Cultural industry spatial agglomeration; professional division of labor theory; spatial location theory; Marshall externality theory

1. INTRODUCTION

With the rapid development of cultural industry, there is a new trend of agglomeration in urban cultural space. More and more scholars pay attention to the level of cultural industry agglomeration, and increase the observation and research on the concentration trend of cultural economic activities. The first observation of cultural industry agglomeration in foreign countries is based on the research of "new geographical economics" (Krugman, 1998⁸⁶; Fujita et al, 1999⁸⁷), which defines the investigation of cultural industry agglomeration in the general spatial model of economic activities. Some scholars describe the cultural industry in the framework of industrial organization and regard it as "the spatial state of the combination of culture and economy" (Chris Gibson and Connell, 2004⁸⁸). A large number of scholars have conducted theoretical research on the spatial agglomeration of cultural industry in special areas. Clark (1984), Davis (1990), Schorske (1980), Zukin (1995) and many other scholars have described the phenomenon of cultural industry agglomeration in various urban backgrounds (Alan J. Scott, 2010). Studies on the spatial agglomeration of cultural industries mainly focus on the following aspects:

(1) Research on the spatial agglomeration location of cultural industries.

Alan J. Scott is an earlier and more in-depth scholar on the spatial agglomeration of cultural industry. He believes that the emerging global cultural economy tends to be condensed into geographical landscapes in the form of scattered cities and regional production systems (Scott, 2000), and the spatial distribution of cultural industries tends to gather in the form of spatial agglomeration in major cultural cities around the world, such as New York, Paris, Shanghai, etc. Markusen and G. Schrock (Markusen & G. Schrock, 2006) explained the diffusion and transfer trend of the agglomeration places of cultural and creative industries. Moloch (1983) believes that the distinctive feature of cultural industry is that it tends to form dense specialized industrial areas in the structure of big cities. By investigating the locations of cultural producers in 109 small Canadian cities, Jonathan (2012) found the "anti-urbanization" tendency in cultural industry clusters, and artists were more willing to choose villages with lower living costs and beautiful natural environment rather than cities as new creative destinations. The agglomeration of urban groups also plays an important role in the spatial agglomeration of cultural industries. According to the study of Hall (2000), it is easier for different groups to develop into the location of urban cultural spatial agglomeration in the process of urban agglomeration, communication, integration and collision.

(2) Study on the relationship between spatial agglomeration of cultural industries and cities.

86 P. R. Krugman, A J. Venables. Globalization and the Inequality of Nation [J], *Quarter of Journal Economics*, 1995,110(4): 857-880.

87 M. Fujita, J.-F. Thisse, Does Geographical Agglomeration Foster Economic Growth? And Gains and Loses from It?[J]. *The Japanese Economic Review*, 2003,54:121-145.

City is an important place for cultural industry spatial agglomeration. Sassen (1991) studied the agglomeration of cultural industries from the perspective of the internal spatial structure of big cities. In his opinion, old warehouses and urban fringe areas often play an important role in the agglomeration of urban cultural industries. Hutton (2000,2004) found that the "new production space" of the city could provide some architectural, cultural, environmental, learning and social convenience for the groups and enterprises concentrated in the creative industry. Some scholars have also studied the influence of cultural industry agglomeration on urban development. Mommaas (2004) analyzed the agglomeration strategy of Dutch cultural industries, and believed that the agglomeration of cultural industries could play a positive role in promoting a city's identity identification, innovation and creativity, and the reuse of old space. UNESCO believes that "arts, cultural resources and cultural clusters are engines of sustainable economic development... And urban regeneration policies can be adopted to regenerate cities "(OECD,2005). Montgomery J (2004) regards the construction of cultural industrial parks as a mode of urban regeneration and urban spatial transformation. Sharon Zukin believes that in a sense, the city first appears as a space, so the study of urban culture is also a kind of space research.

(3) Research on the internal organization of cultural industry spatial agglomeration.

In addition to the study on the spatial agglomeration of cultural industries and the relationship between them and urban space, researchers also pay attention to the issue of how cultural industries organize production in aggregates. Scott (2006) attributed the aggregation of cultural and creative industries in urban space to the interaction of human relations, historical cultural precipitation, changes in production organization and institutional arrangement, and believed that producer network, local labor market and creative field were the main factors that promoted the cultural industry agglomeration in urban space. He argues that the increasing differentiation of the labor force, both in the cultural and economic fields of production, strongly demonstrates the aggregation of many specialized but complementary individuals and organizations, constantly changing each other, and thus forming an aggregation of functions and Spaces of interrelated activities. Negus (2002) found that because cultural consumption is concentrated in the region, producers must "closely act" to keep track of competitors in order to keep in touch with the current trend, so as to benefit from the work of cultural media at the same time by virtue of various new technologies. Molotch (1996) believes that with the specialization of the cultural industry, cultural production will lie more in various professionals, who gradually replace individual artists in the traditional sense in all aspects. This process forms a geographical "lock-in" phenomenon in the space of cultural industry agglomeration, and finally forms the identity of products in special places and serves as the exclusive cultural monopoly capital of the place. Harald Bathelt (2006) believes that the cultural industry in Leipzig is controlled by several large local companies. Due to the defect of being over-rooted, the cultural industry in Leipzig keeps loose contact with the outside world, which is detrimental to the development of cultural industry spatial agglomeration. In the research process, some scholars also found that the production activities of cultural industry agglomeration are more inclined to be carried out around projects rather than companies. They (Blair H, Grey S, Randle K) believe that the spatial agglomeration of cultural industry is more conducive to the development of the working mode of project team and project network. Grabher G. (2002, 2004) put forward the concept and research methods of project ecology. He believed that different levels, such as core team, company, cognitive community and individual network, constituted the project ecology of cultural and creative industries, and paid attention to the relationship between projects and the environment. Bassett et al. (2002) discussed the structure of natural history film production agglomeration in Bristol based on the theory of urban growth pole. This study focuses on the origin, stage, depth of regional industrial agglomeration, the relationship between local industrial agglomeration and the world economy, the policy system and support to agglomeration, and the current dynamic changes of agglomeration development. Through empirical tests, the researchers found that the formation of cultural industry agglomeration in Bristol also tends to be based on small and medium-sized enterprises and private individuals.

(4) Research on the main body of cultural industries spatial agglomeration.

Zukin (1988) paid attention to the importance of various cultural producers represented by artists to the formation of cultural industry agglomeration. Richard Florida, puts forward the concept of the Creative Class (Creative Class), and the Creative Class is divided into to the core of the artist as the main body of the Super or Creative Class (Super Creative Class) and management, financial and legal services of professional Creative Class (Creative Professionals), in Richard's view, the Creative economy is different classes such as art, business and technology in the field of cultural and economic integration. At the same time, the contract of cultural and artistic producers, the decision factors of artists' location mobility and relocation, the role and political nature of artists themselves in cultural production, as well as the Life Path of the most creative artists and scientists, have all attracted varying degrees of attention. (Allen Scott Allen Scott) respectively from the Los Angeles apparel industry, furniture industry, and Hollywood animation industry empirical research, from the Angle of labor resources, probes into the cultural industry agglomeration form reason, he pointed out that the accumulation of the cultural professionals make labour market expands, the cultural industry of employees and enterprise benefit (Allen Scott. 2005, 2006). John Hawkins, known as the "father of creative industry", fully affirmed and attached importance to the role of creative talents in cultural industry agglomeration (Hawkins J., 2001). Lee (2001), Markoff (2005), Markusen (2003), Roberta (2012) and other scholars also conducted corresponding studies on cultural industry agglomeration groups.

(5) Research on the formulation of spatial agglomeration policies for cultural industries.

Coe (2000) points out that the development of cultural industry agglomeration depends to some extent on the intervention and guidance of the public sector, and different levels of governments and different styles of management structures can bring different results to the creation and innovation of cultural industry agglomeration. Bauer and Scott (Power & Scott, 2004) especially believe that the establishment of spatial agglomeration of cultural industry has become an important symbol of the current cultural and economic policies. Hitters and Richard (Hitters E. & Richards G., 2002) found that the government's intervention mode in cultural industrial parks from complete non-interference to centralized management has a certain degree of management continuity. Researchers such as Gibbons et al. (Gibson et al., 2002) believe that the defined architectural scope is re-modelled and re-built as a cultural district, and cultural industry activities are used as a means to promote the development strategy of marketized cities and attract floating capital. They are under a strategy of localized manufacturing and urban image regeneration, yet cultural themes describe particular places in ways that enhance or counter the popularity of other places. Because of the recognition of the effect of cultural industry spatial agglomeration on urban economic development, some scholars have also made corresponding research on the relationship between cultural industry planning and urban spatial planning. They believe that urban economy is constantly dependent on the production and consumption of culture, so that cultural industry planning and urban planning are often closely linked or even inseparable (Landry, 2000). Freestone and Gibbons (Freestone & Gibson, 2004) believe that cultural projects are not subconsciously planned strategies, but the result of competition (Bianchini, 1993; Evans and Foord, 2003); Boyle (1997) observed that cultural agglomeration was linked to the civic driven agenda of urban elites in urban planning strategies. Power & Scott (2004) pointed out that when local governments seek to develop their cultural economy, policy makers need to pay attention to promote the collective competitive advantage and establish a modern theoretical cultural industrial district, the cultural economy is an integral part of the contemporary economy, and the state can plan for cultural industrial zones or cultural agglomeration spaces through planning for innovation and creativity centers, through mixed land use or tax incentives, and through recognition of work networks between companies.

On the basis of the original literature research, this paper makes a theoretical analysis of the formation process of cultural industry spatial agglomeration from the perspective of professional division of labor theory. Professional division of labor as a special culture of self-organizing network model, cultural industry agglomeration is not only a pure culture of professional role, but also affected by the economic level and geographic space location, is the cultural accumulation, the industrial agglomeration and spatial agglomeration in the cultural factor, economic factor and the inner mechanism of the locational factors, in the government, market and society three mechanisms of propulsion mechanism under the action of polymerization. The arrangement of this paper consists of five parts: part 1 is the introduction, part 2 the concept definition and feature classification, part 3 is the model construction, part 4 is the empirical test, and the fifth part is the countermeasures and suggestions.

2. CONCEPT DEFINITION AND TAXONOMY

2.1 Culture

(1) Culture concept definition

Culture, as an interdisciplinary concept with rich connotations, is an important part of interdisciplinary studies such as anthropology, sociology, economics, management and history. In the research framework of human sociology, culture refers to the values, beliefs and understanding of the world shared by members of the society. People use culture to explain experience and initiate behavior, and culture is also reflected in people's behavior. The first clear and comprehensive definition of culture comes from Edward Burnett Taylor: "the complex body that includes knowledge, belief, art, morality, law, custom, and any other talents and habits acquired by man as a member of society" (Taylor, 1992). In Taylor's view, the various parts of culture function as an integrated whole. American anthropologists Kroeber and Clark Hong (1952) summarized the cultural connotation into two levels: one is the level of values, the other is the level of science and technology. According to the Australian economic and cultural scientist Throsby, culture includes two meanings: one is the sum total of cultural activities-based, the other is social values and habits (Throsby, 2003). In his book *The Important Role of Culture: How Values Influence Human Progress*, Huntington defines "culture" as "the values, attitudes, beliefs, orientation, and generally held opinions within a society" (Samuel Huntington, Lawrence Harrison, 2002). It can be seen that Huntington defined the concept of culture mainly from the psychological aspects of values, attitudes and so on. According to Malinowski, a British anthropologist, and Fei Xiaotong, a Chinese scholar, culture can be divided into three aspects: the level of objects, the level of institutions, and the level of ideas. As the code of conduct and symbol externalization of values, institutions and implements are determined by cultural concepts in the final analysis. Therefore, the essence of culture is the spirit value concept, way of thinking and code of conduct of cultural subjects.

(2) The role of culture in economy growth

In *The Wealth of Nations* published in 1776, Smith argued that division of labor and specialization promoted economic development, and that human beings, as rational individuals, unconsciously contributed to the increase of social welfare and the prosperity of social economy when they pursued their own interests maximization. The invisible hand refers not only to the market behind a trade, but also to the cultural concepts and consciousness that drive people's trading decisions. Marshall (1890), the epitomizer of classical economics, noted that cultural factors (including religion, morality, ideas, and ideals) and economic motives also determine people's behavior. He thought that every man with a little merit

had a higher character when he was in business. Personal emotion, sense of responsibility and the worship of noble ideals are also fully reflected in business operation. At the same time, Marshall also proposed the famous cultural industry atmosphere theory, he believed that a set of social and cultural norms and practices centered on the production system are related first to an underlying, non-regional production structure, and second to the economic geography of a particular place. Even in a non-regional world, if such a thing were possible, it is entirely conceivable that different cultural expressions associated with particular economic activities would, however, be at present departmental rather than spatial (Alan J. Scott, 2010). Hayek (1976) believed that the unconscious cognition and behavior of individuals contributed to the growth of group and social economy. In other words, the positive promoting effect of system and order on economic development has become the root of path dependence. In conclusion, the classical economists, represented by Adam Smith in the origin and development of the economy, seemingly abstract away people's individual consciousness and the concept of cognition, the man as a rational person, but actually they are the sublimation in the cultural concept to individual behavior choice, inherent in the individual pursuit of economic interests, which is constituted of individual utility preference theory, just did not explicitly proposed the economic concept of the culture. The influence of culture on a single subject, the visible culture is through the cultural concepts, cultural system and cultural products for an individual to influence, different individuals, as the price of the same cultural preferences and choice between formed layers of a particular culture, and formed many different cultural spheres of economic spatial difference of regional culture characteristics.

2.2 Cultural industry

(1) Definition by deferent countries and organization

Most countries in the world define the concept of cultural industry according to their own national emphasis on the development of cultural industry. At present, the general terms include "copyright industry", "cultural and creative industry", "content industry", "cultural and leisure industry" and so on. The following are some representative categories of cultural industry concepts: 1. Cultural Industry. UNESCO was the first organization to use the concept of cultural industry. Since 1986, cultural industry has been defined as "a series of activities in which cultural products and services are produced, reproduced, stored and distributed according to industrial standards". Since then, after two revisions in 2000 and 2009, the concept has continued. In terms of countries, Canada, South Korea, Finland and others also use the concept of "cultural industry". China adopts the definition of UNESCO and also uses the concept of "cultural industry". The cultural industry is defined as "the collection of production activities that provide cultural products and culture-related products for the public." 2. Creative Industry. The UK was the first country to use the concept of creative industries. It was first proposed in the "Creative Britain Action Plan" released by the British government in 1997. The UK specifically emphasizes creative industries in order to distinguish them from traditional industries, including popular design and fashion, crafts, music, design, performing arts, casual software and games. These industries include music, publishing, audiovisual, multimedia, performance, visual arts and crafts, etc. They cover fields such as design, industrial design, graphics, fashion and so on. They integrate the art industry and computer communication, and make them communicate with each other through digitization, making them the new power of the new economy. Other countries such as Singapore and New Zealand, as well as China's Hong Kong and Taiwan also use the concept of creative industries. 3. Copyright Industry. The United States is a typical country that uses the concept of copyright industry. As early as 1990, the copyright industry was included in the U.S. statistical indicator system and used to calculate its contribution to the U.S. economy. It was divided into core copyright industries, cross-copyright industries, partial copyright industries, and marginal industries.

The definitions of cultural industry various from worldwide countries and organizations, but there is no unified definition of cultural industry in the world. Therefore, in the following research of this article, the concept of "cultural industry" will be used uniformly to equate with Industrial concepts such as cultural creativity, cultural leisure, and content copyright. According to Throsby, the cultural industry is the aggregation of all art forms and related service providers within a region, which together constitute the entire art industry within the region, the country or any other region concerned by the research institute. He believed that the cultural industry is an economic group with the core of creative thought extending and expanding outward, and with "creation" as the core and combining with other inputs to form various cultural products. Scott (2001) summarized the cultural industry as "products and services that provide entertainment facilities, social communication, self-cultivation, decorations, social status, etc., which exist not only in elite culture such as movies and music, but also in the combination of more utilitarian functions such as furniture or clothing. Pratt (1997) defined a series of cultural industry production system components: performance, fine art and literature as well as their reproduction forms of expression -- books, periodicals, magazines, newspapers, films, radio, television, audio CD or tape; Art forms such as advertising (also known as print and radio) and the production, distribution and display processes of museums, libraries, theatres, nightclubs, and galleries are linked together. Chinese scholars Jin Yuan Pu will be a cultural industry is "the condition of globalization to people's spiritual and cultural entertainment consumption era demand as the foundation, supported by high-tech technology, dominated by Internet in new ways, with culture and arts and economic comprehensive union for its own characteristics, multinational cross-industry inter-departmental interdisciplinary restructuring or create a new industry cluster." From the above analysis, it can be seen that there is no unified definition and appellation for the cultural industry, whether it is the governments of many countries or the academic circles at home and abroad. Although the appellation concept is different, but the meaning is similar. No matter cultural economy, cultural industry or creative economy, they all express the same meaning: that is, the industrial form

combining culture and economy. The above definitions of the concept of cultural industry respectively emphasize the creativity, spiritual production and service of cultural industry. Based on this, this paper holds that cultural industry is a specialized production and service activity of creative content production based on professional division of labor, taking cultural factors as its characteristics, and spreading and serving with the help of advanced scientific and technological means and information technology.

2.3 The concept of spatial agglomeration of cultural industries

According to the world intellectual property organization (WIPO), the definition of "cultural creative industry cluster" refers to the cultural industry, public welfare, movies, music, publishing, interactive software, design, etc.) in geographically concentrated, it will be voluntary cultural creativity industry together, make the creation of cultural products production, distribution and use of optimization. Scott (1996) believes that spatial agglomeration of cultural industry refers to the non-random concentration or agglomeration in space of independent cultural enterprises or institutions of different scales, mainly small and medium-sized enterprises. The above definition, the former is more of a resultant static description, ignoring the dynamic process of industrial agglomeration formation. The latter ignores the government and cultural practitioners, thus losing the comprehensiveness of the concept description of cultural industry agglomeration. Industrial spatial agglomeration, this paper argues that culture is based on all kinds of cultural professionals in the crowd, based on the established specialized division of labor and collaboration, mainly small and medium-sized enterprises of different sizes of independent cultural enterprises and related government, research institutes, in parks, on the space settlement or building as a carrier of the interpersonal network and space location of focus. The "agglomeration" here lays more emphasis on specific economic logic and industrial association, and is the dynamic response of cultural industry and its industrial chain in spatial agglomeration. A large number of studies by scholars at home and abroad show that the spatial agglomeration of cultural industries is mainly formed in the cultural industrial districts of international cities. Specific appellations are "cultural industry park", "cultural industry area", "cultural industry base" and so on, according to the specific formation of the agglomeration area and have different appellations.

2.4 Cultural industry agglomeration formation mechanism

The spatial agglomeration of cultural industry is not only the agglomeration of industry, enterprises or people, but also the interaction and interaction of economy, location and culture. (Figure 1)

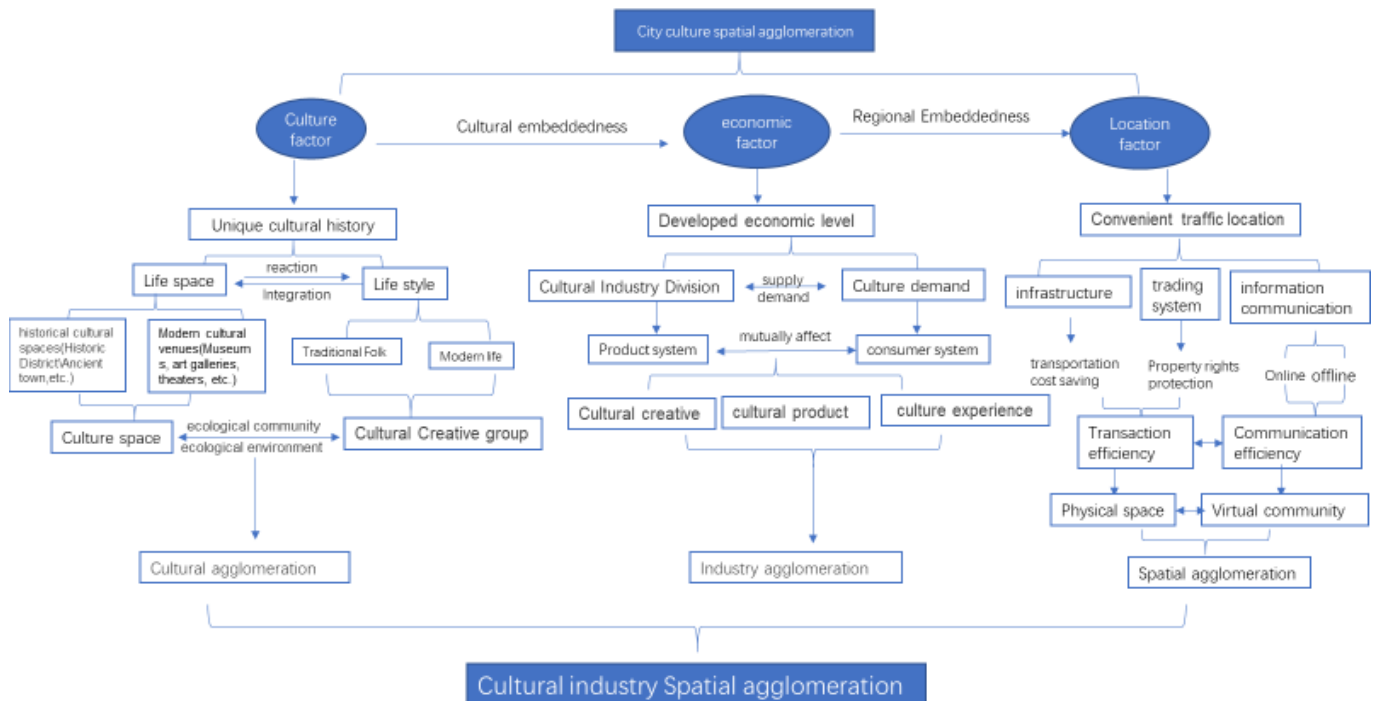

Figure 1. Mechanism of cultural industry spatial agglomeration

Cultural factors form unique cultural concept characteristics through cultural resources, which are often directly reflected by the local traditional living space and lifestyle. Living space includes traditional cultural space such as historical and cultural blocks, ancient towns and ancient villages, as well as modern venues such as museums, art galleries and cinemas. As the representation of specific cultural concepts, lifestyle mainly includes traditional historical folk culture and modern lifestyle. As the excavators and promoters of these two lifestyles, cultural creative groups often choose to gather in specific cultural space to form cultural creative settlement.

The movement of economic factors mainly selects regions with more developed economic level. Under the condition of cultural industry division, through the implantation of cultural factors, the production and consumption system of cultural and creative industries with local characteristics is formed. Due to its own industrial characteristics, cultural industry often has the instantaneity, sharing and replicability of production and consumption. As a labor group in the production consumption system, cultural and creative groups gather together to produce cultural and creative industries driven by economic benefits, including the creation of cultural content, the development and production of cultural and creative products, and the development and operation of cultural experience base. Finally, under the promotion of the industrial chain, the cultural creativity will be gathered in the industry.

The movement of location factor is mainly driven by the convenient transportation and transportation cost. Enterprises often choose the location where the infrastructure is intact, the trading system is sound, and the information exchange is efficient. The construction of infrastructure mainly involves the construction of expressways and public transportation. The most important transaction system of cultural industry is the property right transaction system. Therefore, whether there is a complete property right protection system is an important part in the location selection of cultural industry enterprises. As a knowledge spillover enterprise, information exchange is a necessary way for creative people to improve their creative level and knowledge. The traditional information exchange is mainly face-to-face, but with the development of modern information technology, virtual network space communication is becoming more and more important. Under the joint promotion of transaction efficiency and exchange efficiency, the cultural industry in a specific location gathers in the entity space.

These three factors do not exist independently. The unique regional cultural resources in the cultural factors form the unique cultural embeddedness in the economic factors of cultural industry. At the same time, it benefits from the movement of location factors. The improvement of transaction efficiency and exchange efficiency promotes the regional embeddedness. As the carrier of cultural factors and location factors, economic factors are fixed in the form of industrial system, and finally form the formation of cultural industry spatial agglomeration.

Under the action of the three factors, the post Fort regional and cultural economy shows perfect individual identity. The environment in which all types of cultural production - whether in the form of commodities or not - is rooted in a unique community of practitioners anchored to specific locations. For example, the Brahman painters of Nathd-wara in Northeast India, and a large number of film and television production groups gathered in the film settlement of contemporary Paris or Hollywood⁸⁹. the active centers of social reproduction are formed through these groups. In the process of social reproduction, the key cultural capabilities are maintained and recycled, and continue to play a role, eventually forming a cultural industry cluster with unique regional labels.

3. MEASUREMENT OF SPATIAL AGGLOMERATION OF CULTURAL INDUSTRY

3.1 location quotient measurement

In the existing literature, market concentration index, Gini coefficient, Herfindahl index, Ellison Gleeser index are used to measure industrial concentration. However, these indicators are non-spatial and only rely on the industrial dimension, which can not provide information on where industries are concentrated. Location quotient (LQ) reflects the level of specialization in a region. It can be used to measure the degree of industrial agglomeration and its scale advantage in higher level regions. It has been widely used in the study of creative industries in European countries. The calculation formula of LQ is as follows:

$$LQ_{ij} = \frac{E_{ij}}{E_i} / \frac{E_j}{E} \quad (1)$$

Where in formula (1): E_{ij} is the total number of employees in industry i in region j ; E_i is the total number of employees in industry i in the region; E_j is the number of employees in region j ; E is the total number of employees in the region. $LQ > 1$ means that the degree of specialization of i industry in region j is higher than the regional average, and its scale has a comparative advantage; $LQ < 1$ means that the degree of specialization of i industry in region j is lower than the regional average, and its scale is relatively weak; $LQ = 1$ means that the i industry in region j is at a general level. In the case of a given region and industry, location quotient can also be described as:

$$LQ = \frac{N_1}{A_1} / \frac{N_0}{A_0} \quad (2)$$

Where N_1 is the output value of a certain department in the research area (or the number of employees); A_1 is the output value of all departments in the research area (or the number of employees); N_0 is the output value of a certain department in the background area (or the number of employees); A_0 is the output value of all departments in the background area (Or the number of employees). Comparing the total output value of the cultural industry in each administrative region of Chengdu, we can get the location and degree of the cultural industry in Chengdu.

3.2 location quotient of cultural industry in different regions of Chengdu

3.2.1 Location quotient measurement of GDP added value

According to the cultural industry GDP added value and its proportion in GDP of Chengdu City and its administrative districts and counties in year 2011 and 2013, the location entropy of cultural industry GDP added value of each district

⁸⁹ Alan J. Scott. Translated by Dong Shu bao and Zhang Ning. Urban Cultural Economics [M]. Renmin University of China Press, 2010.

(city) and county is measured, which can investigate the proportion of cultural industry GDP added value in each region and whether there is obvious industrial agglomeration, so as to investigate the degree of cultural industry agglomeration and specialization of each district and county in Chengdu.

Figure 1. location quotient of cultural industry in Chengdu in year 2011

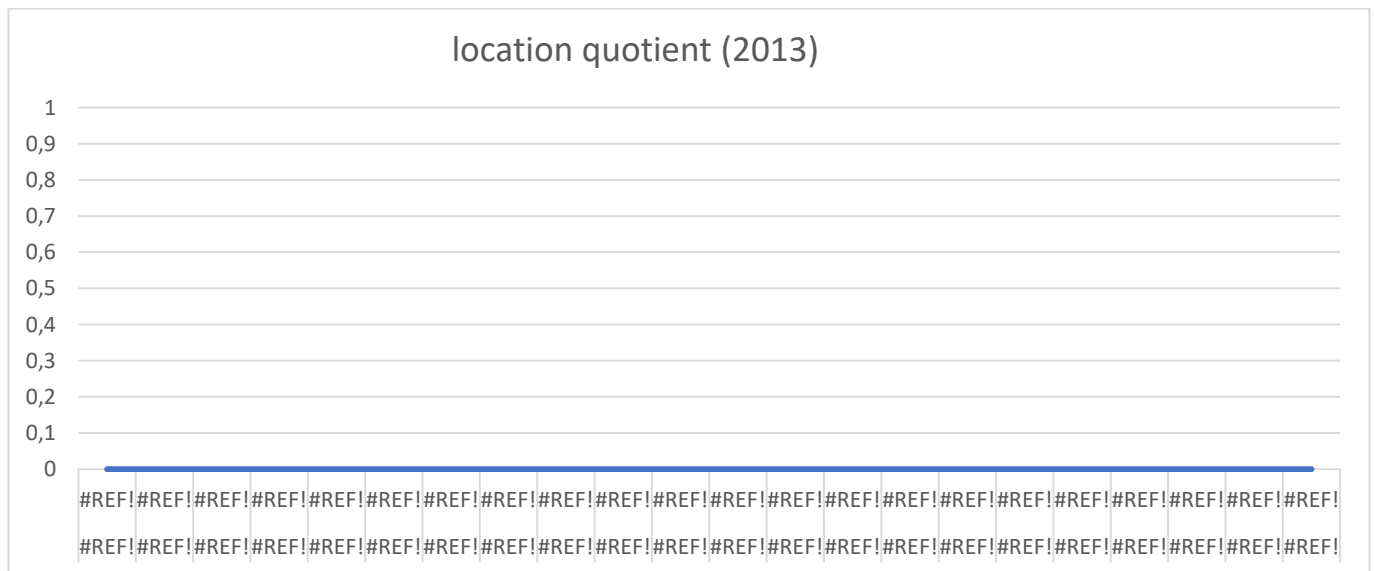

Figure 2 location quotient of cultural industry in Chengdu in year 2013

Figure 3 location quotient of cultural industry in Chengdu in year 2011 and 2013

Data source: Chengdu Municipal Bureau of Statistics

According to the trend chart of cultural industry agglomeration in each district (city) and county in Figure 1-3, whether in year 2011 or 2013, the location entropy of cultural industry in GDP present similar location distribution trend. The city center as the first circle take the obvious agglomeration advantage, and Jinjiang District got the highest location entropy, which further proves that Chengdu City has formed culture industrial agglomeration pattern with the city center as the leading area and Jinjiang District as the core.

3.3 Summary

According to the above measurement results of location entropy of cultural industry, the following conclusions can be drawn:

(1) It's clear that the dominant areas of cultural industry development are concentrated to the main urban area, Jinjiang District has the best industrial agglomeration effect, followed by Qingyang District, Wuhou District and Jinniu District, as well as Wenjiang District and Dayi County in the second circle, which is similar to that the development of cultural industry in Chengdu mainly relies on cultural and museum tourism coincide.

(2) Except for the above six districts and counties, the location entropy of other regions is less than 1, and the agglomeration effect of cultural industry is not very obvious. The development of cultural industry is relatively disadvantaged in the second and third circle, such as Jintang County, Longquanyi District, Pujiang County, Pengzhou City and so on.

(3) By comparing the location entropy of each district and county in Chengdu, we can see that the cultural industry specialization level of Jinjiang District is the highest, which is consistent with the actual situation. Jinjiang District is clearly positioned as the cultural creativity and industrial design concentration area among the 21 industrial concentration areas in the industrial planning layout of Chengdu. Therefore, the cultural industry of Jinjiang District is the most concentrated area of cultural industry development in Chengdu.

4. SPATIAL AUTOCORRELATION TEST

4.1 Moran I index test

In order to test the spatial agglomeration of cultural industry in Chengdu, spatial autocorrelation test is needed. Spatial autocorrelation test includes global spatial autocorrelation test and local spatial autocorrelation test. In spatial statistical analysis, Moran index and Geary are used to study the global spatial correlation, and there is a negative correlation between them. Among them, Moran I index reflects the similarity degree of attribute values of adjacent or adjacent regional units. Moran index is used for statistical analysis.

$$Moran'I = \frac{\sum_{i=1}^n \sum_{j=1}^n W_{ij} (Y_i - \bar{Y}) (Y_j - \bar{Y})}{S^2 \sum_{i=1}^n \sum_{j=1}^n W_{ij}} \quad (3)$$

Among them, Y_i are the observation values of the area i , n is the number of observation areas, there are 20 observation areas in this paper. W_{ij} is the spatial weight matrix of 0-1 distribution

$$W_{ij} = \begin{cases} 1; & \text{area } i \text{ is adjacent with area } j \\ 0; & \text{area } i \text{ is unadjacent with area } j \end{cases}$$

Where $i = 1, 2, 3 \dots n$; $j = 1, 2, 3 \dots m$. Moran' I index can be regarded as the sum of the product of the observed values, and the range of values is between [- 1,1].When the value is close to 1, it indicates that there is spatial positive correlation in the urban spatial scale, and when the value is close to - 1, it indicates that there is spatial negative correlation. According to the results of Moran' I index, the hypothesis test of normal distribution can be used to judge whether n observations have spatial autocorrelation

$$Z(d) = \frac{Moran'I - E(I)}{\sqrt{VAR(I)}} \quad (4)$$

The expected value and variance of Moran' I index were as follows:

$$E_n(I) = -\frac{1}{n-1} \quad (5)$$

$$VAR_n(I) = \frac{n^2 w_1 + n w_2 + 3 w_0^2}{w_0^2 (n^2 - 1)} - E_n^2(I) \quad (6)$$

Among them,

$$W_o = \sum_{i=1}^n \sum_{j=1}^m W_{ij} \quad (7)$$

$$W_1 = \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^m (W_{ij} + W_{ji})^2 \quad (8)$$

$$w_2 = \sum (w_{i.} + w_{.j})^2 \tag{9}$$

If the Z value of Moran' I index is greater than the critical value of 0.05 confidence level of 1.96, it indicates that there is an obvious positive correlation between the spatial scale of cultural industry, and the cultural industry system formed by adjacent regions has spatial spillover effect and proximity effect.

The Moran' I index of Chengdu cultural industry agglomeration in 2011 is calculated by creating the spatial weight matrix of 20 districts and counties by Geoda9.5. By calculating the expected value and variance of I index, we can get the normal statistical value Z (as shown in Table 3). In 2011, the normal statistical value Z is 2.454108, which is greater than the critical value of 1.96 under the significance level of 0.05, which shows that the spatial agglomeration of cultural industry in Chengdu presents positive spatial correlation, that is, spatial dependence, and the spatial agglomeration of cultural industry in Chengdu presents a certain degree of agglomeration.

TABLE 1. Moran' I index and Z value

Particular year	Moran' I index	Moran' I index expectations	Variance var (I)	Normal statistics Z	P value
2011	0.3334544	-0.0526	0.02474626	2.454108	0.003

Next, Chengdu cultural industry space Moran' I is generated. The results show that there are four patterns of cultural industry spatial agglomeration in Chengdu: the first quadrant (H-H) high concentration area of cultural industry, showing positive spatial autocorrelation; the second quadrant (L-H) low concentration area of cultural industry is close to the high concentration area, showing a negative spatial autocorrelation relationship; the third quadrant (L-L) low concentration area of cultural industry is adjacent to the low concentration area, showing a positive spatial autocorrelation relationship Positive spatial autocorrelation; the fourth quadrant (H-L) high concentration areas of cultural industry are surrounded by low concentration areas, showing negative spatial autocorrelation.

Moran's I scatter diagram

Figure 4 Moran' I index scatter chart of Chengdu cultural industry spatial agglomeration

Through the statistics of the data of each district and county, it is found that the areas represented by the points in the four quadrants in the above figure are shown in the following table (Table 2).

Table 2 four modes of spatial agglomeration of cultural industry in Chengdu

	Spatial pattern	Region
Quadrant 1	H-H	Jinjiang District, Qingyang District, Chenghua District and Wuhou District
Quadrant 2	L-H	Jinniu District, Shuangliu County, Longquanyi District, Pixian County, Wenjiang District
Quadrant 3	L-L	Qingbaijiang District, Jintang County, Pujiang County
Quadrant 4	H-L	Dayi County, Chongzhou City, Qionglai City

The table-2 shows that the four regions in the first quadrant (H-H) (the shaded part in the upper right corner of Figure 3) are the intensive areas with high spatial concentration of cultural industry in Chengdu, mainly concentrated in the main urban areas with developed tertiary industry. The five regions in the second quadrant (L-H) (the shaded part in the upper left corner of Figure 3) are areas with low concentration of cultural industry, mainly concentrated in the main urban area with relatively low tertiary industry and the marginal area of the second circle. The five areas in the third quadrant (L-L) (the shadow part in the lower left corner of Figure 3) are low concentration areas, and they are adjacent to each other, that is, low concentration areas are surrounded by low concentration areas, mainly concentrated in Dayi County, Chongzhou city and Qionglai city. The three regions in the fourth quadrant (H-L) (the shaded part in the lower right corner of Figure 3) are high concentration areas. However, due to their geographical location close to the low

concentration areas shown in the third quadrant (L-L), they present a spatial pattern that high concentration areas are surrounded by low concentration areas, as shown in Figure 3.

Analysis shows that agglomeration phenomenon has been existed in Chengdu cultural industry, presenting a pattern of coexistence of spatial dependence and spatial heterogeneity, but mainly manifested as spatial dependence. Therefore, it is necessary to use spatial measurement to test the spatial structure of Chengdu's cultural industry to determine the factors affecting the spatial agglomeration of Chengdu's cultural industry.

4.2 Spatial influence factor test

4.2.1 Measurement model

The traditional economic geography school, the new economic geography school and the industrial policy theory school have their own emphasis on the influencing factors of cultural industry agglomeration. The traditional economic geography pays attention to the influence of geographical location and natural endowment; the new economic geography pays attention to the influence of economic externalities and spatial costs, which include financial externalities and technological externalities, while spatial costs focus on space transportation costs and transaction costs, which are mainly caused by infrastructure such as transportation, posts and telecommunications; industrial policy theory Mainly from the school of economic geography of cultural industry, cultural industry as a semi-public goods, to a large extent, needs the government policy, funds and other aspects to achieve industrial agglomeration in space. Based on the research results of the above three universities, combined with the professional division theory, Marshall externality theory and spatial location theory, this paper sets cultural factors (resource endowment), economic factors (economic agglomeration effect), location factors (spatial location conditions) and policy factors (government investment) to influence the spatial agglomeration of cultural industry in geography as the cultural products of this paper. According to the availability of data, a model framework of cultural industry spatial agglomeration is assumed

$$G=f(x) = Z_0 + \sum[\int(S(x)) + \int(D(x)) + \int(C(x))]$$

It can be seen from the model that the spatial agglomeration level of the cultural industry is a set of functions related to the sum of the three major factors of economic specialization, spatial location conditions and cultural resources, plus the external force of government-related policy actions. Where G represents the spatial agglomeration level of the cultural industry, among which, S(x) represents the level of economic specialization, D(x) represents the spatial location, C(x) represents the level of cultural resources and knowledge spillover, and Z0 represents the government policy behavior, which is the cultural industry Based on the external force of spatial accumulation, the following assumptions are made according to the model:

(1) Cultural factors are positively related to the spatial agglomeration of cultural industries.

The cultural factor here mainly refers to cultural resources and their spillover effects. According to Ohio Forest's natural resource endowment theory and Marshall's industrial location theory, this article believes that in the production process of cultural industries, the amount of cultural resources is a prerequisite for the development of cultural industries in a region. The development level of a region's cultural industry is positively related to the amount of cultural resources it owns. The more cultural resources, the better the development of cultural industries and the higher the spatial agglomeration of cultural industries.

(2) Economic factors are positively correlated with the spatial agglomeration of cultural industries.

The economic factors here mainly refer to the economic development environment and degree of economic agglomeration in a specific area. Here we mainly examine the impact of the development level of the tertiary industry and the per capita disposable income on the agglomeration of cultural industries in Chengdu. As an important part of the tertiary industry, the cultural industry has very high requirements for industrial relevance and needs a good foundation for the development of the service industry. The service industry can provide the necessary information, technology, and industrial cooperation support for the development of the cultural industry. Therefore, the development of the service industry level of the tertiary industry is an important consideration index for the new cultural industry enterprises in the region to choose the space area.

(3) Location factor is positively correlated with the spatial agglomeration of cultural industries.

The level of economic development is directly related to the location and traffic conditions. According to the classical location theory and the viewpoint of the emerging economic geography school, the spatial traffic cost of a region is directly related to the industrial development and economic level of the region. The better the location and traffic conditions, the better the economy. Level of development. Population density is an indicator that reflects the level of population agglomeration in a region. Generally speaking, population agglomeration is positively correlated with economic development. The higher the population density, the more developed the local economy. Therefore, the level of population density also affects the degree of cultural industry agglomeration; the number of employees and legal entities in the transportation sector directly determines the economic relationship between this area and the outside world, and can determine whether the area has an advantageous spatial location. Based on this, this article gives the third hypothesis of the factors affecting the level of cultural industry agglomeration, that is, location traffic conditions and cultural industry spatial agglomeration are positively correlated.

(4) As independent external forces and three factors, policy factors are positively related to the spatial agglomeration of cultural industries.

The development of the cultural industry has benefited to a large extent from the policy promotion and support of the local government, and promotes the spatial agglomeration of the cultural industry through a top-down policy mechanism. Based on the availability of data, this article uses the level of regional government fiscal expenditures to examine the local government's stimulus for the development of cultural industries, thereby examining the impact on the spatial agglomeration of cultural industries.

According to Anselin (1988) on the spatial econometric model, the spatial factors neglected by the classical regression analysis are introduced into the model, and the influence of spatial heterogeneity on the model is fully considered, including spatial lag model (SLM) and spatial Error model (SEM). The expression of the spatial lag model is:

$$G = \rho W_G + X\beta + \epsilon$$

$$G = C + \rho W_G + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \dots + \epsilon$$

G is the explained variable, X is the n×k exogenous explanatory variable matrix, W is the n×n-order spatial weight matrix, and ρ is the spatial regression coefficient, which reflects the degree of spatial dependence of the observations, that is, the adjacent regions. The degree and direction of the influence of the observation value WG on the observation value G in the region, ε is the random error term vector.

4.2.2 Indicators identify

In this paper, the explanatory variable is set as G to represent the output value of the cultural industry in each region. The explanatory variables are mainly inspected by economic factor indicators, cultural factor indicators, location factor indicators and government input indicators, which are represented by X1, X2, X3...Xi, among which economic factor indicators include per capita disposable income represented by X11, and the tertiary industry accounts for The proportion of total output value is represented by X12; cultural factor indicators are related to cultural resources, including the possession of ancient towns, museums, cultural venues, and intangible cultural heritage, respectively represented by X21, X22, X23, X24; location factor indicators mainly examine each district The population density of the county, the number of employees in transportation legal entities, and industries are represented by X31, X32, and X33, respectively. The government input indicators mainly examine the government's fiscal expenditures to various districts and counties in the year, denoted by X0; see Table 5 for the specific indicator system.

Table 5 index system of cultural industry spatial agglomeration

Research index system of cultural industry spatial agglomeration		
index		unit
Economic factor index X ₁	X ₁₁ : Per capita disposable income	yuan
	X ₁₂ : Proportion of tertiary industry in total output value	%
Cultural factor index X ₂	X ₂₁ : ancient town	individual
	X ₂₂ : museum	individual
	X ₂₃ : Cultural Venues	individual
	X ₂₄ : Intangible cultural heritage	term
Location factor index X ₃	X ₃₁ : Population density	Person / km ²
	X ₃₂ : Employees in transportation and postal logistics departments	people
	X ₃₃ : Number of legal entities in transportation and postal logistics departments	individual
Government input indicators X ₀	X ₀ : Local public finance expenditure	Ten thousand yuan

4.2.3 Data description

The data used in this measurement model is the cross-sectional data of the 20 districts, cities and counties in Chengdu in 2011. In order to reduce the measurement error caused by the inconsistent indicators, this paper has carried out a dimensionless treatment on the explanatory variables. The cultural factor index of each region is mainly based on the cultural resources published by Chengdu City and the districts and counties. The economic factor index is mainly based on the economic annual report issued by the relevant statistical departments of Chengdu and the districts and counties, and the third national economic census. Obtained from the Chengdu Statistical Yearbook, the fiscal expenditure data of each district is mainly based on the annual fiscal budget and final accounts data of each district and county published on the Chengdu government website.

4.3 Model analysis

Using the spatial lag model, we found that except for the variables X22 (Museum), X23 (intangible cultural heritage) and X33 (number of transportation legal entities) on the cultural industry output value, the other variables have significant impact on the cultural industry output value.

Table 6 estimation of influencing factors of cultural industry spatial agglomeration (SAR)

	Coefficient β	Z value	P value
X_{11}	0. 004764	1.2	0.229
X_{12}	3. 321259**	1.98	0.048
X_{21}	3.786255*	1.66	0.096
X_{22}	0. 073205	0.1	0.920
X_{23}	3.014261***	4.25	0.000
X_{24}	1. 864454	0.3	0.768
X_{31}	0. 022555*	1.76	0.079
X_{32}	0. 003307***	4.68	0.000
X_{33}	0. 038796	1.08	0.281
X_0	0. 000143**	2.81	0.005
cons	15.22778	1.21	0.226
Wald test of rho=0:		chi2(1) = 5.424 (0.020)	
Likelihood ratio test of rho=0:		chi2(1) = 4.749 (0.029)	
Lagrange multiplier test of rho=0:		chi2(1) = 2.143 (0.143)	

Note: ***,**, and * indicate that they have passed the significance test at 1%, 5% and 10% levels respectively.

From the above analysis model, it can be seen that the per capita disposable income in economic factors has no significant impact on the output value of the cultural industry, which proves that the cultural consumption consciousness of residents in various districts and counties of Chengdu is not affected by income levels, which also proves Chengdu from the side. The living conditions that the people are comfortable with, the high-income class and the low-income class have their own suitable cultural consumption methods. The proportion of the tertiary industry in GDP has a significant impact on the output value of the cultural industry, indicating that the development level of the tertiary industry in a region has a significant impact on the output value of the cultural industry, which can also promote the regional spatial agglomeration of cultural industries. In the cultural factor system, ancient towns and cultural venues have passed the significance test, while museums and intangible cultural heritage failed to pass the significance test, proving that ancient towns as a resource element can well promote the development of cultural industries, which also reflects Chengdu Theoretical analysis of people's fun. As a cultural environment indicator, cultural venues can create a good cultural environment for local residents, thereby cultivating residents' cultural literacy and enhancing residents' spiritual consumption consciousness and consumption ability. The population density of the location factor system and the number of employment in transportation have a significant impact on the output value of the cultural industry, which proves that the cultural industry can get better results in areas with good population agglomeration conditions and areas with busy and developed transportation. development of. Government fiscal expenditure X_0 has a positive effect on the spatial agglomeration of cultural industries. Its coefficient is 2.81, which has passed the test at the 5% significance level. It shows that government investment is an important force for the development of cultural industries and the promotion of cultural industry spatial agglomeration. The expansion of the industrial space scale plays an important guiding role. In summary, the degree of development of the tertiary industry, sufficient space for cultural resources, convenient location conditions, and active government investment have an important impact on the spatial agglomeration of cultural industries in Chengdu, which is consistent with the model assumptions.

5. CONCLUSIONS AND SUGGESTIONS

In the internal mechanism of the spatial agglomeration of cultural industries in Chengdu, cultural factors, location factors and economic factors constitute a three-dimensional industrial space system with urban cultural connotation. In this space system, culture is the soul, and it is the cohesion that links the cultural industry and the geographical position of Chengdu. The economy is the ecological main body of the spatial agglomeration of Chengdu's cultural industry. Through the operation of the economic unit with enterprises as the main body and a large number of freelancers, the vitality and benefits of Chengdu's cultural industry are realized. Location is the root, which is the basis for the origin of Chengdu's cultural characteristics, and also the soil for Chengdu's cultural industry to take root. The construction of a world famous cultural and creative city focuses on the promotion of cultural and creative industries and the construction of city brands. With the proposed status of Chengdu as a national central city, Chengdu government has set up the industrial goal of building the cultural and creative center in the west of China in the aspect of cultural industry. From the perspective of the theory of professional division of labor, the Western Cultural and Creative Center pays more attention to the establishment of the professional division of labor system of the cultural industry. Compared with the famous historical and cultural city which is solely based on historical and cultural resources, it needs to pay more attention to the establishment of the cultural industry network space system with Chengdu characteristics. The focus needs to start from the following three aspects:

(1) Based on cultural factors, build the urban brand cultural atmosphere of Chengdu.

To build an international city cultural brand supported by the world famous cultural and creative city, the first step is to build a unique urban brand cultural atmosphere of Chengdu. Urban brand cultural atmosphere is the branding of urban cultural atmosphere, which is based on the high integration of Chengdu cultural factors, economic factors and location

factors. Furthermore, it is the unification and abstraction of urban cultural concept, professional division of urban cultural industry and urban geographical location. Chengdu city culture atmosphere, is based on the appreciation of leisure inclusive culture trait and play the life interest, with tourism, animation games for advantage industries, traditional history culture resources superiority and the modern science and technology bring out the best in each other, through diversification by different cultural spheres of professional event and exhibition to promote. According to the action mechanism of cultural factors on the spatial agglomeration of cultural industries (see Figure 7-3), urban cultural factors with leisure and inclusion as the core penetrate through the expression layer, space layer and agglomeration layer of cultural industries, and finally manifest themselves through different spatial agglomeration bodies of cultural industries. Implementation of Chengdu city cultural atmosphere of the brand, first of all, to be closely related to the urban culture of leisure tolerance factor, refined abstract Chengdu culture life style and features of cultural products, image, video, audio, advertising for expression, to repackaging of city image and city space, and in film, TV, Internet and other ways for promotion. The advertising video directed by Zhang Yimou for Chengdu, with the slogan "Chengdu, a city you never want to leave once you come", shows the leisure of "never entering the river" in another more modern language, which deeply touches the hearts of every Chengdu person and sets up the urban cultural brand of Chengdu perfectly. Under the goal and mission of building the cultural and creative center in western China, Chengdu city brand cultural atmosphere needs to build more urban brand image of innovation, entrepreneurship and creativity center, so as to better adapt to the industrial characteristics of cultural industry. Second, to form the cultivation of the basic urban cultural environment. Through public cultural infrastructure construction, digital culture service platform construction, "elegant" Chengdu construction engineering for the urban cultural atmosphere to provide good public cultural environment, enhance the protection and inheritance of history and culture, pay attention to the material and cultural heritage and intangible cultural heritage of the industrialization, at the same time, support enterprises and related organizations and individuals to develop the media animation game, performing arts entertainment, creative design, original works of art, copyright services, publishing, etc. Activate urban cultural resources and urban cultural elements, enhance the brand image of Chengdu as a world famous cultural city and western cultural and creative center, and export the brand and image of Chengdu as an international city culture to the world with the help of international cultural exchanges and trade activities.

(2) Promote the integration of cultural factors and economic factors to form a network space for specialized cultural production.

The core of the integration of cultural factors and economic factors lies in the specialized production of culture. Cultural industry in Chengdu in the operation of the inner mechanism of the spatial agglomeration, culture is specialized in the urban historical and cultural resources on the basis of the economic factor of cultural production system works - consumers, culture specialized production network space through the specialized production promotion network effects, formed the so-called "industrial agglomeration externalities" Marshall, promote cultural industry agglomeration spatial extension. Therefore, compared with the traditional definition of famous historical and cultural city or cultural capital, Chengdu municipal government puts more emphasis on the role of specialized division of labor in putting forward the western cultural and creative center. In order to construct Chengdu's cultural production network space, the first step is to construct the cultural production-consumer system exclusive to Chengdu, and form the microbiota of cultural industry specialized production. Specifically, is to build to the cultural industry projects, professional production team as the driving force, innovation to create more and better cultural content of products, such as games, anime, movies, novels, plane design, etc., at the same time extend the culture industry production chain, through theater, drama, dance, film, television, music and so on way to content the high-quality goods again creation again spread, on this basis, developed a series of experiential gen products, cultural content, the scene is rich in content and level consumer spending. Therefore, Chengdu cultural production network space should cover cultural content creation team, cultural product operation team, post-production team, communication and promotion team, etc. Under the specialized production and the Internet information technology support, the team's operation can be implemented on a global scale to mobilize resources and operational projects, by helping to develop more international vision and global height of the Chengdu local team, to bring more excellent international level of Chengdu cultural activities and cultural work, strengthening the construction of cultural infrastructure at the same time, promote the development of cultural industry park and characterization, differentiation, and will be built in Chengdu is more advantageous to the development of the regional culture characteristic, multicultural integration cultural and creative cities.

(3) Improve the trading efficiency of the cultural industry and optimize the agglomeration space of Chengdu's cultural industry.

Under the framework of new classical economics, transaction efficiency is an important way to improve the economic performance of specialized organizations. As a self-organizing network, the spatial agglomeration of cultural industries, in addition to the network effect of specialization, whether the optimization of transaction efficiency can be achieved is an important indicator to measure the spatial agglomeration benefit of cultural industries in a region. This paper believes that the influencing factors of the transaction efficiency of cultural industry are composed of three aspects: concept system, infrastructure (including communication technology, public cultural buildings and road facilities) and humanistic quality, which is also the path and direction of the spatial agglomeration transaction efficiency improvement of cultural industry in Chengdu. First of all, in terms of concept system, with Chengdu becoming a national central city, under the guidance of the goal of building a world famous cultural and creative city, it is necessary to establish international cultural industry-related policies, systems and industry standards, especially the copyright protection law and related regulations

related to the production of cultural content. At the same time, through holding international cultural industry conferences, forums, exhibitions, etc., to promote Chengdu to become an international center of multicultural exchange. Secondly, strengthen the construction of cultural infrastructure, fully integrate the ancient Shu culture, water culture, Three Kingdoms culture and other traditional cultural elements, and build a number of historical and cultural blocks, architectural communities and cultural landscapes represented by "Chengdu Center" and bearing the memory of Chengdu's urban culture. Enhance the cultural and creative transformation of the abandoned buildings in the old city center, create more space carriers for cultural industry agglomeration, and effectively promote the further realization of the Renaissance and cultural prosperity in the old city center. At the same time, with the help of modern information technology, strengthen the construction of urban cultural public information platform network, Chengdu public culture to realize the omnipresent sense. Finally, to enhance the efficiency of urban cultural industry trade needs as consumer group Chengdu citizens cultural consumption cognitive ability, increase the public welfare culture construction, let more people have the opportunity to understand and into the cultural industry, promote the communication between the subject and public cultural industry, optimize the environment of culture industry communication, improve the humanities cultivated manners of the city and convenience of transaction efficiency, promote cultural industry so as to further promote the cultural industry agglomeration optimization in the center of the city.

LONG-TERM ORGANIZATION OF URBAN GROWTH IN FRANCE (1800-2015). WHICH REALITY IN TIME AND SPACE OF STOCHASTIC PROCESSES "À LA" GIBRAT?

[Aureliz Lalanne](#)

University of Bordeaux, France

ABSTRACT

Globalization, migratory phenomena, and transformations of production systems reflect processes driving change and evolution in cities. However, despite these ongoing disturbances, urban hierarchies maintain a stable state over time (Duranton, 2007). This stable state of urban systems is studied through many works on a national scale (see among others: Davis and Weinstein, 2002, Bosker et al., 2008, Gonzalez-Val, 2010). These studies provide an interesting but reductive approach to the processes at work in these systems. Indeed, it is accepted that two laws summarizing their functioning govern national urban systems. Urban hierarchies converge towards a stable state in time (Zipf's Law) thanks to a stochastic process (Gibrat's Law) (Gabaix, 1999). Zipf's law assumes that the city size distribution (that is, the ranking of cities from largest to smallest) is linear and continuous^[1]. Gibrat's Law seeks to explain the linear and continuous shape of the city size distribution by describing urban growth processes (Gibrat, 1931). Gibrat's law is a stochastic process that implies that growth rates depend on a number of factors and that the effect of each of these factors is marginal growth. Simon (1955) and Ijiri and Simon (1977) conclude that Gibrat's law is confirmed if the long-term growth rate of cities is the same and does not depend on the size of urban areas.

This paper explores the reality of the stochastic processes "à la" Gibrat thanks to long-term censuses data of French municipalities from 1800 to 2015. Several assumptions are tested in this paper to improve our knowledge of the stochastic urban growth processes. In the literature, Gibrat's law is tested independently of the effects of time and space, yet there is no reason why some periods or places are not more sensitive than others to stochastic dynamics. All these hypotheses will allow us to nuance and better apprehend the stochastic processes at work in a European country with a very long urban history.

In the first assumption, we will test the validity of Gibrat's law over the two centuries studied. More precisely, we question the possible convergence of this Gibrat's law from the industrial revolution onwards. We also test a second assumption on the relevance of stochastic growth processes as a function of urban size. Is Gibrat's law more valid for small or large cities? Finally, we wonder whether the dynamics observed at the national scale are also valid at the regional scale. For that purpose, we compare the national dynamics to the regional dynamics so as to reveal the diversity of growth processes depending territorial and regional specificities. The linearity depicted at aggregate national scales actually obscures variation observed in a multi-scale regional analysis (Bessey, 2002).

^[1] Simply, it means that the size of the city of rank two is equal to half of the size of the city of rank one; the size of the city of rank three is equal to one-third of the size of the city of rank one, etc.

SMART CITY – RESILIENT CITY: SYNERGIES AND TRADE-OFFS**Daniela-Luminita Constantin¹, Cristina Serbanica^{2,1}**¹Bucharest University of Economic Studies, Romania. ²Constantin Brancoveanu University of Pitesti, Romania**ABSTRACT**

According to the 2030 Agenda for Sustainable Development, making cities and human settlements „inclusive, safe, resilient and sustainable” (UN, 2015, p.26) represents one of the major goals, pointing out the close relationship between resilience and sustainability, which work together for the well-being of a system. City/urban resilience contributes to this paradigm „the capacity of individuals, communities, institutions, businesses, and systems within a city to survive, adapt, and grow no matter what kinds of chronic stresses and acute shocks they experience” (100 Resilient Cities, 2019, p.1). It is already considered an increasingly relevant topic for international development and urban studies, becoming a “framework for thinking” and a background for planning, development and management “with regard to life and assets protection and maintaining continuity of functions through ‘any plausible shock or stress’” (UN Habitat, 2017, p.6). The resilient city concept is relating to other concepts like ‘sustainable city’, ‘smart city’, ‘eco city’, ‘liveable city’, etc. and systematic explorations of these connections and their significance for urban development policy and practice are still required. This paper aims to examine the smart city - resilient city nexus, seeking answers to the following questions: How do ‘resilient cities’ relate to ‘smart cities’? How can ‘smart solution’ address ‘resilience challenges’? What are the synergies and trade-offs between smart and resilient cities? Based on a starting point that acknowledges the diversity of urban resilience challenges, the role played by the contextual factors and the emphasis on innovation and smart solutions when it comes to solutions to resilience challenges, the paper proposes a three-step research methodology, using the database of the 100 Resilient Cities (100RC), as follows: first, the most frequent resilience challenges are identified and a taxonomy is created by means of hierarchical cluster analysis; second, the smart solutions proposed within the framework of the “Urban Resilience Strategies” for 74 cities participating in the 100RC are pointed out using the content analysis with ‘smart’ and ‘digital’ as search queries; third, the ‘smart solutions’ are connected to ‘resilience challenges’. The results have made it feasible to integrate the city resilience framework with the smart city framework, highlighting the synergies between the two concepts. At the same time, the trade-offs are discussed, emphasizing additional resilience challenges that can be brought in by smart cities and the fact that smart technologies can improve outcomes before, during, and after shocks and stressors occur but “smart cities solutions are not a panacea for all urban sustainability and resilience issues” (Hurley, 2019).

FARAWAY, SO CLOSE! THE INTERREGIONAL TRADE BETWEEN SPAIN AND MOROCCO

[Fatima El Khatabi](#), [Carlos Llano](#)

Universidad Autónoma de Madrid, Spain

ABSTRACT

For the first time, this paper analyzes the methodology and results of a new database on the region-to-region trade flows between Spain and Morocco. Following the experience of previous estimates of region-to-region flows within the EU, the new dataset combines the most updated statistics available in Spain about region -to-region (Nuts 3) freight flows (tons) by different transport modes (road, ship, air) between the two countries, and the official and solid information about the Spanish trade (tons and Euros), split at the province-to-country level (Nuts3-Nuts1), covering all transport modes and the period 2010-2018. Once the estimation of this database is completed, the flows are analyzed in the context of the gravity equation, studying the robustness of the figures obtained, exploring the spatial and sectoral dimension. Due to geographical proximity, Spain remains Morocco's main trading partner, and it is the top destination for Spanish exports in Africa and the Arabic world, with more than 20,000 Spanish companies operating in the country. In 2019, 45.5% of Spanish exports to Africa were destined to Morocco. In 2020, the rate increased to 47.5%. It is also interesting to look that Morocco has developed strong value chains linkages over last 20 years. The European Union is an important GVC partner of Morocco, in fact, this integration in the global value chain has become the dominant paradigm in the trade relations and strengthens the ability to compete in a global marketplace.

Regular Session: RS14.2 - The spatial dimension of sustainable development

11:00 - 12:15 Wednesday, 26th May, 2021

TECHNOLOGY DIFFUSION AND CONSUMPTION GROWTH: IDENTIFYING SPATIAL EFFECTS

Nailya Bagautdinova, [Ekaterina Kadochnikova](#)

Kazan Federal University, Russian Federation

ABSTRACT

In the context of a pandemic, consumer-controlled digital technologies are one of the key determinants of the sustainable development concept: they lead to the replacement of labor with capital, the growth of information and knowledges, reduce economic costs, expand consumer choice, take into account consumer preferences, and integrate the economic space. As we learned from the theory, the spread of technology leads to an equalization of growth rates in the long term for leaders and technological followers. Therefore, the aim of the study is to analyze the convergence of consumption, taking into account the spatial specifics and the impact of digital technologies on the average growth rate of consumption. *Research questions:* is there a spatial relationship in consumer spending per capita? Is there a β -convergence of the average consumption growth rate in the long term? *The hypothesis of the study:* Russian regions are not making full use of the households digitalization in achieving sustainable development. The data sample is obtained from the "Regions of Russia. Socio-economic indicators. 2019" material. Dependent variable: the average growth rate logarithm of consumer spending per capita in 2014 prices. Independent variables: income per capita, share of population using the Internet; number of active subscribers of mobile broadband access to the Internet per 100 inhabitants, the deposits of individuals, savings rate ((income per capita, consumer spending per capita)/monetary income per capita). We used the boundary weight matrix, global Moran and Geary spatial correlation indices, and local Moran indices. In a study in the R software environment (plm package, splm package), models of unconditional and conditional β -convergence are constructed on panel data without/with a spatial component (according to the SAR, SEM, SAC types) with fixed effects and with random effects (Barro R., 1992):

$$1/T \cdot \ln(Y_i(t_0+T)/Y_{it0}) = \alpha + \beta \cdot \ln Y_{it0} + \sum \gamma_j X_{jit} + \rho W \ln(Y_i(t_0+T)/Y_{it0}) + \epsilon_{it};$$

$$1/T \cdot \ln(Y_i(t_0+T)/Y_{it0}) = \alpha + \beta \cdot \ln Y_{it0} + \sum \gamma_j X_{jit} + \lambda W_{iit} + \epsilon_{it};$$

$$1/T \cdot \ln(Y_i(t_0+T)/Y_{it0}) = \alpha + \beta \cdot \ln Y_{it0} + \sum \gamma_j X_{jit} + \rho W \ln(Y_i(t_0+T)/Y_{it0}) + \lambda W_{iit} + \epsilon_{it}.$$

The analysis revealed a positive spatial dependence of consumer spending in the Russian regions, the impact of shocks in neighboring regions on the consumption growth rate in this region. Local Moran indices indicated the presence of local spatial clusters in consumer spending similar to neighbouring territories, regions, Moscow and Moscow region, Ural Federal district, Siberian Federal district, North Caucasus Federal district. All types of models predict beta-convergence of consumption in the long term, which corresponds to the concept of their sustainable development. No visible direct and indirect effects on the share of the population using the Internet and the number of mobile Internet subscribers on the growth of consumption predictably confirms the hypothesis of weak use of household digitalization in achieving sustainable development. Therefore, it is advisable for strategic management institutions to influence the demand and digitalization of households in neighboring regions, to develop online services in the practices of households. The measurement of the beta-convergence of consumption as an indicator of the sustainable development of regions, based on spatial-econometric models, provides *the novelty* of the work.

TOWARDS A CIRCULAR DEVELOPMENT APPROACH TO INTEGRATE LES BIDONVILLES WITHIN CASABLANCA

Oumkaltoum Boudouaya¹, Marcin Dąbrowski²

¹ Department of Urbanism, Faculty of Architecture and the Built Environment, Delft University of Technology, The Netherlands, keltoum.boudouaya@gmail.com; ² Department of Urbanism, Faculty of Architecture and the Built Environment, Delft University of Technology, The Netherlands, M.M.Dabrowski@tudelft.nl.

ABSTRACT

Slums represent a global ethical challenge that affects the well-being of cities. The vast majority of these areas are located in and around cities of the Global South because of the fast urbanisation and globalisation trends that have been met with insufficient employment, infrastructure and housing opportunities.

This paper will explore alternative slum development through the lens of circular economy (CE) principles. While CE has become a major policy goal in Europe and other “Western” contexts, it is hardly used in the developing context, still, circular processes are deeply embedded in the socio-economic realities in cities of the Global South. The main focus of the paper is to evaluate the potential of CE to alleviate poverty and address the challenges of informal settlements. Can CE be applied in cities of the Global South to reduce socio-spatial segregation?

Building on notions of spatial justice and urban survivalism as well as the literature on the dynamics and resilience of informal areas, the paper proposes a contextualised circular economy (CCE) framework for the integration of slums. The framework is then tested empirically on the case of Casablanca, Morocco. Taking existing assets of les bidonvilles as a starting point for development of circular activities, which potentially can lead to the integration of these slums at local and metropolitan scales by providing new economic opportunities as well as links across the socio-spatial dividing lines. The empirical material is collected through a combination of methods: stakeholder interviews, spatial analysis and mapping, site observation of (circular) socio-economic activities and spatial conditions and explorative spatial design. On that basis, the paper identifies the key opportunities and barriers for harnessing local assets for a contextualised circular economy as a means for integration of les bidonvilles into the socio-economic systems of the city. This is done by proposing a circular slum integration design that takes the local scale as a starting point to inform the vision on the city scale.

The paper contributes to the literature by investigating the (often neglected) spatial dimension of circular economy and exploring the potentials for improving the well-being and socio-spatial integration of vulnerable urban groups. It also innovates by demonstrating the potential of relatively low-tech solutions, based on traditional crafts or necessity-driven entrepreneurialism. While this paper offers policy and planning recommendations mainly for cities in developing countries, potential lessons can also be drawn for local circular economy strategies in more developed economies.

Casablanca, Circular Economy, Global South, Productive Identities, Planning.

1. INTRODUCTION

The cities around the Global South tend to suffer from economic and racial segregation, spatial inequality, and entrenched poverty. These deep inequalities are exacerbated in the context of rapid urban expansion and the growing urgency of environmental challenges, while the municipal authorities in those cities struggles and fail to address them.

One can argue that the rising rates of extreme poverty is one of the most critical concerns of Global South countries. Poverty encompasses and generates many other problems such as crime, violence, safety and social exclusion, which all have impacts on space. The spatial aspect of destitute poverty is partly manifested in the existence and fast expansion of slums. At the same time, climate change impacts the poor and vulnerable areas the hardest. The responses to those challenges seldom take into consideration the context and the specific socio-spatial and economic challenges of slums. With the advent of sustainability transitions of cities, insufficient attention has been paid to circular economy (CE) pathways in developing countries and, in particular, to the potentials and opportunities that circular transitions can bring for the urban poor dwelling in slums, despite considerable innovation and policy progress happening in this field across the globe (Pretson et al., 2019). CE has a potential to generate positive socio-spatial outcomes once social and institutional dimensions are treated intrinsically with the transition (Moreau et al., 2017).

CE has several definitions that mostly revolve around closing of material cycles and increasing resource efficiency (Ayres et al. 1996; Von Weizsacker et al. 1998). The most cited definition is that of the Ellen McArthur Foundation (EMF):

A circular economy is restorative and regenerative by design, and aims to keep products, components, and materials at their highest utility and value at all times. The concept is a continuous positive development cycle that preserves and enhances natural capital, optimises resource yields, and minimises system risks by managing finite stocks and renewable flows. It works effectively at every scale. (EMF, 2015)

Casablanca, a city that has always been a laboratory of urban experiments (Cohen and Eleb, 2002), will be taken in this paper as a study case to explore potentialities of CE in mitigating socio-spatial and economic challenges of its slums. Generally, most cities have their own local terms for slums, most of which are descriptive of the look of the degraded settlements or of the way that they were formed. In the case of Morocco and French colonised countries in Africa, the French term *Bidonvilles* - which means 'oilcan cities' - describes the way they were built, by using cans from nearby landfills which represents the method used by rural migrants consisting of using local materials to build shelters. This nomination by itself represents one of the fundamentals of the circular economy concepts: building with local, often discarded, materials.

Since the emergence of the first bidonvilles in Casablanca in the 1920's, these areas are seen by the authorities as territories that need to be eradicated. They represent the extreme life conditions of a vulnerable population in dwellings that were built without plans or building permits and often do not have access to drinking water and/or sewage, electricity and experience unsanitary conditions. Therefore, authorities pushed the bidonvilles dwellers out of the city by providing "formal" social housing in the outskirts. The implications of these processes are harmful and do not remedy the poverty symptoms (which is the root cause). On the contrary, it makes it even worse since this population survives on informal practices that occur within the city fabric.

This reveals the urgency of questioning the existing development methods and thinking about an alternative model where the vulnerable inhabitants are part of the transformation processes and the city goals to achieve resilient economic growth on a global scale. This paper will explore the potential of CE to provide opportunities for integration of slums within the 'formal' city and to reduce socio-spatial segregation in cities of the Global South. The paper also seeks to identify the barriers for seizing those potentials. This exploration will be carried out on the case of Casablanca, a city which could be considered a typical example of a rapidly expanding city of the Global South with deepening inequality and growing tensions around slums.

The remainder of the paper is organised as follows. The next section will discuss the failures of slum clearance policies to date and posit that informal survivalism and entrepreneurialism which prevail in these areas could be seen as fertile ground for experimentation with CE, used as a means for socio-spatial integration of slums. Then, methodology and the features of the case study will be outlined. After this, the empirical section will overview the existing circular practices in selected slums of Casablanca and built on those to shed light on the potential of CE to be used as vector of socio-spatial integration of slums within Casablanca. The article closes with a discussion and conclusion, summarising the key insights and contribution to the literature and outlining the implications for planning and policy as well as areas for future research.

2. SLUM DEVELOPMENT AND CIRCULAR ECONOMY

2.1 The failure of slum clearance policies

The problem of slums has been experienced - at some point of time - by almost all the major cities in the developing countries. As mentioned in the introduction, slums can be defined as the physical and spatial manifestation of urban poverty and intra-city inequality. Slums and urban poverty are not only indications of a population explosion, demographic change, and the forces of globalisation that bring people toward cities, but also the result of a failure of housing policies, laws and delivery systems, as well as national and urban policies (UN-Habitat 2003).

Resettlement is one of the most commonly used approaches in dealing with slums. It consists of moving the slum inhabitants in public housing provided by the state. However, this approach revealed many limitations with severe consequences (Amado et al., 2016).

In this section, several arguments against resettlement processes that were privileged and used the most will be laid out. While trying to argue why resettlement processes failed several times in different places and not only in Morocco are the question of financial affordability, the way of living, social relations and access to income generating activities (Bolay et al., 2016).

Argument 1: Displacing Poverty does not solve it... it can even worsen it!

The relocation of residents, often far from their original residential location, decreases access to income that they were able to earn within the city and their neighborhoods. Thus, relocation tends to destroy a very fragile but very real economic fabric (Bolay et al., 2016, p: 231).

Argument 2: Resettlement causes Urban Sprawl.

Resettlement of inner-city communities served as an instrument to reinforce the development of 'new towns' or 'satellite towns'. In the case of Casablanca, 600ha of public space have been made available for mobilisation and planning at the expense of fertile valuable agricultural land. Still, this land supply is not enough to relocate all slum dwellers. This represents a huge bottleneck for resettlement in Casablanca. And not only the availability of land but also the construction of flats as well as the 'new town' concepts with all the required new infrastructure could no longer be financed by the governments and did not meet with the social and economic problems the urban poor faced.

Argument 3: Resettlement kills the strong community bonds.

The move into apartments weakens people's sense of community and solidarity networks that are major driver of collective action in bidonvilles (cf. Zaki 2010; Iraki 2006; Essahel 2015).

And women suffer the most. In the new sites, women have more difficulty integrating and end up staying at home more often (Toutain and Rachmuhl 2014, 34-35).

Argument 4: Resettlement is expensive for both parties.

Physical intervention in a space that has already developed is obviously less complicated, as land holdings for the creation of basic infrastructure like water and sanitation systems, or the paving of certain main streets, are clear, do not require the displacement of residents and can begin quickly.

Argument 5: Resettlement is refused by the people who are supposed to benefit from it.

More often than not, communities have not been involved in the primary choices pertaining to their own development, but rather have been asked to adhere to a program that had, to a large extent, been previously defined.

There are indeed people who want to move out and get out of the misery, and that is their right. But their right is also to know the consequences of resettlement and give them enough instructions and a holistic picture in order for them to be able to make an informed decision.

2.2 Informal survivalism and entrepreneurialism as an opportunity for Contextualised Circular Economy

So much has been said about the challenges and problems of the slums and so little about their potentials. In these extreme daily life conditions, the slum dwellers developed innovative abilities in order to be able to survive and make a living. This fosters creativity and gives them a very important entrepreneurial character that needs to be highlighted. As Mike Davis stated in his famous Planet of Slums that 'informal survivalism' is the new primary mode of livelihood in a majority of Third World cities' (2004, p:24).

Although, it is true that these conditions could lead to other negative turn of events (violence, ecological vulnerability, terrorism, safety issues...), media and governments rarely show the positive side depicted above, which consequently, limits the potential and proliferation of these ideas, knowledge and underutilised intelligence.

Obviously, no city can afford to neglect the capital of 30 - 40% of its population. Especially if this population possesses special adaptive capacities that make it resilient by character in very vulnerable contexts. An example of this impressive capacity is the Dharavi slum in Mumbai. This slum represents a true economic success story that grew from a small settlement in the marshlands to become a million dollar economy model providing food to Mumbai and exporting goods worldwide (Roy 2015).

Another important incentive to look at this entrepreneurial character is the necessity to focus first on upgrading the slum dweller rather than the slum itself. Gilbert (2007) argues that in poor cities, housing improvements can be counterproductive as "the priorities of the desperately poor almost always lie beyond shelter".

"Above all else, the poor need to eat and to drink clean water. Overcrowding is clearly undesirable but hunger is worse!" (Gilbert, 2007, p: 709)

Therefore, the integration process should start by looking at these potentialities in specific identities and expertise by observing and analysing the 'survival' behaviour rather than focusing on getting rid of these areas. Then, by looking at structuring systems you can inform the space. In other words, the most problematic flows such as food, water, and waste can be catalysts of change, present economic opportunities, and can upgrade the quality of the living environment. Furthermore, in order for this to happen, closer attention should be paid to governance issues by investigating how 'bottom-up' approaches should be presented and integrated with the 'top-down' approaches in a balanced model.

Survivalism presents opportunities for CE, because it is based on reuse of waste materials out of necessity. By the same token, CE as a new paradigm of sustainability (Geissdoerfer, 2017) and sustainable urban development, offers opportunities of integration of slums within the 'formal' city, by making them integral element of the circular economy transitions / strategies. Therefore, the integration process should start by looking at these potentialities in specific identities and expertise by observing and analysing the 'survival' behaviour rather than focusing on getting rid of these areas.

To achieve this we propose a Contextualised Circular Economy (CCE) concept that follows the CE principles while taking under consideration the sensitive character of the targeted population, the weak institution structure of developing countries and the limited resources. CCE investigating existing economic practices (Productive Identities), connects them to the urgent social issues in order to improve the spatial conditions.

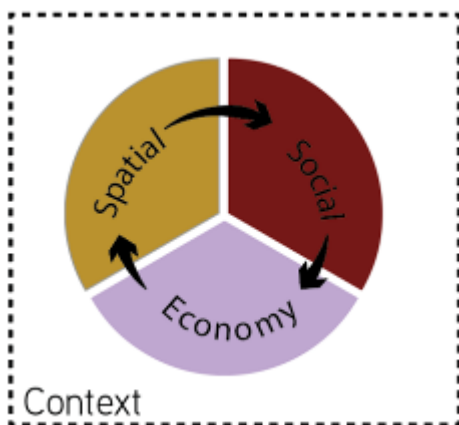

Figure 1: Contextualised Circular Economy Diagramme

3. METHODOLOGY AND CASE STUDY

3.1 Introduce Casablanca as a case study

The city of Casablanca is located in the north-western part of Morocco on the west coast of the Atlantic Ocean. This rapidly growing North African port city can also be classified as an “emerging megacity”. The Grand Casablanca metropolitan area is the most densely populated area of Morocco. It is a crossroads city for the land-based transport network and a convergence point for trade and the national and international flow of goods, which makes it the driving engine of the Moroccan economy. Its power radiates across the entire country (Gisek et al. 2015).

Within 100 years, Casablanca has grown from a small coastal settlement of 20,000 inhabitants to a metropolis of more than 4.6 million. Casablanca can be qualified as a fragmented and a segregated city. The city conveys a strong image of poorly articulated fragments of urban mosaics. Socially speaking, Casablanca is a city under tension, with serious violence linked to the increasing inequalities and poverty that is becoming more and more visible. Its metropolitan character is the frame of socio-spatial transformations that represents daily life challenges for its inhabitants - urban sprawl, high density, increasing recourse to activities of the street economy, persistence of slums, impoverishment of public facilities, dilapidated housing, insufficient transport network. This raises the question of the experience of socio-spatial differences linked to the size of the differences between standards of living (Anglade, 2016).

The forces that contribute to socio-spatial segregation are many and vary from place to place. It is considered to be a major social pathology that often results in unequal living conditions and unequal access to services and labour markets. In Casablanca, segregation dates back to the beginning of the colonial era: the city was colonised by France from 1912 to 1956. The French refused to cohabit with locals inside the inner city centre -the Medina- while they also refused to let Moroccans live in the newly built area. However, they still needed labour forces for the growing industrial areas.

The “bidonvilles” are settlements built by their inhabitants out of canisters (French: bidon) and arose on the outskirts of North African cities from the 1930s onwards. They were perceived as overcrowded, putrid and unsafe. In 1931, an attempt to ban their construction failed (Cohen and Eleb, 2002, p. 222).

Morocco’s bidonvilles were partly, a product of colonisation. Hygiene concerns and the fear of potential uprisings against the colonial hegemony made the French implement strict plans of spatial ethnic segregation by keeping the medinas untouched and building new European cities next to them. (Beier, 2019, p:58)

The growth and expansion of the bidonvilles was a result of a rural-to-urban migration. By the end of the French protectorate in 1956, around 75% of Casablanca’s population had immigrated from the countryside (Puschmann, 2011). Chasing prosperity in the newly global city and the illusion of escaping poverty in the countryside, pushed many Moroccans - especially from the southern part of the country - to leave their rural and familial lives. In this process, they lost contact with their tribes and villages and the communal support, just to replace it with feelings of isolation, disconnections and overcrowding. The rural migrants, becoming now bidonvilles dwellers, found it hard to integrate within the city since there were neither provisions in housing nor public facilities (Cohen and Eleb, 2002, p:325).

And even though the emergence of most of the existing bidonvilles is closely connected to industrialisation, occupations amongst residents are diverse and spread all over the city: varying from mobile street vendors in the bidonville itself or in the city to teachers, employed professionals in Maarif (one of the wealthier inner-city districts of Casablanca) and business owners who value the bidonvilles as a safe place within the city without exorbitant rents (Beier, 2019).

If we fast forward in time and we go to 2003, one bidonville, Sidi Moumen, was home to perpetrators of bomb attacks in Casablanca in 2003. These attacks instilled an even greater sense of urgency into the commitment to eradicate slums. In response to these bombings, the most recent strategy surged. In 2004, the Villes Sans Bidonvilles (VSB) programme (Cities without slums), had been announced by order of the King. However, ignoring urban blight until it became a security threat had dire consequences for the states' ability to address its “slum problem.” (Zemni and Bogaerts 2011)

The objective of the “Villes Sans Bidonvilles” programme is to provide decent accommodation to the households living in urban slums across Morocco by 2010. Evaluations of previous slum upgrading programmes provided an overview of learnt lessons and suggestions, which gave further motivation for new plans for substandard housing. The basic principles of the Government’s new bidonvilles upgrading strategy were as follows:

- a. the integration of single operations at city-wide level
- b. contractual engagements of private and public actors in the slum eradication efforts
- c. increased provision of social housing by private developers
- d. the involvement of the slum population through a process of social support and participation. (Ministry of Land Use and Planning, 2019).

3.2 Research Methods

Data for this research was collected over a period of several months in 2019-2020. The research design is based on a critical case study approach. Critical cases are the ‘most likely’ or the ‘least likely’ cases that can help clearly refute or confirm research propositions or hypotheses (Flyvbjerg, 2006). In this study, Casablanca can be considered as a ‘most likely’ critical case, being a typical example of rapidly expanding large city located in a country of the Global South, with dramatic socio-spatial inequalities and presence of slum areas, which are the object of ‘slum clearance’ policies to make way for more ‘desirable’ and ‘formal’ urban development. The research can also be considered an exploratory case study (Yin, 2014), typically used to answer the ‘what’ and ‘how’ questions and explore social under-researched social phenomena in their context, without a predetermined outcome.

The data for the study was collected through a combination of qualitative research methods. First, planning and policy documents were collected and analysed to explore the approaches and practices to slums, urban development and circular economy, in particular. Second, to triangulate the insights from document analysis, semi-structured interviews with local planning institutions, civic and private sectors actors dealing with CE and slum integration, academic experts were conducted. Third, to gain insight into the social and spatial conditions of the slum dwellers and identify circular economy practices conducted by them, site visits were conducted in several *bidonvilles* located in the core of Casablanca, combining photographic evidence collection, observation of public space use, and street interviews with the inhabitants. Fourth, multi-scalar spatial analysis was conducted on the basis of Google Earth maps and satellite photography. Validity of findings is ensured by a combination of those various methods, allowing for triangulation of results and cross-checking insights from each of them, allowing to paint a nuanced and balanced picture of the conditions on the ground and the stakeholders' perspectives on the slums question and circular economy's potentials for socio-spatial integration of slums and their dwellers within the city.

The limitations that we had to face were difficult access to official spatial information and to the stakeholders in the slums. The latter was due in particular to mistrust of slum dwellers towards an 'outsider' and safety concerns during site visits by a female researcher. These limitations were mitigated by collaborating with local inhabitants (to ensure access to slums and safety during the site visits) and local non-governmental organisations. To avoid biased perspective a diverse set of stakeholders was interviewed, representing different points of view and interests. To overcome difficulty in access to spatial data tracing and manual mapping was done on the basis of satellite imagery and site photographs.

4. CIRCULAR ECONOMY AND CASABLANCA

4.1 Catalogue of existing circular processes

Inspired by the appellations; "Joutiya" for local markets, which is a Moroccan slang term coming from French: *Jetez-là* meaning throw it away or the term *bidonvilles* itself, one cannot help but wonder about the essence behind these nominations.

Re-use of materials is a concept part of the culture and consumption trends are pretty low due to the poverty state. Moreover, looking at closing the loops in the main flows of a city is the big focus of the Circular Economy. Lastly, the imperativeness of thinking of new sustainable business models in order to create new job opportunities is part of the Circular Economy agenda. These three elements were also identified as potentials that can be guided by circular economy and better governance.

The main hypothesis is that Circular Economy can be a proposal for an alternative framework that covers the spatial, social, economic and ecological aspects of the problem in question. The research conducted by Pretson, Lehne and Wellesley (2019) states that Circular Economy offers a promising alternative strategy for industrial development and job creation by providing new opportunities for economic diversification and value creation.

As an example, *Derb Ghallef* bidonville in the centre of Casablanca. It is a notorious informal market that is visited by at least half of the country's population annually. It is portrayed as a hub of creative intelligence and vital IT knowledge. It also has the notion of *Ghallel Valley* attributed to it (Mörtenböck and Mooshammer, 2015). It is located within the city centre and connected to the tram network. It has the identity and reputation of fixing and repairing electronics. The success of this bidonville is mainly related to the repair, reuse and recycle behaviours in relation to the e-waste. And parallelly it makes it a safer and more enjoyable destination compared to the other bidonvilles.

Another example of already existing circular activities with high social impact is *Ressour'In* association; a social enterprise for integration and recovery of plastic and paper waste. From the conducted fieldwork

Three workshops were developed to allow the integration of people having hard time to find employment, and are in a precarious situation. They contribute in the creation and manufacturing of designer products, from creators, from collected waste: - creation of plastic pouches and handbags, woven paper packaging - manufacture of furniture and lighting in recycled plastic - manufacture of recycled paper. Ressourc'In was founded by the NGO Ikram for social insertion of the most vulnerable.

This demonstrates the possibilities and potentials of social integration and waste valorisation. The brand is called Koun, which literally translates to "Be" or "Exist".

A final example is waste workers. Garbage can quickly suffocate the million inhabitants of Casablanca. However, small hands are making sure that large quantities of waste do not pile up on landfills by giving them new life. Despite the amount of work, they remain excluded from society because of the informal aspect of their work, and where they come from. Waste workers live on the margins of legal urban areas, in slums and makeshift houses, which are regularly demolished or threatened by real estate and urban projects. While working in the streets, they are often victims of violence either committed by the authorities or other inhabitants (Florin & Azaitraoui, 2017). The business of recycling factories and export wholesalers depends heavily on the activities of street collectors. Thus, working on improving the livelihoods of this vulnerable population while leveraging the recycling sector, present a path to explore.

In this section, we presented examples of three existing circular, necessity driven and bottom up circular practices that provide not only livelihoods and socio-economic integration opportunities for the bidonvilles dwellers, but also they provide services for the dwellers of the more affluent parts of the city. Thus, they demonstrate the potential for integration of slums in that sense. These potentials are further explored in the next section where we will investigate a bit further the social and spatial dimensions and potentialities on the map.

4.2 Social and spatial potential

Activities and flows shape the cities we live in. They shaped the current spatial characteristics of the bidonvilles and made them what they are. And what makes them special and different in that sense, is that the people who built these spaces did not look at what needs to be built first and then what kind of materials are required; it is the other way around. What materials are around and what can be done with that.

Improving the spatial conditions of these areas should also follow the same path, and bring out what is existing around to connect, attract and create. Connecting to the existing opportunities (formal or informal), attracting by phasing out gradually the flows or activities negatively impacting the general conditions and creating new ones that fit the agenda and help the development process.

The elaboration of alternative slum development approaches requires a shift in the **common negative perception of slums**. Thus, an important element to mention is the destigmatisation_processes that are essential for the social integration throughout the scales.

Figure 7: Zoom in. Map by Author

Designing for plinth activation, small urban scale interventions in opportunistic locations can play a big role in how the place is perceived.

Bringing out to the formal city all of these informal activities in attractive settings is also a step towards destigmatisation. However, it is important that this process should be consolidated by the government. In other words, Villes Sans Bidonvilles slogans should be banned and replaced with more accepting and empowering messages. A first step would be to map these areas and not assume that they are already gone in the official documents.

5. CONCLUSION AND DISCUSSION

This study set out to explore the potential of contextualised circular economy practices to drive the process of spatial, social and economic integration of slums in Casablanca. This potential was clearly identified, building on the existing, necessity-driven and long-established circular practices, involving recycling and upcycling of waste products and materials or repair services offered to people not only within the slums, but also the city at large. We also showed how circular economy practices and spaces designated for them could play a role of connectors between the formal and informal areas of the city, breaking down the physical barriers between them and reducing the social stigma associated with les bidonvilles by creating space for encounter and economic activities and making the socio-economic value of slums more evident to the outsiders.

An important caveat is that there are many social and institutional barriers for unlocking that potential of circular economy to promote slum integration. These relate mainly to focus of the city authorities and planners on unjust urban development involving 'modernisation' through clearance of slums and displacement of their dwellers to the periphery of the city to make space for dwellings for high income populations and the service sector. In this approach, based on deeply entrenched social stigma associated with slum dwellers, there is hardly any room for experimentation, acknowledgement of the value of the activities taking place in and the socio-economic potential of slums, deemed undesirable and unsightly.

To overcome that stigma and overcome the path dependency concerning the approach to slums among the planning professionals and the general public, one needs to promote the awareness of the negative social consequences of slum clearance policies and of the circular economy potentials for valorising the existing circular practices in slums, providing arguments for integration of existing slums as important providers of circular products and services within, as opposed to outside, of the core city. Showcasing the existing 'unplanned' success stories of such integration, as that of Derb Ghallef, and experimentation with spatial and social interventions to promote and valorise similar kinds of stigma-breaking integration through circular processes in slum areas with diverse contextual potentials for creating links across the formal-informal boundary using circular principles are needed to change the narrative on slums in the wake of the new paradigm for urban sustainability based on circular economy. Beyond this, there are also important barriers for

implementing the Contextualised Circular Economy approach in Casablanca related to the lack of data of waste flows, which could make integration strategies for slums based on circular processes more precise and evidence-based.

This study contributes to the literature in at least three ways. Firstly, it offers a fresh perspective on the potential of CE could that could be harnessed for slum integration and reducing inequalities in the cities of the Global South, by capitalising on context-specific socio-spatial features and 'survivalist' economic practices. By the same token, these practices are commonplace in slums and deprived urban areas across the world, but their potential to support place-based circular transitions strategies in cities is overlooked. Secondly, the paper responds to the call to deepen our understanding of the neglected socio-spatial factors in transitions towards CE (see Moreau et al., 2017, Williams, 2019), by bringing new empirical evidence on how the spatial, socio-cultural and economic contextual features could be mobilised to support CE strategies going beyond spatially blind industrial symbiosis approach to CE. Thirdly, we demonstrate how a Contextualised Circular Economy approach could work in a particular context of a highly polarised city of the Global South. In this, we propose to build on place-specific potentials, linked to endogenous everyday practices, and harnessing CE to address local socio-spatial challenges rather than following the good practices in CE emergin from the leading cities of the Global North, which tend to focus on designerly or high-tech solutions to use waste as a resource and reduce material consumption.

The case of Casablanca, discussed in this paper, offers lessons for other cities in Global South that circular economy strategies could underpin urban development and slum integration policies by building on the existing circular processes and services carried out by the slum dwellers, thus changing the negative narrative on slums and their inhabitants. In a nutshell, the case of Casablanca presented here shows the potentials of slums as urban circular economy hubs. Thus, redevelopment of slums oriented towards valorisation of circular processes present opportunities not only for the slum dwellers but for the sustainable development of the city as a whole, offering circular services for its inhabitants and reducing social tensions, stigma of the bidonvilles and, potentially, also the resulting violence. To achieve this we need education and awareness-building among planners, developers, and industrial actors to overcome the negative bias towards the informal settlements and make them realise that there are 'hidden' potentials of slums to drive urban sustainability transitions and experiment with circular economy. In other words, this will require a change of perceptions of slums from a socio-spatial phenomenon to eradicate, to a place where sustainability can be catalysed.
