The limitation of this study was that it merely took a 'snapshot' of the situation in Casablanca and identified potentials for change, while we need to observe and evaluate how those potentials can be seized and deployed as part of spatial planning process and slum integration policy over a longer period of time. Future research should conduct more exploratory case studies to identify further potentials and examples of circular practices and services in slums to collect a critical mass of knowledge on valorising 'informal survivalism' as part of circular economy transitions in the cities of the Global South. We also need more interdisciplinary research to integrate sociological knowledge and identify means to overcome the mistrust and stigma which are the main barriers for using circular economy as a vector of slum integration and for changing the approach to slums in the planning practice.

GEOECONOMICS OF TRANSFORMATION AND ECONOMIC BORDERING OF CENTRAL AND EASTERN EUROPE

[Zoltán Gál](#)^{1,2}, [Szilárd Rácz](#)¹

¹Centre for Economic and Regional Studies, Hungary. ²University of Pécs, Hungary

ABSTRACT

This contribution relates the process of economic bordering to the systemic and geo-economic features of Central Europe's post-socialist integration process. The major pattern that emerges is one of a high dependency on FDI, foreign multinational firms, European Union funds and exports to Western Europe. An innovative aspect of this contribution is the argument that long-term problems of capital accumulation in the context of centre-periphery dependency (and world systemic models) reflect bordering processes that are both structural as well as political in nature. The economic transition of Central Europe, and Hungary in particular, was fuelled by neoliberal ideologies and political agendas of "East-West convergence" that involved marketization and privatization. Both of these created a moral, legal and structural environment that rapidly cemented new modes of dependent integration into the EU and the global division of labour. At the same time, the most important historical dependencies of the CEE region, such as financial, technological and market ones, have remained constant (Gál and Schmidt 2017). This is complemented with the large energy dependency of CEECs on Russia. This not only further strengthens the external vulnerability of the region, but also makes re-interpretable the geopolitical and geo-economic features of Central Europe as a 'buffer zone' situated between German and Russian spheres of interest.

We will first examine the geo-economic features of the externally managed and financed integration of post-socialist transition countries of CEE into the global economy and the European Union. We will also focus on the impacts of FDI and European Union structural funds on growth, gross fixed capital accumulation, per capita GNI and export in selected Central European countries. Preliminary results do not indicate a strong correlation between convergence and FDI, rather domestic savings and higher incomes are the most important factors. As a result, domestic policies based on wage competition and that give little support to small and medium-sized enterprises exacerbate core-periphery asymmetries and support an economic buffer zone narrative. In conclusion, we suggest that such economic bordering processes within the EU could have long-term consequences for political and economic cohesion in the EU as a whole.

DIGITAL INNOVATION HUBS AS NEW PARADIGM IN EUROPE FOR DIGITAL ECOSYSTEM DEVELOPMENT IN SMART CITIES

Tamas Gyulai

Doctoral School of Regional and Business Administration Sciences, Széchenyi István University, Győr, Hungary, Hungary

ABSTRACT

Regional development in European Union have been connected to digital transition and the strict restrictions due to COVID made it even more significant. Consequently, the re-starting of a "new normal" operation of cities and regions require new methods for creation of more resilient communities and regional ecosystems alike. The new European network of Digital Innovation Hubs shall therefore provide a new layer of regional actors that can help primarily SMEs but also provide services to the public sector which shall open up new ways for cooperation between regions and cities. The city of Szombathely in Hungary is a good example of smart city development with the support of the Intelligent Cities Challenge that brings together more than 100 cities in Europe with the objective to shape together the cities of the future in Europe. The Digital Innovation Hub in Szombathely is called am-LAB which was selected as the winner of the European Digital Innovation Hub Challenge in 2021. Consequently, the ecosystem in Szombathely is a good example of coordinated development initiatives for green and digital transition between the administration of the city and the regional stakeholders.

The first part of the presentation describes the key factors of success in Szombathely and the second part of the presentation compares it to similar cities in Central Europe with the objective to draw conclusions and make some recommendations for city planning.

Artificial intelligence shall be described as one of the key elements that shall guide the strategic planning of the sustainable and resilient cities therefore the human factor shall also be analysed beyond the technological aspects. The lessons drawn from the analysis can be used for practical implementation of smart city policies especially in cross-border zones of economic development activities.

Research actions with future scope for human-machine interaction that can complement the already realised work of the international team of researchers shall be presented in the final part of the presentation.

ONSLAUGHT OF URBANIZATION AND ANTHROPOGENIC ACTIVITIES ON KAMWARI RIVER: DYING RIVERS IN THE GLOBAL SOUTH

[Oneza Farid](#)

Aqsa Women's Degree College, India

ABSTRACT

The Global South is undergoing an urban revolution. Not only major cities are experiencing significant rise in population, but thousands of new towns are born every year. This city making process is expanding the built-up area and severely damaging the natural environment, specifically water bodies. The ponds, lakes and other wetlands, on which the communities were traditionally dependent for freshwater and food supply, are being reclaimed for settlement building. This is mainly due to unchecked human induced activities happening in the name of development at the banks of rivers. Study of Rivers has become very vital as unpredicted unexpected anthropogenic activities occurring habitually. The present study is basically focused on impact of population leading to disappearance of the water bodies with reference to religious, cultural, municipal activities and present status and future strategy for conservation of Kamwari River in Bhiwandi. Bhiwandi being a power loom Industry, how these Power loom and dyeing industries in the vicinity have been discharging chemical effluents into the river resulting in its deterioration. The direct release of untreated effluents from these sources along with untreated sewage water in the river has worsened the situation. The present study is mostly based on primary survey and interviews conducted in the vicinity. The study intends to understand the current pollution status of Kamwari River and other water bodies. The rivers which used to be lifelines for lakes, ponds, wetlands and used to wash out the pollutants with their flows have become special victims of this urbanization process. The rivers are not only being destroyed through land filling for expanding settlements and other infrastructure but also town garbage (both solid and liquid wastes) are being discharged indiscriminately into the same. Rivers initially nurture the cities and towns with their water, but now the same cities and towns are eating up and destroying the water bodies. This paper examines the interrelationship between urbanization disappearing rivers, water shortage and water environment changes in cities in the global South. The case of Kamwari River in Bhiwandi for demonstration of argument it was concluded that the sewage textile industries discharge causes pollution to the water bodies and serious problem for living being and ecological environment. Therefore, the urbanization should be planned and the effluent water to be discharged by these industries must be adequately treated before discharge.

SUSTAINABLE URBAN MOBILITY INFRASTRUCTURE IN CITIES OF THE GLOBAL SOUTH: EVIDENCE FROM MUMBAI METROPOLITAN REGION

Sanjukta Sattar

University of Mumbai, India

ABSTRACT

The Global South is undergoing an urban revolution in terms amassing people in cities and also massive building of cities (Datta and Shaban 2016). However, this urban revolution is characterized by what Albert O Hirschman (1958: 89) called 'disorderly' and 'compulsive' development as this amassing of the population in cities is not preceded by the infrastructure development, rather its following of the demand in gradual and piecemeal way, be it housing, water supply, educational or health infrastructure. Among these, the congestion and unplanned development of the cities, accompanied by the lack of resource allocation and sustainable policies of urbanization, have created enormous issues to urban transport infrastructure and mobility. Indian cities are typical example of this symptom and can be called as archetypes of this problem.

The present paper examines the urban mobility policies, modal transportation and development in Mumbai Metropolitan Region (MMR). The paper demonstrates that Mumbai, the financial capital of India and the core of the MMR, could not keep pace with the infrastructural requirements for the urban mobility and in recent years it has become more exclusionary and 'disorderly'. The paper is based on review of the policy for urban mobility in Mumbai Metropolitan Region, specifically the Mumbai Municipal Corporation, and data on the commuters and means of transportations from various departments of the Government. The factors determining the urban mobility will be identified from the existing literature on urban mobility which will be used to select indicators like "passenger-carrying capacity, public-private carrying capacity ratio, vehicle density by area, vehicle density by population, energy intensity of travel"(Reddy & Balachandra 2011) to measure the pattern of urban mobility. Interview schedule will be used to collect data about the users of different modes of transport and their opinion about the available transport facilities. Samples will be drawn from different age groups and gender as well as from different occupational background. Also, in-depth interviews of the people using various mode of transportation like suburban railways, metro rails, city buses, autorickshaws, motorbikes, cycles, and pedestrians in the MMR will be conducted. The mobility of the population from one area to different area will be assessed from the information collected from local transport authorities like BEST, Mumbai Suburban Railways, Autorickshaws and taxi organisation. Data will be also collected from pollution monitoring bodies. The data obtained will be analysed using suitable statistical techniques like Cluster Analysis and Principal Components and Factor Analysis. The paper demonstrates the 'disorderly' nature of development of urban mobility infrastructure in the city. The disorderly here means delayed supply following the demand. The paper contributes to the existing literature on urban mobility in the Global South and demonstrates that sustainable urbanization in the Global South is seriously challenged by appropriate development of urban mobility infrastructure.

EDUCATIONAL INTUITIONS IN BRIDGING THE SOCIO-SPATIAL EXCLUSIONS AND PROMOTING SOCIAL MOBILITIES: A STUDY OF MUSLIM AND DALITS WOMEN IN MUMBAI

Zinat Aboli

Mithibai College, University of Mumbai, India

ABSTRACT

The pre-capitalist social institutions play major role in socio-spatial and inclusions in Global South cities (Shaban and Zinat 2021). The caste, religion and ethnicity shape the individual and families' voluntary or involuntary residential choices and options, and, as such, produce enormous segmentations and exclusions. Marginality in space also produces the economic marginality of communities, thus producing the overlaps and superimpositions of both the social and economic (class) marginalities. The socio-spatial segmentations of urban spaces inhibit the possibilities of social mobilization and/or formation of secondary alliances among disparate social and economic groups. However, the educational institutions, specifically the undergraduate colleges have become sites of interactions of youth of these disparate groups and create affections, bonds, networks, and mutual learnings furthering educational and employment/occupational mobilities, specifically, among youths of marginalised communities. The colleges are found to be more important site in this process than schools and universities offering post graduate degrees, because (a) they are situated at intermediate or meso level in spatial scale which cut across the geographies of caste, religions, ethnicity, and class, and (b) the society is reaching to such level of development where families aspire to educate their youth at least till graduate level. As such the colleges are becoming interesting intersection and assemblage sites for the youths. The present paper examines this process in Mumbai. The study is based on the structured interview of more than 2000 college going women from different communities and income groups, and case studies of 15 women from Muslims and Dalit communities, the socio-spatially excluded groups in Mumbai.

WHAT'S NEW FOR UNDERSTANDING AND MANAGING PEOPLE'S USE OF THE BUILT ENVIRONMENT?

Alice Pomè, Silvia Leoncini, Chiara Tagliaro

Politecnico di Milano, Italy

ABSTRACT

SCOPE:

Cities consume over two-thirds of the world's energy and produce 70% of global CO₂ emissions, mainly due to construction activities and buildings' functioning. Urbanization is one of the great challenges of this century, therefore the development of sustainable strategies to manage (and reduce) energy and natural resources demand in buildings is urgent. The way people use buildings plays a central role. Building performances are impacted by how people utilize spaces, maintain them, and adapt them to their changing needs. Today ranges of technological tools make it relatively easy to understand how users' behaviours occur into buildings and cities, and to inform people's interactions with the built environment. However, only few studies investigate users' behaviours in buildings, and consider them in environmental models. Thus, it is interesting to understand how sensors and digital tools can help to reduce buildings' impact by informing, on one hand, the end-users and, on the other, developers, building owners, and facility managers. With the aim to fill this gap, the objectives of this study are to: a) Map available tools, methods and data, including the scale of their application; b) Detect the extent to which tools, methods, and data integrate with one another, and evaluate new information that can be obtained by matching them; and c) Figure out the involved actors: who plays a role in data collection and analysis? Who produces data?

METHODS:

Through a literature review, the paper compares existing tools and methods for data gathering on space utilization and user behaviour, in particular: a) The most diffused technological/digital tools for space utilization analysis; and b) The most diffused approaches/methods for energy and resource consumption analysis (i.e. Life Cycle Assessment, Ecological Footprint, and Post Occupancy Evaluation). These are analysed by: the data they rely on, their scale-up potential (from different types of buildings, to cities and territories), the actors involved in their application, and the beneficiary of the information produced.

RESULTS AND PROVISIONAL CONCLUSIONS:

Results will show the extent to which different data and methods can be matched to obtain novel insights. It will be discussed how this match can advance extant models to manage users' behaviours toward reducing energy consumption. The article drafts possible protocols of data collection and analysis that can be applied at different scales, and that will involve different stakeholders. This study has the potential to encourage the digitalization of built environment products and processes, which can support real estate management strategies and responsible users' behaviours. Potentially, these could be expanded to the urban scale, through urban planning and crowd management models.

IDENTIKIT OF PROPTECH PLAYERS FROM ITALY TO FINLAND: UNDERSTANDING THE REAL ESTATE EVOLUTION

Alessandra Migliore¹, Chiara Tagliaro¹, Vitalija Danivska², Silvia Leoncini¹, Alice Pomè¹

¹Politecnico di Milano, Italy. ²Aalto University, Finland

ABSTRACT

In the past five to ten years the real estate sector has been facing the beginning of an evolution, mainly due to the introduction of digital technologies. These are embedded into a variety of products, are modifying traditional processes, and are shaping new cultural approaches to managing buildings and the built environment. This phenomenon is commonly defined as 'PropTech', because it merges property and technology. However, this term still lacks a proper definition. It includes a wide range of companies, from start-ups to major real estate players. It embraces a vast array of building types, from residential to commercial and industrial. Furthermore, it comprehends a broad selection of industries, from legal to construction. Due to the newness of PropTech, theoretical studies are still scant. Especially, a quantification and qualification of the different companies that work in the PropTech sector does not exist yet. Many PropTech maps are available for different countries, but the criteria to include or exclude companies from these maps remain fuzzy and unclear. Methods for PropTech scouting are mainly based on a roll-your-snowball approach. A better understanding of the nature and main activities of these companies could support: (i) more precise definition of PropTech; (ii) analysis of trends; and (iii) development of policies and measures to support this new-born sector. The goal of this paper is to provide an exploratory study on PropTech players. This will compare players in two different European countries: Italy and Finland. Extensive lists of Italian and Finnish PropTech companies will be searched on multiple databases (e.g. UNISSUU, Orbis, CBInsights), in order to build a comprehensive picture of the sector in the two countries. Data elaboration will attempt to explain the differences in categorization/terminology between the countries. This can enable to identify inclusion and exclusion criteria in existing PropTech maps. The Italian and Finnish PropTech players will be compared, to shed light on country-specifics including business characteristics and ecosystems around PropTech. In conclusion, the paper proposes an identikit of PropTech players that can support the elaboration of a taxonomy and proper definition of this promising sector.

LOCATION ANALYSIS: NEW PERSPECTIVES FOR REAL ESTATE PLAYERS

Chiara Tagliaro, Gianandrea Ciaramella

Politecnico di Milano, Italy

ABSTRACT

The real estate market relies on traditional business models that are driven by building types and functions (e.g. housing, retail, offices, etc.). Social and economic changes have been requiring an evolution of these models. Location becomes one of the most important factors to attract demand. How can real estate players find the best location for their investments? This choice can be grounded on solid data, not only about the physical asset in itself, but also about the urban context (e.g. consumption models, demographic trends, purchasing power, safety & security, etc.). Despite massive data being available today, an appropriate tool is still missing to combine all useful information on cities and territories into an integrated platform to support decision-making. The objective of this work is to propose a categorization of useful data and a first exploration of integration opportunities into a unified system that real estate actors can use for their investment decisions. In this paper, the following research questions are addressed: 1) What kind of tools exist to guide operators and investors in the location analysis process? 2) What data categories are available to different actors? 3) How could these data be organized and integrated in order to support various actors? In the first part, the paper reviews the state of the art of existing tools to check what data is already available and can be considered for merge. In the second part, the paper proposes a demo version of an integration tool. The instrument is composed of six sections that can be filled with data extracted from public sources and/or search engines. Through a weights system, a data ranking is created, based on the supposed interest of future investors and operators. Finally, this tool is tested in the hospitality market. A trial application is built on an electronic datasheet. Nine case studies located in Milan (Italy) are compared and ranked through the tool to determine which investment option is more desirable. The main advantages and limits of the proposed tool are discussed. Especially, the tool shows to be useful for simplifying and supporting selection of new investment opportunities on the Italian territory, where the combination of key information for real estate players is still challenging. Digital implementation and extension to the other real estate sectors and countries are considered as possible developments of the proposed tool. In conclusion, solutions to support data elaboration should take into account that analyses must be dynamic and constantly updated. New expertise is necessary besides the traditional real estate competences. New jobs might emerge in the near future, hybridizing proficiency in economics, programming/analytics and territorial planning.

LOCAL VARIATIONS OF SPATIAL COLOCATION OF CREATIVE INDUSTRIES AND COWORKING SPACES IN EUROPEAN METROPOLITAN AREAS

Pavel Bednář¹, Ilaria Mariotti², Lukáš Danko¹, Federica Rossi²

¹Tomas Bata University in Zlin, Czech Republic. ²Politecnico di Milano, Italy

ABSTRACT

The post-Fordist economy transition in developed countries featured by economies of scope and flexible specialization has brought into cities new challenges transforming their urban economics, land use, and commercial structure. The structure is gradually transformed by development of ICT technologies and advantages of economies of agglomeration resulting in Jacobs spillover and economies of density based on spatial proximity of suppliers or providers. Such transformation of commercial structure in European metropolitan areas have been affected by rapid increase of knowledge intensive business services - here represented by creative industries allowing flexible jobs due to digitalisation (Architecture, Advertising, Design, and Media), and new form of working places representing sharing economy - coworking spaces. Their spatial interactions given by their location decisions based on trade-off theory resulted in local variations of spatial collocation. Previous studies have confirmed Tobler's 'First law in geography' in investigation of such spatial association both in general or specifically setting spatial distances. Nevertheless, this study examines such collocation on particular coworking centre. The given approach allows to use an asymmetric approach to the study as preceding research studied a symmetric variation of the problem whether a collocation is present or not having missed any inspection of the issue whether coworking spaces are spatially attracted by specific creative industries sector or vice versa. The presented study treats the issue by a research question on whether coworking spaces are spatially attracted to creative industries; i.e. alternatively that location of a particular coworking space is spatially dependent on location of specific neighbouring creative industries sector firms. Applying investigation of such spatial collocation on particular coworking centre the study contributes to the research on the given type of the third place by a question whether multiply collocations in local variations of spatial interaction between coworking spaces and specific coworking spaces exist and whether such multiple collocations are spatially clustered or not. To fulfil presented research questions, the study uses a Localized Collocation Quotient for investigating spatial association between coworking spaces and creative industries sectors and choropleth map for revealing spatial clusters of coworking spaces showing multiply collocation. Comparing two European metropolitan areas, namely Milan and Prague, which are a commercial capital of the country with the highest number of coworking spaces. The preliminary results show that coworking spaces are collocated to creative industries sectors by means of local variations and several coworking spaces have demonstrated a multiple collocation. To summarize the preliminary results spatial dependency of coworking spaces on creative industries clusters has been confirmed in particular places. Specifically, comparing Milan and Prague, Milan has displayed much profounder of coworking spaces collocation to Architecture comparing to Prague. Subsequently, all revealed collocation is going to be analysed and explained by the local variation of urban development trajectories.

LOCATION PATTERNS AND SPATIAL DISTRIBUTION OF CO-WORKING SPACES IN ISTANBUL

[Meltem Parlak](#), [Tuzin Baycan](#)

Istanbul Technical University - City and Regional Planning, Turkey

ABSTRACT

Co-working spaces are a rising phenomenon for cities to attract creative workers and to enable knowledge exchange. These spaces provide a flexible, shared working environment for small firms, start-ups, and freelancers to collaborate, share ideas, and network. İstanbul, as the country's cultural and creative capital, hosts the most significant number of co-working spaces in the country. They locate in different city locations, from the CBD to new emerging working environments of the city such as airports. Although their rapid expansion becomes more visible in the city, the literature on the analysis of their location effect is absent. This empirical study aims to understand their geographical footprint and location patterns. It shed light on understanding the location factors of co-working spaces in İstanbul deeply. In this context, it discusses the location concept in three levels: building level, the neighborhood level, and the city level. It investigates the former use and the current function of the building at the building level where the co-working spaces are nested. At the neighborhood level, it identifies the motivation behind their location decisions from the co-founders' perspective. At the city level, it aims to understand their spatial distribution in the city by mapping their locations. The study's finding contributed firstly to the so-far very limited empirical data on the spatial analysis of co-working spaces. Second, it provides a perspective to discuss a policy framework to strengthen the city's co-working space ecosystem.

GEOGRAPHIES OF COLLABORATIVE SPACES IN POLAND**Grzegorz Micek¹, Karolina Małochleb¹, Katarzyna Wojnar²**¹Jagiellonian University, Poland. ²Centre for European Regional and Local Studies (EUROREG), University of Warsaw, Poland**ABSTRACT**

Before COVID-19 pandemic era the increase of various types of collaborative spaces had been observed. Even if during the pandemic period, such spaces as coworkings, makerspaces and hackerspaces are making their attempts to survive, they may still play an important role in collaborative behaviour. It is argued that collaborative spaces (CSs) provide facilitative milieu for knowledge sharing and enhance proximity in various dimensions (Micek, 2020).

Since recently, little was known about spatial patterns of CSs. Some case studies (e.g. Mariotti et al., 2017) revealed their location is central and they tend to heavily concentrate in metropolitan areas. However, the recent research carried out in the most advanced economies showed that there is also a tendency of spatial diffusion of CSs to small-sized cities and rural areas.

The paper looks at geographies of collaborative spaces in a very specific national context. The case study of location patterns of collaborative spaces in Poland as one of the largest countries in post-socialist Europe, is conducted. It is based on the longitudinal database of various types of collaborative spaces. The database has been constructed based on registries of CSs such as coworker.com, spacing.pl, but also numerous other web resources on makerspaces and hackerspaces.

The research carried out in two spatial scales: regional and intra-urban. The spatial structure of collaborative spaces is compared and contrasted with the distribution of other economic and social indicators. The dominance (hypertrophy) of the capital city of Warsaw in terms of attracting collaborative spaces is revealed. The large role of other metropolitan areas is also shown. Rural peripheries and small-sized cities in Poland do not house collaborative spaces as it is becoming common in the US, Western and Northern Europe. In this respect, it shows the semi-peripheral position of Poland in the evolution of spatial patterns of collaborative spaces.

Intraurban spatial patterns are examined in the case of the capital city of Warsaw. Spatial patterns of collaborative spaces largely follow the location of old and new business districts. The number of CSs in intraurban peripheral locations is highly limited in Warsaw.

MAPPING SPATIAL PATTERNS OF CO-WORKING SPACES IN EUROPE

Tüzin Baycan, Gülfiye Özcan Alp
Istanbul Technical University, Turkey

ABSTRACT

Digitalization has transformed the economy, the ways of working and spatial arrangements of businesses and co-working spaces have emerged as a new type of workplace organization in the last decades. Following the first co-working space established in San Francisco in 2005, the number of co-working spaces has increased and spread around the world rapidly. Today, major cities of the world have increasing number of co-working spaces. According to the global survey conducted by co-working magazine deskmag.com, the estimated number of co-working spaces in 2020 is 26.300. Globally, it is estimated that 2.680.000 people are working in these spaces. The average annual growth rate of co-working spaces has been 58% for the years between 2011-2017. It is obvious that the co-working market presents a growing trend in all over the world. This rapid spread of co-working spaces all over the world has raised new questions: How do co-working spaces present themselves distinctively in different countries and regions? How do location choices and spatial patterns of co-working spaces transform our cities? In order to answer these questions, this paper aims at investigating and mapping spatial patterns of co-working spaces in Europe at the country and city levels. Using the data from the specific website of coworker.com and addressing 3838 co-working spaces in Europe, this paper compares European countries and cities in order to understand similarities and differences in spatial patterns of co-working spaces.

REGIONAL VALUE CHAINS: AN INPUT-OUTPUT MODEL APPLICATION

[Joao-Pedro Ferreira](#)

University of Florida, USA. GOVCOPP, University of Aveiro, Portugal

ABSTRACT

This work details the concept of value chain at the regional level and how they can be defined by a particular good, produced by a specific industry in a certain region. The main idea is that the location analysis of the production activity should not only consider the top of the chain, meaning the specific place and industry that produces the product that is ready to be consumed as final demand. Value chain analysis is a method that allows to allocate the value-added to the specific industries and regions that are involved in the production process and to estimate how much was their contribution to the final product. Here, we suggest the use of multi-regional input-output analysis as a method that allows to disentangle the complex web of intersectoral and interregional dependencies that characterize the modern and global economies. In this work, we will also present several examples of value chains estimated for Portugal.

**REGIONAL SCIENTISTS IN PORTUGAL: AN ANALYSIS OF WHAT THEY
THINK THEY ARE**

Tomaz Dentinho

University of Azores, Portugal

ABSTRACT

Science is the object of analysis of science. In recent years, many studies have been developed to understand the boundaries of the state of the art in various scientific domains with structured consultations with specialists. This chapter aims to contribute to the analysis of the dynamics of regional science in Portugal based on the application of Method Q to 23 of the 94 regional scientists of the Portuguese Association for Regional Development, who were asked to rank 27 sentences about what is and what matters to regional science. Results indicate that there are complementary views on regional science or the study of the creative human interaction within space. Geographers and social scientists favour understanding, academics with rooted theories and economists and engineers prefer methods. It is suggested an evolution of regional science to territorial medicine where the effort of science mobilizing various disciplines is oriented towards decisions that promote the development of people, sites and places.

HOW TO DEFINE ENTREPRENEURIAL ECOSYSTEMS?

[João Leitão](#)^{1,2}, [Sónia de Brito](#)¹

¹University of Beira Interior, Portugal. ²ICS, University of Lisbon, Portugal

ABSTRACT

This paper carries out a systematic literature review on Entrepreneurial Ecosystems (EEs). Innovation, clusters and open innovation are revealed to be the most important streams of literature. From an analysis of social networks, word co-occurrence and co-citations, and cluster analysis, EEs are defined as a set of interdependent actors and coordinated factors, in order to allow entrepreneurship within a given territory. Here, innovation is considered to reflect a new idea and that clusters originating in the spatial concentration of principal and supporting companies use open innovation combining intentionally internal and external knowledge flows, to accelerate internal innovation and market expansion for the purpose of using innovations externally.

SPACE AND TERRITORY IN THE CONTEXT OF REGIONAL DEVELOPMENT

[João Lourenço Marques](#), [Paulo Batista](#), [Eduardo Castro](#)

University of Aveiro - GOVCOPP, Campus de Santiago 3810 Aveiro, Portugal, lijmarques@ua.pt

ABSTRACT

The debate around the broader notion of space has a long history, becoming an important topic in several scientific domains, in physics, philosophy, geography, planning, and of course in regional science. Many authors in these domains of knowledge have developed different theoretical frameworks and conceptions of space (see, for example, the works of Benenson & Torrens (2004), Harvey (2006), Lefebvre (1991) or Park (1984)), however, still exist some lack of conceptual clarity, if not in the definition of the concept, in how these different notions of space are operationalized. If the analysis of space, in physics and mathematics, is done with great rigour, defined by metrics and objective criteria, in the social sciences the difficulty is obscured by the undefinition of what space is. If time is what is measured with a watch, what is space and how is it measured? Can we say that space is what is measured with a ruler? To a certain extent, yes, but it all depends on the type of ruler we are using.

Space can be more than two-dimensional Euclidean geometry and can be more than a medium in which social, economic and political processes operate. Two main ideas emerge throughout this reflection, the first is that space involves not only a concept associated with its physical arrangements, but is also socially lived and produced, and can mean different things to different people. A distinction is made between a geometric view of space, in which it can be described and analysed by the position of objects in space itself and the relationship established between those objects (perspective associated with the concept of absolute and relative space of (Harvey, 2006)); and a view in which space is not a "container", but a product of biunivocal relations, which result from the permanent interaction between objects and the space itself, reinforcing the idea that space depends both on physical constructions, but also, and above all, on different conceptions and cognitive perceptions.

Starting from a positivist vision (the desire to create a spatial order), the scientific disciplines which have space (territory) as its primary object of analysis, have rapidly evolved towards a post-structuralist perspective, focusing on socially produced space and place. As a consequence, the understanding of space has also followed this change, towards an apparent loss of the physical and isotropic substance of the notion of space, becoming more immaterial and intangible. This reflection also allowed us to assess the challenges associated with the analysis of space, identifying four distinct but interdependent elements, namely, i) the definition and measurement of the attributes of objects, ii) the assessment of the spatial patterns of these objects (heterogeneity), iii) the analysis and interpretation of the relationship between these objects (dependence, interaction or spillover effects) and, finally, iv) the level of detail or resolution at which these phenomena are described and understood (scale).

THIRTY YEARS OF REGIONAL SCIENCE IN PORTUGAL

Francisco Carballo-Cruz

Universidade do Minho and NIPE, Portugal

ABSTRACT

In this session, some papers from Portuguese academics will be presented. Additionally, I will moderate a short discussion on the last three decades of Regional Science in Portugal, from the creation of the Portuguese National Section of RSAI. We will use as starting point for discussion a recent book that gathers some contributions by the most prominent Portuguese regional scientists.

Regular Session: RS07.2 - Migration and regional labor markets

13:15 - 14:30 Wednesday, 26th May, 2021

MARKET POTENTIAL WITH REGIONAL PRICE DEFLATORS

[Bartłomiej Rokicki](#)

University of Warsaw, Poland

ABSTRACT

Does market potential decrease or increase, if regional price differences are taken into account? This paper applies regional price deflators to calculate regional market potential and compares its values with the ones obtained without taking into account the existence of regional price differentials. Furthermore, we assess the impact of newly estimated market potential on regional wages. Additionally, we verify the relative adequacy of the market potential approach and the wage curve approach in terms of explaining regional wage differentials. Applying data for the US and Poland, we find that market potential changes significantly if regional price indices are included. We also prove that the impact of market potential on regional wages is weaker than previously assumed. Moreover, we show that it has less explanatory power in explaining regional wage differentials as compared to the wage curve.

AN ITALIAN GOOD PRACTICE OF INCLUSIVE TEACHING FOR MIGRANT STUDENTS IN AN INTERSECTIONAL PERSPECTIVE

Giovanna Filosa¹, Maria Parente²

¹ Inapp, Corso d'Italia, 33 – Rome, Italy, g.filosa@inapp.org; ² Inapp, Corso d'Italia, 33 – Rome, Italy, m.parente@inapp.org

ABSTRACT

The Covid-19 emergency hit like a tsunami on the education and training system, requiring a sharp rethinking of traditional ways of organizing education for children, young people and adults. The introduction of distance learning on one hand has brought down strenuous resistance to the new technologically enhanced learning tools, on the other it has highlighted all the limitations of training interventions that are not adequately designed. The quality of training/education does not only concern the introduction of innovative technological tools (hardware and software infrastructures capable of supporting them), and the digital competence of the professional figures who have to use them (teachers and trainers), but also and above all, a methodologically based design.

The reference context of this research is the State Institute of Specialized Education for the Deaf (Isiss) "A. Magarotto" in Rome that includes the cycles of kindergarten, primary school, lower secondary school and upper secondary school. It was born from a school inclusion project, developed by the CNR, which transformed a boarding school for the deaf into a specialized school that hosts hearing and deaf students with various disabilities, mainly of Italian nationality but also of other origins ("second generations"). The goal is to describe a good practice in terms of inclusive distance learning, which can also be extended to other public and private schools, and to give policy indications regarding the post-Covid education and training system. The hypothesis of this paper is that a methodologically based design is a critical success factor for teaching and an important indicator for the quality of the training offer as an alternative to face-to-face teaching. From this case study, a good practice of inclusive teaching was reconstructed, able to adapt to the specificities of individual deaf and /or foreign pupils. Distance learning, accompanied by individualized interventions for deaf children with autonomy and communication assistants, ensured the necessary didactic continuity even in the most dramatic phases of the pandemic. This practice could also guide other school contexts in a post-Covid period. As a matter of fact, distance learning is not a substitute for face-to-face teaching, but could be considered from a complementary perspective.

Disability, distance learning, emergency, health

1. INTRODUCTION

Distance learning is not a new phenomenon: it dates back to just before the mid-nineteenth century with the aim of overcoming the space-time limits that characterized traditional training. The first distance university course was organized in 1921 in Salt Lake City, USA. Meanwhile, in Europe, in 1926, Radio Luxembourg and the BBC created educational radio programs. In the 1980s, thanks to the birth of the video recorder, video cassettes, floppy disks and, later, CD-Roms and DVDs, it became possible for a large group of people to take advantage of real self-learning courses. But it is with the creation of the Internet and telematic networks that we have passed from the information society to the knowledge one, with a sharing in the creation of knowledge by a vast audience. The distance education learning model, therefore, pushes towards the modernization of the school's methodological approach, starting from these premises (Fundarò 2020).

1.1 The international context

At the beginning of the pandemic, the closure of schools was an almost generalized measure worldwide, while the causes, epidemiological dynamics and possible remedies for the Coronavirus infection were not yet well known. From a study by the Institute for International Political Studies (Ispi 2021), on UNESCO data, it emerges that in the midst of the pandemic (21 April 2020), almost all countries on every continent, have adopted local or national school closure measures. This closure involved 90% of primary, secondary and university students in the world, for a total of about one and a half billion students.

Obviously, the possibility of activating digital teaching that compensated for these closures was a "luxury" that could be afforded only by the countries with advanced economies: around half of the students in the world do not have a computer at home, a percentage that rises to 89% in sub-Saharan Africa. Observers and international researches immediately analysed the impact of Covid on educational inequalities and educational poverty, reaching alarming conclusions (D'Addio 2020).

1.2 The Italian context

In Italy, following the closure throughout the national territory of educational services for children, educational activities in schools of all levels and higher education, established by the Prime Ministerial Decree of 4 March 2020, many Italian schools, in order not leave students alone, tried to "invent" a teaching method, unknown to most of the people⁹⁰.

In our country, as elsewhere, some justified questions immediately arose regarding the impact of the Coronavirus on educational poverty⁹¹, and on the adequacy of distance learning in replacing, at least temporarily, face-to-face teaching, to minimize the impact (Mascheroni *et al.* 2021).

A first limit is constituted by the possibility of access by the students to digital teaching, characterized by a strong heterogeneity throughout the national territory. An Invalsi (Istituto nazionale per la valutazione del sistema educativo di istruzione e di formazione) study (Argentin *et al.* 2021), showed that just about one third of students of all levels were able to use distance learning; because they had:

- an internet connection at home (regardless of the quality/speed of the connection itself);
- a workstation used for studying, with connected PCs or tablets;
- both teachers of the main subjects (Italian and mathematics) who regularly use any digital device to teach.

From the point of view of teachers, almost a third of them tend to reject digital tools, with negative repercussions on satisfaction with their distance teaching activity (Agasisti *et al.* 2021), while 73.6% would like to continue to use technology also in face-to-face teaching and 91.2% require specific training on it (Inapp 2020: 8).

Distance learning has created many complications also from parent's perspective: it was mainly mothers who had difficulty in reconciling work at home and teaching assistance for their children (Pastori *et al.* 2020), with negative repercussions also on employment levels and on the economic condition of women in general (Ipsos 2021).

2. THE IMPACT OF DISTANCE LEARNING ON THE SCHOLASTIC INCLUSION OF PUPILS WITH DISABILITIES

Further and legitimate concerns arise regarding the effectiveness of distance learning regarding the inclusion of disadvantaged children/young people: because they are disabled (Fondazione Agnelli 2020), and/or with a migratory background⁹², or with specific disorders learning (SLD) and special educational needs (SEN)⁹³ etc. Many authoritative commentators have underlined the fact that Covid has not created new inequalities, but has exacerbated and exasperated the already existing ones: gender, socio-economic status, opportunities to access digital etc. (Guidetti 2021). Not to mention that, from an intersectional perspective, discrimination on the base of disability is often a multiplier factor⁹⁴.

Disadvantaged pupils represent a numerically important reality in the Italian school landscape: 268,671 pupils with disabilities and 808,953 pupils with non-Italian citizenship were expected in the school year 2020/2021 (out of a total of 7,507,484 students, from kindergarten to upper secondary school) (Ministero dell'Istruzione 2020a).

According to Istat data, in the academic year 2018/2019 pupils with disabilities were equal to 3.5% of those enrolled, but between April and June 2020 over 23% of them did not take part in lessons (among other students the percentage of those excluded from the distance learning drops 8%, with highest peaks in southern Italy). Among the reasons for non-participation of pupils with disabilities in distance learning: the severity of the disease (27%), the difficulty of family members to collaborate (20%), the socio-economic problems (17%), the difficulty in adapting the IEP (Educational plan for inclusion) to the distance learning (6%), the lack of technological tools (6%), the lack of specific teaching aids (3%), (Istat 2020a).

These difficulties are added to the scarcity of specialized teachers and assistants in autonomy and communication especially in the South of Italy (among these only 5% know the sign language, essential for communicating with deaf signing children), the lack of training in educational technologies to support people with disabilities, the scarce availability of technology as a facilitator of school inclusion, the lack of computer stations in the classroom, architectural barriers and the difficulties linked to the poor digital skills of the Italian population including parents and caregivers, (Istat 2021).

2.1 The impact of distance learning on the inclusion of pupils with a migrant background in school

Even before the pandemic (academic year 2018/2019) one in ten students were foreigners, and foreign students represented 13.4% of students with disabilities, with varying percentages depending on the region, with a higher presence in northern Italy "Ministero dell'Istruzione (2020b)".

Pupils with a migratory background (with or without disabilities), therefore, deserve special attention from our school system: inclusion for them, like learning (especially digital), is a lifelong process, from childhood to old age. The gaps that could be accumulated already at an early age, in the learning path of the host country's language, can have repercussions on subsequent education cycles, leading them to lose the connection with the system of training and job placement in adulthood. Furthermore, a failure to acquire or reacquire basic digital skills (also given their rapid obsolescence) puts their future permanence in the school-training system as well as in the production system at risk.

91 <https://www.invalsiopen.it/impatto-coronavirus-poverta-educativa/>.

92 <https://www.piuculture.it/2020/04/alunni-stranieri-dad/>.

93 In Italy, pupils with SEN represent almost 9% of those enrolled. More than half are students with SLD, while 35% are students with socio-economic, linguistic or cultural disadvantage (Istat 2020a).

94 <https://www.fishonlus.it/progetti/multidiscriminazione/azioni/>.

At the same time, the digital divide of their families of origin makes participation in the digital learning more difficult (Papavero and Menonna 2021), just as any linguistic and cultural gaps of their parents affect their academic performance even in face-to-face learning (Istat 2020b).

3. DIDACTIC METHODOLOGIES

The tsunami of the Covid-19 emergency has therefore forced a sharp rethinking of the traditional ways of organizing education for children, young people and adults. From a lifelong perspective, the introduction of distance learning and smart working, on one hand has brought down strenuous resistance to the new technologically enhanced learning tools, on the other it has highlighted all the limits of didactic interventions that are not adequately designed.

The quality of training/education does not only concern the introduction of innovative technological tools (hardware and software infrastructures capable of supporting them), and the digital competence of the professional figures who have to use them (teachers and trainers), but also and above all, to a methodologically founded planning.

In a first phase, after having overcome the initial bewilderment, many teachers limited themselves to transferring the traditional model of frontal lesson, based on the explanation-interrogation dyad, onto the platform; it was soon understood that this model, which was already showing its limits in face-to-face teaching, was totally ineffective in a digital environment. As emerged from various testimonies from headmasters and teachers⁹⁵, it was necessary to radically rethink didactic planning in a more participatory, interactive and inclusive way, taking into account the fundamental mechanisms of formal and non-formal learning, as codified in decades of researches⁹⁶.

In this direction it would be useful to rediscover constructivist (Piaget 1971) and constructionist (Papert 1989) didactics, already successfully used in training. They have placed three fundamental elements at the center of the learning processes (Deplano 2020):

- a reliable and qualified source of information (teacher or trainer, but also the didactic material they provide);
- an environment of social interaction, with the teacher but also between peers (class or classroom), real and/or virtual, synchronous but possibly also asynchronous;
- a concrete goal, to be achieved through the knowledge acquired, which is motivating: any learning, as a matter of fact, involves both the cognitive axis (skills, abilities, skills) and the emotional axis (interests and motivations).

In simple terms Covid has further highlighted the need for a paradigm shift, useful in face-to-face learning but indispensable in distance learning: the transition from the so-called "Nuremberg funnel" model to a constructivist teaching, based on the centrality and autonomy of the subject who learns. The schools that already practiced this kind of teaching in an inclusive perspective, were probably more easily able to translate it into distance learning, in order to ensure the necessary didactic continuity without an excessive dispersion of attention and energy. The schools and training organizations that already practiced inclusive teaching were advantaged in distance learning, probably because their methodologies, theoretically founded, already aimed at creatively exploiting all the tools, technological and otherwise, aimed at facilitating learning to all, able-bodied and disabled. From this point of view, diversity (not only functional, but also cultural, ethnic and social) was truly a resource that "taught" how to transmit content in an accessible way to the widest possible audience of learners (Filosa, Parente 2020).

4. THE CASE STUDY

4.1 Methodology

On the web, it is possible to find several virtuous examples of inclusive distance learning based on participatory and innovative methods, and various useful tools⁹⁷. In this work it is presented the experience of Isiss Magarotto in Rome, through a case study carried out through in-depth interviews with privileged witnesses (teachers, parents, operators, Headmaster, for a total of six interviews) coming from the context taken in exam, with the aim of describing a good practice in terms of inclusive distance learning. The hypothesis is that a methodologically based planning is a success factor for teaching and an important indicator for the quality of the training offer alternative to face-to-face one.

The selection of the reference context took place by combining a criterion of opportunity (convenience sampling), linked to the availability of a school in the territory of Rome and therefore accessible in a pandemic period, with a criterion of a reasoned choice (purposive sampling), aimed at involving a specific category of disabled pupils, the deaf signers, whose problems (mainly related to the sphere of language and communication) are similar to those of foreign pupils.

The conduct of the interviews was preceded by a desk analysis of the three-year educational offer plans (PTOF) and the self-assessment reports (RAV) of the school, including the results of the Invalsi tests.

The focus of the interviews, carried out from July to the end of August 2020 (after the first lockdown period), focused on teaching methodologies, coping strategies regarding the Covid emergency of teachers, parents, pupils, and lessons learned for the post-Covid period.

A qualitative textual analysis was carried out on the transcription of these interviews. The research combines, from an anthropological point of view, an emic perspective (the "native" perspective) with an etic one (the external observer's perspective, Headland *et al.* 1990).

⁹⁷ Cf. Digital resources in the appendix

4.2 The reference context

The State Institute of Specialized Education for the Deaf (Isiss) "A. Magarotto" in Rome includes kindergarten, primary school, lower secondary school and upper secondary school. It was born from a school inclusion project, developed by the CNR, which transformed a boarding school for the deaf into a specialized school that hosts hearing and deaf students with various disabilities, mainly of Italian nationality but also of other origins ("second generations"). It has a total of 7 places, 5 of which in Rome, one in Turin and one in Padua.

The tenured teachers are in possession of the monovalent specialization title; for substitutes who do not hold this qualification, basic LIS (Italian Sign Language) courses are organized to promote inclusion and communication and meet the needs of deaf signing and bilingual students. As a matter of fact, LIS is a curricular subject also for hearing students. A large part of the teaching staff also has Ecdl (European Computer Driving License) certification.

The training offer is enriched by various figures in support of teaching, such as the signing psychologist, the deaf and/or hearing assistant (AsCo) (figure provided for by Law 104/92, art.13), the educational operator for the school autonomy (OEPA), the speech therapist, the logogenist, the LIS interpreter for interviews with deaf parents.

The expert teachers have a wide repertoire of teaching strategies, and in the Ptof 2019 / 2020-2021/ 2022 various innovative methodologies are listed for participatory and inclusive teaching:

- active and participatory lesson, guided discussion;
- accessible teaching, laboratory, skills, metacognitive, experiential teaching;
- problem solving;
- flipped classroom;
- Montessori methodologies;
- brainstorming;
- cooperative learning;
- problem setting e finding;
- tutoring e modeling;
- peer education;
- debriefing;
- circle time;
- research and action;
- role playing;
- team teaching;
- mastery learning;
- participatory heuristic method;
- learning by doing;
- audiovisual and multimedia tools: tablet, digital camera, DVD player, multimedia room, computer room, video library;
- interactive multimedia whiteboard (IWB).

The attendance of hearing students is in an "equal" relationship, so that the concept of disability becomes absolutely marginal, in order to enhancing differences as an expression of the uniqueness of each individual. The limited number of students per class allows a real individualization and personalization of learning paths.

The methodological approach chosen by the school aims to encourage active and interested participation, pupils are guided in the acquisition of knowledge starting from "knowing how to do" to "knowing how to be"⁹⁸. Inclusion projects are proposed every year to promote integration between deaf and hearing pupils and reduce early school leaving. The Institute also has frequent relations with the social context in which it operates.

4.3 Interviews: Magarotto during the lockdown

The Magarotto Institute, like all Italian schools, during the lockdown, tried to find a solution that would guarantee educational continuity, not leaving students and families alone. This dynamism and attention to inclusiveness is evident in the interviews carried out, although the objective difficulties, due to the emergency situation, are not hidden.

In the stories of the first lockdown it emerges that the first measure taken by the Institute, since the beginning of the period of health crisis, was to try to guarantee students all the IT support they needed: a survey on the need for computer equipment (computers, tablets, etc.) of the children and their families, as well as the computer equipment of the various locations and plexuses, and a sort of ranking has been conducted.

Thanks to the help and funding of the Ministry of Education, the Institute immediately proceeded to purchase and distribute the computers to the various locations and families who needed them, sending some computers, in full lockdown, from Padua to families residing in Milan or Trapani, in a few days.

In the general difficulty in finding an effective tool to continue lessons, after an initial moment of bewilderment, teachers tried to maintain contact in every way with the students, using all the available platforms (Google Meet, Zoom, etc.) and even WhatsApp, until it was established a single platform throughout Italy.

⁹⁸ <https://www.isiss-magarotto.edu.it/silvestri/45-silvestri/generico-silvestri/69-metodologie-didattiche.html>.

It was then implemented a careful didactic planning, based on listening to the needs of students and verifying the effectiveness of the interventions. They tried to have, as reference models, the schools and masters already operating in the distance learning sector.

After the first 15/20 days, it was possible to structure a precise defined timetable: with lessons duration of no more than 2/3 hours a day, except for the primary and secondary schools, where pupils were already used to full hours until the afternoon, and where it was decided to do 4 hours.

The maximum duration of each lesson was 40 minutes, to allow pupils to maintain concentration. They tried to respect what was the weekly routine, in continuity with the school in presence, trying not to exceed. As a matter of fact, it was important that teaching was "targeted and measured", trying to "explain less and activate more", with a lot of flexibility⁹⁹. It was fundamental to rethink the teaching strategies: the frontal lesson, which was initially used, was replaced by a much more integrated teaching method, participated by the students. The model used was the flipped classroom, that is the upside-down class, giving the subjects of the lesson in advance to the students. Thanks also to a reinforced interaction with the families, the children began to understand what would be discussed the following day, thus creating greater awareness. The same process was used in the verification tests: at the beginning it was used the traditional oral questioning, then there was the necessity to find different tools. They proceeded by learning from experience, by trial and error, thanks also to the support of communication assistants, who translated both the lessons and the audiovisual tools into sign language and used sometimes a second screen.

Several deaf children, as a matter of fact, made use of a double screen: one to follow the teacher and the class, and another dedicated to the AsCo, which translated in sign language everything the teachers and classmates said. In addition to group lessons, some individual meetings were also organized, their maximum duration was 30 minutes, with deaf children and the teacher or with the teacher, the deaf child and the communication assistant, depending on the children's needs.

In particular, with deaf foreign children, if they had difficulties with Italian language, individual meetings were organized with the communication assistant or with the teachers, to repeat the topics already addressed during the synchronous lesson with the class, in order to make an individualized and personalized teaching in response to the diversified needs of the students. The arrangement of individual meetings was very flexible: they were done even at the weekend, or in the evening, in order not to be held during parent's smart working (Eccas 2021).

The teaching model followed by the Magarotto Institute has always been extremely visual, and especially during the lockdown, it was aimed at fully exploiting the potential of new technologies and multi-media, intended both as effective tools for transmitting content and as digital skills, object of learning.

Games have been used as a resource and a didactic tool, especially to keep the attention of children high. Interactive educational games were also used: teachers sent a link of *edutainment* games available on the web or designed specifically for them as tests.

There were several technical problems relating to the internet connection, due to the patchy spread of broadband throughout the country, or to the lack of computer stations dedicated exclusively to study and not shared with parents in smart working. However, these efforts have pushed children in the direction of a greater digital autonomy, and have forced a sharp acceleration of digitization in education.

Another problem was the risk of addiction and fatigue of children, due to the many hours spent in front of the computer. On the other hand, this has led parents to a greater awareness, towards a more responsible use of IT tools and greater attention to the student's learning rhythms.

Many of the teaching strategies that were already used in face-to-face learning have been transposed into the distance learning of the Magarotto Institute, not only adapting them to the emergency situation, but also strengthening them to stimulate a greater interactivity and autonomy of the students in finding and using educational resources, digital and otherwise. The experience during the distance learning will contaminate also face to face teaching, in a reciprocal and virtuous exchange of instruments and methodologies.

In a post-pandemic future, it is expected to use distance learning, in synergy with face-to-face teaching, for example during online meetings of teachers, for homework and for hospitalized students, with chronic illnesses or with health problems, (Ministero della Salute, 2020).

5. CONCLUSIONS

From this case study, a good practice of inclusive teaching was reconstructed, able to adapt to the specificities of individual deaf and/or foreign pupils, who have never been left alone. The distance learning, accompanied by individualized interventions for deaf children with autonomy and communication assistants, ensured the necessary didactic continuity even in the most difficult phases of the pandemic. This practice may also guide other school contexts in post-Covid, in order to reduce inequalities in educational paths. As a matter of fact, distance learning is not a substitute for face-to-face teaching, but complementary to it.

Although in several schools there has been a "physiological" loss of some students, due to lack of familiarity with technologies, in other realities online teaching has tried to be at least as functional as face-to-face one, especially for some types of more receptive pupils or with character problems such as social anxiety or shyness.

In the case of foreign children who have just arrived in Italy and have difficulties in understanding Italian, a model of visual teaching, similar to that used at Magarotto for deaf children, can be useful as well. Foreign children, on the other

⁹⁹ This is what emerges from the testimonies of several teachers, including the intervention at the Invalsi seminar "Evaluation and enhancement in the Dad" by Prof. Paola Andreoli of Liceo A. Maffei - Riva del Garda (Invalsi 2020).

hand, are often very familiar with the internet and social networks: young foreigners represent a spearhead of the generation of digital natives (Istat 2020b), but they are often among the most disadvantaged for what concern digital environments useful to develop their potential.

The lack of socialization opportunities is another one of Covid's biggest problems in recent times. In the case study, for example, it was made an attempt to support children also from a psychological point of view, with a service desk activated by a signing psychologist, who has organized a meeting with more or less each class.

The impossibility of socialization, as experienced in face-to-face learning, has led to a rediscovery of the emotional and social dimension of learning. The collaboration of families has proved to be fundamental, especially for the little ones, for whom an "alliance" between parents and teacher has often been created. Family participation was most evident during the first lockdown, when all families were housebound, and to a necessarily lesser extent more recently, upon resumption of work (Eclass 2021).

The experience of distance learning has also contributed to making students acquire a methodological habit that will be useful in the future: an "important challenge", to which the teaching staff, in the best cases, responded by reviewing their teaching strategies, with a change of perspective compared to the past, a conspicuous effort in training that has led to a general growth of the digital school.

Only thanks to this careful and flexible planning work distance learning can prove to be a useful tool for inclusion even in non-emergency situations, not repropounding traditional teaching, but articulating it in a more congenial form to the needs of deaf students as well as students with other forms of disability¹⁰⁰.

That's not what happened everywhere: despite the DPCM of 10 April 2020 renewed the provisions approved at the beginning of March, suggesting a particular regard to the specific needs of students with disabilities, in many cases it was necessary to ascertain the absence operational plans capable of avoiding the harmful effects that the new suspension of face-to-face teaching would have had on the training of young people and, in particular, on the maturation and social inclusion of pupils with disabilities and sensory deficits. Entire cohorts of students, who were entitled to educational accompaniment, were unable to enjoy this possibility in the second half of the 2019/2020 school year. When the schools were closed, what happens inside the classroom walls became even more evident, namely the delegation of this inclusive function only to specialized teachers. They found themselves managing distance learning without having adequate strategies for educational success (Massagli 2020).

How to respond, then, to the countless critical issues that have arisen? We should think of calibrated and well thought-out training activities for users (teachers) that can be classified at different levels. A certain cyclicity in training should be considered because in technologies subjects a course alone is not enough, but a repeated and monitored practice is necessary. If we have to consider that teaching could have new interruptions and a more widespread use of technologies, a well-calibrated training on users, must be planned adequately and in time (Ajello 2020).

It would also be desirable to consider more accurately the relationships between analogue culture, which is typical of the generation of teachers, and is characterized by deepening, reflection and selection, and the digital one, to which children are more accustomed, and which is exclusively a knowledge of the internet, that conveys "another way of looking", more attentive to speed, to colors, which is now widespread among the entire population, and which entails a rethinking, of a magnitude similar to the difficult relationship between orality and writing considered by Plato (Ajello 2021).

Even if distance learning can never completely replace the presence in the classroom, nor can compensate the social interaction typical of traditional schools, it still represents a methodological device and a digital tool that goes in the direction of ensuring the right to education, maintaining direct contacts between teachers and students even in situations of extreme emergency, as well as a way of learning that in the future can advantageously complete the face-to-face activity. It would be a real shame if we wouldn't capitalize on this experience.

SPATIAL HETEROGENEITY IN THE SPANISH LABOUR MARKET AFTER THE GREAT RECESSION

ABSTRACT

The Spanish labour market is characterised by strong and persistent spatial differences in unemployment rates. These differences could have been affected by the internal wage devaluation policy adopted during the Great Recession and the 2010 and 2012 reforms promoting greater wage flexibility. In this paper we apply a geographic and time weighted regression to estimate a dynamic spatial panel wage curve using microdata from the Continuous Sample of Working Lives for 2002-2018. Our results show spatial heterogeneities in the time varying relationship between wages and unemployment that must be considered to assess regional resilience capacity for future crises.

KEYWORDS

GTWR, Resilience, Spatial panel, Unemployment, Wage curve.

1. INTRODUCTION

Economic downturns have a deep impact on regional labour markets, with varying effects and responses. The depth and diversity of such reactions have been evident since the 2008 Great Recession, as job losses and unemployment skyrocketed and local labour markets became sluggish for several years. The concept of resilience entered economic discourse as key tool to describe responses to shocks to local economies. Martin and Sunley (2015) describe three main interpretations of the concept: engineering resilience (the ability to recuperate from a shock), ecological resilience (changes in growth patterns after a shock), and adaptive resilience (course changes in economic activity after a shock). As highlighted by Ubago Martínez et al. (2019), there are no standards for measuring resilience, although measures of employment outcomes are commonly used, as employment takes longer to recuperate than output, it is not dependent on deflation, and it is statistically stable (Martin, 2012, Di Caro, 2015 and Sensier et al., 2016). Moreover, considering employment allows for an accounting of the determinants of resilience (Fratesi and Perucca, 2018) and contributes to the study of labour market conditions (Eriksson and Hane-Weijman, 2017). Other works use alternative indicators to capture resilience: Lewin et al. (2018) use personal income data, Pontarollo and Serpieri (2020a, 2020b) use GDP per capita, and several other use composite indicators of economic and employment outcomes (Rizzi et al., 2018, Ubago Martínez et al., 2019).

Interestingly, most analysis of the impact of the Great Recession has concentrated on the analysis of output or employment measures and not on unemployment, with the exception of those estimating the so-called Okun's law (see, for instance, Groot et al. 2011). Our paper departs from this literature,¹⁰¹ as we investigate how the global shock affected the stability of the wage curve, i.e., the negative relationship between regional unemployment and the real wage level, for the Spanish labour market. Following the seminal works of Blanchflower and Oswald (1990, 1994, 2005) and the meta-analysis of Nijkamp and Poot (2005), a consensus has emerged (an empirical law of economics, according to Card, 1995) on a stable long-term elasticity of wages with respect to regional unemployment, which has been averaged between -0.07 and -0.1, although there are substantial disparities over population and employment groups.

The wage curve parameter can be analysed as a measurement of wage flexibility, as strong and fast wage responses to growth in unemployment can lead to lower rates of unemployment, and consequently, to a faster recovery from economic shocks (Johansen et al., 2019). Consequently, our work allows for a novel inspection of resilience. We do not analyse employment or economic outcomes, but the underlying mechanism of efficiency in labour markets, which is behind regional recoverability. We try to better understand previous results in the literature, such as that more developed economies are expected to be more resilient (Deller and Watson, 2016).

Our work is innovative in several ways. First, it is the first to implement a flexible approach to the wage curve, both in terms of all spatial and time units, using Geographical and Temporal Weighted Regression (GTWR) techniques. Second, we implement the analysis over a full economic cycle of the Spanish economy, starting in 2002 and ending in 2018, once the economic recovery after the Great Recession was fully stabilised. Third, we link the study of labour market flexibility

¹⁰¹ Monastiriotis and Martelli (2021) also adopt a different approach to examine adjustments to shocks in Greek regions during the Great Recession. Using micro-data from the Greek Labour Force Survey (LFS) they first estimate the contribution of various individual and household characteristics to individual unemployment risk during and after the crisis. Next they apply a decomposition analysis to identify the relative contribution of the shock, compositional effects, and price adjustments.

with the literature on resilience, as we study the association between wages and unemployment within the framework of the wage curve in a very interesting period from a policy perspective, as the strategy of the Spanish government was precisely to increase wage flexibility as a way to restore international competitiveness during the crisis.

Our main findings show that the elasticity of wages to regional unemployment is associated with the business cycle and the changes in labour market institutions, including two labour market reforms in 2010 and 2012. We also find large heterogeneities in the elasticity of wages to regional unemployment rates, and also in the changes in the parameters. The wage curve can be seen as a measure of resilience and efficiency of local labour markets, as less dynamic regions have less elastic wage curve parameters—a result that clearly establishes the relevance of structural characteristics of regional labour markets in Spain.

In relation to the literature, our paper connects, on one hand, to studies on labour market resilience, and on the other hand, to papers looking at the spatial dimension of the wage curve. Both strands are described in section 2, while section 3 presents the case of study and the Spanish labour market in the context of the resilience and wage curve literatures. Section 4 presents the empirical strategy, section 5 describes the data used in our analysis, and section 6 discusses the results. Finally, section 7 concludes with the main findings and implications of this study.

2. LITERATURE REVIEW

The interest of scientists and policy makers has recently moved to analyse the factors that have allowed some regions and cities to resist and/or to recover from the large shock experienced by the Great Recession in 2008. The notion of regional resilience has found currency among those interested in economic geography. In economics, resilience has been defined as the return to a status of equilibrium (Christopherson et al., 2010). Labour market resilience usually refers to the deviation of unemployment from its pre-crisis structural level, usually proxied by a counterfactual trend considering potential employment rates and demographic outcomes (Hitzen, et al., 2017).

Resilience in the labour market, from a spatial perspective, is linked to adjustment channels: migration, wages, and unemployment are three ways workers and firms adapt to changing conditions. National labour markets that are more flexible are those in which people move *between* local labour markets, looking for more and better job opportunities, while *within* labour markets wages adapt to increasing unemployment rates, making regions and cities more competitive. The association between wages and unemployment rates defines the so-called wage curve, an empirical regularity that is backed by several theoretical approaches by Blanchflower and Oswald (1995). Card (1995) criticises the labour contract model for its inconsistency with the compensating differentials model, which assumes a positive correlation between wages and unemployment in the long run. In a proposal based on the work of Shapiro and Stiglitz (1984), the efficiency wage approach, employers will offer a premium to workers in order to minimize costs related to monitoring workers' productivity. In the labour turnover model, employers use higher wages to discourage current employees from quitting (Campbell and Orszag, 1998).

These theories do not consider the possibility of migration, which ensures spatial equilibrium in wages and the erosion of the wage curve, for instance, due to compensatory wage differences (also in line with Harris and Todaro, 1970). Still, as migration is a costly and slow process, regional disparities slowly fade away, and the wage curve becomes a short run phenomenon (Blien, 2001) reinforced by the existence of costs associated with job searching or commuting.

Following a spatial economics perspective, Suedekum (2006) provides a justification for the negative association between wages and unemployment by considering a theoretical model based on increasing returns in production. Large and affluent regions enjoy higher wages and employment levels, while sluggish areas deal with the bad side of the curve. According to this model, such a relationship holds both in the short run and in the long run. Also, from a spatial perspective, Longhi et al. (2006) consider the theory of monopsonistic competition and assume that local labour markets are not isolated islands: workers can commute and migrate, and consequently unemployment elasticity may depend on employment opportunities in neighbouring areas. Longhi et al. (2006) argue that local monopsony power due to fewer job opportunities can result in more pronounced wage curve relationships. Similarly, Baltagi et al. (2012), Baltagi and Rokicki (2014), and Cholezas and Kanellopoulos (2015) find lower elasticities in larger cities than in smaller cities or rural regions, although Jokinen (2020) finds that the impact of agglomeration disappears when accounting for unobserved worker heterogeneity.

One can also expect to observe changes in labour market institutions or in other global characteristics affecting the functioning of the labour market. Local wage responsiveness to unemployment is contingent on labour market institutions, such as the (de)centralisation of wage bargaining systems. These characteristics are usually shared by all regions in a country, and still, there is evidence of heterogeneous slopes of the wage curve across regions of the same country (Deller, 2011). Changes in labour market institutions have been considered drivers of changes in wage curve elasticity. Devicienti et al. (2008) and Daouli et al. (2017) analyse the change in elasticity as a result of labour market reforms in Italy and Greece: both works find that legislative changes played a role in promoting labour market flexibility. Examples of these reforms are changes in the bargaining process or declines in the level of minimum wages.

It is worthwhile, then, to study the changing patterns of the elasticity of wage curve in light of institutional changes in the labour market and over the business cycle. Alternative and competing theories stress the differentiated short versus long run dimension of the wage curve. Consequently, we inspect the evolving changes of elasticities over time in order to gain further knowledge of tidal movements of spatial labour markets.

3. THE SPANISH LABOUR MARKET

The impact of the Great Recession on the Spanish economy has been huge, particularly in a European context. It was the deepest and longest crisis since the civil war in the 1930s: unemployment rates climbed to 25% and 3.5 million jobs were destroyed. Despite these catastrophic outcomes, the recovery has been formidable, averaging some 400,000 net jobs created per year from 2014 to 2019.

Several authors have studied resilience in Spanish regions. According to Cuadrado-Roura and Maroto (2016), the most resilient Spanish regions are those previously specialised in dynamic and productive industries, which are reinforced by location advantages (Angulo et al, 2018). Ríos et al. (2017) remark on the role of social and demographic factors as resilience predictors, while Geelhoed et al. (2020) emphasise the role of inequality in employment resilience.

Ramos et al. (2015, p. 127) describe the Spanish labour market as “characterised by an intermediate collective bargaining system with high coverage, high firing costs, a quite generous benefit system, and a very high volatility of employment, with very high rates of unemployment during economic crisis.” Melguizo and Royuela (2020) describe the active role of migration in the spatial labour market equilibrium. Several other authors confirm that there are persistent and wide employment growth disparities linked to the business cycle (Bande and Martín-Román, 2018; Sala and Trivín, 2014). The limited flexibility of wages is compensated by a large share of fixed-term contracts, which are linked to the monopsonistic power of firms to settle wages and, subsequently, to the existence of a wage curve. This empirical law has been confirmed in a number of studies (García-Mainar and Montuenga-Gómez, 2003, 2012, Sanromá and Ramos, 2005). The spatial dimension of the wage curve has been analysed by Bande et al. (2012) and Ramos et al. (2015). Both articles reinforce the importance of spatial spillovers and the need to deepen the analysis of the spatial heterogeneity of the association.

From a historical perspective, the Spanish labour market displays inadequate adjustment mechanisms, with strongly volatile cyclical responses, important contract duality, weak and rigid growth in real wages, massive job losses during recessions, and high structural unemployment rates. The persistence of these circumstances helps to affirm that it is simply not true that the weaknesses of the Spanish labour market are due to temporary or cyclical circumstances (Hidalgo, 2012). In the context of labour market regulations, two important reforms were undertaken in 2010 and 2012. Both reforms, developed by governments of different political parties, tried to improve labour market efficiency (see Doménech et al., 2016, 2018, for further details). These transformations mainly sought to improve internal flexibility in terms of wages and worked hours rather than in terms of employment and deriving collective agreements that aligned with the changing economic conditions. The reforms focused on improving the decentralisation of the collective bargaining system, prioritising agreements at the firm level; reducing the cost of dismissal; and increasing internal flexibility mechanisms. Our hypothesis is that these reforms should have increased the responsiveness of wages to labour market conditions in the different labour markets, with greater effects on regions that were more affected by the crisis.

4. EMPIRICAL STRATEGY

We focus on the analysis of wage curve elasticities as a measure of the efficiency and adaptation resilience of Spanish local labour markets by estimating local responses to the changing labour market conditions. Our empirical approach involves estimating local wage curves, assuming spatial heterogeneity in local labour markets.

Blanchflower and Oswald’s (1990, 1994) specification of the wage curve consisted of a regression of the logarithm of individual wages on a number of control variables related to individual and job characteristics and the regional unemployment rate. However, as Moulton (1986) demonstrates, the OLS estimation of this equation, which includes a variable of interest (unemployment rate) that is defined at a higher level of aggregation than the dependent variable (individual), will bias the values of the test of individual significance for this variable upward. Moreover, the inclusion of additional variables in order to correct for the possible omission of relevant variables at the regional level usually induces collinearity problems.

For these reasons, the standard approach in more recent literature consists of applying a two-step procedure, as in Bell et al. (2002) and more recently in Ramos et al. (2015) for the Spanish case. The first step consists of a Mincer equation estimated at the individual level, including controls at the individual and the firm level and time-varying regional dummies. These dummies can be interpreted as adjusted wages in the local labour market, corrected for composition effects. In particular, the first step of the procedure involves estimating the following equation:

$$\ln(w_{irt}) = \alpha Z_{irt} + \delta_{rt} + \pi_t + \theta_r + \varepsilon_{irt} \quad (1)$$

where $\ln(w_{irt})$ is the natural logarithm of the wage of individual i who lives in region r at time t ; Z_{irt} is a set of individual factors that can affect the individual’s wages, such as the level of schooling, his/her experience, or other characteristics such as occupation; π_t and θ_r are monadic period and region fixed effects; while δ_{rt} are region-period dyadic specific effects that can be interpreted as average wages in region r at time t corrected for composition effects and free of global business cycle and region fixed effects. Finally, ε_{irt} is a random error term that follows a normal distribution with zero mean and constant variance.

In the second step, the wage curve is estimated using the composition corrected wages δ_{rt} obtained in the first step, as the endogenous variable and the natural logarithm of the regional unemployment $\ln(u_{rt})$ is introduced as an explanatory variable together with time fixed effects γ_t , that control for all common shocks to the considered regions; regional fixed effects δ_r , capturing unobservable regional heterogeneity; and additional time varying regional characteristics Z_{rt} that can also affect regional wages, such as aggregate regional productivity:

$$\widehat{\delta}_{rt} = \beta \ln(u_{rt}) + \theta Z_{rt} + \gamma_t + \delta_r + v_{rt} \quad (2)$$

Usually, this second equation is estimated by OLS or instrumental variables procedures, depending on the assumption of the endogeneity of the level of unemployment on wage formation. There is a vast body of literature developing spatial analysis in order to capture the spatial nature of the association. Nevertheless, we are not interested in the estimation of the elasticity of the wage curve alone. We want to describe the local response of every administrative region, which we see as a strong enough approximation to every local labour market, during the Great Recession. Consequently, we are interested in the local heterogeneity of such elasticity.

Several works have been focused on the study of the spatial heterogeneity of the wage curve. Longhi et al. (2006) hypothesise that the cause of spatial non-stationarity is differentiated labour market accessibility, and that this parameter can be stronger in rural than in urban areas. Both Longhi et al. (2006) and Deller (2011) estimate cross section Geographic Weighted Regressions (GWR) to show local heterogeneity in the wage curve, finding important differences over the space. Other works consider heterogeneity from different points of view, including rural-urban (Baltagi and Rokicki, 2014; Jokinen, 2020), level of development (Bande et al., 2012), and time (Devicienti et al., 2008, Daouli et al., 2017).

In our work, we simultaneously consider a double source of heterogeneity. Specifically, we use a GTWR approach to simultaneously account for spatial and time heterogeneity in the estimation of equation (2). GTWR (Huang et al., 2010, Wu et al., 2014, Fotheringham et al., 2015) is an extension of GWR accounting for local effects in both space and time. The main advantage of the chosen approach is that time effects are not constrained to being constant over space. This technique extends the traditional regression framework and assumes the existence of non-stationarity. In addition to GWR, time is also a variable considered in the weighting scheme of the estimation. The GTWR can be expressed as:

$$Y_i = \beta_0(u_i, v_i, t_i) + \sum_k \beta_k(u_i, v_i, t_i)X_{ik} + \varepsilon_i \quad (3)$$

The parameters will vary in space and time, and the estimation is based on a weighting scheme in which the weighting matrix depends on the spatial and time distance between observations. In the traditional GWR framework, weights are defined as spatial kernels based on the physical distance, d_{ij} , and are usually transformed following Gaussian or bi-square functions, which can be fixed or adaptative. In GTWR models, distances are also complex, as they include time distance. Wu et al. (2014) propose a spatio-temporal distance between observations i and j observed in different locations and times, labelled as t_i and t_j :

$$\begin{cases} d_{ij}^{ST} = d_{ij}^S \otimes d_{ij}^T = \lambda d_{ij}^S + \mu d_{ij}^T + 2 \sqrt{\lambda d_{ij}^S \mu d_{ij}^T} \cos(\xi), & t_j < t_i \\ d_{ij}^{ST} = \infty & t_j > t_i \end{cases} \quad (4)$$

where d_{ij}^{ST} is the spatio-temporal distance, d_{ij}^S and d_{ij}^T are the physical and time distance respectively, and λ, μ and $\xi \in [0, \pi]$ are adjustment parameters that can be optimised with cross validation procedures in terms of R^2 or AIC values. The interaction between space and time is governed by parameter ξ : when $\xi = 0$, space and time have the maximal effects, while if $\xi = \pi/2$, if there is no interaction between both dimensions. In practical terms, the weight assigned to the spatial (λ) versus the time distance (μ) can be normalised assuming $\mu = 1$, which leaves parameter λ with the relative weighting role. Consequently, in addition to the usual spatial kernels parameters, two additional parameters, λ and ξ , need to be chosen.

5. DATA

In this paper, we use information from the Continuous Sample of Working Histories (*Muestra Continua de Vidas Laborales*; hereafter MCVL). In particular, we use data from the 2006 to 2018 waves. Every wave provides information on more than one million individuals (representing around 4% of the total population) who have had relationships with the Social Security system during that year, regardless of the duration or the nature of the type of relationship (work, unemployment benefits). The MCVL is an administrative longitudinal matched employer-employee dataset that reproduces the labour history of affiliated workers starting from their first job. To build our sample, we have merged the 2018 wave with the waves from 2017 to 2006. Since we know the full work history of these workers, we have information back to 2002.¹⁰² We have limited our analysis to individuals between 16 and 65 years old without disabilities who are observed for at least for two quarters during the considered period. The total number of observations considered in the analysis is 33,462,242 covering 52 provinces, the NUTS III level regional units in Spain that provide a good approximation to local labour markets. This is also the maximum regional level of detail for which unemployment rate data is available from the Labour Force Survey carried out by the Spanish National Institute of Statistics (INE).

MCVL provides information on monthly wages, type of contract (permanent/fixed-term), part-time/full-time, occupation (*grupo de cotización*), and the number of workers, the activity sector, and the location of the firm. It also contains information about the worker such as gender, country of birth, age, and schooling levels, that can be transformed into schooling years and allow us to compute potential labour market experience by applying the usual expression, age-schooling years-6.

Regarding wages, as provincial unemployment rate data from the Labour Force Survey is only available at the quarterly frequency, we construct earnings by averaging monthly wages considering the time worked by each individual. If the individual had more than one job during the considered period, we took the job with the greatest earnings. We use

¹⁰² Considering years before 2002 increases the risk of attrition, because the database is not representative in this time frame, except for in the years where extraction is done. However, from 2002 to 2006, the Spanish economy was in an expansionary phase with no significant regional differences.

quarterly averages of provincial Consumer Price Indexes provided by the INE to deflate quarterly wages, expressed in real terms and transformed using natural logarithms.¹⁰³

Finally, we have also constructed a quarterly indicator of aggregate regional productivity using provincial Gross Domestic Product (GDP) per Worker from the *Contabilidad Regional de España* carried out by the INE. However, as these data are only provided at the annual frequency, we have applied Denton's (1971) method using as indicator the quarterly data on GDP per worker at the national level as provided by the *Contabilidad Trimestral de España* (INE).

6. RESULTS

In this section, we present the results of estimating the models discussed in the previous section. The results of estimating equation (1), the Mincerian wage model, are shown in Table 1. As we can see in in this table, the results are well in line with those in the literature. There is a wage gender gap of around 10 log points in favour of men in the Spanish labour market after controlling for several characteristics. Coefficients related to schooling year and potential experience are statistically significant at the usual level and show the expected signs, detecting a positive relationship between human capital and wages. Individuals who worked only part-time received significantly lower wages than those who worked full-time. The dummy variables related to fixed-term contracts also show the penalisation that these workers experience in the labour market compared to those with permanent positions. Workers in publicly-owned firms also have a positive wage premium compared to those employed by private firms. Occupational dummies also have the expected sign, as the reference category corresponds to high-skilled occupations while firm size also has a positive effect on wages. Information related to industry sectors (not reported but available from the authors on request) permitted us to control for the effect of the various productive and employment structures in the various provinces. Time dummies allowed us to control for common shocks to all regions in each quarter (also not reported but available from the authors on request), while province dummies control for permanent differences in local labour markets.

In equation (2), we use the estimates of time-varying region specific effects from equation (1) as the endogenous variable, and the natural logarithm of regional unemployment is introduced as an explanatory variable together with the logarithm of regional aggregate productivity and time and regional fixed effects. Table 2 presents the main results of the global model with no time or spatial varying effects. As can be seen in this table, the elasticity of adjusted wages to unemployment rate is quite weak. Once we account for regional productivity and province and period fixed effects, the parameter is significant and negative, but the size is rather small: -0.007. This value is in line with the impact parameter in Ramos et al. (2015), although it falls below their total effect once they account for the spatial effect (-0.073).

Note: Robust standard errors in parentheses. Significance: *** p<0.01; ** p<0.05; * p< 0.1. For the fixed effects we consider 68 periods of time (2002.q1-2018.q4) and 52 provinces.

We next look at the results of estimating equation (2) applying GTWR, in which we see time and spatial varying effects of unemployment on wages. In order to balance spatial and temporal distances, we opted to work with the maximum interaction parameter ($\xi = 0$), and we performed a battery of estimations to find the optimal weight for space/time. The parameter was obtained considering a fixed kernel and using a cross-validation procedure in terms of goodness-of-fit, reporting a value of parameter $\lambda = 0.0001$ ($\mu=10,000$).¹⁰⁴ We first display the results of two extreme situations of the GTWR specification. When $\lambda = 0$, the specification fully accounts for time varying effects. On the contrary, when $\lambda = 1$, all variation is spatial. Panels (a) and (b) of Figure 1 plot the results of these analysis, and panel (c) plots the results for $\lambda = 0.0001$ and $\xi = 0$.

As seen in panel (a), the temporal evolution of the parameter increases until the first quarter of 2006. Beyond that period, and close to the start of the Great Recession, we observe a decreasing pattern in the parameter. Interestingly, despite the start of the recovery of the economy in 2014, we can see a further decline in the value of the elasticity of adjusted wages to the unemployment rate, which we interpret as an improvement in the efficiency of the labour market. We want to believe that the reforms of the Spanish labour market are somehow associated with these results.

Results in panel (b) capture the cross section dimension of the data, as time has no impact on the weighting function of the GTWR estimates ($\lambda = 1$). We observe a strong spatial heterogeneity of the parameters. We find negative and significant parameters in Eastern regions (including Catalonia and Valencia and Aragon), Northern regions (such as the Basque Country, Cantabria, and Asturias), and some neighbouring Castilian provinces. These provinces are in line with the traditional negative sign of the wage curve: as unemployment increases, wages experience a declining pattern, in line with the efficiency wage approach, the labour turnover model, and the spatial model based on increasing returns in production. On the opposite side, we find southwestern provinces (particularly the less dynamic region of Extremadura), other western Andalusian provinces (including Seville), and some neighbouring provinces in the Castilian La Mancha. For these provinces we find non-significant and even positive parameters, a result that is opposite to findings explained in the literature by the theory of monopsonistic competition and the lack of employment opportunities. Consequently, our results report that more dynamic regions display more elastic and efficient labour markets, while the less developed regions are characterised by wages that are not responding to the local conditions of the labour market. These outcomes are in line with those of Bande et al. (2012), who find a stronger negative sign for more dynamic provinces, and they are partially aligned with Melguizo (2017), who detects spatial heterogeneity in provincial parameters of the Okun’s law (that there is an inverse relationship between unemployment and GDP).

¹⁰⁴ We have used the `gtwr` command of the `GWmodel` package in R (Gollini et al. 2015, Lu et al. 2019). Figure A1 in the Appendix displays the details of parameter selection according to goodness of fit (Adj R2) and AICc statistics, while Figure A2 displays the relative distance resulting from different parameters of λ . The final results using different parameters of weighting space and time did not change the main results of the basic specification. Additional results with different combinations of values for these parameters are available from the authors on request.

Next, Table 3 and Panel (c) in Figure 1 report the results of the GTWR model with additional combinations of parameters that depart from the extreme cases shown in Figure 1, and they optimise the adjustment criterion. Figure 1c displays a new picture of the wage curve. In line with what we find in Figure 1b, there are negative and significant parameters of the wage curve in the northeastern provinces, while we hardly find any positive and significant parameters other than some periods in Castilian provinces such as Avila. Non-significant parameters are present in large areas, including in the northwestern and central provinces. Interestingly, southern provinces, such as Seville and Málaga, display results that are negative and significant, in contrast with what we found in the cross-section picture resulting from Figure 1b. In addition to the spatial heterogeneity, Figure 1c adds to the results the evolution of these parameters in every province. Figure 2 complements the results by linking the evolution of the parameters in every province by sub-periods over the business cycle.

Effective degrees of freedom (n-2trace(S) + trace(S'S)): 2620.05									
AICc: -21569.65									
R-square value: 0.818									
Adjusted R-square value: 0.755									

The provinces with greater elasticity (those with lower parameters), mostly located the northeast, (such as Barcelona or the Balearic islands), saw more important declines, even becoming more elastic. As can be seen in Figure 2, these declines are stronger and mainly observed in the deep period of the Great Recession (2008-2014). Interestingly, we see a different direction in the subsequent period of recovery (2014-2018), when provinces with stronger elasticity in the wage curve are the ones moderating such effect.¹⁰⁵

Overall, we see an increasing importance of unemployment in the formation of wages. Before the Great Recession, only 18% of the estimated parameters were negative and significant. In the fourth quarter of 2005, a mere 4% of provinces (2 out of 52, Balearic Islands and Melilla) displayed a significant and negative parameter. Over the 2008-2013 period, that percentage increased to 36%, while in the recovery period (2014-2018), 50% of the estimates displayed a negative and significant parameter, with a peak in the third quarter of 2017, when 85% of the provinces (46 out of 52) report significant and negative wage curve parameters.

From a spatio-temporal perspective, our results clearly display a heterogeneous behaviour of the main parameter in the wage curve. Clearly, we see cyclical behaviour in the elasticity of wages, as there is an important decline since the start of the crisis. Nevertheless, after the labour market reforms in 2010 and 2012, the economic recovery initiated in 2014 did not affect elasticity in the same way. On the contrary, the lowest values of the wage curve are observed in the more recent period, which can be interpreted as an indication that labour market reforms have been effective.

It is important to remark that despite the important structural differences in local Spanish labour markets, we do not observe marked differences in the impact of the labour market reform. Although some of the labour markets experienced changes in the elasticity of the wage curve, these changes took place well before the institutional change was initiated, as can be seen in Figure 2. From a labour market resilience perspective, we understand our results in terms of wage flexibility to changes in local labour market conditions. Less developed areas display wage curve parameters that are opposed to flexibility, and consequently, they are less resilient to economic shocks. Our picture is very similar to the one

¹⁰⁵ Figure A3 in the appendix displays the box-plot over provinces and time of the parameters considered.

drawn in Cuadrado-Roura and Maroto (2016), and it is also in line with the results of Deller and Watson (2016). While these authors devote their work to connecting resilience to sectoral specialisation, we add as an explanation the heterogeneous behaviour of local labour markets. From an institutional labour market perspective, we see how a non-spatial policy, such as the labour market reforms in 2010 and 2012, had limited effects in terms of improving the conditions in non-efficient local labour markets.

Figure 2. Changes in the elasticity of wages to unemployment over time: 2002-2018

Note: Scatterplots represent the 52 Spanish provinces. The horizontal axis displays the parameter in the starting period and the vertical axis represents the change over the subsequent years.

Specific attention to Madrid, the strongest and most dynamic province in Spain, is warranted. We find few significant and negative results for this region. In this case, we interpret the results as a combination of the dynamic effect of the province itself and the weaknesses of surrounding provinces, which are being *absorbed* by the capital of the country. One can argue that Madrid can be understood as having the opposite situation of monopsonistic competition in the labour market, as firms face a very competitive environment and difficulties in lowering salaries.

Finally, figure A4 in the appendix plots the GTWR results for the log of GDP per worker. The results are positive and significant, and consequently the adjusted wages respond to changes in our measure of productivity, although this effect declines in more recent periods.

We checked the robustness of our results to several estimation techniques. We have inspected the role of the spatial bandwidth in our results. While we have mainly opted for Gaussian kernels, we considered spatially adaptive rather than fixed kernels. While there were some alternative results, the overall picture and our main conclusions do not change.¹⁰⁶

7. CONCLUDING REMARKS

In this paper, we have studied the resilience of local labour markets in Spain during the Great Recession. Rather than analysing traditional outcomes such as income and employment, we study the association between wages and unemployment, the so-called wage curve. This association is a measure of labour market flexibility, a characteristic that helps local labour markets to achieve a faster recovery from economic shocks—a key dimension of resilience. We have used microdata from the Continuous Sample of Working Lives, a random sample of 4% of all individuals who contributed to the social security system, and we have computed adjusted wages free of personal characteristics for all Spanish provinces (NUTS-III), our main unit of analysis. We have analysed the responsiveness of the locally adjusted wages to unemployment rates between 2002 and 2018 and considered the spatial heterogeneity in a dynamic wage curve by means of a Geographic and Time Weighted Regression (GTWR).

Our findings show weak elasticity of wages to the unemployment rate. Still, we observe an increasing pattern in the absolute value of the parameter during the Great Recession, which continues over time despite the start of the economic recovery in 2014, which we link with the reforms of the labour market implemented by two consecutive governments (2010 and 2012). We also find a strong spatial heterogeneity of the parameter, which is negative and significant in a subset in the northeast of the country. On the opposite side, we find southwestern provinces, particularly the less dynamic region of Extremadura and other western Andalusian provinces. When we estimate together spatial and time varying parameters, we find a time-varying response that is more intense in those provinces with already high elasticity values.

Our results suggest that the labour market reforms of 2010 and 2012 had important effects, which are observed nationally and at the local level. Nevertheless, the effect is heterogeneous over local labour markets. In policy terms, we

¹⁰⁶ These results are available upon request.

find that global labour market reforms are important mechanisms to improve the efficiency of the labour market. Nevertheless, they should be also be defined in local terms, as suggested by López Mourelo and Malo (2015). We understand that our work can be improved a several areas. First, we assume that we could have worked with a more sophisticated empirical model, for instance assuming lagged wages as an explanatory variable or including spatial dependence in the analysis, as other papers in the literature have done. In any case, as our focus is the analysis of spatio-temporal heterogeneity, we believe that our results are not invalidated for alternative specifications. We also agree that we do not perform a causal evaluation of the labour market reforms, which is not our main aim. Finally, we understand that the inspection of the causes of the observed heterogeneity in the spatial labour markets can be of substantial interest for further research.

ABSTRACT

We study the employment effects of minimum wage changes by uncovering and explaining inter- and intra-regional heterogeneities. For this purpose, we explore variations in the minimum wage bite across age groups, economic sectors, regions in time. Compared to previous studies, we use a novel, multidimensional panel data approach that allows us to simultaneously analyze the heterogeneous effects of minimum wage changes on employment elasticity among different groups of workers. We found regions characterized by factors that simultaneously stimulate employment elasticity and rigidity. Those factors influence different groups of workers and tend to mitigate the impact at a regional level.

KEYWORDS

Employment, minimum wage, regional labor markets, hidden heterogeneities, Poland

FUNFING

1. INTRODUCTION

Considerable research has been conducted on the relationship between minimum wages and employment; however, both the direction and strength of this relationship have not been unanimously determined. Meta-analyses for both developed (see Neumark and Wascher, 2007) and developing countries (Neumark and Munguia Corella, 2019) point to the heterogeneity of the workforce as the main source of inconsistency in the results. Minimum wage increases tend to negatively affect the employment of vulnerable groups of workers (young and less educated).

Workers with basic qualifications and less labor market experience usually receive the lowest wages. Moreover, the diverse levels of qualification required in some occupations, together with both personal and firm characteristics, cause differences in the distribution of low-wage workers across economic sectors and regions. Therefore, as Autor et al. (2016) argue, changes in minimum wages may have different impacts across regions and their effects on employment can induce heterogeneous responses. Analyses performed among US regions indicated that employment elasticity due to minimum wage changes is significantly diversified across states (Williams, 1993) and counties (Thompson, 2009).

Most prior analyses of minimum wage changes on employment usually considered only two dimensions. The employment effects were investigated across, for example, age groups, educational groups, or regions, over time. This study adopts a multidimensional panel model to account for the latent heterogeneities in the minimum wage effects on employment. Given the contentious background in the minimum wage and employment literature, Wang et al. (2019) argue that the versatility of the panel model in accommodating heterogeneity offers a fresh approach to this long-standing issue.

In our approach, we take advantage of the extensive database of individual wages and employment characteristics available and analyze the effects of minimum wage changes on employment across four dimensions simultaneously. We construct a panel using three-dimension cells formed by three age groups, three economic sectors, and 16 regions, separately for each year. These cells are our units of observation.

We commence by estimating the average employment elasticity concerning a minimum wage for all cells before applying the slope homogeneity verification test recently developed by Bersvendsen and Ditzen (2020) for panel data. After rejecting the homogeneity of the employment effect across cells we simultaneously vary the parameter of the minimum wage variable across cells (age-group, economic sector, and region). Finally, we perform a cluster analysis to explain the differences in employment elasticity across clustered cells of workers.

The multidimensional approach enables analyzing differences in employment elasticities for relative minimum wage among regions, economic sectors, and age groups. Moreover, we can simultaneously analyze the differences in employment effects within regions: for the same age groups but in different sectors, or the same sector but for different age groups. For example, we compare employment elasticity in a group of young workers in an industry for a given region to that obtained by the same group in another region. We can also compare employment elasticity in a group of young workers in an industry in a given region with the employment elasticity in the group of middle-aged or older workers in the industry in the same region. Thus, we can conduct these analyses for all age groups, all economic sectors, and all regions.

This multidimensional approach has the inevitable advantage over prior studies in that it allows for a more detailed picture of the analyzed phenomenon. We study differences among regions together with heterogeneous reactions to policy changes within regions. We observe how regional differences in the sectoral and workforce age composition affect employment with increases in the minimum wage. To the best of our knowledge, this is the first study of this kind.

This study presents the empirical application of this approach to the Polish labor market. Analysis of the employment effects of minimum wage changes in Poland is interesting for several reasons. First, is the long history and simplicity of the minimum wage policy—it is conducted at a national level and covers almost all workers (see Appendix 1). Second, is the extent of its coverage. According to Eurostat data, Poland has amongst the highest share of minimum wage workers of all European economies. Third, a sustained increase in the national minimum wage in Poland was observed in recent years. Fourth, Poland exhibits large and enduring regional differences.

We use data on individuals from the Structure of Earnings Survey 2006–2016, the most comprehensive and reliable database on individual wages in Poland. We analyze employment in non-agricultural private sector firms with at least 10 workers, computing precise minimum wage bite measures based on regional, sectoral, and age-group wage distributions. In contrast to previous studies, we construct two minimum wage bite indicators—a nominal and real relative minimum wage. The latter uses both real minimum wage and real average wages (with different deflators), thereby creating a more robust bite measure of minimum wages.

In confirming the existence of regional differences in employment elasticity arising from changes in minimum wages, we discovered latent heterogeneities in the regional employment effect, with some regions simultaneously experiencing both negative and positive employment effects of minimum wage changes. Negative employment effects are observed mostly in the youngest groups of workers, while positive employment effects are predominantly in the groups of workers aged 50 and over.

The employment effect of changes in the minimum to higher wage levels is the result of a combination of regional labor market features. Negative employment effects are more probable in small, private sector firms where it is more difficult to increase the prices of goods or services produced. Conversely, positive employment effects are more probable in regions with high share of employed in public sector and with high share of employed in large enterprises. Significantly, these two completely different labor market environments can coexist within a given region which may explain why the empirical analyses at a regional level often indicated insignificant values of employment elasticity for minimum wage changes.

The remainder of this study proceeds as follows. Section 2 contains the literature review. Section 3 describes the data and the empirical approach. Subsequently, Section 4 reports the results and robustness analyses. Section 5 concludes.

2. REVIEW OF LITERATURE

In theory, the potential impact of minimum wage increases on labor demand depends on the market structure. While negative employment effects are expected in a competitive price-taker setting, a monopsonistic labor demand does not imply negative effects in general. Depending on the minimum wage level, the demand for labor may increase when workers are paid below the marginal product of labor (Caliendo et al., 2018).

The empirical literature on the employment effects of minimum wage increases is enormous, however, no definite consensus has been reached. Most studies indicate a small and negative impact of minimum wage growth on employment, particularly among the young and less educated (Neumark and Wascher, 2007; Kuddo et al., 2015; Broecke et al., 2017; Neumark and Munguia Corella, 2019). The findings that young workers are particularly vulnerable to minimum wage changes have been confirmed for many countries. Recently, Kiss (2018), using a sample of EU countries, found young workers to be characterized by significantly higher negative employment elasticities than older workers.

Moreover, a growing number of authors underline the heterogeneity of labor markets across regions as the main source of inconsistent elasticity estimates. Williams (1993) found that the elasticity of employment due to minimum wage changes in the US is highly heterogeneous among states, with the lowest elasticity observed in those less developed. Thompson (2009) confirmed the existing differences in employment elasticity with respect to minimum wage across US counties. Recently, numerous studies in Germany have been conducted. The vom Berge and Frings (2017) study finds that the minimum wage caused a contraction in employment growth in East Germany with a relatively high bite, while the Western part of Germany experienced no change in employment. These results were confirmed by Ahlfeldt et al. (2018). In Poland, few studies confirmed significant differences in employment or unemployment elasticity arising from minimum wage increases across regions (Melnyk, 1996; Majchrowska and Żółkiewski, 2012; Broniatowska et al., 2015; Majchrowska et al., 2016; Albinowski and Lewandowski, 2020).

Numerous studies also underline the impact of the regional labor market structure on the vulnerability of employment levels to minimum wage changes. Harasztosi and Linder (2019) found that disemployment effects were greater in industries that found it more difficult to pass the wage costs onto consumers. Munguía Corella (2020) found the elasticity of youth employment due to minimum wage changes negative and significant under perfect competition and positive, but insignificant, effects were found under full monopsonistic labor markets.

In this study, we follow the approach suggested by Card (1992), which relies on the extent to which regional labor markets are affected by the minimum wage. Wages differ among regions due to differences in the characteristics of workers and employers. This variation implies that the minimum wage affects workers in each region to a different extent. The minimum wage is supposed to affect less skilled and less experienced workers, for whom the literature has consistently established negative and significant employment effects. Therefore, the uneven distribution of young or less-educated workers across economic sectors and regions may result in differences in the impact of minimum wage on

employment in particular sectors of regional labor markets. We adapt this framework to the Polish case and apply a multidimensional approach to analyze the effects of the minimum wage changes on employment.

3. DATA AND MODELING APPROACH

3.1 Data

To identify the minimum wage effects on employment across subgroups of workers we need comprehensive and reliable wage data on the eligible population and their employment level, thus we use individual data on wages and employment characteristics from the Structure of Earnings Survey (SES). The SES is a large enterprise sample survey providing detailed and comparable information on the relationships between the level of remuneration and individual characteristics of workers (gender, age, occupation, work experience, and the highest educational level attained, among others) and those of their employers (economic activity, ownership sector, size, and the location of the enterprise). The SES, conducted biennially, covers around 13% of all enterprises of the national economy that employ more than nine workers. We select data from 2006 to 2016, totaling 6 periods. The advantages of this database include its high reliability and extent. The high reliability of the information on salaries is because wages are reported by the accounting departments of enterprises. Each sample is very large—over 660,000 observations in 2006 and nearly 800,000 in 2016. Although the database represents only entities employing more than nine workers when considering the employment structure in Poland with its very high share of self-employed individuals operating without job contracts (own-account workers), the authors estimate that the SES database covers nearly 90% of all contract workers in Poland¹⁰⁷.

We make adjustments to the initial database. First, we focus on the workers for whom the minimum wage is binding; we exclude workers younger than 18 years old or above the retirement age (older than 60 for women and 65 for men) from the initial sample. Second, we analyze only the private sector because the share of minimum wage workers¹⁰⁸ in the public sector in Poland is negligible—0.3% in 2006 and increasing to 1.2% in 2016. In the private sector, the share of minimum wage workers was 11% and 15% in 2006 in 2016¹⁰⁹, respectively. Third, we analyze those employed in non-agricultural sectors. Fourth, we include both full-time and part-time workers. The wages of part-time workers are recalculated as full-time equivalents.

The SES database is our source of data about the number of workers and their average wages. The other data included in the model (regional and sectoral GDP, population by age groups, and unemployment rate) is based on the 16 regions according to the NUTS2 level of regional classification and taken from the local data bank of the Central Statistical Office of Poland, Poland's largest publicly available database of the economy, society, and the environment.

3.2 Modeling approach

From the SES database, we obtain information about monthly salaries and individual characteristics of workers. Since the survey sample is randomly drawn every reporting period, it is impossible to create a panel of individuals. However, it is possible to simultaneously analyze the elasticity of employment across different sub-groups of workers, including by *age group*, *economic sector*, and *region*. We construct three-dimension cells separately for each year comprising three age groups (up to 30 years old, 30-50 years old, and 50 years and older), three economic sectors (manufacturing and construction, market services, and non-market services), and 16 regions at the NUTS2 level. These cells are our units of analysis.

We follow the standard approach proposed in the literature and estimate the parameters of the log-linear relationship between employment, minimum wage measure, and other variables. In particular, following the theoretical model proposed by Dickens et al. (1994) we include both demand and supply-side variables in the model. We use *gross value added* in economic sectors and regions as a measure of local demand shocks. We also include time effects to control for the aggregate demand shocks. *Population size* approximates the supply shocks. *Workers' unemployment rate* approximates business cycle changes. The 4-dimensional panel data model we used in our analyses is expressed as

$$emp_{R,N,A,T} = \alpha_0 + \alpha_1 wrel_{R,N,A,T} + \alpha_2 gva_{R,N,T-1} + \alpha_3 pop_{R,A,T} + \alpha_4 ur_{R,T} + \sum \delta_{R,N,A} + \sum T_T + \varepsilon_{R,N,A,T} \quad (1)$$

where

$emp_{R,N,A,T}$ indicates the logarithm of the number of workers employed¹¹⁰ in region R (R=1, 2, ..., 16), economic sector N (N=1 - industry and construction, 2 - market services, 3 -non-market services), age group A (A=1 - less than 30 years old, 2 - 30-49 years old, 3 - 50 years old and above) in year T (T=2006, 2008, 2010, 2012, 2014, 2016);

$wrel_{R,N,A,T}$ represents the logarithm of the relative minimum wage (minimum to average wage ratio) in region R, economic sector N, age group A, at time T;

$gva_{R,N,T}$ indicates the logarithm of gross value added in region R, economic sector N, at time T (millions of PLN, constant 2010 prices);

$pop_{R,A,T}$ denotes the logarithm of the population in region R, age group A, at time T (thousands of people);

$ur_{R,T}$ is the logarithm of the unemployment rate of male workers of working age in region R at time T (%);

$\delta_{R,N,A}$ is the cell fixed effect;

107 According to the data from the Central Statistical Office in Poland, only 34% of workers in micro firms in 2016 were employed on a job contract.

108 According to the Eurostat definition we treat minimum wage workers as those receiving less than 105% of the minimum wage (https://ec.europa.eu/eurostat/statistics-explained/index.php/Minimum_wage_statistics#Proportion_of_minimum_wage_earners).

109 Source: SES data; own calculations.

110 We use small letters for the variables in logarithms, and capital letters for the variables in real values.

T_T are time effects, and

$\varepsilon_{R,N,A,T}$ represents the error term.

As a measure of employment, we take the number of workers in a given cell—those employed in enterprises with at least 10 workers within the non-agricultural, private sector in Poland. Following Caliendo et al. (2018) we decide to use the log employment level, not an employment-to-population ratio because the latter not only reflects changes in employment levels but also changes in the population. We include population at the cell level as a control variable.

The definition of minimum wage bite used in the model is crucial to our analysis. Prior studies mainly focus either on the Kaitz index (which measures the ratio between the minimum wage and the mean wage) or the proportion of minimum wage workers in the given group—both have advantages and disadvantages (see Caliendo et al., 2018). Our minimum wage bite measure is the Kaitz index—the relative minimum wage calculated as the minimum to average wage ratio for a given cell. Specifically, the intensity with which wages need to change following minimum wage changes is heterogeneous between regions, age groups, and economic sectors. In those cells where the minimum wage bites hardest, adaptations in wages will be stronger along with those of labor demand (Caliendo et al., 2018).

For our analysis, we calculated both the nominal and real relative minimum wage. In the first approach, we use the difference between the log of nominal minimum wage level applicable in a given year and the log of nominal average wages (average monthly wage of individuals without bonuses) in a given cell. Since the minimum wage is unique to all workers, the variation in this minimum wage bite measure comes from minimum wage differences over time and the differences in average wages across cells over time. This variable—*nominal relative minimum wage*—can be shown as

$$wmin_T - wave_{R,N,A,T} = nwrel \quad (2)$$

where $wmin_T$ is the log of the national minimum wage at time T and $wave_{R,N,A,T}$ is the log of the average wage level in a given cell consisting of region R , economic sector N , and age group A , at time T .

However, as Card and Krueger (1994) observed, in times of prosperity, both employment and average wages rise, causing a decline in the calculated value of the relative minimum wage measure. Similarly, in times of recession, employment and the average wages fall, generating a rise in the relative minimum wage. As a result, there is a negative correlation between employment and the relative minimum wage due solely to movements in average wages, regardless of whether employers respond to a higher minimum wage with lower employment or recruitment levels (Belman and Wolfson, 2016).

Consequently, another proposition in the literature is to use a real minimum wage measure (Williams, 1993)—the ratio of the real minimum wage to real average wages. The problem frequently encountered in empirical analyses is the unavailability of regional price indices. We took advantage of the data availability of regional price levels and constructed the real value of the minimum wage and real average wages. The nominator and denominator were deflated using two different price level measures: i) to calculate the real regional average wage a consumer price index published by the Central Statistical Office of Poland is used and ii) to calculate the real value of the minimum wage at the regional level we use the information on the minimum subsistence (social) level calculated and provided by the Institute of Labor and Social Studies¹¹¹ (see Appendix 2 for more information). The rationale for using two different deflators is straightforward: if we divide the numerator and denominator by the same deflator value, there will be no change at all.

Therefore, for the second approach, we calculated the difference between the log of the real minimum wage in a given region R at time T and the log of the real average wage in a given cell. This variable—*real relative minimum wage*—is shown as

$$real_wmin_{R,T} - real_wave_{R,N,A,T} = rwrel \quad (3)$$

where $real_wmin_{R,T}$ is the log of the real minimum wage (nominal minimum wage deflated by regional price level calculated from the social minimum) in a given region R at time T , and $real_wave_{R,N,A,T}$ is the log of real average wage (nominal average wage deflated by the regional CPI) level in a given region R , economic sector N , age group A , at time T . From further analyses, the real relative minimum wage is our superior option as the minimum wage bite measure of the higher quality. However, having these two minimum wage bite measures allows us to compare whether the employment effects across different groups of workers are systemic. We use the nominal relative minimum wage in the robustness checks.

In our model, we use contemporary values of minimum wage bite variables. In Poland, the information on the minimum wage increase for the next year is usually available in June of the previous year (in September at the latest¹¹²). Therefore, entrepreneurs have sufficient time to adjust their firms' policies to upcoming changes.

We use *gross value added* in a given economic sector and region as a measure of *demand shock* which can affect employment. It is measured at 2010 constant prices and is lagged one period to avoid simultaneity problems—a recently increased minimum wage may influence both the levels of employment and production. Production can be modeled as a persistent stochastic process; and changes in the current minimum wage level do not affect production levels in the previous period. We use the regional male unemployment rate as a measure of the regional business cycle. The unemployment rate affects men of working age as most vulnerable to changes in aggregate demand.

Following the literature, we add the measures of supply shocks affecting employment. In particular, information regarding population size in a given age group and region to capture the idiosyncratic difference among regions. The population is measured in thousands of inhabitants. Table A1 in Appendix contains descriptive statistics of the variables used in the model across the cells. Table A2 contains additional information about the distribution of employment

111 <https://www.ipiss.com.pl/?zaklady=minimum-socialne>

112 For more about minimum wage policy in Poland see Appendix 2.

variables across age groups and economic sectors. It indicates that the number employed in the non-market services sector is much lower than in other economic sectors.

Our main parameter of interest in Model (1) is α_1 which shows the direction and strength of the relationship between the minimum wage bite and employment. Our identification strategy is based on Card's (1992) observation that "a rise in local (state) minimum wage will typically affect a larger fraction of workers in some regions (states) than in others". The induced variation creates a simple natural experiment for measuring the effect of minimum wage change. The intensity of how wages need to change under a new minimum wage should be related to the fraction of workers initially earning less than the new minimum wage (Caliendo et al., 2018).

To test this empirically, we first estimate the parameters of equation (1) for the full sample to obtain an average value of the parameter of interest. We assume the homogeneity of the employment elasticity concerning the minimum wage variable across cells, which we use as units of observations. However, both theoretical consideration and previous empirical results emphasize that minimum wage increases affect different groups of workers to a different extent.

Thus, our second step is to test the slope homogeneity of the coefficient of minimum wage bite measures across cells recently developed by Bersvendsen and Ditzen (2020). It allows for verification of slope homogeneity in a panel data context with no correlation (Pesaran and Yamagata, 2008) or using the heteroscedasticity and serial correlation version (Blomquist and Westerlund, 2003), which we employ due to our cells differing in size. The influence of control variables such as gross domestic product, population, and the unemployment rate is held constant. We start from 4-dimension cells and if the homogeneity is rejected, we reduce dimensionality. As the test requires a panel setting, we are unable to eliminate the time dimension.

In the third step, we relax the homogeneity of the employment elasticity of the minimum wage variable and allow the parameter α_1 in Model (1) to vary simultaneously across age groups, economic sectors, and regions. In the fourth step, we explain the results using cluster analysis.

A generalized least squares technique that allows for heterogeneous error structure is used to correct for heteroscedasticity arising from aggregation. We do not weight the units of observations in the model and treat each cell as a separate observation since we are interested in estimating the employment elasticity separately for each cell and thereby comparing them with each other.

4. EMPIRICAL ANALYSES

We first estimate the parameters of Model (1) for the full sample of non-agricultural, private-sector workers in Poland grouped in cells. As our main minimum wage bite measure the real relative minimum wage is used (nominal relative minimum wage acts as the robustness check). The sample includes workers from all regions, all age groups, and all economic sectors as defined. Time effects are included to control for the common shocks across regions and the fixed effects to consider the cells' specific features. Therefore, to choose the model best fitted to empirical data, different specifications are tested: (a) with no cell fixed effects and no time effects, (b) with time effects only, (c) with cell fixed effects only, and (d) with both cell fixed effects and time effects.

Table 1. Results of Model (1) with real relative minimum wage bite for three economic sectors

	3 Economic Sectors			
	(a)	(b)	(c)	(d)
<i>rwrel</i>	-0.412*** (0.086)	-0.302*** (0.088)	0.037 (0.072)	0.080 (0.071)
<i>gva(-1)</i>	1.621*** (0.025)	1.699*** (0.024)	0.672*** (0.049)	0.347*** (0.126)
<i>pop</i>	-0.219*** (0.033)	-0.235*** (0.036)	0.831*** (0.084)	0.942*** (0.076)
<i>urate</i>	0.116** (0.050)	0.434*** (0.077)	-0.180*** (0.019)	-0.103*** (0.036)
<i>constant</i>	-4.054*** (0.381)	-5.166*** (0.434)	-6.808*** (1.352)	-4.861*** (1.563)
N	720	720	720	720
Cell fixed effects	No	No	Yes	Yes
Time effects	No	Yes	No	Yes

Note. * p<0.1, ** p<0.05, *** p<0.01

Source: Own calculations.

Table 1 presents the estimation results for all specifications. Models without cell fixed effects (a) and (b) the coefficient beside minimum wage variable is negative and significant. When cell fixed effects are introduced into the model the results change substantially. The relationship between employment and relative minimum wage becomes insignificant independently of time effects. The cell fixed effects are significant in all the specifications where they are included. Moreover, the results of the Wald test for the model with and without cell fixed effects— $\chi^2=83.77$ (0.000) and $\chi^2=169.11$ (0.000), respectively—indicate that the time fixed effects should be also included. Therefore, our preferable specification contains both cell fixed effects and time effects (Model (d)). When the minimum wage bite measure is included, the real relative minimum wage is our superior option as the wage bite measure of the higher quality. The average employment elasticity for real relative minimum wage is 0.080 but is statistically insignificant. The results of the

model with nominal relative minimum wage bite measure are similar—with an elasticity of 0.088 and statistically insignificant (see Table A3 in Appendix 3). The statistical insignificance of our parameter of interest value in the full sample follows our intuition and former studies. The sample is based on information from all workers—whether the minimum wage is binding or not. The results of previous research indicate that negative and significant values of employment elasticity for minimum wage applied to the most vulnerable groups of workers (young and less educated) only.

Regarding other variables in the model, we observe that employment is positively correlated with *gross value added* and *population* (see Table 1). Labor demand is derived, hence higher production in a given industry and region translates into higher employment. The level of employment also increases with the size of the population in a given age group and region. Moreover, a negative correlation between the local unemployment rate and level of employment is found. All the results are in line with economic theory and estimates obtained in other research. The value of (lagged) gross value added captures the differences in economic development across economic sectors and regions but also contains a common production trend in the time dimension. Therefore, a statistically significant estimate for lagged gross value added in models with time effects should be interpreted as significant regional and sectoral deviation from this trend. The results in Table 1 show that the value of the parameter by lagged gross value added is significant in specifications that include time effects, which indicates that the regional and sectoral deviation of production from the aggregate trend.

Our model estimated the average employment elasticity affected by minimum wage changes for the full sample, indicating that we assumed the homogeneity of employment effects across age groups, economic sectors, and regions (cells) in time—this assumption is not necessarily valid. Therefore, we perform the Bersvendsen and Ditzen (2020) homogeneity test, with results summarized in Table A4 in Appendix 3. They indicate that when observations are divided into 4-dimension cells, substantial differences in the impact of minimum to average wage on employment are observed. A different picture arises in the case of 3-dimensional cells. The most significant factor causing the diversity of employment effects is regional variation in industry composition and age structure. When these are removed from the model, the impact of relative minimum wage on employment remains identical in each cell defined by age group, economic sector, and time. On the other hand, the model with cells defined by regions and time shows no statistically significant deviation from the homogeneity.

Therefore, in the third step, we relax the assumption of the homogeneity of employment elasticity for minimum wage variable across cells and simultaneously allow the parameter α_1 to vary across age groups, economic sectors, and regions. The estimation results of the elasticity of employment due to minimum wage changes are presented in Figure A1 of Appendix 3. We observe that the elasticity of employment differs considerably across cells. The estimate of the real relative minimum wage variable ranges from -11.0 to 9.0. These very high values of elasticity are difficult to explain from an economic standpoint and are possibly the side effect of using small sample sizes in the case of some cells in the non-market services sector (see Table A2 in Appendix 3). Therefore, we decided to remove the non-market services sector from the sample and analyze the employment effects only in the industrial and market services sectors.

Since the number of observations removed is relatively small, the results for the full sample of workers in 2 economic sectors (see Table 2) do not differ significantly from those obtained with the non-market services sector included. We repeat the Bersvendsen and Ditzen (2020) slope homogeneity test for the panel structure with 16 regions, 3 age groups, and 2 economic sectors. The results show that again the most important factor causing the diversity of effects are regional variations in age structure and industry. Removing one of these from the model is insufficient in not rejecting slope homogeneity—when they are both removed from the model, the impact of minimum to average wage on employment remains identical in each region (see Table A5 in Appendix 3).

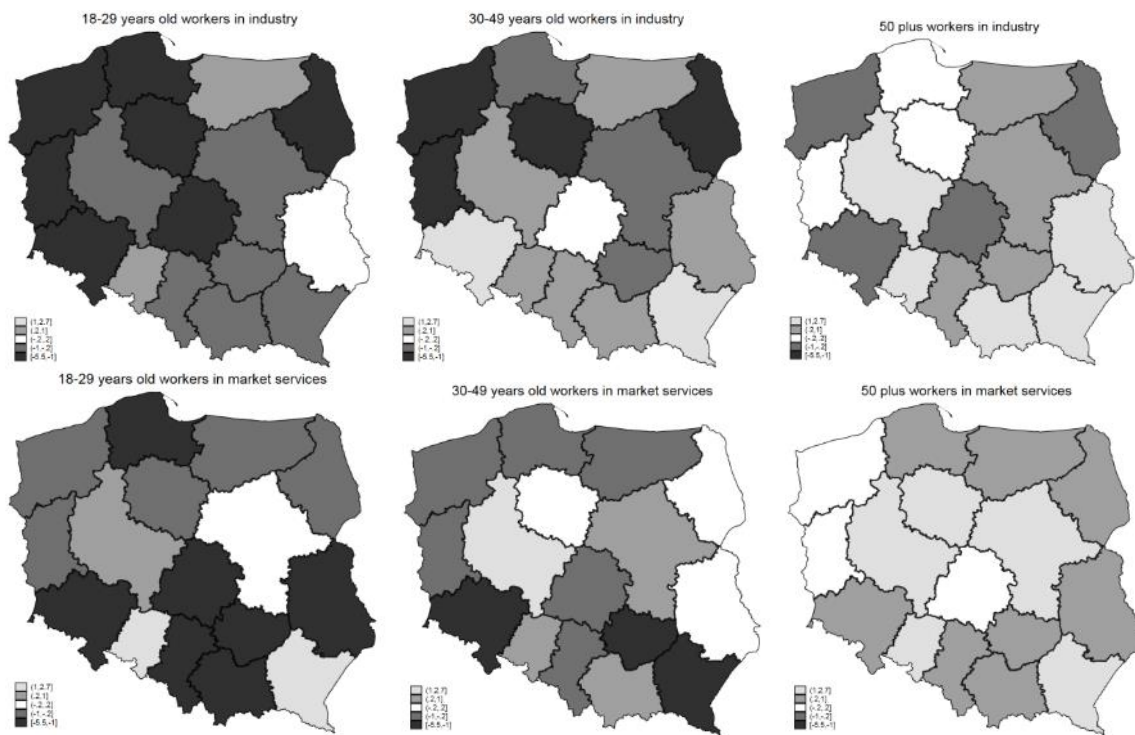

Figure 1. Elasticity of employment for real relative minimum wage across age groups, two economic sectors, and regions in Poland (2006–2016)

Note. Darker colors denote regions with negative employment elasticity across given age groups and sectors. Lighter colors indicate regional labor markets with positive employment responses. Small, mostly insignificant employment effects, are indicated in white.
Source: Own calculations.

Figure 1 presents the elasticity estimates for the model with two sectors (industry and market services) only¹¹³. The employment elasticity estimates are far more reasonable: they vary from -5.4 to 2.6. The results show that elasticity of employment for real relative minimum wage differs significantly across cells. Young workers (less than 30 years old) in the industrial and market services sectors are the most vulnerable to minimum wage changes (see Figure 1). Some regions indicate employment elasticities less than -1 while in others the employment effect is weaker; in general, however, in almost all regions, we find negative employment elasticities for young workers regardless of the economic sector.

Middle-aged workers (30–49 years old) are also affected by changes in the minimum wage, however, to a lesser extent. In about half of the regions, employment elasticities for this group of workers are negative regardless of the economic sector. In other regions, the reaction was either positive or insignificant. For workers aged 50 and older, we observe negative employment effects due to minimum wage changes only in four regions and the elasticity is less than -1. For this age group in most of the regions, positive and significant relationships are noted both in the industrial and market services. For robustness, we estimate models with nominal instead of a real relative minimum wage, the results of which confirm the main findings (see Figure A2 in Appendix 3).

Noteworthy in our approach is the fact that we can see the existing heterogeneity within regions. These differences are undetectable in one-dimensional or two-dimensional approaches. Prior studies indicated that, in some regions, employment levels were unaffected by minimum wage changes. By contrast, our approach indicates that statistically insignificant values of employment elasticity at the regional level very often completely mask diverse employment effects across age groups and economic sectors. Existing factors in those regions favor high elasticity of employment on minimum wages, including low levels of employment in sectors with high elasticity of demand with respect to prices or in the public sector with factors that simultaneously stimulate labor market rigidity, such as high employment in agriculture and large firms. Those factors influence different groups of workers, therefore they tend to be mitigated at an aggregate level.

The crucial question of why employment elasticities differ strongly among regions arises. Why in some regions do minimum wage changes negatively affect young workers but not in others? Why in some regions are middle-age workers negatively affected by the minimum wage and not in others? Why in some regions are negative relationships between youth employment and the minimum wage observed in the industrial sector and not in the market services and vice versa?

To explain these differences in employment elasticity among cells we further investigate the available regional employment structures and both employers' and workers' characteristics. These include educational structure (share of

¹¹³ With 96 employment elasticity estimates (16 regions times 3 age groups and 2 sectors) for cells it is difficult to present the results in tables. Full results are available upon request.

the population with lower than secondary education), the size of the employer (small versus large firms), and the proportion of workers in the agricultural, manufacturing, and public sectors. We also utilize the proportion of minimum wage workers and the minimum to average wage ratio.

Following prior empirical findings, we expect less-educated workers to be more vulnerable to minimum wage changes, with cells containing a larger share of workers with lower than secondary education indicating a greater elasticity of employment. Disemployment effects should be more pronounced in industries where it is difficult to pass wage costs onto consumers. Therefore, in the cells with a larger share of workers employed in the tradable sector, approximated by manufacturing, the elasticity of employment should also be greater. Similarly, following the empirical evidence (see Gibson and Stillman, 2009), we expect that large enterprises pay higher wages than small firms whose elasticity of employment should be higher. Conversely, we expect employment elasticity to be positively correlated with the proportion of workers in the public sector. Alfonso and Gomes (2014) show that the growth in public sector wages and employment positively affects the growth of private-sector wages. We expect that in less competitive environments—in cells with a higher proportion of workers in the public sector—the elasticity of employment is lower than in cells with more private-sector workers. Similarly, we expect the elasticity of employment to be lower in regions with a larger proportion of agricultural workers.

We perform a k-medoid cluster analysis with a Manhattan distance. We cluster employment elasticities using all the factors as data group determinants separately for each elasticity interval¹¹⁴, and choosing the best solution according to the Caliński and Harabasz criteria.

The cluster with the highest negative elasticity of employment (less than -1) is composed of young and middle-aged workers. These cells are characterized by the low proportion of workers in the public sector and a relatively high share of employment in manufacturing which indicates that in a more competitive environment the effect on employment is greater. These cells consist to a large extent of low-wage workers in some cells with 60% having less than secondary education, and with a relatively high minimum to average wage ratio. In these cells, we observe a relatively high proportion of workers in small firms. Interestingly, the group with very high employment elasticities consists of practically the same number of industrial and market services cells.

The cluster with a lower, but negative, elasticity of employment [from -1 to -0.2) includes workers across all age groups. Their characteristics are similar to those noted in the first cluster. This cluster consists of two sub-clusters: i) mostly less-educated middle-aged and older workers and ii) young, better-educated workers employed mainly in low-paid jobs. The relationship of the minimum to the average wage in both sub-clusters is high as well as is the share of minimum wage workers. A significant proportion of them is also employed in small manufacturing firms. All these factors make these workers vulnerable to minimum wage changes.

Apart from these clusters with negative employment elasticities, there are comparable numbers of cells where employment positively reacts to minimum wage changes. The cluster with the highest (above 1) and the second-highest (between 0.2 and 1) positive elasticity of employment consists of workers aged 50 and older and middle-aged workers. Positive values of employment elasticity are noted both in the industrial and market services sectors. These cells are characterized by a relatively large share of those employed in big firms (with 250 or more workers) where both the propensity and possibility to dismiss workers are lower than in smaller enterprises. Moreover, these cells exhibit the highest share of workers in the public sector suggesting that private employers are likely to follow public sector wage policy. These features explain why in these cells we do not observe negative employment elasticity even though a sizable proportion of low-wage workers is observed.

5. CONCLUSIONS

Our study aimed to analyze the differences in employment elasticity involving minimum wage changes across different groups of workers. We analyzed the employment effect of minimum wage changes across age groups, economic sectors, and regions simultaneously. According to our best knowledge, it is the first study of this kind.

At first, we assumed homogeneity of the employment elasticity of minimum wages. Next, using Bersvendsen and Ditzen's (2020) approach, we tested that assumption and rejected slope homogeneity. Then we constructed a four-dimensional panel to allow employment elasticity to vary across age groups, economic sectors, and regions simultaneously. Finally, we explained the obtained results using cluster analysis.

We confirmed the existence of regional differences in employment elasticity due to minimum wage changes. However, we discovered latent heterogeneities in the effect on regional employment. We were able to find regions with insignificant employment elasticities at the overall regional level but existing, latent heterogeneities inside. In many of the regions, the insignificant and close to zero overall results contain both strongly positive and strongly negative values of employment elasticities due to minimum wage changes for different groups of workers. It explains why the average value of the employment elasticity for all the groups is small and insignificant. Without implementing our four-dimensional approach finding these heterogeneities would be impossible.

Age is found to be the most important determinant of employment elasticity diversity. Negative employment effects are observed mostly among the youngest groups of workers. Conversely, positive employment effects are observed mostly in the groups of workers aged 50 and older. Among middle-aged workers, both negative and positive reactions are observed. However, the reaction of employment to changes in the minimum wage is also the result of the combination of other regional labor market features. In some regions, there is a high intensity of features that increase the probability of

¹¹⁴ Intervals used: $(-\infty, -1)$; $[-1, -0.2)$; $[-0.2, 0.2]$, $(0.2, 1]$, $(1, \infty)$.

negative employment effects, in some regions, there is a high intensity of features that increase the probability of positive employment effects.

Negative employment effects are more probable with a larger proportion of workers in the private sector, industries where it is more difficult to increase the prices of goods or services produced, and where small firms are widespread. In these regions, the employers act in a highly competitive environment, have more bargaining power, and the probability of unemployment is relatively high not only for young workers but also for middle-aged workers, especially those less-educated.

A positive employment effect is more probable in regions with a high share of workers in the public sector, large enterprises, or in the agricultural sector. In these regions, private sector employers have less bargaining power because they have to adjust their wage policy to wages offered in the public sector or to the income arising from agricultural production. Being employed in a big firm also diminishes the probability of dismissal even among less-educated workers. Significantly, these two completely different labor market segments coexist within a given region which explains why the empirical analyses at the regional level often resulted in insignificant values for the minimum wage parameter.

Our study presents limitations. First, the data used included only companies with at least ten workers. Unfortunately, individual data on micro-firms in Poland are not available. Small firms are usually found in the market services sector, in which labor costs are more important than capital cost, and those firms probably are more intensively affected by minimum wage changes. This may cause the effects of market services which we have ascertained can be underestimated. The second limitation stems from only being able to construct a biannual panel. Thus, we are unable to capture very unsuccessful firms that only survived for a shorter time. Third, there is a discrepancy in the data. Since workers are identified in the data through their firms, we infer the residence of the worker as the location of the firm. Since workers can commute to work over a long distance, spatial interactions should be considered. However, due to this being a very broad topic it should be subject to a separate study.

Appendix 1. Minimum wage policy in Poland

The national minimum wage in Poland is regulated by law. The level of the monthly gross minimum wage is established every year through negotiations within the Socio-Economic Council, composed of representatives chosen from the government, employers' organizations, and trade unions. If the Council is unable to reach a consensus, the minimum wage level for the following calendar year is decided solely by the Council of Ministers by no later than September 15th. The minimum wage in Poland is set up at the national level and covers workers in almost all sectors, regions, and occupations.

The annual increase in the minimum wage is guaranteed to be at least match the amount of the rise in price levels projected for the following year. In 2005 the Polish government introduced an automatic annual increase in the minimum wage, which reflects two-thirds of the forecasted GDP growth rate. This rule is set until the minimum wage reaches half of the average monthly wage in the national economy (Minimum Wage Act of October 10th, 2002 with changes).

Observing the evolution of the national minimum wage in Poland during the period analyzed it is noticeable that for 11 years it has more than doubled. It increased from 899 PLN¹¹⁵ in 2006 to 1850 PLN in 2016. Even in real terms, an increase of almost 70% is significant (see Figure 1). It is mostly due to a substantial increase from 2008–2009. In that period the national minimum wage in Poland was augmented by 20% and 13% y/y (16% and 10% respectively in real terms).

Figure A1.1. Minimum wage level (left scale, PLN) and minimum wage growth (right scale, %) in Poland (2006–2016)

Source: Eurostat and Central Statistical Office of Poland data; own calculations.

Appendix 2. The calculation of minimum wage deflator at regional level.

The Local Data Bank of the Central Statistical Office of Poland (CSO) does not provide any data regarding regional variations in price levels. The only data at the regional (NUTS2) level includes price dynamics as chain indices. However, to calculate real minimum wages at the regional level we need data on regional price level. To overcome that problem and anchor wage dynamics we used data from the Institute of Labor and Social Studies (ILSS) on the minimum subsistence (social) level. The social minimum is defined as the bundle of resources that a person needs to lead a minimally decent life in their society¹¹⁶. The social minimum is calculated separately for different types of households, defined by the number of adults and their age, and the number of children and their age. Unfortunately, the information regarding the number of households of different types is not available annually. Therefore, we decided to compute the

¹¹⁵ Polish New Zloty (PLN)—official currency of Poland.

¹¹⁶ See: <https://www.ipiss.com.pl/?zaklady=minimum-socialne>

average value of social minimum for all types of households excluding retired persons. The results are presented in Figure A2.

Figure A2.1. Minimum wage level and social minimum level in Poland (2007–2017) at current prices, PLN

Source: Own calculations based on CSO data.

Significantly, the dynamics of minimum wage and average social minimum are very similar. The actual correlation coefficient between these two measures is 0.96. For instance, up to 2012, the social minimum level for a one-person household was about 70% of the minimum wage level. Additionally, the consumption structure of households with a single minimum wage earner is similar to the consumption structure of a social minimum household.

ILSS provides data on the social minimum not only at the national level but also separately for each NUTS2 region. We use this variation to mimic variation in the real minimum wage level in 2007. For the subsequent years, we used the dynamics of the social minimum to deflate the minimum wage in a given region.

FLASH FLOOD HAZARD DIAGNOSIS BASED ON GEOMORPHOLOGY, HYDROLOGY AND GIS TECHNIQUES (CASE STUDY OF KERT BASIN, MOROCCO)

Imane Boutahri¹, Larbi Barhazi², Rachida El Morabet², Taieb Boumeza¹

¹Faculty of Art and humanities, Morocco. ²FLSH Mohammedia- Université Hassan II de Casablanca, Morocco

ABSTRACT

Of all the natural disasters that hit the world each year, flash floods remain the most damaging and deadly. This study focuses on the assessment of sudden flood risk in the Kert basin based on the detailed morphometric characteristics of the Kert basin and its sub-basins. For a detailed study, a geographic information system (GIS) and mathematical formulas were used to evaluate the linear, superficial and relief aspects of the morphometric parameters. Twenty-five morphometric parameters were measured, calculated and interconnected to produce nine effective parameters for assessing the flash flood hazard in the study area. Two methods were used to assess flash floods and generate flood hazard susceptibility maps. The first method is the El-Shamy approach and the second is the morphometric risk assessment method. Based on nine morphometric parameters that affect the hydrological behavior of Wadi as a function of concentration time. The mapping of flood zones aims, in particular, at the identification of the fields of flood expansion to preserve urbanization. In terms of natural risks, the absolute prerequisite for information, prevention and protection actions is the proper identification of the risk. The latter is assessed by the evaluation of two notions: "the hazard", the potential for destruction or degradation that represents the natural phenomenon and "the stake" which represents the value of this who is exposed to the incident. The hazard maps produced are intended to help planners and decision-makers develop appropriate plans to mitigate the adverse effects of floods and cope with flood risks.

COUNTRIES CLUSTERING IN THE CONTEXT OF THE PANDEMIC COVID-19

[Carolina Guevara-Rosero](#)

Departamento de Economía Cuantitativa, Ecuador

ABSTRACT

As early as 2019, the Global Preparedness Monitor Board called for political action to be prepared for global health emergencies. Recommended actions were to build solid systems with high responsibility and community participation that generates confidence among population (GPMB, 2019). Nevertheless, the rapid growth of COVID-19 has revealed the state of underlying conditions of countries in terms of health system, sanitary infrastructure, income inequality and governance. Governments have managed the pandemic given such pre-existing conditions. Other than this, the response of governments in terms of regulations and actions to halt the spread of the pandemic was a decisive factor. Such responsiveness has been varied across governments. The measures ranged from travel restrictions to lockdown restrictions. Some countries acted more rapidly than others and not necessarily according to their level of development. Although it is expected that developed countries perform better in face to the COVID-19 pandemic, different dynamics are in play and developed countries are highly affected. In this respect, this study aims to classify countries in function of COVID-19 variables such as the lethality rate, the contagion growth and the number of days that elapsed until the country registered the first case with respect to China.

To determine the clusters, we use a set of 209 countries from all regions (24 from East Asia and Pacific, 59 from Europe and Central Asia, 42 from Latin America and The Caribbean, 22 from Middle East and North Africa, 6 from North America, 8 from South Asia and 48 from Sub-Saharan Africa) for two periods: 30 days and 150 days. The k-means partitioning method is used to conduct the clustering analysis. This approach consists in constructing partitions and evaluate their intra-class and inter-class similarity. The results show that the collection of observations is partitioned into 4 clusters. The first cluster corresponds to the countries that first presented confirmed COVID-19 cases after China and report lower contagion growth and lethality rates with respect to other countries. The second cluster is characterized by countries that experienced confirmed COVID-19 cases after the first cluster countries, the highest contagion growth rates and low lethality in the first 30 days but high lethality rate in the 150 days. The third cluster corresponds to countries with more days of the first confirmed COVID-19 cases with respect to China. These countries present low contagion growth and lethality rates. Finally, the fourth cluster is characterized by the largest period of time that elapsed until the first confirmed COVID-19 case with respect to China. These countries record a low contagion growth rate but high lethality rate at first and then a moderate level of the lethality rate. Based on these characteristics, we have named these four identified clusters as:

1. Very rapidly infected countries with moderate contagion and moderate lethality
2. Rapidly infected countries with severe contagion and increasing lethality
3. Slowly infected countries with low contagion and low lethality
4. Very slowly infected countries with low contagion and decreasing lethality

MANAGED RETREAT IN THE FACE OF CLIMATE CHANGE: WHAT INFLUENCES BUYOUTS OF FLOODPLAIN PROPERTIES

Qing Miao¹, [Meri Davlasheridze²](#)

¹Rochester Institute of Technology, USA. ²Texas A&M University at Galveston, USA

ABSTRACT

This paper uses a double-hurdle model to empirically examine the factors influencing government buyouts of floodplain properties, with a particular focus on the local fiscal resources and flood management practices. Using nation-wide panel data of buyouts funded through the federal Hazard Mitigation Grant Program, we find that counties with more property tax revenues or a lower fiscal reliance on property taxes have more buyouts. We also find that higher flood insurance take-up rates are associated with smaller amounts of floodplain buyouts. Our results provide insights into the barriers and challenges for government buyouts and managed retreat.

BEDFORMS CHARACTERIZATION OF THE BOUREGREG ESTUARY USING REMOTE ACOUSTIC TECHNIQUE

Linda Jemily, Nadia Mhammdi, Amine Raki

Institut Scientifique, Morocco

ABSTRACT

Bouregreg estuary is located on the Atlantic side of Morocco at the junction between Rabat and Salé. Both present large populations and new infrastructure development. During the last years, remote acoustic technique has revolutionized the way we are able to image, map and understand the riverbed environment. An integrated approach, combining side scan sonar (SSS), echo sounder (ES) and seabed sediment sampling collected with a Van Veen bottom grabber, was performed to characterize subtidal and intertidal dune morphology on the Bouregreg estuary. In addition, morphometric parameters and temporal variability, to estimate migration rate according to the dune type, were analysed. The aim of this work is to improve knowledge about the formation, evolution and present-day dynamics of these bedforms on a mesotidal estuary receiving little sediment input. The results led to the identification of different groups of bedforms. The main groups of bedforms in the area are ripples, 2D dunes, 3D dunes, flat bottom. The dunes are exhibiting different morphological configurations differentiated into straight, sinuous and barchan dunes. The largest dunes of the estuary reach 6 m of heights and 100m of wavelengths. The dunes, mostly asymmetrical in cross-section with a downstream direction, shows an NNW-SSE orientation. The estuarine channel is filled by sandy to muddy sediments. From geometrical analysis of the morphometric parameters, the dunes show no clear correlation between dune height and wavelength as too between dune height and water depth.

CLIMATE CHANGE IMPACT ON SPATIAL DISTRIBUTION OF MOROCCAN FOREST ECOSYSTEMS

Said Moukrim¹, Said Lahssini², Hicham Alaoui³, Adnane Labbaci⁴, Laila Rhazi¹

¹Mohammed V University, Morocco. ²National Forestry School of Engineers- Sale, Morocco. ³Climatic and forest risk management center, Morocco. ⁴Ibn Zohr University, Morocco

ABSTRACT

Climate Change (CC) is one of the extreme factors that threatens biodiversity and affects all organisms and their habitat. It will lead to degradation of the natural environment, ecosystem productivity, food security and could create conditions of social instability. Understanding the impacts of CC on forest ecosystems is a prerequisite for any strategy that underlies their conservation and restoration. This study aims at studying CC impact on two remarkable species of Moroccan forest ecosystems (*Argania spinosa* et *Cedrus atlantica*). It was based on species distribution modeling using the Maximum Entropy approach. Results of this work could contribute to improve our knowledge related to the biogeography and the ecology of these species through identifying environmental variables, which limit their distribution, developing predictive models and characterizing geographical extent of the areas, which is favorable to these species under current and future climate conditions. Predicted potential suitable areas show that large parts of Morocco are bioclimatically suitable for these two species and that the suitable areas are site specific and will be negatively affected by the future climate. The use of predictive suitability maps of these forest species are valuable tools for developing adaptive strategies in time and space to deal with CC. These results will provide technical and scientific support to scientists and forest managers in order to improve decisions process and to include CC into conservation and rehabilitation strategies to avoid any future extinctions of these hotspots of national biodiversity.

ASSESSING THE ECONOMIC IMPACTS OF SILTATION IN THE DAM OF OUED EL MAKHAZINE

Widad Darif¹, Abdellatif Khattabi²

¹Département des Eaux et Forêts, Morocco. ²Ecole Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

The large hydraulic structures are strategically important, they fulfil multiple functions that sustain the economy of the country. They contribute decisively to supply water sectors, mainly irrigation, drinking water and energy production. They provide also protection against flooding of large areas of the country, improving the environment and water quality. Unfortunately, siltation is detrimental to these large hydroelectric structures, whose consequences generate significant economic losses through negative impacts on the population, sectors and on the state. The Oued el Makhazine dam is not immune to this problem of siltation, because the watershed upstream of this dam has pedoclimatic characteristics that make it particularly vulnerable to erosion. This study aims to estimate economic losses based on the relationship between erosion and yield loss in off-site effects. While for on-site effects, the analysis focused on the costs caused by siltation on storage capacity, the supply of irrigation water, the supply of drinking water and industrial and the production of hydropower. Calculations were made using 2013 as a base year data. The results show that siltation cause relatively large losses in this area. At the scale of the entire Oued El Makhazine watershed, economic losses are estimated at 1.80 billion dirhams, including off-site costs of 1,6 billion DHS and those on-site of 190 million DHS.

ECONOMIC VALUATION OF ECOSYSTEM SERVICES IN AL HOCEIMA NATIONAL PARK

Youness Kasstib, Abdellatif Khattabi

Ecole Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

Ecosystem services refer to the tangible and intangible benefits provided by natural ecosystems. In many studies' ecosystem services are not taken into account in economic studies. Failure to take this externalisation into account leads to wrong decisions on the use of land and resources. Indeed, the absence of a value indicator with a price has often led economic actors to attribute a zero value to these goods and services of nature at the time of decision making. Additionally, these ecosystem services are subject to degradation due to overexploitation and lack of public awareness of their value. In the Moroccan strategy elaborated by the HCEFLCD for the conservation of fauna and flora, the Al Hoceima National Park was created in 2004 in the heart of the Western Rif. It is endowed with an exceptional physical and biological originality that offers numerous ecosystems providing goods and services (fishing, grazing, diving, bird and dolphin watching, exploitation of dwarf palm and Alfa, beach in summer, dead wood lying, ...). But also, this area is at great risk of resource disturbance due to the economic activities of the local population in addition to the behaviour of visitors. The present work aims to contribute to the identification and categorization of the different supply services that the park offers. As well, to propose a monetary evaluation of each service determined according to an appropriate method. The first part sheds light on the monetary evaluation of the supply services according to the market price method. The second part deals with the monetary valuation of biodiversity using the contingent valuation method and the third part is devoted to the economic valuation of ecotourism using the transport cost method.

OPEN INNOVATION, THIRD PLACE AND LIVING LAB: STATE OF THE LITERATURE RELATING TO THE NEW GENERATION OF TERRITORIAL DEVELOPMENT MODELS

Elbroumi Soufiane, Eddelani Oumhani, Eddahmouny Hicham

FSJES FES, Morocco

ABSTRACT

In the new landscape of open innovation, we are witnessing the emergence of strategies, concepts, ideas or organizational forms, which aim to strengthen the role of users and of civil society in responding to diversity and complexity of their needs. In this context, third places, and more particularly Living Lab approaches, are experiencing considerable growth on a global scale in several fields of activity. (Dubé et al, 2014; p. 12). Living Lab approaches have historically emerged from user association practices in the definition and development of solutions inspired by information and communication technologies and are part of the evolution of territorial models of innovation. They bear witness to major transformations in the very conception of the development of territories and of the role that the different types of actors must play in it. It shows social experiments which present new arrangements between these actors and which aim to build conditions which promote the well-being of communities. (Doyon & Al, 2017, p.2). Based on an analysis of the literature and via the “Living Lab” approach, this research aims to examine the contribution of open innovation and third places in terms of territorial development. To this end, we will briefly present the concepts of open innovation and third place before focusing on the main concept of this research, in this case the Living Lab. We will then identify the forms, the forms of contributions of these new approaches to innovation in terms of territorial development. References: Doyon, M, Klein, J-L, & Arsenault-Héту, C. TRADITIONAL AND INNOVATIVE MONITORING METHODS AND TOOLS TO IMPROVE THE MANAGEMENT OF FLOWS AND 'OVER-TOURISM' IN (WORLD) NATURAL AND CULTURAL HERITAGE SITES: THE CASE STUDY OF THE DOLOMITES UNESCO WHS

[Andrea Omizzolo](#)¹, [Dario Bertocchi](#)²

¹European Academy of Bolzano/Bozen (EURAC), Institute for Regional Development, Italy. ²Ca' Foscari University, Italy

ABSTRACT

The natural and cultural sites recognized through UNESCO programs, thanks to their extraordinary importance and outstanding value, represent case studies regarding tourism flow management in limit-situations and can provide very useful reference examples at a global level. UNESCO, through its programmes (World Heritage Convention, Man and the Biosphere Programme, UNESCO Global Geopark), has contributed to define the concept of world heritage as a value to be shared at a global level, transforming already known places into popular icons that 'every tourist must'. This type of recognition has contributed at increasing the attractiveness of these sites but, in many cases, it has led to compromise the balance between the opportunity and the quality of the visit and the integrity of the heritage. Moreover, this can also negatively affect the perception and willingness of the local communities to accept any new constraints and to actively support the preservation of the Site. Therefore, the overall management strategies of recognized sites normally include medium- and long-term socioeconomic monitoring actions of the effects of the recognition. In many cases, in an attempt to manage tourist pressure in iconic places, are also studied and implemented various methods and tools based on data and information collected from different sources and using different techniques. In the case of the Dolomites WHS the Overall Management Strategy has recently been developed and monitoring studies and socio-economic analysis have been carried out. Special attention was given to visitors, economic operators and inhabitants of the municipalities within and close to the Site. Traditional methodologies and techniques have been used such as qualitative interviews, the use of data from classical sources such as national and regional statistical databases and studies such as carry capacity using consolidated knowledge. In addition, big data analysis, carrying capability study and the use of data from social networks have also been tested. Author aim to present and bring to a common discussion the first results of the analyses carried out and to evaluate the use of different and 'new' sources and techniques to actively contribute to the overall aim of managing tourism-related flows and to tackle or prevent the potential phenomenon of 'over-tourism' in these worldwide but fragile Sites.

NETWORKED REGIONAL URBAN SYSTEMS, COMMUNITIES OF INTEREST OR PLACE? INVESTIGATING REGIONAL APPROACHES AND DECENTRALIZATION IN RENEWABLE ENERGY TRANSITIONS OF URBAN CITIES

Christina Hoicka, Jessica Conroy

York University, Canada

ABSTRACT

Renewable energy transitions are associated with major land use and landscape changes and new actors, leading to increasing investigation of regional approaches and decentralization. This study considers how 47 urban and highly populated cities, “urban cities”, are pursuing goals of carbon neutral and 100% renewable energy cities to shed light on how the largest demand centres propose to influence spatial patterns of energy production and consumption. The main findings that this preliminary analysis offers is that there are a number of dense urban cities pursuing large shares of renewable energy, and that these involve a range of stakeholders, RETs and innovations. The full range of stakeholders, RETs and innovations were not specified by location as on-site, district/neighbourhood scale, with the city’s boundaries, or imported into the city. Despite this, the findings demonstrated that urban cities are employing a range of spatial strategies with different approaches to decentralization, reflected in four categories: 1) relying on incumbent actors in centralized approaches, consistent with a hierarchical regional urban system (n=13); 2) a local focus, in which urban citizens and firms invest locally as communities of place, and some municipally owned utilities source energy (n=5); 3) local focus combined with coordinating with the region, in a networked regional urban system, and neighbouring communities, as communities of interest (n=12); 4) a diversified approach combining all three strategies (n=5). Future investigation can compare strategies for effectiveness, and examine how geographic and governance aspects affect their emergence. For the urban cities with more decentralized plans, further analysis of the benefits to citizens and firms in the urban city and surrounding region could be compared to the benefits in a centralized or less regional approach. These benefits could, for example, include labour and equity considerations, increased revenue to communities and firms and sectoral growth, affordability and reliability of energy.

INTERNATIONAL COLLABORATION IN GREEN ENERGY TECHNOLOGIES: EMPIRICAL EVIDENCE ON OECD AND BRIICS COUNTRIES

[Nicoletta Corrocher](#)¹, [Maria Luisa Mancusi](#)²

¹ICRIOS - Bocconi University, Italy. ²Università Cattolica, Italy

ABSTRACT

The development of environmental innovations has the potential to reduce the environmental impacts of economic activities, by addressing different environmental challenges referring to energy production and distribution, transport, buildings, and waste management among others (Haščič and Migotto, 2015; Fabrizi et al., 2018). Cross-country cooperation in environmental innovations generates sizeable benefits (Haščič et al., 2012; Shapiro, 2014; Haščič and Migotto, 2015), as confirmed by the tendency of countries to collaborate more in climate change mitigation technologies than in other technological domains (Haščič et al., 2012; Kahrobaie et al., 2012; Shapiro et al., 2014). The issue is particularly relevant for the energy sector: developing countries have to engage heavily in emission reduction, but most innovations occur in the developed countries (Bosetti and Verdolini, 2017). Thus, the development of international collaborations is important to stimulate the exchange of knowledge and technology across countries, allowing latecomers to embrace a process of sustainable growth. This paper investigates the determinants of the intensity of international collaborations in energy-related technologies across OECD and BRIIC countries through a gravity model. It focuses not only on the geographical and cultural distance between countries but also on the distance in the stringency of environmental regulation, as well as on the economic relevance of the energy sector and on the revealed technological advantage in energy-related technologies. The gravity model has been used to analyse the patterns of bilateral trade in (Anderson, 1979; Baldwin and Taglioni, 2006; Ceglowski, 2006; Disdier and Head, 2008) and the internationalization of and cooperation in inventive activity across countries (e.g., Maruseth and Verspagen, 2002; Montobbio et al., 2010; Picci, 2010; Scherngell and Barber, 2011; Cecere and Corrocher, 2013). To our knowledge, however, no research exists that has applied such a model to the international patent collaborations in green energy-related technologies. The analysis relies upon an original dataset, which merges time-series data between 1995 and 2014 on green patents and co-patenting activity, indicators of environmental policy stringency, and economic, geographical and cultural variables. Preliminary results show that the distance in market-based policy measures is a positive determinant of cross-country collaboration in green energy innovation in BRIICS, but not in OECD countries. Furthermore, the distance in non-market-based measures also shows a positive effect on collaboration involving BRIICS, however, it acts in the opposite direction for collaborations among OECD countries. Interestingly, technological specialization does not play a role in BRIICS. The paper contributes to the existing literature on green technological development in two ways. First, while scholars have already provided some descriptive evidence on the co-patenting activity in green technologies (Shapiro, 2014; Haščič et al., 2012; Haščič and Migotto, 2015; Walz et al., 2017), we provide an in-depth analysis of the determinants of collaboration in green energy-related sectors across different sets of countries. Second, we put emphasis on the role of environmental policy stringency, assessing the role of the distance in environmental regulation between countries in affecting co-patenting activities in green energy-related technologies (Dechezlepretre et al., 2015; Bosetti and Verdolini, 2017).

ENERGY EFFICIENCY-ENHANCING POLICIES AND FIRM PERFORMANCE: EVIDENCE FROM THE PAPER AND GLASS INDUSTRIES IN ITALY¹¹⁷

[Andrea Caragliu](#)

Politecnico di Milano, ABC Department, Piazza Leonardo da Vinci, 32, BLD 5, 20133 Milan (MI), Italy.
andrea.caragliu@polimi.it

ABSTRACT

This paper presents an empirical analysis of the impact of adopting energy efficiency measures, labeled “*White Certificates*”, on the economic performance of companies active in the paper and glass sector in Italy. White Certificates, launched in 2005, represent the longest-lasting and effective policy tool to stimulate energy efficiency, in particular for the manufacturing industry.

My analyses exploit financial statements of Italian companies available from the AIDA (Computerized Analysis of Italian Companies) database with the aim to quantify the impact of these measures on the performance of firms in the two industries. The impact of energy efficiency policies is assessed on both productivity and profitability, and the effect is broken down into direct and indirect impacts, obtained by calculating spatial lags of energy efficiency support based on geographical as well social, relational, and technological proximity matrices.

Results suggest the existence of a positive and significant association between White Certificates and firm performance. This effect is fostered when support also goes to other firms that are relationally, socially, and technologically close to treated firms. Instead, no synergy between social, relational, and technological connectivity and the geographical co-location of firms is found.

KEYWORDS

Energy efficiency; spatial spillovers; geographical proximity; relational proximity; social proximity; technological proximity; firm productivity.

SPREADING RESILIENCE: A SPATIAL ANALYSIS OF THE BENEFITS OF HARDENING TECHNIQUES FOR A TROUBLED POWER GRID

[Marcello Graziano](#)^{1,2}, [Adam Gallaher](#)², [Maurizio Fiaschetti](#)³

¹Southern Connecticut State University, USA. ²University of Connecticut, USA. ³University of Nottingham, United Kingdom

ABSTRACT

Tree-trimming operations (TTOs) are costly, yet widely used grid-management procedures utilized by electric utility companies globally. As diffused generation, electrification of the economy, and climate change pose challenges to utility companies, power grids and their reliability play an increasingly important role for developed and developing regions. Using data from a uniquely detailed dataset of outages and tree-trimming operations from 2009-2015 undergone by Eversource Energy in Connecticut, this study identifies the relationship between tree-trimming operations and power outages from three perspectives: i) number of outages; and ii) number of affected customers for occurred outages; and iii) duration of occurred outages. Methodologically, we employ four sets of models: Panel Fixed-Effects, Difference-in-Difference, Spatial-lagged models and a Temporally Spatial Autoregressive models. Areal units are author-specified raster, with a size of 2by2km (preferred), and 4by4km (as a robustness check). This modelling strategy accounts for both spatial and temporal relationships. Our results show that at the 2-km cell size TTO translate to 4.17% fewer tree-associated outages per year. In addition, occurring outages affected 465,187 fewer customers. These results are consistent at a lower resolution. In addition, TTOs have relevant spatial and temporal spillovers. Our work represents a novel approach in the quality of the grid-level data and the temporal coverage utilized. Our results are particularly relevant to utility companies and policymakers in areas exposed to climate change such as the U.S. Eastern Atlantic Coast, and they support further expansion of expensive, yet effective TTOs in densely forested regions.

Special Session: SS33 - Plastic pollution and its environmental impact

**ASSESSMENT OF VISITORS' PERCEPTION OF SOLID WASTE
POLLUTION AND THEIR WILLINGNESS TO PAY IN THE AL HOCEIMA
NATIONAL PARK BEACHES**

Abdellatif Khattabi, Zakia Rahmani

Ecole Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

Al Hoceima National Park is the most important protected area on the Mediterranean coast of Morocco. Although this protected area is important from an ecological and economic point of view, it is increasingly under pressure from human activities (productive fishing, pollution, etc.). One of the main causes of the degradation that this park is undergoing is pollution from solid waste. This solid waste has considerable negative impacts on the environment. They constitute a threat to human and animal health and the degradation of the natural landscape. This study aims to find out the perception of visitors to the beaches of Al Hoceima National Park, the suggestions of visitors for an improvement in the landscape quality of these beaches, and their willingness to pay for this improvement. Questionnaire and face-to-face surveys were conducted during the month of August 2019 on five important beaches of the park (Bades, Torres, Cala iris, Tala Youssef and Boumehdi). It emerges from the results of the study that 57.8% of the visitors consider that these beaches are clean. The statements of 79.6% of the visitors interviewed show that the most common waste found on the five beaches are bottles and their caps, while 61.2% of visitors cite cigarette butts as the dominant waste. In order to avoid the nuisance produced by waste, 76% of the interviewees agreed to participate financially in an improvement action of solid waste management in the beaches. The majority of the visitors interviewed (83.2%) proposed the organization of awareness programs in schools or through websites to inform people about the problem of waste and its impact on the natural environment and on the population.

WASTE QUANTIFICATION (MACRO_MICRO) IN THE BEACHES OF THE AL HOCEIMA NATIONAL PARK

Zakia Rahmani, Abdellatif Khattabi

Ecole nationale forestière d'ingénieurs, Morocco

ABSTRACT

Al Hoceima National Park, much of which is marine, faces significant environmental challenges, including solid waste pollution. The pollution is a complex and multidimensional problem with negative implications for the marine, coastal and continental environment. The objective of this study is to characterize and quantify the solid wastes (macro and micro) that accumulate on the 5 beaches of al Hoceima National Park (Bades, Torres, Cala iris, Tala Youssef and Boumehdi). This knowledge would allow enlightening the decision making in order to bring solutions adapted to the reduction of this pollution or its eradication. Two waste collection protocols (micro-macro) were used. The collection of macro waste was carried out on three plots of 100m² each, for each beach; and the collection of micro waste was carried out on 3 quadrats of one square metre each on each beach. Using a 10cm² model, five random samples were taken from each quadrat. The results showed that 69.3% of the collected waste is of plastic type, 13.4% are of paper/cardboard and 13.2% are of organic composition. The main types of products identified among the collected waste are cigarettes butts (11.22%); plastic bottles and plastic caps (9.28%); and 6.01% are polystyrene pieces. Secondary mesoplastics and other primary micro-plastics are the majority of waste. They represent respectively 55.53 pieces collected and 49 pieces (Polystyrene: fragments and balls). These results show that plastic pollution is the main source of solid waste on the five beaches of Al Hoceima National Park.

POTENTIAL IMPACTS OF MICROPLASTICS IN THE MEDITERRANEAN MARINE ENVIRONMENT: AL HOCEIMA BAY CASE STUDY

Oumayma Bouadil¹, El Ouarghi Hossain¹, Benomar Mostapha², Benbrahim Samir²

¹National School of Applied Sciences of Al Hoceima, Morocco. ²National Institute for Fisheries Research, Tangier, Morocco

ABSTRACT

Micro-plastics contamination of the marine environment has been the subject of growing concern among scientists around the world. They have been reported to be ubiquitous contaminants in all marine environments all over the globe. Micro-plastics are characterized by their spatio-temporal variability due to sea currents, as well as by their physico-chemical characteristic, on the one hand and they are known by their persistence and their toxicity on the other. Due to their high absorption capacity, these contaminants can facilitate the transfer of hydrophobic pollutants from the water to the biota, in particular Polycyclic Aromatic Hydrocarbons (PAH), and therefore they involve indirectly the trophic chain degradation. It is in this context in which our thesis work lies, which generally aims to assess the extent of pollution of Al Hoceima Bay by these micro-pollutants. This project targets specially various objectives, firstly the identification of microplastics concentration sites, by distributing the sampling points within Al Hoceima bay, secondly the characterization of microplastics that exist in the bay, by summarizing their properties, their nomenclatures and their sources, thirdly the quantification of the abundance, density and distribution of these contaminants in this marine environment and finally the environmental impact assessment of Micro-plastics on the marine environment (water, sediment and biota) in our study area. To ensure the smooth functioning of our work, we did a bibliographic study in view of synthesize the various works carried out on the site of our study or on similar sites. Furthermore, we realized a summary of the various methods used to identify, characterize and analyze Micro-plastics. Moreover, we performed a prospective study in order to identify and locate the concentration sites of Micro-plastics inside Al Hoceima bay. During this study, we developed sampling and analysis methods for Micro-plastics in favor of each compartment of marine environment. In this regard, we did several field missions to collect samples from the three bay compartments. Concerning the surface water sampling we used the Manta net and for the sediment sampling we used the Van Veen tipper. Microplastics samples taken from 19 sampling sites showed various shapes, colors, composition, sizes, surface morphology, abundance and strong spatial heterogeneity. Microplastics collected from samples were classified into four types: fiber, film, granule and fragment. Some impacts of these micro-pollutants have been assessed through the analyzes that have been made in aquatic sediments, surface waters and marine organisms. Altogether, our study provides a better understanding of microplastic pollution status and prevention policy-making of Al Hoceima region habitats.

SOLVING A PLASTIC POLLUTION PROBLEM WHILE CREATING BETTER INCOME FOR MARGINALIZED WOMEN

[Diane Pruneau](#)¹, [Abdellatif Khattabi](#)², [Zakia Rahmani](#)²

¹Université de Moncton, Canada. ²École Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

The «Plastic-Free Surf Project» took place in Bades, in Al Hoceima Park, in Morocco. It was aimed at reducing local plastic pollution and at contributing to increase the local craftwomen's income. In this Park, located along the Mediterranean Sea, the presence of plastic waste negatively impacts the continental and marine biodiversity.

Three intervention tools were chosen to support 20 craftwomen in the search for solutions to the plastic problem: design thinking, Facebook and Whatsapp. The research question was: What is the relevance of the solutions proposed by craftwomen to the problem of plastic, when they are supported with design thinking and Facebook?

Twenty artisans were accompanied by researchers for a year with the aim of reducing plastic objects thrown in the region. The idea was to allow these women to manufacture new products that would reduce the plastic objects used locally or reuse the plastics composing these objects. In workshops and on a Facebook group (during Covid-19 confinement), the project followed the steps of design thinking: observation, synthesis, ideation, prototyping, testing and communication. On Facebook, the craftwomen and the researchers shared, assessed and improved prototypes.

After 9 months, Canadian and Moroccan evaluators (n=37) were invited to comment and to put scores on 35 craftwomen's prototypes. They analyzed the participants' prototypes with creativity criteria: environmental value, adaptation, novelty, originality, elaboration and fluidity. The craftwomen made jewelry, home decorations, toys and fashion accessories from plastic. They created innovative manufacturing techniques: sticking microplastics on paintings, stuffing objects with plastic scraps and used bags, assembling compact discs to make decorations, embroidering plastic jewelry covered with felt, etc. The environmental value of their products was judged as quite good. Several prototypes contributed to reduce the quantity of plastics thrown into the Sea. The adaptation criterion (marketable product) was given a good score. The criteria of novelty and originality were fairly reached. The elaboration criterion received a lower score. The participants carried out the construction of varied prototypes, meeting the criterion of fluidity (large number of ideas).

PLENARY SESSION III

**REGIONAL EXTERNALITIES OF THE ANGOLAN OIL INDUSTRY: AN
INTERREGIONAL INPUT-OUTPUT ANALYSIS**

Cesar Pakissi

FEC-UJES, Angola

ABSTRACT

The economy of Angola is highly dependent up on the oil industry whose production is concentrated in the northern part of the country. In this paper we analyze the economic effects of this natural-resouce-based export amounted sector in the contexto of an integratted interregional imput-autput system calibrated for the 18 Angolan provinces. The model takes into account the regional interdependence imbedded in the production structure of the country trough linhages. We show that in spite of the averall importance of the oil sector for the economy, it does not genarate strong interregional spillovers to the rest of the country, runforcing regional disparteis in Angola.

TOURISM AND NATURE CONSERVATION IN THE HUAMBO PROVINCE. AN ANALYSIS OF VISITORS TESTIMONIALS

Amália Salomé Chissoca

Instituto Superior de Ciências de Educação - Huambo, Angola

ABSTRACT

This paper analyses tourism in the Province of Huambo, its interrelation with the natural and cultural heritage and nature conservation. Tourism is an important element in society, because it addresses the multidisciplinary nature of sciences. It is a natural phenomenon, of cooperation between peoples, linked to the science of life, promoting development, understanding and mutual respect between men and society. Tourism has been at the center of attention in the current and future perspective, it is the largest service industry in the world because it aggregates complementary businesses, and however, it is among those that cause more impacts and negative effects on the receiving location. However, it can contribute to the development of the city of Huambo, with indicators pointing to the ranking of economic activities that generate income, foreign exchange and direct and indirect employment in its different modalities. From the studies carried out, it was analyzed the data collected by questionnaire to a sample of 39 visitors. The statistical analysis of the responses obtained, carried out with the support of the Q method, made it possible to identify the factors of choice of the tourist spots to visit, namely the heritage value and the quality of the environment, confirming the hypothesis of the relationship between tourist attractiveness and environmental quality. The research has a non experimental character, mixed because it uses qualitative and quantitative techniques having as variables the knowledge and the visitation and transversal because it makes the connection with other sectors of the economic apparatus of the Country and the Province. The method referred to above has made it possible to ascertain that tourism in Huambo is done in a raw way and at shy steps, and the tourist sites still need more attractions and environmental quality, besides the beyond the natural beauty, and the little that is known and explored is mostly consumed by domestic tourists, and domestic tourism being the most prevalent. In addition to being an economic engine, tourism can be used as an alternative for nature conservation.

KEYWORDS

Tourism, conservation of environmental nature, environment Huambo, Angola.

1. INTRODUCTION

Tourism is an important component of regional and local development, since it has the potential to generate work and income, and is in the index of activities that have grown the most in the last 30 years worldwide. Its exploitation has a direct link with the environment and with the natural and cultural heritage, in which the product to be sold is the nature and culture that values it. Tourist activity depends on supply and demand.

The province of Huambo is a region with great natural and cultural biodiversity (waterfalls, mountains, forests, valleys, crevices, climate, altitude, culture, rivers, diversity of animals, plants and historical stones) which encourages the development of tourist activity, transforming it into a tourist destination preferred by domestic and foreign tourists, and converting tourism into the strategic sector for the development of the Province. However, it has been a great challenge to create and maintain the points of attraction for tourism activity due to the economic crisis in Angola associated with the fall in the price of oil. Thus, it is thought appropriate to know the context of tourism in the city of Huambo and what interactions between tourism and nature conservation, in ways to leverage the tourism sector in Huambo province, taking into account the aspects of environmental sustainability.

The scientific question is what are the interactions between tourism and nature conservation in Huambo? More specifically it is intended to know the engines and conditioners of tourism in Huambo and their impact on nature conservation. For this we propose to build a theoretical framework on tourism and its effects on nature conservation. Based on a questionnaire given to a significant sample of tourists identify the most visited sights, the reasons for visit and the conservation status of the tourist sites in Huambo province. And also propose solutions to enhance tourism and motivate the conservation of tourist sites.

1.1 Concept of Tourism

According to the WTO (World Tourism Organization), tourism is on the scale of the main economic activities as the second largest activity in the world in income generation, foreign exchange and jobs, (Silva, at all, 2016). Second, tourism allows the growth of income from the place visited with the entry of foreign exchange, disparta investors, creates jobs, affects wealth, and enables the integration of peoples. Given the importance of the activity, the alternative possibilities, needs, responsibility should involve all actors in the tourist market (Medeiros, at all, 2013).

Tourism integrates different activities. First ly the tour, carried out by the tourist who moves from his comfort area to other areas in search of difference, the unusual, the imaginary, the fantastic, the incredible, especially the natural beauty, associating with them leisure and fun. Secondly, the accommodation that becomes the most important concern of the tourist, because, it needs the tourist to know if the place where he sleeps has conditions of hygiene, comfort, health and safety to which is added the latest concerns with the conservation of nature and the preservation of the environment. When analyzing different statements it is perceived that tourism is linked to the action of traveling, but the purpose may differ from each other, among them, the business, the search for health services, rest, leisure, visit to friends, relatives and others. Thus it is understood that tourism is an activity carried out by people moving from their usual surroundings to another for a period of more than twenty-four hours and less than one year for the purpose of resting, leisure, health search, business, research, knowing other cultures and establishing a close relationship with nature. Tourism is a social phenomenon of political, technological, inter-people exchange, and its main attraction is nature.

1.2 Types de Tourism

There are several types of tourism. Heritage tourism, arts tourism, urban tourism, rural tourism, ethno tourism, indigenous tourism, ethnic or nostalgic tourism, religious tourism, creative tourism and many others.

Table1:Types of Tourism

Types	Caraterização Characteristic	Lugares Places
Heritage tourism	Directly linked to the interpretation and representation of the past, it refers to visits and activities to know sites, goods or property expressions. All related to the Unesco World Heritage Site, (Smith, 2003).	Visits to castles, palaces, cottages, archaeological sites, monuments, architectural works, museums and others.
Arts tourism	It refers to visits and tourist activities carried out for the purpose of enjoying or representing the arts, such as theater, dance, music and visual arts, cinema and other creative industries. Activities can be developed in the form of concerts, concerts, exhibitions and performances, among other modalities, (Smith, 2003).	Visits to the theatre, concerts, art gallery, festivals, events and events, sites of literary or cinematographic interest
Urban tourism	They are visits to urban centers of different dimensions to know or revisit places of interest, such as parks, museums, historic buildings, neighborhoods, traditions or commerce, among others, (Sernatur, 2008).	.Visits to historic cities. cities or industrial sites, coastal border protection projects, infrastructure, shopping centres or nightlife sites.
Rural tourism	It refers to activities that occur in a rural environment, with customs and activities that are lived in environments far from cities and industrialized areas, such as villages, farms, etc.(UNWTO, 2015). Agrotourism is a derivative of rural tourism that is characterized by bringing visitors to the activities of the agrarian world and its productive processes, showing you the systems of cultivation of land, crops or forms of irrigation and giving them the possibility to participate in some tasks and become familiar with rural life, (CNCA, 2011) .	Visit to small towns, farms or agrotourism initiatives, ecomuseums, cultural landscapes, national parks, product routes and historical routes.
Indigenous Tourism or Ethnotourism	It includes all the instruments and means by which the tourist activity is developed tending to make known the way of life, culture and customs of the native peoples (Ministry of Tourism, 2018). The condition is that indigenous peoples do not necessarily participate in the planning or implementation of these activities. Tourist activity addressed and managed by indigenous communities and/or families that develop in a rural or natural area, historically occupied by indigenous peoples, combining their customs and traditions, ancestral and contemporary, thus fostering a process of cultural exchange with the visitor or tourist (Castro, K., Liancarleo, 1993). Contrary to the definition of "ethnotourism", the definition of "indigenous tourism" places the focus on the provision of service by indigenous communities or families themselves, and incorporates the characteristics of the space where it is developed and the traditional and contemporary expressions of the indigenous host groups.	Visit to the communities, visits to cultural centers and museums, festivals, arts and crafts.
Ethnic or nostalgic tourism	It includes visits to places of own or ancestral origin and which, therefore, consists of visits motivated by the desire to know their roots, whether in the places where the visitor spent part of his life or those where the ancestors of the family spent all or part of his life, (CNCA, 2011) .	Visits to sites of biographical importance. Typical kitchen
Religious tourism	Includes commuting activities and motivated mainly by the faith of visitors His most typical expressions are pilgrimages to places considered sacred or of high spiritual value, religious or spiritual meetings and festivities, and itineraries or roads that lead to places of pilgrimage, (O.M.T, 2007).	Visit to religious sites: temples and / or sacred sites. Meetings and religious festivals. Pilgrimage routes.
Creative tourism	It offers visitors the opportunity to develop their creative potential through active participation in learning experiences that are	Photography, painting, pottery workshops, local cooking classes,

Types	Caraterização Characteristic	Lugares Places
	characteristic of the tourist destinations for which they are taken and this is linked to the development of cultural industries (Richards, Gy Raymond, 2000). The global trend towards creativity suggests that there is an opportunity for the art and culture organizations of the territories to create interactive and active experiences for visitors, provided that they want to live experiences that engage them, challenge and allow them to develop their creative potential.	craft workshops. Language learning to.
Sports or Recreational Tourism	It offers the tourist an opportunity to participate or observe a sports activity.	Sports practice and sports activities
Environmental Tourism	Refers to the interest of tourists in moving to places to enjoy the amenity and recreational value resulting from the relationship with nature.	Jardins, mantenhas, florestas, rios, mares, cachoeiras e outros. Gardens, keep, forests, rivers, seas, waterfalls and others
Cultural Tourism	It refers to visits to localities with the aim of interacting with the community and knowing more about lifestyles the festive representations ritual habits and customs or are motivated visits to know other worship, traditions historical sites, monuments art, architecture and festivities characteristic of a society.	Visit to communities, monuments and historical sites.
Internal Tourism	In this the tourist is resident of the locality itself, this becomes the consumer of the local tourist products, (Brazil, n.d.).(Pimentel, T.D., Pimentel, M. P. C., Vidal, 2017)	Visit to different locations
External Tourism	It refers to the tourist coming from other localities, this one that has a different look to that of the locals, because he can find more news in the way of speaking, in gastronomy, culture, in history, which is no longer news will put the inhabitant himself, (Brazil, n.d.).(Pimentel, T.D., Pimentel, M. P. C., Vidal, 2017).	Visit to different locations

1.3 Advantages and disadvantages of tourism

Modern tourism is an activity that has grown a lot in the last 30 years, generating many benefits for the development of communities and the environment, if well planned, otherwise it can produce great damage, (Chilembo, 2017)

The tourist activity introduces major changes in the receiving place, not only from a positive point of view but also from a negative point of view (Medeiros, Linbdenberg da Câmera e Moraes, 2013). A Tabela 1 sintetiza as desvantagens e vantagens para o turismo para os descritores ambientais e socioeconômicos.

Table 1: Advantages and Desadvantages of Tourism

	Advantages	Disadvantages
Environmental	<ul style="list-style-type: none"> - High investment in infrastructure destroys agricultural and forestry areas - Destruction of ecosystems (Mountains, natural parks, coastal shores); - Water pollution, increases waste production, the exploitation of freshwater reserves, the large number of tourists and their numerous oversights. - Degradation of the resources of fauna, flora, mineral products, semiprecious stones etc.; - Disappearance of natural landscapes due to real estate construction - Degradation of the landscapes of historical sites and monuments due to increased pollution 	<ul style="list-style-type: none"> -Valorization of natural and constructed heritage; -Facilitates the close relationship between man and nature; (Kraemer, 2005) -Recognition of the natural potential of places; - When well planned, it can stimulate the conservation of ecosystems and natural resources. (Chilembo, 2016);
Economic and social	<ul style="list-style-type: none"> - Promotion of low-quality jobs in a single period of the year; - Lack of spatial planning. In particular on the coastline; - Dependence on foreign investors and tour operators; - Use and exploitation of child labour; - Increased poverty and social exclusion due to the gulf between the wealth of resorts and poverty of the population. 	<p>It is the largest industry in the world, because it is linked with the different sectors of life (Maria & Manuel, 2017)</p> <ul style="list-style-type: none"> - Increased improvement of infrastructure (airport, road networks, basic sanitation, etc.); - Allows the entry of foreign currency, since tourists make expenses with accommodation, food, activities and purchases; - Creates jobs in hotels, travel agency, contributes to the wealth and economic growth of a country. - Promotes the development of other activities such as transportation, commerce, crafts, banks. <p>Helps promote local and regional products and keep alive and disseminate traditions Of Singing, costumes, gastronomy.</p>

1.4 Tourism and Nature Conservation

In many tourist places some visitors adopt behaviors that harm the environment visited, which shows that they have no responsibility and or concern to preserve and preserve the traces of nature, beauty and originality of the places, because because they have paid, they understand how sacred their free time and with rights and the short time that remain there find it very small so that they are responsible for the damage caused to the environment (Maria & Manuel, 2017).

The tourist activity developed taking into account the conservation and preservation of nature is called by (Beni, 1999) ecotourism and defines it as the displacement of people to natural spaces delimited and protected by the State, private initiative or controlled in partnership with local associations and NGOs. This in turn presupposes a controlled use of the place, with a management and planning of use within the parameters of the sustainability of nature and cultural resources, perceived through an environmental impact study

There are several concepts about sustainable tourism, although none of them are fully accepted; (Swarbrooke, 2002) (...) says that any definition of sustainable tourism emphasizes the environmental, social and economic elements of the tourism system. It also explains that all theories can bring us the following concept "sustainable tourism means tourism that is economically viable, but does not destroy the resources on which tourism in the future will depend, mainly on the physical environment and the social fabric of the receiving community. because tourism developed in localities with ecological potential, in a conservationist way, seeking to reconcile tourism exploration with the environment, harmonizing actions with nature, as well as offering tourists an intimate contact with the natural and cultural resources of the region, seeking the formation of an ecological awareness.

(Doris, 1997) makes an appeal in relation to tourism in the near future, stressing that "'soft', ecological, naturalistic, personalized and carried out in small groups of people tends to characterize the tourist flows of the future". The same author also points out four special characteristics that surround the sustainable development of tourism, where she explains, that the former are directly related to the services offered and the last to the visitor; I then state them:

- a) *Respect for the natural environment: tourism cannot endanger or irreversibly harm the regions in which it develops;*
- b) *Harmony between culture and the social spaces of the receiving community: without harming or transforming it;*
- c) *fair distribution of tourism benefits among the community*
- d) *Receiver, tourists and entrepreneurs of the sector; A more responsible and attentive tourist, receptive to environmental conservation issues, sensitive to limitations with the receiving communities, educated to his understanding and understanding of the peoples and places visited (Ramos & Direito, 2004.*

1.5 Tourism of África, Angola and Huambo

In Africa, the OMT foresees a major expansion of tourism in the coming years, especially for Botswana, Cape Verde, Namibia and South Africa (Chilembo, 2017).

In 2014 the Daily Government of Angola published that the country has 7 biogeographic regions considered wonders, and the province of Huambo is one of them, with a great diversity of landscape and is privileged with tourist destinations to develop tourist activities through which one can have a close relationship with nature without leaving aside aspects related to the conservation of natural elements. To this end, we will cite sites such as:

The Morro do Moco, highest point in the country, the águas frias and quentes do Alto Hama, the Pinturas Rupéstris do Okaniñgili, the Mupas do Rio Cuiva, Reserva Florestal do Kavongue, Centro Agronómico da Chianga, Albufeira do Cuando, Albufeira e Barragem do Ngove, Museu Antropológico Municipal, Ruínas da Embala Grande, Túnel Subterrâneo do Soba Candumbu, Morro de Santo António do Bailundo, Complexo turístico da ilha dos Amores, As Pedras de Ganda la Kawe, Morro do Moco, Águas Térmicas do Wama, Águas Térmicas do Lépi, Monte Mbanjela, the Monte Halavala, the ilha do Cuilo, the Mupas da Rio Luvulu II, the Mupas do Rio Cutato, the Mupas do Rio Cuiva, the Nascente do Rio Cubango, the Tumulo do Wambo Calunga, the Estufa-fria, the Praça do Governo Provincial Dr. António Agostinho Neto, the Catedral de eventos, the Mercado da Alemanha, centro turístico cantinho da paz from Chipipa.

Moreover, the Development Plan of the Government of the Province of Huambo demonstrates that the Province has a hotel network of 75 lodging establishments between hotels, inn, residential, guesthouses, hostels, resorts, which represents 2.2% of the country's total hotels, 50 restaurants, 150 transport agencies, a daily flight to other provinces, with the possibility of the train making two weekly trips to Benguela , Bié and Moxico (Chilembo, 2017); the author continues and maintains that tourism in 2014 employed 1981 people making 3.1% of all employment in the Province having received 28,160 tourists that same year, which represents, 2.4% of the total universe of visits in the country, a lower amount compared to other provinces visited by tourists. Still the Master Plan mentions 157 (one hundred and fifty-seven) places of tourist attraction, despite the places being registered, still many of these places are practically abandoned with a low rate of visitation, without assistance and maintenance. In Huambo, tourism began with the inauguration of the bridge over the Kuito River in September 1993, the bridge workers held a lunch there, having requested the approval of the local king (soba Chipala) with knowledge of the administrator of chipeco (Senhor Raposo) and the attractions of the island of loves that preserve the infrastructure built by the settler for tourist activities. Such activities grew with commercial practice, to point out that the most frequent tourism was business tourism.

The province of Huambo is a region with vast natural and cultural biodiversity, which boosts the desire to develop tourism activity and can become a tourist destination more preferred by nationals and internationals. Huambo was once considered the second largest commercial and industrial park in Angola before the war. Today, despite the economic crisis, the provincial government continues to focus on tourism as a development factor for the province and the country, (Chilembo, 2017).

2. METODOLOGY

The present work presents a non-experimental, mixed investigative character because it uses qualitative and quantitative techniques with knowledge and visitation and transversality as variables because it is linked with other sectors of the economic life of the country and the Province of Huambo. The scientific novelty is based on its contribution to the development of forms of integrated actions between the Ministry of Tourism and the Ministry of the Environment with other sectors of economic life. Interviews and questionnaires were chosen as a data collection instrument and to approach the questions, the Q method was used.

2.1 The Method Q

The question is what are the interactions between tourism and nature conservation in Huambo? For this we will analyze to what extent the preferences of visitors for the various tourist sites of Huambo are related to nature conservation? And to what extent are these choices explained by the characteristics of visitors?

The approach to these issues is done through the use of the Q methodology, (Stephenson, 1953) to understand the motivations of the agents (Hermans-Thissen, 2009.) who are responsible for the choices, namely the analysis of the hierarchy they make of the selected tourist sites, allowing to address the subjectivity of the respondents and establish the implicit factors that bring them closer and distance them (Addams, & Proops, 2000).

The Q Sort Method aims to structure the speeches of respondents on a topic that concerns them. It has three steps:

- a) first, through the analysis of documents, the places of visitation are identified;
- b) Second, through a questionnaire, the evaluation of the places of visitation is requested;
- c) Finally, an analysis of the choices of the respondents is carried out, identifying points of agreement and disagreement.

2.2 Presentation of Collected Data

The Methodology Q requires that the number of respondents is less than the number of choices. Thirty-nine questionnaires were collected, of which 15 were validated, complying with the formula $Q \frac{28 \times 27}{2} = 378$ comparisons, whose data we present in Table 3, 4 and 5.

Viaja (Sózinho =0; Mais 1=1;Mais 2=2; Mais de 2=3)	0%	23%	5%	0%	33%	38%					
Objetivo da Visita (Trabalho=0; Lazer=1; Família=2; Outro=3)	41%	36%	18%	5%							
Onde Fica no Huambo (Hotel no Centro=3; Hotel Periferia=2; Casa Centro=1; Casa Periferia=0)	10%	31%	10%	49%							
Quantos dias fica 1,2,5,10	0%	13%	3%	18%	0%	3%	0%	23%	5%	0%	36%
Como chegou ao Huambo (Automóvel=1; Autocarro=2; Comboio=3; Avião =4)	0%	44%	21%	3%	33%						
Como se desloca no Huambo (Pé=0; Autocarro=1; Taxi=2; Automóvel=3)	5%	0%	36%	59%							

The analysis of Table 3 allows us to better understand the respondents:

- a) 5% of respondents are domestic, 8% students, 59% civil servants and 28% private.
- b) 26% believe they have a low income, 33% a low average income, 28% a high average income and 3% a high yield.
- c) 23% visit Huambo more than once a year, 5% two and three times a year, and 71% more than four times a year.
- d) 41% visit Huambo for work reasons, 36% for leisure reasons, 18% for visiting family and 3% for or for reasons.
- e) 10% stay in a house on the outskirts, 31% in a house in the center, 10% in a hotel on the outskirts and 49% in a hotel in the center.
- f) 44% stay less than 4 days and the rest tend to stay more than a week.
- g) 44% arrive by car, 33% by plane, 21% by bus and 3% by train.
- h) In Huambo 59% travel by car, 36% by taxi, and 5% on foot.

In the evaluation of the places of visitation by the respondents, without any consideration, it is verified that the Provincial Government Square, the Cathedral, the Mbanjela Hill and the Ngove Dam and Albufeira are the most valued places and that the Springs of the Cuando River, the Ruins of the Big Embala and the Mupas of the Cutato River and Luvulu II are the places apparently least valued.

However, if we make a linear regression, having as control variables the knowledge of the place and the characteristics of the respondent, it is verified that the Provincial Government Square, the Cathedral, Mount Ombanjela and the Ngove Dam and Albufeira remain the most valued sites and that the valuation of the rest is not significant.

This time it is interesting to note that the knowledge of the places of visitation increases the value by 1.4 points on a scale from 1 to 10 and that the visitation adds 4 points to the value of the sites. The level of education and income has no significant influence on valuation but, compared to students, staff and private individuals devalue visitation sites by about 4 points on a scale of 1 to 10, Interestingly men tend to value the visitation sites less by about 0.5 points and the fact that the person was born in Huambo lowers the value given by 1 point.

3. DATA ANALYSIS AND PROCESSING

The Analysis of the Rotated Main Components explains 71% of the data Variance being the first rotated component responsible for 25% of the total data variation and the first five components explain 55% of the data.

Figura 1: Variância Total Explicada

The classification of the Main Components extracted by the Q Method is very important for the analysis and discussion of the results and it is convenient to relate it as much as possible with the theoretical framework presented in Chapter II.

Tabela 2: Características dos Questionados associados às Componentes

	Idade	Género (M=1;F=0)	Anos Estudar fora	Anos de Escola	Moram Cidade do Huambo	Moram Provincia Huambo	Moram em Angola	Nascera m Cidade Huambo	Nascera m Provincia Huambo	Nascera m em Angola
C1	42	0,50	2,83	14,2	67%	67%	100%	67%	67%	100%
C2	41	0,50	3,30	16,8	20%	20%	100%	60%	60%	100%
C3	25	0,50	0,00	9,0	0%	0%	100%	0%	0%	100%
C4	45	1	0	20,0	0%	0%	100%	0%	0%	100%
C5	36	1	0	18	100%	100%	100%	100%	100%	100%

All respondents from the five most representative components are residents of Angola and were born in the country. There are, however, differences between supporters of the various components.

Component 1: Reservoirs

Component 1 is mixed, with supporters who have studied abroad, two-thirds of whom are residents and naturals of the city and province. The chosen sites are reservoirs and dams, gardens and monuments. The least valued places are distant places.

Component 2: Urban Attractions

Component 2 only differs from the first because it has 80% of residents and naturals from outside the city and 40% from outside the province. It strongly values urban sites such as the German Market or the Cathedral and does not favor more peripheral sites such as the Gove Dam and other reservoirs.

Component 3: Central Green Zones

What characterizes the supporters of Component 3 is the low level of education, being residents and naturals from outside the city and the province and the lower age than those adhering to the other components. They will have heard of the Gove Dam, but prefer urban green areas such as the Cold Greenhouse or Government Square.

Component 4: Peripheral Green Areas

Components 4 and 5 have male supporters with high education level. The difference in Component 4 is that its supporters reside and are from outside the city. They prefer green areas in peripheral areas such as the Tourist Complex of The Island of Loves and do not like the German Market.

Component 5: Morro do Moco

Supporters of Component 5 reside and are from the province. They prefer Morro do Moco, Chianga's Agronomic Research Center and Government Square as visitation sites.

4. DISCUSSION OF RESULTS

The literature shows that tourism is the action of traveling to distant places, from the place where the person resides with a certain purpose, be it rest, leisure, visit to relatives and friends, seek health, research, knowledge of other cultures and another, because (O.M.T, 1993), refers to tourism as the activity carried out by people who want to move from their

usual environment to another, which is not part of your productive environment. In this, there should be no paid activity. Travel reasons can range from the need to do business, health, rest, leisure, visit and others. Thus it is understood that tourism is an activity carried out by people moving from their area of residence to another for a period determined for the purpose of rest, leisure and to know other cultures.

It is well known that the development of tourism activity depends heavily on supply and also on demand, in component 1, Respondents are 40-year-olds, living in Huambo, of both genders and with an average level of schooling. They value and appreciate more the Reservoirs, Mount Ombanjela, the German Market and chianga's Agronomic Research Center, to remember that this is the most representative component.

Making a synapse with the literature review and taking into account the characteristics of the respondents, one can explain the reasons for choosing the following: first because they are places closer to the city, and with easy accessibility, regardless of the type of vehicle, because they are located mostly in places where there is connection by asphalt, which makes a point in favor, the fact that our province has the main road network that connects to the municipalities all the roads and the visit to these places above, involves less costs, as mentioned (Almeida, et al, 2017), accessibility allows the places to be more visited, so that places with access receive more tourists compared to those with access difficulties.

Secondly, they are places with more attractive and safe conditions and show that they benefit from more attention on the part of the entities in preserving them per hour.

On the other hand, the most distant places are less valued, because they are places further away from the urban strip, the striped urban road network does not extend to these same places, which makes it difficult for visitors to access tourist places. The difficulties of the forum of the transport conditions and the high costs involved in such visits should be raised. There are several places, each with its natural beauty, but mostly need to be explored and more disseminated. Moreover, in the view of (Almeida, et al, 2017) for the development of tourism, it is not enough to exist natural resources, but it is necessary the intervention of man to transform them into tourist attractions, because it is the diversity of attractions that invites tourists to visit existing tourist sites whether in urban centers or in peripheral centers. The tourist centers of huambo province, with greater expression of peripherals, only have their natural potential, and do not exploit this potential, which makes them in only a beautiful place and that only depends on the simple will and predisposition of the tourist to visit that same place. Still component 1, reveals a predominance of internal tourism, because the respondents are residents and naturals of the city and province, Huambo, these being the ones that shows more interest in knowing and visiting the existing tourist places, remember that internal tourism is one in which residents are the main consumers of the local tourist product, as it maintains (Fernando, 2015), while in foreign tourism the tourist is foreign. When making marriage with the types of tourism, in relation to the motivations of visitors, we have the practice of sports that we are reputed to sports or recreational tourism, visitors travel with the aim of carrying out artisanal fishing in the Ngove reservoir and the race of water bikes and speedboats in the Cuando reservoir, to remember that the two reservoirs are in the raking of the visitors' choices, we point out that sports or recreational tourism, being one of the main drivers of visitor travel, its main motivation is the participation and /or observation of sports activities. Still, nested to this interest, it is noted that there is an attraction for landscape beauty and the desire to maintain a closer relationship with nature, which is related to environmental or ecological tourism, because here the tourist moves in order to carry out activities in landscape dwellers, which should awaken the entities in order to ensure that this activity does not wear the resources currently exploited. Generally, the visit time is three days onwards, depending on the conditions of the place, the type of activity and the fishing conditions. When the travel time lasts less than 24 hours, then it is considered excursion.

The most visited monuments are mostly related to religious activity, which reminds us of religious tourism, motivated by the faith of visitors.

It is worth remembering that one of the moires motors to develop tourism activity is local development, because it is certain that a developed locality offers more conditions to be able to carry out the tourist activity, as mentioned (Doria, 2016) and (Cunha, et al, 2013), so tourism requires a marriage with other sectors, such as the construction sector, the emigration sector and foreign, the energy, water and basic sanitation sector, the hospitality and restaurant sector, the communication sector. The tourism industry depends heavily on the progress of other sectors, which is why the development of the country and Huambo can define the development of tourism in Huambo and Angola still makes reference (Fernando, 2015).

In Huambo tourism has many weaknesses, it is timidly practiced in an insipid way, for lack of infrastructure to relaunch it, because there is a lack of roads and public transport to improve access, lack health services, safety and communication, lack of energy, water and basic sanitation, lack hotels and restaurants in the periphery and lack of entertainment in the city of Huambo to boost the tourist machine.

Component 2: Urban Attractions, shows that 80% of respondents are people who elected Huambo as a city of residence, which differs from component 1, but these also value urban sites more, such as the German market for being a shopping center, we can mark here commercial or business tourism and tourism can be considered as a gateway to capital and people, still tourists may be motivated by the interest of acquiring some local products; the Cathedral of Events is a hall where festive activities take place with a certain frequency and is located within a tourist space, feet although considered dormant. Peripheral sites do not favor, nor are they valued by respondents, because they do not offer attractiveness to them. It should be noted that the urban component offers more convenience and safety as mentioned in the previous component.

Component 3 highlights the central green areas, still remains the same mat of preferences, although the respondents are of low level of education, residents and natural people from outside the city of Huambo and are the youngest. They prefer the cold greenhouse and the square Dr. António Agostinho Neto. Young people use these places as a meeting point to

discuss points of view, for leisure, to make photographic posters, to note that the cold greenhouse is a place where the landscape offers us a relative calm to rest and study, even without created conditions, such as changing rooms for example. The square Dr. António Agostinho Neto is the center of the city and you can enjoy from this point the architectural and landscape structure of the city. This fringe of visitors values leisure more and have no interest in knowing peripheral places. Unlike component 4, supporters prefer peripheral green areas, are mostly male with high education level and are residents and naturals of the city of Huambo, but do not like the market of Germany, since component 5 brings the Morro do Moco as the first place elected by residents and naturals of the city of Huambo, in addition to chianga's Agronomic Research Center and government square. It is noted that the level of education appears as a great conditioning factor for components 3, 4 and 5, because it significantly improves income, because it is directly related to quality of employment, interest in travel, level of curiosity, also grow with the level of education, achieved by years of study which encourages the individual to meet history, note that the level of education associated with employment facilitates in the process of social integration..

Analyzing the five components, with main enhancement components 3, 4 and 5, it can be noted that the respondents attribute little value to peripheral sites, because they hardly attend these places, so the marriage between tourism with the aspects of nature conservation in the green areas now elected, both urban and peripheral, tends to negativity, because the devaluation of the places is directly linked to the lack of attractions that would boost the motivations of tourists. Behavior that proves threatening to nature conservation.

It is interesting to note that the knowledge of the places of visitation increases the value by 1.4 points on a scale from 1 to 10 and that the visitation adds 4 points to the value of the sites, but it is not a satisfactory fact. Making a synapse with the motivations of tourists to move to the tourist sites, there is a lack of attractiveness in tourist sites because, despite these are places possessing a natural potential, they are just a beautiful place, and it is the diversity of tourist attractions that attracts, because they are the ones that will add the attractive value to the places, these are infrastructures to support tourist activity, which is consequently reflected in the tourist's behavior in observing aspects related to nature conservation.

The tourist when meeting in a place without supervision, in most situations, can adopt by an irresponsible behavior that can harm nature and shows no concern for nature conservation. This is a consequence of the lack of exploitation of most potentially touristic places, and tourism can be a good alternative for nature conservation, acting as a supervisory and management body.

The level of education and income has no significant influence on valuation but, compared to students, employees devalue visitation sites more, by about 4 points on a scale of 1 to 10, Interestingly men tend to value the visitation sites less by about 0.5 points and the fact that the person was born in Huambo lowers the value given by 1 point.

When the level of education increases, the level of knowledge increases and consequently the concern with the environment around us, should also increase, but our research shows us that the reality in Huambo is very different from what the literature shows it should be, the fact that by increasing the level of education, the level of knowledge grows and also the individual should have moral awareness, ethical and responsible in its relationship with the natural environment.

The level of income may increase the possibility of the individual traveling on his own, but the behavior to be adopted in relation to the care to be observed with the place visited, from the point of view of conservation should not have a direct influence, the same can be thought about men, employees and naturalness.

The conservation of nature shows that tourists grouped into 5 components described above, relegate this aspect to the background, with an average of 4 points, on a scale of 1 to 10. However, with the relaunch of tourism activity, concern with the conservation and preservation of nature must grow in ways to avoid consequences such as the destruction of agricultural and forest areas, the destruction of ecosystems, pollution of water, increased production of waste, the exploitation of freshwater reserves, the large number of tourists and their numerous oversights, the degradation of the resources of fauna, flora, mineral products, semiprecious stones etc., disappearance of natural landscapes due to the deposition of real estate construction waste, degradation of historical sites and monuments due to increased pollution. The provisions refer to the conclusion in Chapter IV.

5. CONCLUSIONS

Depending on the objectives of the research, the documentary methodology carried out shows that:

Tourism can be used to promote local development and as an alternative to nature conservation, within an integrated management.

The tourist places of Huambo Province, although registered, few are disclosed, and appear in a confusing way, so much so that Morro do Moco, one of the seven (7) natural wonders of Angola is replaced by Mount Luvili in the Google search engine.

The most visited tourist sites are the closest to the urban centers, due to the conditions of access and attractiveness they offer since others are only natural resources.

The interactions between tourism and nature conservation in Huambo tend towards negativity, due to the lack of exploitation and supervision of tourist sites that are mostly abandoned or without proper use.

The Province of Huambo has many tourist places, but there are the most appreciated, valued and most visited by tourists, such as the Provincial Government Square (Dr. António Agostinho Neto), Mount Ombanjela, the Gove Dam, the Events Cathedral, which suggests an underload of use in these places which in itself becomes negative from the point of view of sustainability.

The tourist sites of the Province have connoisseurs residing in Huambo and other provenances. Tourists are mostly in the 34 to 46 year old age group, are young, with gender balance and higher education level. Tourism in Huambo is still done in a rudimentary and incipient way because it needs more attractions, because the many resources still need to be transformed into tourist attractions.

6. RECOMMENDATIONS

That the Government of Huambo invest more in tourism support infrastructure and, without harming nature, disclose the tourist product, and create an e-mail address of publications to attract local and foreign investors.

May the provincial government find in tourism an alternative tool for the conservation and preservation of tourist spaces most valued, appreciated and visited by tourists.

That the Government favour the incorporation of good sustainable tourism practices by operators and service providers. That the tourist agents of the Province provide conditions that favor the realization of tourism animation to add value to places of tourist interest.

That an environmental awareness be created in the individual from an early age, through lectures, studies related to the environment, seminars, workshops and tele and radio information.

INTERPROVINCIAL TRADE IN ARGENTINA: MAIN DETERMINANTS

Pedro Elosegui¹, Marcos Herrera^{2,3}, Jorge Colina⁴

¹BCRA, Argentina. ²IELDE- UNSa, Argentina. ³Conicet, Argentina. ⁴IDESA, Argentina

ABSTRACT

This paper is part of a broader agenda and constitutes a first step to empirically understand the main determinants of the interprovincial trade in Argentina. We use a novel database of regional trade flows between the 24 Argentinean provinces for 2017. Using a structural gravity model and novel econometric techniques we analyze the main variables influencing trade between the provinces. In fact, the main determinants of trade flows between the provinces are analyzed by adding to a canonical gravity model several variables that can possibly affect trade between sub national jurisdictions, such as informality, commercial channels, government transfers, financial inclusion among other variables that may be correlated with formal trade. Additionally, the potential impact of shocks in the regions is considered according to their origin and transmission capacity through trade flows. The results indicate that national transfers from the redistribution federal arrangement are an important determinant of inter provincial trade generating relevant spillover effects between the provinces.

LONG-LASTING EFFECTS OF PANDEMICS: THE CASE OF THE 1918 INFLUENZA PANDEMIC IN ARGENTINA

Fernando Antonio Ignacio González¹, Juan Antonio Dip², Silvia London¹

¹Instituto de Investigaciones Económicas y Sociales del Sur, Universidad Nacional del Sur/CONICET (IIESS, UNS-CONICET), Argentina. ²Facultad de Ciencias Económicas. Universidad Nacional de Misiones, Argentina

ABSTRACT

The 2019 novel coronavirus disease pandemic poses a severe threat. While its short-term effects are evident, its long-term consequences are a matter of analysis. In this work, long-lasting negative effects derived from exposure in utero to a great pandemic 1918 influenza pandemic are analysed for the Argentine case.

Outcomes of interest include educational achievement and unemployment status in adulthood -50 years after the pandemic. Based on a Local Linear Regression plus a Difference-in-Difference regression specification, temporal differences in the spread of the pandemic and between close birth cohorts are exploited.

The results indicate a significant reduction in educational achievement for people exposed in utero to the pandemic. However, the decline in educational attainment is not homogeneously distributed across the different regions of Argentina. In the region with the highest incidence of cases (Noroeste), this reduction is 0.5 years of education. There are no significant changes in the chances of being unemployed. Besides, the results are also robust to the implementation of placebos in which the treatment group is falsely defined based on cohorts that were not exposed to the pandemic. As expected, no significant differences are observed. In the context of climate change, these results constitute a call of attention for the implementation of child protection policies from gestation.

Some caveats should be made regarding the results of this paper. For the Argentine case, the estimates are subject to the limitations of the primary sources of information. In the future, it is desirable to explore the specific channels through which exposure to natural biological disasters can generate long-lasting negative effects. Two of these channels widely indicated in the literature, malnutrition and maternal stress, take on relevance in the current economic crisis and obligatory social distancing. The availability and easy access to microdata for a broad population group are essential to advance in this analysis direction.

BEYOND THE POLITICAL OR ADMINISTRATIVE DEFINITION OF THE ARGENTINEAN ECONOMIC REGIONS, DO THEIR PROVINCES HAVE A COMMON ECONOMIC CYCLE?

Facundo Sigal¹, Jorge Camusso², Ana Inés Navarro³

ABSTRACT

In this article, the clustering methodology is applied to group Argentinean provinces by regions according to the cyclical behavior of their economies. We implemented three grouping techniques: the well-known k-means procedure, first without imposing geographic contiguity in the grouped provinces, and then with contiguity restrictions, and the third based on agglomerative hierarchical grouping. On the other hand, we measured the economic cycle of each of the Argentinean provinces by constructing coincident indices using the Stock and Watson (SW) methodology. This approach, based on probabilistic state space models, rest on the hypothesis that the observed co-movements in indicator series can be captured by a single unobserved variable that represents the unknown “state of the economy”. Instead of applying equal weights as traditional NBER’s methodology does, SW uses maximum likelihood procedure to estimate the weights of the component series that best identifies that single underlying factor, so it is statistically more rigorous. We find that clustering provinces according to their economic cycle, presents differences regarding the official regionalization of the Argentinean Institute of Statistics and Censuses (*INDEC*). We also find that the provinces that concentrate the country’s agro-industrial production and exports -*Córdoba* and *Santa Fe*- present similarities in their cyclical behavior, which are robust to the different grouping methods. Finally, provinces such as *Formosa* and *San Luis* appear repeatedly grouped with provinces that belong to other *INDEC* regions. Even in some cases, the results show isolated provinces, surrounded by others with marked differences in their economic cycles, such as *Jujuy*, *Misiones* and *Entre Ríos*, which are grouped with neighboring provinces only when contiguity is a restriction. Our work makes a valuable contribution to the empirical literature on regional economic dynamics, scarce in studies of the state of the economy in Argentina. Additionally, we contribute by obtaining coincident indices for the twenty-four provinces, with a statistically precise methodology, which until now has been used exclusively to calculate indices in a few bunch of provinces. As a whole, the results show that regionalization based on static criteria may not be the most appropriate approach when dynamics matter.

Business Cycles, Coincident Indicators, Clusters, Regional Economic Activity

1. INTRODUCTION

Subnational heterogeneity among the regions in which the Argentine provinces are generally classified, has been studied in aspects such as unemployment (Félicz, Panigo and Pérez, 2000; Figueras, Díaz Cafferata, Arrufat, Descalzi and Rubio, 2002; Galiani, Lamarche, Porto, and Sosa Escudero, 1999, 2005), returns to education (Paz, 2009) and distributive inequalities (Zacaria and Zoloa, 2005). However, for the most part, subnational studies limit the analysis to the provincial level or for a bunch of them, which composed a particular region. One of the exceptions is the recent article by Blanco, Elosegui, Izaguirre and Montes-Rojas (2019), in which the authors analyze the possible asymmetric effect of monetary policy on employment, at the level of provinces as well as for the Argentinean economic regions. In addition, subnational business cycle has also been studied from the provincial perspective to show whether they are correlated or not with the national cycle (Garegnani and Di Gresia, 1999), or the effects of the national business cycle on provincial tax revenues (Carrera and Saller, 2000), the degree of synchronization between the economic cycle of an urban area with the provincial and national cycle (Lapelle, 2015), or seeking to build a coincident national index and its counterpart for each of the twenty-four Argentinean provinces, like Muñoz and Trombetta (2014).

The estimation of coincident synthetic indices at the provincial level is quite widespread in Argentina from the pioneering studies of Jorrot (2003, 2005) for the Province of *Tucumán* and later for *Córdoba* (Michel Rivero, 2007), *Santa Fe* (D’Jorge, Cohan, Henderson and Sagua, 2007) and *Misiones* (Heredia and Alvarez, 2017), as well as Lapelle (2015) for the area of *Rosario*, are based on the traditional methodology of the National Economic Research Office (NBER). On the contrary, in Berardi, Navarro and Uría (2010), a coincident synthetic index for the Province of *Santa Fe* was presented, following the methodology of Stock and Watson (Clayton-Matthews and Stock, 1998/1999; Stock and Watson, 1989, 1991), and then, in Navarro and Sigal (2012), several modifications were introduced to the index seeking to adapt it to changes in available information. However, there have been no attempts to measure regional cycles, using the Stock and Watson methodology (SW from now on), except one incipient program that is being developed by a group of researchers at *Universidad Austral*

for the provinces grouped in a politically defined region called "*Región Centro*" (*Santa Fe, Córdoba and Entre Ríos*) due to its location at the center of the country.

For some economic interesting issues, the Argentinean Institute of Statistics and Censuses (*INDEC*) groups the Argentinean provinces into five or six regions¹¹⁸ and defines the "Central Region" of the country made up of the three aforementioned provinces of the "*Región Centro*", plus the Province of *Buenos Aires* and the Autonomous City of *Buenos Aires (CABA)*, the latter being sometimes presented isolated as the sixth region. In addition, for employment statistics the *INDEC* groups the main urban agglomerates of the three aforementioned provinces together with others from the Province of *Buenos Aires* and *La Pampa*, calling it "*Región Pampeana*".

In general, these definitions of the Argentinean economic regions respond to similarities in a broad set of socioeconomic and territorial characteristics at a point in time. This type of approach resembles the Bureau of Economic Analysis (BEA) one, which since the 1950s has grouped the fifty states of the United States into eight regions based primarily on cross-sectional similarities in their socioeconomic characteristics. As Crone (2005) points out, economists have tended to use the BEA regions to examine various regional trends and cycles assuming that the regions are properly defined.¹¹⁹

However, when the analysis focuses on business cycle phenomena, multistate regions based on similarities at a given moment may not be the appropriate set of observations. For this reason, Crone (2005) groups states into regions based on similarities in their business cycles. Using a consistent set of coincident indexes, estimated from a SW-type model, the author applies k-means cluster analysis to the cyclical components of these indexes to group the forty-eight contiguous states into eight regions with similar cycles. Then, the author determines the relative strength of cohesion among the states in the various regions and finally provides a comparison of the regions thus defined with the BEA regions. Likewise, Miller and Sabarrese (2012) estimate a state space model for Georgia and test if it produces reasonable forecasts for the real growth rates of the gross domestic products of Alabama, Florida, Georgia, North Carolina, South Carolina, and Tennessee for 1991 through 2008. For Argentina, Brida, Garrido and London (2012) study the economic performance of the Argentinean provinces –using real per capita Gross Domestic Product (GDP)- during the period 1961-2000. Applying hierarchical clustering techniques, they detect groups of provinces with similar performance, but their regions do not correspond with *INDEC*'s regions, at all.

The main objective of this work is to investigate whether the provinces that make up the *INDEC* regions and in particular those that make up the so-called "*Región Centro*" have a common economic cycle. The specific interest in the latter lies in the fact that most of the country's agro-industrial production and exports are concentrated there. This study uses information from a wide set of series at the state and metropolitan area level for the twenty-four provinces obtained from different official sources and sectoral chambers that have been compiled and seasonally adjusted. Based on Crone (1998/1999, 2005), composite indices are constructed for each of the twenty-four provinces of Argentina. These indices are estimated following the SW methodology, which is especially suitable for constructing synthetic indicators for provinces and regional economies because it does not require having a timely series of regional GDP, due to the assumption that the "state of the economy" underlying is unobservable. Then, we group the provinces into five or six regions using cluster analysis.

This paper is inserted on the field of empirical analysis that studies regional economies performance and, specifically, into the empirical study of the regions' composition from a dynamic perspective of cyclical similarity of the provinces that comprise them.

One contribution of this paper is the application of clustering methodology to select the provinces that make up the different regions according to the cyclical behavior of their economies. In turn, when applying this analysis to Argentina, it allows us to observe whether the regional disparity found in developed countries between the definitions at a point in time and those that arise from analyzing cyclical behavior of the provinces that make up regions, is also verified in an emerging economy. An additional contribution consists of obtaining coincident indices for the twenty-four provinces, with a statistically precise methodology, which until now has been used exclusively to calculate indices in a few bunches of provinces.

One of the main results of our work is that, beyond the clustering method applied, grouping provinces according to their economic cycle presents some differences with the official regionalization of the *INDEC*. However, some clear patterns regarding regionalization were found in our results. A particularly interesting result is that *Córdoba* and *Santa Fe* - provinces that concentrate the country's agro-industrial production and exports- appear together in almost all the clustering procedures.

The outline of the paper is as follows. In Section 2 data and methodology for building coincident indices for each province and the procedures to combine them in regions based on the similarity of their economic cycles are presented. Section 3 show the results of our cluster analysis and the comparison of these respect to the official regionalization of *INDEC*, with particular interest in the analysis of *Región Centro*. Finally, the study closes in Section 4 with a global evaluation of the results.

2. DATA AND METHODOLOGY

2.1 Data

118 *Área Metropolitana de Buenos Aires (AMBA), Región Cuyo, Región Noreste Argentino (NEA), Región Noroeste Argentino (NOA), Región Pampeana and Región Patagonia.*

119 See Crone (2005) for a complete list of studies.

When subnational coincident indexes are used to compare the state of the economy across the whole country, they must have a certain degree of consistency. To achieve it, the indexes should be constructed from the same set of indicators for each jurisdiction. Several criteria have been proposed in the literature to select the variables better suited for that purpose.¹²⁰

The data used herein comes from the database named *Indicadores Regionales* built by *IDIED-Universidad Austral* which compiles public and private economic information for the twenty-four provinces of Argentina. For each province we have about fifty monthly series to analyze them in light of canonical criteria. This bunch of time series could be classified in eight broad categories: employment, consumption, investment, sector production, energy, prices and wages, public finance, and financial services. On these, for selecting the series to be incorporated in the coincident index we apply the standard economic and statistical criteria.

First, we verify that the length of the series reaches the minimum amount of one hundred twenty months for each indicator and that these variables have economic significance. Second, to check for smoothness, we construct the boxplots for each of the series that pass the first selection stage. Third, we analyze the business cycle properties of the series. Since a key notion of the business cycle is that fluctuations are common across all sectors, the series should exhibit a consistent timing pattern over time as a coincident indicator and fit well with the business cycle. Following Stock and Watson (1989), for each variable we analyze both the basic univariate characteristics and the co-motion properties with the aggregate activity. For this we need a reference series for the business of the entire economy. Ideally, the reference series would be the Gross State Product, but this is reported on an annual basis and with a lag of several years. Thus, we use the number of employees registered in the Private Sector, an indicator available for all provinces that naturally shows an adequate correlation with the economic activity in most of them. This amount comes from the Argentine Integrated Pension System (*SIPA*). The criterion of consistent timing is tested by calculating the co-movements -through contemporaneous correlations- between each series and *SIPA*'s employment. Since we are looking for strong indicators, we prefer the series with high correlation, notwithstanding, *a priori* we do not discard any of the series based on a lower level of correlation.

There are twenty-one series that best accomplished all the tests for being included in the coincident index. All these series were included in the estimation of successive versions of the index. The model finally selected was the one that produced the best index in terms of smoothness and conformity. This means that it satisfies the required assumptions of SW model. The series finally included in the best model are "registered employees"¹²¹, "total tax collection", "electric power provided", "car sales", "gas provided", "cement sales" and "gasoline sales".¹²²

2.2 Methodology

2.2.1 Background in the empirical literature

For a frequent and timely monitoring of the "state of the economy", the empirical literature usually estimates a composite index of coincident indicators since, by aggregating the movements of several key economic indicators, it represents a single summary statistic that tracks the economy's current state. The National Bureau of Economic Research (NBER) based in Mitchell (1927) and Burns and Mitchell (1938, 1946), developed one of the first methodologies to estimate this type of composite indexes, which has been widely used since then.¹²³ The NBER approach it is easy to understand at conceptual level and the calculations it involves are not complex. However, since business cycle is not precisely defined, it is not entirely clear what the index is really measuring. Moreover, the vector of weights used to aggregate the set of data series and construct the index is exogenous and arbitrary, so it is not based in a statistical or economic optimization process.¹²⁴

Given the limitations of the traditional approach, in the late 1980s NBER's economists developed new methodologies to construct coincident and leading indexes (Stock and Watson, 1989, 1991). The SW methodology, mathematically based in probabilistic state space models, rest on the hypothesis that the observed co-movements in indicator series can be captured by a single unobserved variable that represents the unknown "state of the economy". This methodology assumes that each series has a component attributable to the unique variable unobserved and a particular or idiosyncratic component. The problem to be solved in this approach is to estimate the current state of the economy, namely the common element in the fluctuations of each time series. The main contribution of their research was the use of a statistical technique called the Kalman filter for the estimation of the optimal weights on the component indicators. In contrast to the traditional composite index methodology which applies equal weights once the volatility in each series

¹²⁰ See, for example, Crone (1998/1999) and Muñoz and Trombetta (2014).

¹²¹ From the SW methodology it is not clear whether the variable used as a reference for the selection of series - when the GSP is not available - could also be included in the estimation of the coincident index. For this reason, and considering that employment is naturally related to the state of the economy, we decided to include the *SIPA*'s employment series in the estimates of our coincident index. In addition, the possible problems are reduced due to the fact that the weight that this variable has in the index is relatively low. Also, we are currently exploring new results by selecting the component series by using alternatives criteria.

¹²² A great advantage of the seven selected variables is that all of them are published almost simultaneously. Another advantage is that these series are published by the national offices of each area, so we can trust that the series for each state are calculated with the same methodology.

¹²³ In Argentina, this traditional approach was widely applied in academic works for the measurement of the evolution of subnational and national economic activity (Arredondo *et al.* 2009; Jorrat, 2003, 2005; Michel Rivero, 2007).

¹²⁴ Burns and Mitchell (1938, 1946) define the coincident indicators as coincident with the "reference cycle," that is, with the broad-based swings in economic activity known as the business cycle. This definition is intuitively appealing but, as Burns and Mitchell (1946) recognized, lacks precise mathematical content, so is unclear what conclusions one should draw from swings in the index.

is standardized, in SW approach are statistically estimated the weights of the component series that best identifies the single underlying factor that is time dependent and that best represents the co-movement in the components, using a maximum likelihood procedure. Hence, from a statistical point of view this approach is more rigorous than the former NBER's methodology (Orr *et al.*, 1999) and the index also provides a better definition of the underlying state of the economy from a mathematical perspective. This statistical optimal methodology is currently being used for several estimations both at state or regional level (e.g., Crone, 1998/1999; Crone and Clayton-Matthews, 2004; Méndez, 2007; Orr *et al.*, 1999; Orr *et al.*, 2001; Tebaldi and Kelly, 2012) and at national (e.g., Dias, 1993; Fukuda and Onodera, 2001; Hall and Zonzilos, 2003; Reklaitė, 2011).

2.2.2 Stock and Watson's Model

The underlying assumption of SW's methodology is that in addition to stochastic component that represents an idiosyncratic movement, each macroeconomic variable has a common unobserved component, called "state of the economy". The authors formulate a linear model in the unobserved variable for estimating the common component using the Kalman filter to build the likelihood function and to obtain the maximum likelihood estimators of the parameters of the model. Following Clayton-Matthews and Stock (1998/1999), the structure of the model as applied here is:

$$\Delta \mathbf{x}_t = \boldsymbol{\beta} + \gamma(L)\Delta \mathbf{c}_t + \boldsymbol{\mu}_t \tag{1}$$

$$D(L)\boldsymbol{\mu}_t = \boldsymbol{\varepsilon}_t \tag{2}$$

$$\varphi(L)\Delta \mathbf{c}_t = \delta + \eta_t \tag{3}$$

where $\Delta \mathbf{x}_t$ is a $G \times 1$ vector of observable series in first-difference log form to achieve stationarity and $\text{var}(\eta_t) = 1$. A scalar latent stationary series that is common to the G observable series is captured by $\Delta \mathbf{c}_t$ which, in this context, can be interpreted as deviations from the average growth rate of the economy or, alternatively, as the growth rate of the unobserved state of economy. This component follows an autoregressive moving average (ARMA) process and enters in the equation (1) with different lags and weights. The $\boldsymbol{\mu}_t$ vector, called the idiosyncratic portion, consists of G mutually uncorrelated, mean zero, stationary ARMA processes. The $G \times 1$ vector $\boldsymbol{\varepsilon}_t$ and the scalar η_t comprise $G \times 1$ mutually uncorrelated white noise processes. The symbol L is the lag operator, i.e., $L^k \mathbf{x}_t = \mathbf{x}_{t-k}$. The lag polynomial matrix $D(L)$ is assumed to be diagonal, hence $\boldsymbol{\mu}_t$ in each of the G series in equation (2) are serially uncorrelated among them. The parameters of the model can be expressed as follows:

$$\gamma(L) = [\gamma_1(L), \gamma_2(L), \dots, \gamma_G(L)], \text{ where } \gamma_g(L) = \gamma_{g0} + \gamma_{g1}L + \gamma_{g2}L^2 + \dots, \quad g = 1, \dots, G. \tag{4}$$

$$D(L) = \text{diag}[d_1(L), \dots, d_G(L)], \text{ where } d_g(L) = 1 - d_{g1}L - d_{g2}L^2 - \dots, \quad g = 1, \dots, G. \tag{5}$$

$$\varphi(L) = 1 - \varphi_1L - \varphi_2L^2 - \dots \tag{6}$$

$$\Sigma = \text{cov}(|\boldsymbol{\varepsilon}_t, \eta_t|) = \text{diag}(\sigma_1^2, \sigma_2^2, \dots, \sigma_G^2, \sigma_\eta^2) \tag{7}$$

The system of equations (1)-(3) is estimated by maximum likelihood procedure. It is accomplished by representing the system in state space form, using the Kalman filter. Following the literature, we normalize each of the coincident series x_{it} by subtracting its mean difference and dividing by the standard deviation of its differences. This identifying restriction constrains the constant $\boldsymbol{\beta}$ to be zero. Therefore, the obtained Kalman filter, denoted by $\Delta \mathbf{c}_{t/t}$, can be considered as a composite coincident index of the economic activity, constructed using data on the coincident variables available through time t .

Following Clayton-Matthews and Stock (1998/1999), we perform a calibration of the coincident index of each province transforming its first two moments of growth -the average growth rate and the average deviation tendency- in the first two moments of a common indicator for all provinces. We use *ICASFE*, a coincident index estimated by *Bolsa de Comercio de Santa Fe*. By doing this, the level and scale of the index is comparable to other indexes.

2.2.3 Cluster analysis using coincident indexes

As a first approximation, we implement a clustering procedure in the spirit of Crone (2005) but with some modifications to group the twenty-four provinces into regions based on the cyclical behavior of their economies and their geographic proximity. We use k -means procedure, which separates the observations into a predetermined number of clusters (k) based on minimizing some measure of dissimilarity among the observations in each cluster. Our measure of the dissimilarity is the squared Euclidean distance from the center of the cluster:

$$\sum_{m \in c} \sum_{i=1}^N (X_{im} - \bar{X}_{ic})^2 \tag{8}$$

where X_{im} is the variable i ($i = 1, 2, \dots, N$) for observation m ($m = 1, 2, \dots, M$), and \bar{X}_{ic} is the center of cluster c to which m is assigned, or the average X_i for all the observations in cluster c . The set X includes two types of variables. First, following Crone (2005), we include our estimated coincident index but on a biannual frequency, averaging monthly values of each semester. Thus, since our period analysis covers ten years, we have twenty variables that represents the business cycle of each province. Second, we add twenty-four dummy variables that indicates if a given pair of provinces are or not contiguous¹²⁵, to consider geographic proximity as information but not as a constraint. Since we expressed the coincident indexes on a biannual frequency instead of a monthly basis, there is an equilibrium between the number of variables that captures business cycle and dummy variables for geographic proximity. Regarding the predetermined number of regions, we apply two variants, consisting in five and six clusters respectively, to do our clustering exercise comparable to *INDEC*'s regionalization.

125 For example, the dummy variable "Santa Fe" assumes value one for all provinces that are contiguous to *Santa Fe* (including the province itself) and zero for the others.

As a second step, we use a contiguity-constrained version of *k*-means procedure, following the algorithm of Costanzo (2001), which is specifically designed for classifying spatial units. Applying this method, we not only group provinces in a region taking account of their economic cycles, but we restrict clusters to be formed only by contiguous provinces. The difference with the approach explained above is that Costanzo’s algorithm incorporates contiguity as a restriction not as information for clustering. Since this latter method does not require including dummy variables for geographic proximity, we use coincident indexes on monthly frequency. Again, we restrict the number of clusters to five and six, respectively. Finally, we use an agglomerative hierarchical clustering procedure (Anderberg, 1973). With this technique, initially each data point is considered as an individual cluster. Then, at each iteration, the similar clusters merge with other “bordering clusters” until one cluster or *k* clusters are formed.¹²⁶ Since we restrict the number of regions to five and six, we cut the hierarchical tree when five or six clusters are formed.

3. RESULTS

As mentioned in the introduction, firstly, coincident composite indexes were estimated for each province using the SW methodology. Here, we present the results obtained from the clustering process and the resultant regions based on these indicators.

As explained in Section 2, three different clustering techniques were applied in order to build groups of provinces according to their business cycle similarities and geographical proximity. Since we restrict the number of regions to be five or six¹²⁷, we obtain a total of six clustering scenarios, whose results are shown in Figure 1.

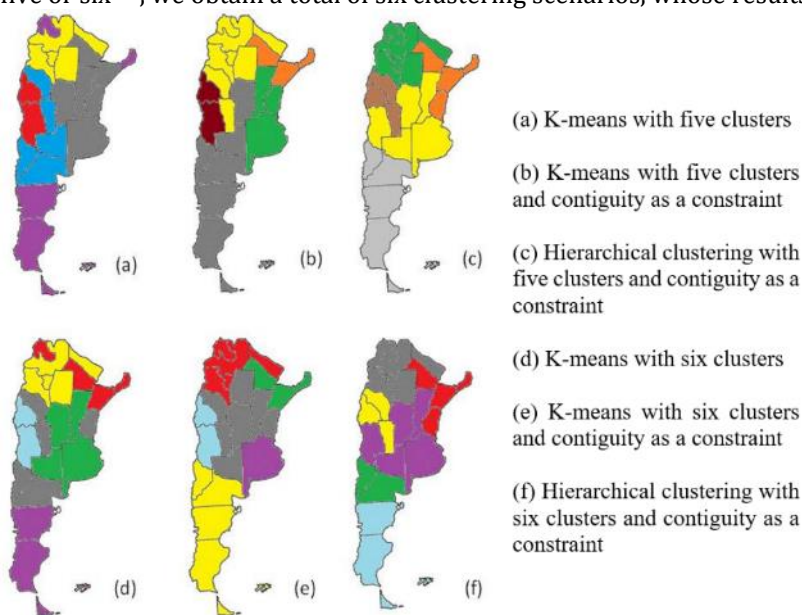

Figure 1: Resulting clusters applying three different techniques with five and six clusters.

Source: own elaboration with data from different official sources and sectoral chambers.

The application of *k*-means clustering techniques generates different groupings of provinces, which in turn change when the predetermined number of clusters is modified. On the contrary, the addition of a sixth group in the hierarchical approach produces minor modifications, only changing the composition of a single group, the most southern one.

Beyond the clustering method applied, one of the main results of our work is that grouping provinces according to their economic cycle presents some differences with the official regionalization of *INDEC*. However, some clear patterns regarding regionalization were found in our results.

Applying the aforementioned techniques to construct five regions, very varied results are found, but with a certain regularity that can be highlighted. For example, the three clustering techniques match *Formosa* -a province located at the northeastern part of the country- with all the northwestern provinces, while *Jujuy* -a province located at the northwestern part of Argentina- is excluded from this group in the first estimate. Besides, *San Luis* -a member of *Región Cuyo*- is repeatedly grouped together with provinces that belong to other *INDEC*'s regions. An interesting result is that we found that some provinces are isolated, surrounded by others with noticeable differences in their economic cycles, such as *Jujuy*, *Misiones* and *Entre Ríos*, that only are grouped with neighboring provinces when contiguity is a constraint.

¹²⁶ The basic algorithm is straight forward: first, compute proximity matrix (in this case, with Euclidean distance measure); second, let each data point be a cluster; third, merge the two closest clusters and update the proximity matrix, repeating this process until determine where to cut the hierarchical tree into final clusters. The third step of this process is restricted according to contiguity. In this sense, each cluster is restricted to be formed by, at least, two contiguous provinces.

¹²⁷ *INDEC*'s statistical regions are six, but one of them is *Buenos Aires*' Metropolitan Area (in Spanish, *AMBA*). Because of this regionalization, the selected number of clusters is six. The techniques were also proven with five clusters, considering *AMBA* as a city belonging to the same region of Province of *Buenos Aires*.

Likewise, the three southern provinces are grouped together in all estimates that constrain the number of clusters to be five. The Province and the City of *Buenos Aires* appear grouped in all the techniques, although they are not distinguished on the maps. In the estimations with six clusters, corresponding to the three lower maps of Figure 1, some of the regularities found with five clusters are maintained, but the Central Region is more unstable in its configuration.

Comparing the results of the six clustering scenarios, only the hierarchical clustering with five groups produces a similar classification to the *INDEC*'s regionalization (Table 2), coinciding exactly in the case of the Patagonian region, and having differences in a single province in each of the other four regions. According to *INDEC*, *Mendoza* belongs to *Región Cuyo*, along with *San Juan* and *San Luis*. Although, the mentioned clustering technique groups *Mendoza* with Central Provinces such as *Córdoba*, *Santa Fe* and *Buenos Aires*. Also, *Entre Ríos* is clustered in Northeast Region, and not in *Región Pampeana* as in *INDEC*'s regionalization.

As is mentioned before, *Formosa* is clustered with Northwestern provinces, while according to *INDEC* it belongs to *Región NEA*.

Table 2: INDEC's regionalization and clusters resulting from hierarchical clustering in five groups

<i>INDEC</i>	Hierarchical clustering with five groups
<i>Neuquén, Río Negro, Chubut, Santa Cruz and Tierra del Fuego (Región Patagonia)</i>	<i>Neuquén, Río Negro, Chubut, Santa Cruz and Tierra del Fuego</i>
<i>Córdoba, Santa Fe, Entre Ríos, La Pampa and Province of Buenos Aires without Gran Buenos Aires (Región Pampeana)</i>	<i>Córdoba, Santa Fe, Mendoza, La Pampa, Province of Buenos Aires and City of Buenos Aires</i>
<i>Mendoza, San Juan and San Luis (Región Cuyo)</i>	<i>La Rioja, San Juan and San Luis</i>
<i>Jujuy, Salta, Tucumán, Santiago del Estero, Catamarca and La Rioja (Región Noroeste Argentino - NOA)</i>	<i>Jujuy, Salta, Tucumán, Santiago del Estero, Catamarca and Formosa</i>
<i>Chaco, Corrientes, Formosa and Misiones (Región Noreste Argentino - NEA)</i>	<i>Chaco, Corrientes, Entre Ríos and Misiones</i>
<i>City of Buenos Aires and Gran Buenos Aires (Área Metropolitana de Buenos Aires - AMBA)</i>	(included in the second cluster)

Source: own elaboration with data from different official sources and sectoral chambers.

Given the different clustering scenarios commented above, which one offers the “best” statistical results? It is well-known that a good clustering method must minimize within-group distances and maximize between-groups distances. As Table 3 shows, whenever k-means technique is used, these goals seem more feasible. On the contrary, largest distances within-groups and smallest distances between-groups were produced by hierarchical clustering. Among the methods that used k-means, the ones that produced non-partitioned clusters -that is, clusters with adjoining provinces- are preferred and the best performance is achieved by the k-means with six clusters, considering business cycle as an input and fixing contiguity in every group.

Table 3: Descriptive measures for different clustering techniques applied

Technique	Clusters' sizes	Average distance within groups	Average distance between groups
K-means with five clusters	2 - 7	34.84	34.76
K-means with six clusters	2 - 5	32.84	39.74
K-means with five clusters and contiguity as a constraint	2 - 8	35.43	33.31
K-means with six clusters and contiguity as a constraint	2 - 7	31.45	32.24
Hierarchical clustering with five clusters and contiguity as a constraint	3 - 6	43.57	24.59
Hierarchical clustering with six clusters and contiguity as a constraint	2 - 6	40.00	27.59

Source: own elaboration with data from different official sources and sectoral chambers.

The provinces that concentrate agro-industrial production and exports in Argentina -*Córdoba* and *Santa Fe*- seem to have much similarity in their economic cycles. These provinces, in addition to *Entre Ríos*, make up the *Región Centro*, which is a regional integration bloc created from a political decision of their governors. Although, our results suggest that, beyond geographical proximity, the similarities of the economic cycles of *Córdoba* and *Santa Fe* are stronger than those shared, separately, with the Province of *Entre Ríos*. Besides, *Córdoba* and *Santa Fe* are grouped in five of the six scenarios, the exception being only one of the k-means applications, which corresponds to the method with contiguity restrictions and five groups. Secondly, *Entre Ríos* qualifies in the same *Santa Fe* group three times, and only twice with *Córdoba*. Thus, the grouping estimates kept all the *Región Centro* provinces in the same group only twice, when k-means without restriction is applied with five groups, and when the same technique includes contiguity restriction and six groups. As can be seen in Figure 2, the movements in the economic cycle are very similar for *Santa Fe* and *Córdoba*, while *Entre Ríos* moves away from the pattern.

Figure 2: Business Cycle (ILCE) of *Región Centro* provinces from jun-10 to dec-19.

Source: own elaboration with data from different official sources and sectoral chambers.

As a robustness test, we compare the average economic cycles of each cluster that includes the provinces of *Santa Fe* and *Córdoba* to see if they move simultaneously in a similar way. As can be seen in Figure 3, the economic cycles estimated for four clusters that include both provinces have similar inflection points and peaks. Furthermore, it is interesting to note that the one calculated with k-means for six clusters plus contiguity restriction has less variability than the others.

Figure 3: Average Business Cycle (ILCE) of clusters that include *Santa Fe* and *Córdoba* simultaneously, from jun-10 to dec-19

Source: own elaboration with data from different official sources and sectoral chambers.

Given the latter results, the case of *Región Centro* is a useful and illustrative precedent to show that regionalizing the country ignoring economic cycles and only considering political or geographical issues may not be the most appropriate choice when formulating targeted economic policies.

4. CONCLUDING REMARKS

In this paper, we construct coincident composite indices for the twenty-four provinces of Argentina as a measure of their economic cycles applying the SW methodology, a statistically precise procedure which until now has been used exclusively to calculate indices in a few bunches of provinces. Then, by implementing three clustering methods, we group the provinces whose cyclical behaviors are similar among them and different from the rest. In this sense, our work also makes a valuable contribution to the empirical literature on regional economic dynamics, scarce in studies of the state of the economy in Argentina.

The application of different clustering techniques generates different groupings of provinces, which in turn change when the predetermined number of clusters is modified, except in the case of agglomerative hierarchical clustering, in which,

due to the characteristics of the method, the differences between the results only imply dividing one of the five clusters in two.

Beyond the clustering method applied, one of the main results of our work is that grouping provinces according to their economic cycle presents some differences with the official regionalization of the *INDEC*. In this sense, provinces such as *Formosa* -that according to *INDEC* regionalization belongs to *Región NEA*- or *San Luis* -a member of *Región Cuyo*- repeatedly appear grouped together with provinces that belong to other *INDEC*'s regions. Even in some cases, the results show isolated provinces, surrounded by others with noticeable differences in their economic cycles, such as *Jujuy*, *Misiones* and *Entre Ríos*, that are only grouped with neighboring provinces when contiguity is a constraint. Different is the case of the City of *Buenos Aires*, which only borders the province of the same name, which is always grouped together with the latter. On the other hand, applying hierarchical clustering for five clusters, the closest grouping to the statistical regions determined by *INDEC* is obtained, being exactly coincident in the case of the Patagonian region, and having differences of one province at most in each of the other four regions.

Another particularly interesting result of our work is that *Córdoba* and *Santa Fe* -provinces that concentrate the country's agro-industrial production and exports- appear together in almost all the clustering procedures. This was expected, since the coincident composite indicators obtained for both provinces have an almost perfect linear relation, with a correlation coefficient close to one. The same is not the case with the Province of *Entre Ríos*, also a member of the -politically defined- *Región Centro*, in which the correlation of its coincident index with respect to those of *Córdoba* and *Santa Fe* is considerably lower.

Finally, the results as a whole show that, at least in those cases where the purpose is to analyze the economic performance of a region over time, the impact of a national economic policy or the effects of an external shock on the performance of the economic activity, it seems that groupings based on static criteria may not be the most appropriate.

EFFECTS OF INDUSTRIAL AGGLOMERATION ON THE EVOLUTION OF REGIONAL LABOR PRODUCTIVITY (2010-2017)

André Luiz Silva¹, Marcelo Bentes Diniz²

¹Institute of Applied Social Sciences - Federal University of Pará (ICSA/UFPA), Brazil. ²Graduate Program in Economics - Federal University of Pará, Brazil

ABSTRACT

The production stagnation that affected the Brazilian industry since the Crisis in 2008, is due, in part, to the lack of protagonism of the technology-intensive sectors, which were unable to induce the necessary transformations to sustain long-run growth. On the other hand, the strong international demand for energy, agricultural and mineral commodities has stimulated the growth of sectors that are intensive in natural resources. This problem can be examined through regional differences, in which regions based on the production of capital goods and durable goods would be growing less than those specialized in the production of commodities.

Thus, this paper aims to estimate and analyze the regional impacts of changes in industrial labor productivity in Brazil in the period 2010 to 2017. To facilitate the analysis, labor productivity indices from 26 industrial activities were aggregated according to four regional technological standards: (1) Traditional industry, (2) Mineral commodities, (3) Chemicals, energy and fuels, (4) Capital goods and durable goods. This identification is an important initial step for the control of spatial heterogeneity, a typical problem in spatial models of panel data.

In model, productivity gains result from access to value chains in the international market, as well as domestic factors related to local markets, such as externalities formed by density in the labor market, and by multifirm interactions within the local productive structure.

Among the main results, it is worth mentioning.

1. There is a high productivity corridor forming in less dense regions, in the North and Midwest of Brazil. Growth in these areas is driven by exports, reinforced by Marshallian externalities and local intersectoral connections.
2. The production of mineral commodities is strongly concentrated in Pará and Minas Gerais. As it brings together exporters of basic products, its performance does not depend on connections with dynamic sectors, and there is no evidence of externality on the labor market, refuting the labor pooling hypothesis.
3. The growth of the Brazilian industry is driven by Chemicals, energy and fuels. The main refining firms seek to establish themselves in the vicinity of offshore oil and gas fields. The strong international insertion, strengthened the labor market and the connections with Capital goods and durable goods.
4. The critical point of the analysis is the export performance of capital goods and durable goods, whose elasticity coefficient was estimated with a positive and significant sign, but below average. Furthermore, productivity did not react significantly to agglomerations within the standard itself, nor between different arrangements.
5. Finally, econometric tests have shown that the SARFE (Spatial Autoregressive with Fixed Effects) model has better control over space spillovers imputed by the performance Chemicals, energy and fuels. In other technological standards, more efficient control results from the SEMFE (Spatial Error Model with Fixed Effects) model.

CHARLES BOOTH AND GEODEMOGRAPHICS: HIS LONDON LEGACY IN HISTORICAL PERSPECTIVE

[Peter Batey](#)

University of Liverpool, United Kingdom

ABSTRACT

Geodemographics is concerned with the classification of neighbourhoods into categories or clusters based on their socio-economic characteristics. In layperson's terms, it can be said to be 'the analysis of people by where they live'. It uses a qualitative description – a 'pen portrait' – to summarize the distinctive attributes of each category or cluster. It works on the principle that 'birds of a feather flock together': people who live close by (i.e. in the same neighbourhood) are assumed to have more in common than a random group of people.

Urban planners and policy-makers have long had a practical interest in geodemographics, usually directly related to policy formulation, analysis and evaluation. Typically, the aim is to develop a consistent and systematic approach to spatial resource allocation, involving the definition of priority areas to receive favoured treatment. Such areas may be defined in relation to particular policy sectors, such as education, housing, crime or health or, in a more general sense, as in the case of designating 'inner city areas'. The geodemographic classification here serves as a composite measure of need and is usually constructed using census data, where feasible supplemented by other sources of small area data. It generally takes the form of a map displaying the spatial distribution of neighbourhood types, together with a set of pen portraits.

Use of the term 'geodemographics' is comparatively recent, dating from the 1980s, but the basic principles, in one form or another, have a much longer history. The earliest example is generally attributed to philanthropist Charles Booth who prepared pioneering street-by-street surveys and poverty maps in late nineteenth century London. Booth wanted to find and present clear evidence of the extent of poverty in London, in an effort to convince politicians to take urgent action. The full results of his research, including his poverty map, were published under the general heading of the Life and Labour of the People of London.

As the world's first urban social survey, Booth's survey had a big influence in London and elsewhere. Here we present an historical review, starting with Booth's original survey and drawing on three later efforts to produce surveys of London Life and Labour, intended to show how, over the years, London's social and economic spatial structure had changed. We focus particularly on how geodemographic classifications have evolved as an analytical planning method, spurred on by advances in computing power and the increased availability of small area socio-economic data. In a final section, again focusing on London, the paper first examines the recent development of workplace geodemographic classifications, to sit alongside the more familiar residential classifications, opening up the possibility of creating a classification of travel to work flows and, secondly considers the availability of open geodemographics, where users have the opportunity to customise their geodemographic classification according to the application they have in mind.

THE BATEY-MADDEN MODEL: FORTY YEARS AND COUNTING (OR SHOULD THAT BE MULTIPLYING?)

[Peter Batey](#)

University of Liverpool, United Kingdom

ABSTRACT

In 1980, the present author and his late colleague, Moss Madden published their first paper in an international regional science journal^[1], on regional demographic-economic forecasting. The paper identified a serious flaw in modelling the effect that population has on the economy. Up till that point a population forecast would typically be fed into the final demand vector of an input-output model as consumption. This consumption then produces changes in the gross outputs of the industrial sectors represented in the model, which are combined with changes caused by other factors (such as exports) to represent overall changes in the economy. The problem is that in order to obtain a consumption vector from a population, we have to know (or make some assumption about) unemployment, which is a determining factor in the level of consumption.

Batey and Madden developed a solution to this problem by embedding an extended input-output model within an activity-commodity framework. The key innovation here was that instead of having one type of household, in the extended model there were now two types: employed and unemployed. The activity-commodity framework had a number of benefits: it offered flexibility in the choice of variables (demographic and economic), in the units in which these variables were measured, and in its solution method (in the form used here solved by inverting the (square) matrix of coefficients to give a single determinate solution.

The inverse of this new, extended input-output model, known as the Batey-Madden model, provides a rich source of impact multipliers that are more realistic, including so-called Type 4 income, employment and production multipliers, and a range of demographic-economic multipliers that measure the effect of population change upon the regional economy. What is more, the model provides a simultaneous solution to the inconsistency problem, so that by inputting economically active to the model, consistent values of unemployment are calculated.

Activity-commodity frameworks have proved useful in many ways, providing a means to compare the structure of existing models, as well as serving as a useful tool in designing new forms of extended model.

In this paper, several aspects of the Batey-Madden model are explored: how the model came about; the benefits of activity-commodity frameworks in developing extended input-output models; why the household sector matters so much in regional modelling; a survey of how the model has been applied, where and when; new forms of the model capable of measuring the economic impact of changes in particular population cohorts, including an ageing population, an enhanced skill structure, and the impact of changing dependence on in-migrant workers.

The paper aims to show that more than forty years after it was first introduced, the Batey-Madden model continues to offer useful insights about the nature of demographic-economic change.

EXPLOITATION OF EUROPEAN HAKE AT THE PORT OF LARACHE OF MOROCCO

Chaimae El Bouzidi¹, Mounir Hassani Zerrouk², Said Benchoucha³, Mohammed Bakkali¹

¹Faculté des Sciences et Techniques de Tanger, Morocco. ²Multidisciplinary Faculty of Larache, Morocco. ³Centre Régional de L'inrh, Tanger, Morocco

ABSTRACT

The Atlantic region of Morocco is rich in marine resources. Its marine ecosystem is characterized by exceptional biodiversity. For thousands of years, its marine species have been a source of human livelihood, on the one hand, and the engine of the region's national economies, on the other hand. However, population growth and increased demand for marine resources raise concerns about the decline of species and the loss of local marine diversity as a whole. Besides the potential overexploitation of marine resources. For a long time, demersal species occupy a major place in the fresh fishing of the Moroccan North Atlantic region. Among these species, we have chosen, as part of this project of this research; the European hake (*Merluccius merluccius*) which represents the most important of the demersal fish species with high commercial value exploited at the port of Larache from the point of view of landings, which reveals the economic importance attributed to this port. European hake are targeted by both inshore and artisanal fishing, however, European hake catches come mainly from trawl fishing. These last ten years, a drop in landings has been observed reducing the catches by half. This is likely due to the combined effects of fishing and the environment conditions. In this context, appropriate management measures are necessary to be able to rectify the state of this stock. In fact, the *Merluccius merluccius* has been exploited, especially in the northern part of Morocco, by the Moroccan, Spanish and Portuguese fleets until the end of the fishing agreement with the European Union in 1999. After this year, only the Moroccan fleets made up essentially of small longline trawlers with short range and the boats continued to fish this resource. This work took up a diagnosis of the state of exploitation of the stock of this species (*Merluccius merluccius*) by monitoring the state of the resource which is ensured by examining the exploitation indicators which are: catches of hake common in level of the port of Larache, the fishing effort of the trawlers exerted on the stock at the level of the port of Larache and the catch per unit of effort (CPUE) also called index of abundance is used to estimate the level of exploitation of the resource, in order to follow the exploitation status of the hake and show the interest of the species landed at the port of Larache during the period 2005-20014 by the trawl fleet.

IV-SDID: MODEL AND APPLICATION

Sandy Dall'erba¹, Bill Ridley¹, Andre Chagas², Yilan Xu¹

¹UIUC, USA. ²U. Sao Paulo, Brazil

ABSTRACT

The most recent report of the IPCC predicts a continued increase in the frequency and intensity of extreme weather events. Agriculture, the economic sector most sensitive to changes in weather conditions, will be greatly affected by such changes regardless of a country's geographical location. Because of concerns about food security, a growing literature has investigated the capacity of international trade to act as a major adaptation mechanism to climate change. In this paper, we rely on a difference-in-difference setting with endogenous trade interactions (IV-SDID) to assess how the trade of wheat, a crop grown across 89 countries, and its production respond to drought. Based on fine spatial and temporal resolution drought data, our panel data results indicate that a drought promotes export when it takes place in the importing country, but it discourages export when it occurs in the exporting country. As a result, the true marginal effect of a drought on wheat production is based on a combination of its local impact and its impact abroad. Projections based on future weather and drought data by 2038-2070 challenge the estimates of the current climate impact literature by revealing that international trade is capable of mitigating the impact of adverse weather events on yield.

URBANIZATION AND HUMAN DEVELOPMENT INDEX: CROSS COUNTRY EVIDENCE

Sabyasachi Tripathi

Postdoctoral Research Fellow, National Research University Higher School of Economics, 20 Myasnitskaya St., 101000, Moscow, Russia; Assistant Professor of Economics, Adamas University, Kolkata, India.

ABSTRACT

We assess the impact of urbanization on the value of country-level Human Development Index (HDI), using random effect Tobit panel data estimation from 1990 to 2017. We find that total urban populations, percentage of the urban population, and percentage of urban population living in the million-plus agglomerations have a positive effect on the value of HDI. Urban population growth rate and percentage of the population residing in the largest cities negatively affect on the value of HDI. Therefore, developing countries need to promote balanced urbanization with an improvement of urban basic services for improving the HDI rank.

KEYWORDS

Urbanization, human development index, cross country

JEL CLASSIFICATION

1. INTRODUCTION

No country has developed without sustainable urbanization. Urbanization has a potentially positive effect on economic activity, higher provision to employment opportunities, and enhances access to basic services. Cities switch low-productivity agriculture into high productive industry and service sector-led economy. In developing countries, cities are the engine of economic growth. Cities account for about 70 percent of global gross domestic product (World Bank, 2009). Several studies (Williamson, 1965; Martin and Ottaviano, 1999; Fujita and Thisse, 2002; Baldwin and Martin, 2004; Henderson, 2003; Brülhart and Sbergami, 2009; Tripathi, 2013) found that urbanization has a positive link with economic growth.

Urbanization is a typical characteristic of development and a process strongly associated with economic and social development. Hence, urbanization has a direct positive effect on the income of a country if it is managed properly. However, it is important to know, whether urbanization has led to an improvement in a person's capabilities and wellbeing. It is well known to all of us that the Human Development Index (HDI) is far more crucial than a gross domestic product (GDP) in capturing the progress that has been achieved. HDI captures not only GDP but also the other two important aspects such as life expectancy and education. However, higher urbanization does not mean that higher rank in HDI. For instance, the Russian Federation has 74.6 percent urban population but it holds 49th rank in HDI ranking by all countries in the world. In contrast, Switzerland with a similar rate of urbanization ranked in the second position in HDI ranking in the world. Therefore, countries with a higher level of urbanization do not guarantee a higher rank in the HDI ranking. This compels us to assess the impact of urbanization on the HDI.

Very few studies attempted to establish a link between urbanization and HDI. Anisujjaman's (2015) district-level analysis found that there is a positive relationship between the level of urbanization and the HDI in West Bengal, India. Huang and Jiang (2017) conducted a partial correlation analysis between the HDI and urbanization rate whilst controlling for the effects of the GDP for Mongolia. They found that urbanization rates are positively correlated with the HDI even when they controlled the effects of the GDP ($p < 0.001$). Maiti (2017) argued that China was able to create a greater intensity of sustainable development from urbanization than India. The author also found that HDI has a negative and statistically significant effect on the urban population growth rate for China and India. Malik (2014) argued that the relationship between urbanization HDI is not direct and is dependent on how urbanization is managed. Though urbanization offers many opportunities, it can also drive places of deprivation, inequality, and exclusion. For example, though Sub-Saharan Africa has a higher level of urbanization compared to South Asia, but its human development performance is lower than South Asia. Overall, an increasing level of urbanizations is associated with a higher level of HDI.

The study by the United Nations Human Settlements Programme (UN-Habitat, 2016) examined the relationship between the degree of urbanization and HDI by considering countries from Asia, Africa, and Latin America. The analysis suggested that there are huge variations among continents, although the association is positive for all countries except the Philippines and Sri Lanka. Among the African countries, Botswana and Ethiopia have reached a threshold level of the HDI where the index becomes inelastic to the urban population growth. Only in Thailand, among all other Asian countries, HDI reached a threshold level of 0.72 and became inelastic to the degree of urbanization at the level of 44.08 percent of the urban population. Except for Bolivia, all countries in Latin America, the HDI reached a threshold level at some point

from 2005 to 2013. On the other hand, in the rest of the Latin American countries, the HDI became inelastic to the urban population as they have reached a saturation level in terms of the urban population.

However, the HDI not only depends on only urbanization but also many other factors. A cross country study by Shah (2016) found that GDP, life expectancy rate, literacy rate have a positive effect on the HDI, while the Gini index, fertility rate, and Co2 emissions have a negative effect on it. Arisman (2018) found that for the ASEAN countries population and per capita income growth rate affects the HDI, while inflation rates and unemployment rate do not have an impact on it. Bhowmik (2019) argues that there were significant long-run causalities from education expenditure, health expenditure and GDP per capita to the HDI of SAARC but they had no short-run causalities. Khan et al. (2019) find that in the case of Pakistan, information and communication technology and economic growth promote the HDI. On the other hand, urbanization, trade, and foreign direct investment (FDI) discourage it. Sangaji (2016) found that life expectancy at birth and gross domestic per capita had a positive effect, while the variables of inflation and the fertility rate had negative effects on the HDI in several Buddhist countries in the world. Binder and Georgiadis (2011) argued that macroeconomic policies affect development with less delay than suggested by conventional econometric frameworks, yet impact HDI with longer delay and overall less strongly than GDP.

A brief review of the literature indicates that the relationship between urbanization and economic development is well established. Higher income which is generated by a higher level of urbanization does not guarantee that quality of life has improved. Therefore, it is pivotal important to assess the impact of urbanization on the HDI from cross country perspectives. In this context, the present study assesses the impact of urbanization on the HDI. We consider 187 countries for the analysis. We find evidence that urbanization has a positive impact on HDI. We also analyze by considering high, upper-middle, lower-middle, and low-income countries separately. We estimate the random effect of Tobit panel data models for the period of 1990-2017. We start with 1990 as this is the year when Pakistani economist Mahbub ul Haq created HDI. The results are very important for the promotion of urbanization in the world mostly from developing countries perspectives.

The paper adopts the following structure. The next two sections present the conceptual and empirical frameworks, respectively. Regression results are given in section 4. Discussions based on the estimated results are highlighted in section 5. The major conclusions and policy implications are made in section 6.

2. CONCEPTUAL FRAMEWORK

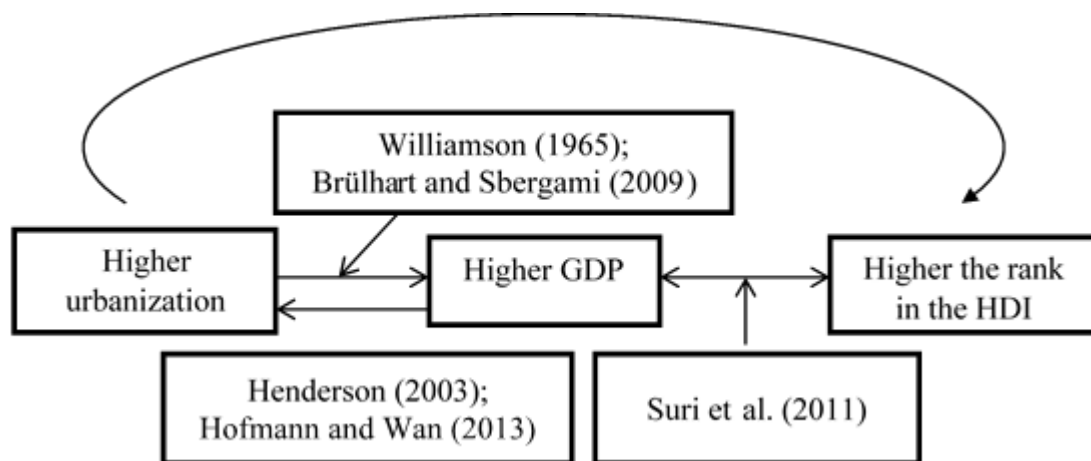

Figure 1: Linking between urbanization and the HDI

Figure 1 presents the main conceptual framework for linking between urbanization and the HDI. Our conceptual framework for linking urbanization and the HDI is based on two famous and prominent hypotheses. First, Williamson (1965) suggested that agglomeration matters for an early stage of development. When transport and communication infrastructure is limited and the reach of the capital market is scared, efficiency can be significantly enhanced by concentrating production in space. However, as availability of infrastructure improves and the market expands, congestion externalities may favor a more dispersed economic geography. This structure is consistent with the model of urbanization and growth with the focus on human capital accumulation by Bertinelli and Black (2004).¹²⁸ Brülhart and Sbergami (2009) found evidence that supports the “Williamson hypothesis”: agglomeration boosts GDP growth only up to a certain level of economic development. Henderson (2003) found that urbanization does not seem to cause growth. Hofmann and Wan (2013) argued that the direction of causality runs from growth to urbanization.

Second, Suri et al. (2011) suggested that there is a two-way relationship between economic growth and human development, building on an earlier work by Ranis et al. (2000). They found that human development is not only a product of economic growth but also important to it. They hypothesized that upgrading human development for higher subsequent economic growth, in turn, leads to improved human development.

Now the question arises if urbanization may affect HDI via GDP, can we measure the causal relationship between urbanization and HDI. The answer is yes. As higher urbanization does not mean higher GDP. For example, in terms of the

¹²⁸ More details explanation can be seen from Brülhart and Sbergami (2009).

percentage of the urban population, Jordan is ranked 13 whereas in terms of per capita GDP its rank is 116 out of 180 countries in the world in 2017. Similar stories can be repeated for Chile and Brazil too. On the other hand, a higher GDP does not guarantee a higher rank in the HDI. For example, as per the per capita GDP Luxembourg is ranked top whereas it is ranked 22 in the HDI ranking out of 180 countries in the world in 2017. In contrast, Sri Lanka is ranked 110 in per capita GDP whereas it stands 76 in the HDI rank with only 18% urbanization for a similar comparison. Therefore, it is not always true that urbanization impacts on the HDI via GDP. It is also to be remembered that HDI depends on life expectancy and education rather than the only GDP. So, higher development as per higher GDP per capita always does not guarantee that the country will rank high in the HDI and the results also differ for different income group countries (Dev, 2015). On the other hand, urbanization provides higher employment opportunities, higher productivity, wages, localized technology spillovers, greater efficiency benefits, and enhances access to basic services. Therefore, urbanization may have a positive effect on the HDI. In fact, Cutler et al. (2005) found that the reductions in mortality and improvements in life expectancy have been induced by technology improvements, which came from improved incomes, helped by improvements in education. Therefore, it is expected that higher urbanization not only improves income but also the HDI. Based on these theoretical arguments, the present study quantifies the associations between urbanization and quality of life which is measured by the human development index.

3. EMPIRICAL FRAMEWORK

The Tobit model or censored regression model is used to estimate the linear relationship between the HDI and urbanization as we find the evidence of the right-censoring in the dependent variable of HDI. Histogram in the Appendix of Figures A1 confirms that HDI is right-censoring. A Tobit model with random effects is used as it is capable of accounting both serial correlations and censoring effects. The random effect Tobit model is efficient to account for correlations across observations in addition to unobserved heterogeneity.

The Tobit model for panel data is defined as follows

$$y_{it}^* = x_{it}\beta + \epsilon_{it} \tag{1}$$

$$y_{it} = \begin{cases} 0 & \text{if } y_{it}^* \leq 0 \\ 1 & \text{if } y_{it}^* \geq 1 \\ y_{it}^* & \text{if } 0 < y_{it}^* < 1 \end{cases} \tag{2}$$

Where y_{it}^* is an unobservable latent variable, ϵ_{it} is normally, identically, and independently distributed with zero mean and variance σ_u^2 . x_{it} is a vector of explanatory variables and β , a vector of unknown coefficients.

Following, Sangaji (2016), who investigated relevant determinants of HDI in several counties, we also consider random effect model for the estimation. The rationale behind using random effect model is that the variation across countries is assumed to be random and uncorrelated with the independent variables included in the model.

The following equation is specified to assess the impact of urbanization on HDI.

$$HDI = \nu_i + \beta_1 urbanization_{it} + \beta_2 Co2_{it} + \beta_3 FDI_{it} + \beta_4 fertility\ rate_{it} + \beta_5 gdp\ growth\ rate_{it} + \beta_6 Gini_{it} + \beta_7 inflation\ rate_{it} + \epsilon_{it} \tag{3}$$

where i and t represent country and time, respectively, while, ν_i is the random effects term which follows normal distribution with mean 0 and variance σ_u^2 , and ϵ_{it} is the disturbance term which follows normal distribution with mean 0 and variance σ_u^2 . Our data set contains up to 187 countries, over the period 1990-2017. The HDI data is sourced from the United Nations Development Programme (UNDP) and other data are from World Development Indicators (WDI) provided by the World Bank. Appendix table 1 provides the definitions of variables used for the regression analysis.

Based on Henderson (2003), Brühlhart and Sbergami (2009) and Tripathi (2013), we measure urbanization in five different ways: percentage of urban population, total urban population, annual urban population growth, population in urban agglomerations of more than 1 million to total population, and population in the largest city to urban population. Five different measures of urbanization have very important implications for capturing various patterns of urbanization in different countries. Some countries/cities are over urbanized and some of them are under urbanized. Some cities are overcrowded and some of them are less. Therefore, these five measurements of urbanization are very crucial to capture the urbanization dynamics. Overall, a positive effect of urbanization on the HDI is expected, as urbanization is associated with higher employment, GDP, availability of infrastructure, provision of basic services, and lower poverty (Li et al., 2012; Khan et al., 2018). Thus, urbanization contributes to socio-economic development by promoting the state economy and increase the value of the HDI [Khan et al., 2019].

On the other hand, based on review of literature on determinant of the HDI (Arisman, 2018; Khan et al. 2019; Sangaji, 2016; Bhowmik, 2019), we expect that GDP growth rate has a positive effect on the HDI.¹²⁹ On the other hand, higher CO2 emissions, fertility rates, and the Gini index have a negative effect on the HDI. The higher rate of inflation reduces the purchasing power of money, makes investment less desirable, so it may reduce GDP and the HDI. However, the Phillips curve shows that high inflation is consistent with low rates of unemployment. This implies that inflations have a positive effect on economic growth. Therefore, inflations may have a positive or negative effect on the HDI. The FDI stimulates the labor market and economic growth, a high tax incentive environment. Therefore, a positive impact of FDI on the HDI is expected [Khan et al., 2019].

129 As per-capita GDP, life expectancy at birth, and adult literacy rate are considered to construct HDI, we did not consider these variables in the regression analysis.

4. REGRESSION RESULTS

Before we go to regression results, first we present the descriptive statistics of the variables. Table 1 presents the summary statistics of each variable used in the regression models. The coefficient of variation (CV) measures the dispersions of data points in a data series. HDI, Gini coefficients, fertility rate, percentage of the urban population, and population in the largest city have lower values of a CV, which indicates that little differences in their means, implying a more symmetrical distribution. However, it is not the case for inflation rates, total urban population, foreign direct investment, and GDP growth rate. Table 1 also presents the variance inflation factor (VIF) for the explanatory variables based on a simple OLS model.

Table 1: Descriptive statistics of panel data variables

Variable	No. of observation	Mean	Standard deviation	Minimum	Maximum	CV	VIF
Human development index (HDI)	4725	0.655	0.166	0.2	0.95	25.4	-
Percentage of urbanization (PU)	5230	53.86	23.39	5.42	100	43.43	2.96
Total urban population (TUP)	5227	1.66e+07	5.31e+07	4873	8.00e+08	319.88	1.52
Urban population growth (UPG)	5226	2.24	2.06	-7.18	17.76	92.31	2.57
Population in urban agglomerations of more than 1 million (PUAM)	3301	23.831	16.833	2.105	100	70.63	2.83
Population in the largest city (PLC)	4107	33.059	17.342	2.867	100	52.46	2.40
CO ₂ emissions (CO ₂)	4347	0.281	0.243	0.005	2.12	86.54	1.35
Foreign direct investment (FDI)	4848	6.50	39.81	-58.32	1282.63	612.05	1.10
Fertility rate (FR)	5096	3.24	1.68	0.901	8.606	51.83	2.60
GDP growth rate (GDPG)	5004	2.11	6.33	-64.99	140.37	300.46	1.14

Inflation rate (IR)	5004	38.41	496.61	-36.56	26765.9	1293.01	1.10

Source: Author.

Table 2 presents the raw correlation coefficients. The estimated values of correlation coefficients quantify the direction and strength of the linear association between the variables. The results show that the HDI has a positive association with the percentage of the urban population, the population in million-plus urban agglomerations, CO₂, and foreign direct investment. In contrast, the values of the HDI are negatively correlated with urban population growth rate, fertility rate, populations in the largest city, Gini coefficients, and GDP growth rate.

Table 2: Correlation coefficient of the variables used in regression model

	HDI	PU	TUP	UPG	PUAM	PLC	CO ₂	FDI	FR	GDPG	GINI	IR
HDI	1.00											
PU	0.73	1.00

Note: See Table 1 for variable definitions. The correlation coefficients are based on 945 observations.

Source: Author.

Except for fertility rates, there is no strong correlation between HDI and other explanatory variables. This lessens the probability that regression results are inconsistent and biased. Correlation coefficients together with variance inflation factors (VIF) (Table 1, the last column) recommend that multicollinearity is not present in regression analysis.

Table 3 presents the estimated random effect Tobit regression models of equation 3. The sigmas signify the variances of the two error terms μ_i and ϵ_{it} . Their relationship is explained by the variable rho, which informs us about the relevance of the panel data nature. When rho is zero, the panel-level variance component is unimportant, and the panel estimator is not different from the pooled estimator. As can be seen from Table 3, the panel data structure of the model has to be taken into account. The significant values of Wald chi² specify that for regression models 1-6 fit well; all coefficients in the model are different from zero. The higher values of log-likelihood for regression models 1-6, our regression estimations are good. The statistically significant values of likelihood-ratio tests for all the regression models reject the null hypothesis that there are no panel-levels effects.

The size of our country sample for estimations varies between 105 and 153, depending on the explanatory variables that are included in the regressions. Regression model 1 presents the full model, which includes all variables identified by the literature review. Regression models 2-6 report results for a parsimonious model, excluding controls that are not found

to be statistically significant in our data and to estimate the impact of particular independent variables on the dependent variable. In other words, regression models 2-6 are designed to capture the effect of each urbanization variables on the HDI separately.

The regression model 6 shows that FDI has a positive and statistically significant effect (at 1 % level) on the HDI. The coefficient 0.001 indicates that for a unit increase in FDI, there is a 0.001 point increase in the predicted value of HDI. On the other hand, CO2 emissions, fertility rate, GDP growth rate, Gini index, and inflation rate have a negative and statistically significant effect on the HDI. The sign of the estimated coefficients is matched with the expected sign. The impact of the Gini index, fertility rate, and Co2 emissions on the HDI support the findings of Shah (2016) and Arisman (2018). In the line of Khan et al. (2019), we also get a positive impact of FDI on the HDI. However, the negative impact of economic growth on the HDI does not support the findings of Khan et al. (2019). It is most of the developing countries in the world are having a higher growth rate but the rank in the HDI is very low, so only economic growth cannot increase the HDI value. For example, India has experienced a 7.08% GDP growth rate between 2000 and 2016 but India's rank in the HDI is 130. So if growth does not guarantee education and health, it cannot increase alone the HDI rank. Inflation rates have a negative and statistically significant effect on the HDI. This shows that higher inflation is bad for economic growth and it reduces the HDI values.

Source: Estimated using equation 3

Turning now to our main focus of interest, we observe that the percentage of urbanization and urban population have a positive and statistically significant effect on the HDI, while higher urban population growth rate has a mixed effect on it. Populations in million-plus agglomerations have a positive effect on HDI whereas the population in the largest city has a negative effect on the value of HDI.

Regression model 1 shows that a 1 unit increase in the percentage of urban population leads to a 0.004 point increase in the predicted values of HDI. Moreover, a 1 unit increase in total urban population associated with a 0.0001 point increase in the predicted value of HDI. To avoid collinearity of the urbanization variables, we obtain separate regression results for 5 independent variables used for measuring urbanization regression models 2 to 6. Regression models 2, 3, and 5 are consistent with results are obtained in the regression model1. Regression model 4 shows that the urban population growth rate has a negative effect on the HDI whereas regression model 1 shows that the urban population growth rate has a positive effect on the HDI. Therefore, the urban population growth rate has a mixed effect on the HDI. Regression model 5 indicates that the percentage of urban population living in million-plus agglomerations has a positive effect on the HDI. The coefficient 0.009 specifies that for a unit increase in the percentage of urban population living in million-plus agglomerations, there is a 0.009 point increase in the predicted value of the HDI. In contrast, regression model 6

shows that the percentage of urban population living in the largest city has a negative and statistically significant effect on the HDI. It implies that though bigger city sizes have a positive impact on the HDI there is a limit.

Table 4: Marginal effects of the overall expected value of estimated random effects Tobit coefficients

VARIABLES	Model 1	Model 2	Model 3	Model 4	Model 5	Model 6
Percentage of urbanization	0.348	0.408

Source: Author.

Table 4 presents the marginal effects of the overall expected values of the estimated random effect Tobit coefficients. In regression model 1 shows that a one-unit increase in the percentage of urbanization (or total urban population) is associated with an increase of 0.348 (0.004) units on the HDI. Most importantly, regression model 5 shows that a one-unit escalation of the percentage of urban population living in million-plus agglomerations contributes to a 0.290% higher probability of an increase of the HDI. Among the other important independent variables (except urbanization variables) we find that FDI has a positive effect on the HDI. On the other hand, a higher value of the Gini index, CO₂ emissions, fertility rate, GDP growth rate, reduces the values of HDI. Regression model 1 shows that a one-unit increase of CO₂ emissions (or fertility rate) is associated with a decrease of 0.049 (or 0.164) units on the HDI.

However, regression models 1-6 consider all countries together. As different countries are in a different phase of urbanization, we run the regression models separately for high, upper-middle, lower-middle, and low-income countries as well. We only consider urbanization variables as lower data size of the other explanatory variables do not show robust results.

Table 5 presents the estimated random effect Tobit estimation results where we consider only all the variables of urbanization together. The results are almost similar to the results presented in regression results 1-6 with little variations. The percentage of urban population has a positive and statistically significant effect on HDI for all countries irrespective of income differences. The total urban population has a positive effect on HDI for the regression results are obtained for all countries, high-income countries, lower-middle-income countries, and low-income countries. The effect in upper-middle-income countries is not statistically significant. The urban population growth rate does not have any effect on the HDI for all country-level, high-income countries, and lower-middle-income country's estimation. In contrast, it has a positive (or negative) effect on HDI for upper-middle-income countries (or low-income countries). The percentage of the population living in urban agglomerations of more than 1 million people has a positive effect on HDI except for high and lower-middle-income countries. The percentage of the urban population living in the largest city has

a positive effect on HDI in lower-middle-income countries while it has a negative effect on the results obtained for all countries level and low-income countries. However, it does not have any impact on HDI for high and upper middle-income countries.

4.1 Robustness check

As per theoretical explanations, the relationship between urbanization and the HDI (as GDP is already part of HDI) is the question of reverse causality. Other macroeconomic variables such as CO2 emissions are assumed to be endogenous, because causality may run in both directions—from CO2 emissions to HDI and vice versa. Therefore, regressors may be correlated with the error term. The country-specific effect representing time-invariant determinants of HDI may be correlated with the explanatory variables. To solve this problem we estimate the “system GMM” approach initially proposed by Arellano and Bover (1995) for dynamic panel estimation. The “system GMM” model also takes care of the autocorrelation problem which arises from the use of lagged dependent variables. In summary, the system GMM model better controls for the three sources of endogeneity, namely unobserved heterogeneity, simultaneity, and dynamic endogeneity.

Table 6 presents the estimated results. The panel sample comprises between 105 and 157 countries, depending on which regressors are included. We limit the number of instruments by including a maximum of two lags, to avoid rejection of the null for the validity of overidentifying restrictions. Regression model 12 presents results for the full model, including all regressors we consider. Other regression models report comparable estimates with a parsimonious set of controls. We use parsimonious models as they are simple models with great explanatory predictive power with the consideration of just the right amount of predictors needed to explain the best regression models. Regression models 12-15 consider the number of instruments less than the number of groups/countries. This avoids the problem of ‘too many instruments’ associated with the estimation. All tests for second-order autocorrelation and Hansen J-test are satisfactory. The null hypothesis of AR2 diagnostic tests for all regression models cannot be rejected at a 5 % or less statistically significant level. Therefore, our results have no caution of potential overfitting bias.

Regression results in Table 6 show that the percentage of urbanization, total urban population, urban population growth rate, the population in million-plus urban agglomerations, and FDI all have a positive statistically significant effect on the HDI. On the other hand, the population in the largest city of a country, CO2 emission, fertility rate, GDP growth rates, and Gini index have a statistically significant negative effect on the HDI. The results are consistent with the previous results which are obtained by using the Tobit model in Table 3. However, inflation rates do not have any statistically significant effect on the HDI in Table 6.

5. DISCUSSION ON IMPACT OF URBANIZATION ON THE HDI

The estimated results show that, overall, the percentage of the urban population, total urban population, and percentage of urban population living in million-plus urban agglomerations have a positive effect on HDI. Moreover, it is suggested that urbanization is beneficial for improving the social and economic development of a country. Now the question arises on how urbanization improves HDI. The basic idea is that urbanization pulls resources from the predominantly agricultural sector to more advanced industrial and service sectors. This is part of economic development (Lewis, 1954). Therefore, the process of economic development not only accompanies economic structural change, but also contributes to a higher urbanization rate. It works with two forces: push from the country-side and pull from the city (Lewis, 1954; Fei and Ranis, 1964). The city offers greater specialization of labor (Smith, 1976), which leads to greater efficiency benefits (Marshall, 1890; Duranton, 2008). It is sourced from urban increasing returns (Krugman, 1991), which include sharing (e.g. local infrastructure), matching (e.g. employers and employees), and learning (e.g. new technologies) (Duranton & Puga, 2004). It also spurred the civic leadership to upgrade urban infrastructure and improve the spatial arrangement of towns and cities (Briggs, 1968; Hunt, 2004). Greater efficiency and rising prosperity are the outcomes of what is, on the whole, a virtuous circle [Turok, 2014]. Therefore, urbanization not only improves the income of a country but also the quality of life of its residents.

The results also show that a higher urban population growth rate and a higher percentage of the population residing in the largest city of a country have a negative effect on HDI. This indicates that when a city becomes very large or suffers from over-concentration of population, it challenges the provision of basic public services to the urban dwellers and increases pollution which impacts badly on human health mostly in developing countries. This clearly specifies that over-concentration or urbanization through the largest city harms the quality of life and reduces the value of HDI.

6. CONCLUSIONS AND POLICY IMPLICATIONS

The present paper links the urbanization with HDI. We consider 187 countries from the period of 1990-2017. The random effect Tobit panel data models are estimated for the analysis. Urbanization is measured by the total urban population, percentage of the urban population, urban population growth rate, percentage of the population living in million-plus urban agglomerations, and percentage of the population living in the largest city. In addition to urbanization, we also add other important variables such as CO₂ emissions, FDI, fertility rate, GDP growth rate, level of inequality (Gini index), and inflation rate to investigate the determinants of the HDI.

As different countries are experiencing different stages of urbanization, we also separate our analysis by high-income countries, upper-middle-income countries, lower-middle-income countries, and low-income countries. HDI data is collected from the UNDP and urbanization data is obtained from World Development Indicators provided by the World Bank.

All country-level analysis suggests that the percentage of urbanization, total urban population, and percentage of the population living in million-plus agglomerations have a positive and statistically significant effect on HDI when we run the regression along with controlling all other important variables. On the other hand, the percentage of urban population living in the largest city in a country has a negative effect on HDI. The urban population growth rate has a mixed effect on the HDI. In addition to that FDI has a positive effect on HDI, while higher CO₂ emissions, fertility rate, GDP growth rate, inequality, and inflation rate have a negative effect on it.

The results also are speread by country-level income differences. The percentage of urbanization has a positive effect on the HDI across countries categories by income differences. The impact of the total urban population on the HDI is also positive except for upper-middle-income countries. The urban population growth rate does not have any effect on all country level, high-income countries, and lower-middle-income countries estimations. The percentage of urban population living in million-plus agglomerations does not have any impact on the HDI for high income and lower-middle-income countries. The population living in the largest city of a country does not have any impact on the HDI for high-income countries and upper-middle-income countries.

Based on the results, we suggest that urbanization has a strong positive effect on HDI. The increase in the percentage of urban population is the most important indicator of urbanization to increase the HDI of a country. We need to promote balanced (lower population differences among the cities and towns) urbanization. This indicates that though million-plus cities advantageous for higher HDI, it is not the largest city of a country that is mostly over urbanized and overpopulated. We need to have sustainable urban development which includes the adequate provision of basic services such as urban roads, water, electricity, medical facilities, etc. Most importantly, developing countries like India are experiencing unplanned urbanization with insufficient provision of basic services. Therefore, to reap the maximum benefits of urbanization, we need to have sustainable and balanced (the lower difference in population size among the cities) urbanization, mostly, in developing countries. However, the impact of the HDI on urbanization is a topic for future research.

Table 2: Variable definitions are given by the World Development Indicators

Variable	Definition	Source
CO2 emissions (kg per 2011 PPP \$ of GDP)	Carbon dioxide emissions are those stemming from the burning of fossil fuels and the manufacture of cement. They include carbon dioxide produced during consumption of solid, liquid, and gas fuels and gas flaring.	Carbon Dioxide Information Analysis Center, Environmental Sciences Division, Oak Ridge National Laboratory, Tennessee, United States.
Foreign direct investment, net inflows (% of GDP)	Foreign direct investment are the net inflows of investment to acquire a lasting management interest (10 percent or more of voting stock) in an enterprise operating in an economy other than that of the investor. It is the sum of equity capital, reinvestment of earnings, other long-term capital, and short-term capital as shown in the balance of payments. This series shows net inflows (new investment inflows less disinvestment) in the reporting economy from foreign investors, and is divided by GDP.	International Monetary Fund, International Financial Statistics and Balance of Payments databases, World Bank, International Debt Statistics, and World Bank and OECD GDP estimates.
Fertility rate, total (births per woman)	Total fertility rate represents the number of children that would be born to a woman if she were to live to the end of her childbearing years and bear children in accordance with age-specific fertility rates of the specified year.	(1) United Nations Population Division. World Population Prospects: 2019 Revision. (2) Census reports and other statistical publications from national statistical offices, (3) Eurostat: Demographic Statistics, (4) United Nations Statistical Division. Population and Vital Statistics Reprot (various years), (5) U.S. Census Bureau: International Database, and (6) Secretariat of the Pacific Community: Statistics and Demography Programme.
GDP per capita growth (annual %)	Annual percentage growth rate of GDP per capita based on constant local currency. Aggregates are based on constant 2010 U.S. dollars. GDP per capita is gross domestic product divided by midyear population. GDP at purchaser's prices is the sum of gross value added by all resident producers in the economy plus any product taxes and minus any subsidies not included in the value of the products. It is calculated without making deductions for depreciation of fabricated assets or for depletion and degradation of natural resources.	World Bank national accounts data, and OECD National Accounts data files.
GINI index (World Bank estimate)	Gini index measures the extent to which the distribution of income (or, in some cases, consumption expenditure) among individuals or households within an economy deviates from a perfectly equal distribution. A Lorenz curve plots the cumulative percentages of total income received against the cumulative number of recipients, starting with the poorest individual or household. The Gini index measures the area between the Lorenz curve and a hypothetical line of absolute equality, expressed as a percentage of the maximum area under the line. Thus a Gini	World Bank, Development Research Group. Data are based on primary household survey data obtained from government statistical agencies and World Bank country departments. For more information and methodology, please see PovcalNet (http://iresearch.worldbank.org/PovcalNet/index.htm).

	index of 0 represents perfect equality, while an index of 100 implies perfect inequality.	
Inflation, GDP deflator (annual %)	Inflation as measured by the annual growth rate of the GDP implicit deflator shows the rate of price change in the economy as a whole. The GDP implicit deflator is the ratio of GDP in current local currency to GDP in constant local currency.	World Bank national accounts data, and OECD National Accounts data files.
Urban population (% of total population)	Urban population refers to people living in urban areas as defined by national statistical offices. The data are collected and smoothed by United Nations Population Division.	United Nations Population Division. World Urbanization Prospects: 2018 Revision.
Urban population	Urban population refers to people living in urban areas as defined by national statistical offices. It is calculated using World Bank population estimates and urban ratios from the United Nations World Urbanization Prospects. Aggregation of urban and rural population may not add up to total population because of different country coverages.	World Bank staff estimates based on the United Nations Population Division's World Urbanization Prospects: 2018 Revision.
Urban population growth (annual %)	Urban population refers to people living in urban areas as defined by national statistical offices. It is calculated using World Bank population estimates and urban ratios from the United Nations World Urbanization Prospects.	World Bank staff estimates based on the United Nations Population Division's World Urbanization Prospects: 2018 Revision.
Population in urban agglomerations of more than 1 million (% of total population)	Population in urban agglomerations of more than one million is the percentage of a country's population living in metropolitan areas that in 2018 had a population of more than one million people.	United Nations, World Urbanization Prospects.
Population in the largest city (% of urban population)	Population in largest city is the percentage of a country's urban population living in that country's largest metropolitan area.	United Nations, World Urbanization Prospects.

DETERMINANTS OF WELL-BEING IN THE TURKISH PROVINCES**Zeynep Elburz¹, Karima Kourtit², Peter Nijkamp²**¹IZTECH, Turkey. ²Open University, Heerlen, Netherlands**ABSTRACT**

In recent years, there has been a growing debate on insufficient perceptions of living conditions which relies only macro-economic dimensions. Turkish Statistical Institute conducted a study to measure and compare well-being of individuals and households on the province level and introduced the well-being index for provinces in 2015. Using 11 dimension and 41 indicators of objective and subjective criteria, the study aimed to monitor the well-being of people with all aspects. However, the study iterated only on national level and failed to measure, compare and monitor the wellbeing on province level. This study presents a new approach to well-being literature by creating a new well-being variable using age and family size related variables which have inverse U shape relations. We collect data from 81 provinces between 2012 and 2018 to understand determinants of well-being in Turkish provinces. We use income (GDP per capita), job (female employment), education (female university graduates), health (physician), access to services (road length), agglomeration (population density), governance (NGO), safety (homicide), feel of belonging (migration) indicators with panel data models. According to the results; female employment, female university graduates and share of population who lives in the same province they were born have positively effecting well-being. On the other hand, population density and number of physicians have negative effects. Interestingly, GDP per capita does not have any significant effect on well-being. It is also possible to conclude that time affect well-being positively.

SPATIAL CONCENTRATION OF ECONOMIC ACTIVITIES AND REGIONAL EXPORT VARIETY

Ticiana Grecco Zanon Moura¹, Mauro Ferrante²

¹Universidade Estadual de Santa Cruz, Brazil. ²University of Palermo, Italy

ABSTRACT

This research aims to explore the influence of agglomeration forces on the product variety destined to international markets. For this purpose, the Brazil case study between 2002-2017 has been carried out. The hypothesis is that the Brazilian states (similar to NUTS2) that have the highest economic concentrations are those that export the greatest variety. The product variety that a state sells abroad is calculated by a Theil index prevention of the export's amount accounted by the Harmonized System (HS4) codes for international trade (Ministry of Industry Foreign Trade and Services, 2020). The independent variables are calculated to compound a spatial concentration index proposed by Ferrante et al. (2020) that measures the concentration of the event taking account its spatial distribution. To construct those concentration index for each state and year, the number of firms with more than 100 employees, and number of people with high education come from the Ministry of Labor (2020) and the information of Gross Value Added (GVA) of industry, services, and public administration, as well as data on population and GDP per capita are made available from the Brazilian Institute of Geography and Statistics (2020).

The dependent variable is modelled as a function of one-year lag independent variables through a generalized linear model (GLM), and observations are pooled across years and states. From the methodological perspective, this paper applies a novel index of spatial concentration able to take into account the geographical structure of the phenomenon under analysis. From the applied perspective, a deeper understanding of the underlying dynamic of trade flow generation, and of the impact of regions' dissimilarities on their capability of attracting consumers and firms, is fundamental in order to better orient regional development policies.

ESTIMATING THE LOCAL GOVERNMENT SPENDING MULTIPLIER FOR BRAZILIAN STATES: AN INPUT-OUTPUT AND A GENERAL EQUILIBRIUM ANALYSIS

Raphael Fernandes, Eduardo Haddad

University of Sao Paulo (USP), Brazil

ABSTRACT

The differences in growth rates and economic activity levels between regions within a country motivated the search for strategies to reduce regional disparities. At the initial stages of development, economic activity concentration positively affects national growth rates while raising regional inequality. However, after reaching a certain regional concentration level, increases in the latter would dampen national growth. The fiscal policy aimed at lagging regions configures as a regional policy for their development. Nonetheless, there is no consensus in the economic literature about fiscal policy's role, and there are still limited studies quantifying the multiplier effects at the local level, especially in developing countries. The global financial crisis of the late 2000s revitalized this debate, given the monetary policy's inability to counter the falling of economic levels. From a regional perspective, the heterogeneity in the transmission of a fiscal impulse causes varied effects between regions within a country due to differentials in productive structure and interdependence. In this context, the objective of this paper is to analyze the impacts of Federal Government spending on Brazilian regional GDP and economic growth. Thus, we seek to answer which policies would generate the highest multiplier effect on output. This objective will be achieved through a computable general equilibrium analysis (CGE) for the Brazilian economy, which will measure the impacts from both the aggregate and the regional perspectives. In this sense, this paper offers another perspective on the multiplier effect: at first, by calculating for each state its Federal Government Spending Multiplier; secondly, it decomposes the total multiplier in its intraregional effect and the interregional effect. As a preview of results, we found that the multiplier is higher in more impoverished areas and sensitive to trade openness. These states are more dependent on government spending in the composition of their and GRP and possess a less diversified productive structure. The pattern of the government spending multiplier is similar in all of our simulations, which reinforces our conclusions. Also, in the Input-Output modeling, the multiplier effect estimate is much higher for all regions with the absence of the price mechanism through the substitution channel. When evaluating how the government spending multiplier reacts to variations in substitution elasticity of imports, our results were consistent with other estimates in the literature: increases in import penetration (both from other regions of the country and the RoW, provokes the diminishing of the local multiplier and vice-versa. Nonetheless, when analyzing the sensitivity to the interregional import elasticity, our results suggest possible gainers with the interregional trade (mainly South and Center-West regions). Lastly, it provides evidence that there is no trade-off between mitigating regional disparities and fostering national growth. Our results may vary depending on how the government spending is funded, which we intend to incorporate in later analysis. In this sense, we contribute to the literature on the government spending multiplier at local levels, for a large emerging Market, providing estimates of the multiplier effect for Brazilian states, as the literature quantifying this impact is still limited, especially for underdeveloped economies.

THE BRUMADINHO DAM RUPTURE DISASTER IN MINAS GERAIS (BRAZIL) AND THE PRODUCTIVITY: REGIONAL ECONOMIC IMPACTS USING A COMPUTABLE GENERAL EQUILIBRIUM APPROACH

[Cláudio Eurico Seibert Fernandes da Silva](#)¹, [Victor Eduardo de Mello Valério](#)², [Rayan Wolf](#)³,

ABSTRACT

On 25 January 2019, the Brazilian village of Brumadinho, in the mining-heavy state of Minas Gerais, was taken by the tailings of Córrego do Feijão's dam. This dam rupture is arguably one of the worst human and environmental disasters, leaving over 250 people dead, and spreading a large number of ore tailing into Paraopeba River and the surrounding area. The toxic waste of the mine dispersed towards the villages along the Doce River basin and reached the Atlantic coast. As a typical case of negative externalities, this type of disaster leaves behind large-scale environmental and economic damages at local but also regional levels. The share of the extractive sector in the Brazilian GDP is 2.5%, but Minas Gerais alone is responsible for 23.6% of that production. Characterised by an intensive use of capital and natural resources, the mining production is particularly oriented for international markets. From the economic point of view, public policies are urged in order to help with the regional recovery. This raises the question of what local and regional economic effects generated by the Brumadinho dam collapse are, but also how direct and indirect impacts are distributed among population arrangements. The objective of this study is to evaluate how pollution from this natural disaster affects the economy, whether driven by soil or water contamination, as it increases health problems and reduces the quality of inputs for several economic sectors. Consequently, there are changes in labour productivity, which translate into economic impacts. In this sense, the paper is intended to translate environmental effects into economic phenomenon in an attempt to identify where interdependencies lies on and provide insights to help formulate impact mitigation policy for the long-term. The occurrence of interdependencies in the absorption of negative impacts by the surrounding areas is likely. To that end, we apply a stylized computable general equilibrium (CGE) model for Brazil based on the comparative-static B-Maria model. B-Maria is a Brazilian Regional and Interregional Analysis model developed at NEREUS in the University of São Paulo. It contains detailed information of interregional monetary flows, whereby the origin and destiny of imports and exports of each state are identified. The version of this paper has been adapted for the case of Minas Gerais, the BMaria-MG model. BMaria-MG divides Brazil into four distinct regions: the municipality of Belo Horizonte, the rest of the populational arrangement of Belo Horizonte, the rest of Minas Gerais and the rest of Brazil. This interregional system is calibrated with data of 2015 and 22 productive sectors are specified in each region. The model is run using GEMPACK. Preliminary results indicate a small impact on GDP in all regions. This is due to the low significance of labour productivity in the sectors. Among all regions, the most affected is the rest of Minas Gerais. The largest negative impact is observed for the consumption of households. Despite the small effects at aggregate level, observed impacts are substantial and sector-specific in all regions.

LONG-TERM EFFECTS OF CONDITIONAL CASH TRANSFERS ON CHILDREN: THE BRAZILIAN CASE

[Gabriel Lyrio de Oliveira](#)¹, [André Luís Squarize Chagas](#)²

¹NEREUS - University of São Paulo, Brazil. ²University of São Paulo, Brazil

ABSTRACT

In this paper, we present some long-term effects of the largest Conditional Cash Transfers program in the world, and one of the pioneers, the Bolsa Familia Program (BFP). We focus on the effects on Schooling attained in early adulthood and Labor Market outcomes of our interest cohorts, i.e., individuals that were born in 1996, 1997 and 1998, and were more or less exposed to the BFP during their childhood.

The estimates were enabled by linking identified data from the Single Registry (Ministry of Social Development) from 2012 to 2017, with the Formal Labor Market (Ministry of Labor) from 2002 to 2017, and the BFP Payment Records (Ministry of Social Development) from 2004 to 2017.

The first source allows us to observe the family characteristics and composition in 2012, while our interest cohorts were still teenagers. The second source allows us to observe the Formal Labor Market performance of the parents of these individuals during their childhood, and, of course, the participation and earnings of our interest cohorts during their early adulthood. The third source fills the lack of SR data concerning the program's initial years and enables building the measures of program exposure during the individuals' childhood, since 2004.

In this Natural Experiment, the main identification strategy relies on a specific selection of the sample, considering only individuals from families registered in the SR during its strongest expansion period, between 2004 and 2006. Moreover, we were able to include a rich set of control variables, like the parents' Labor Market performance and schooling attained. We also rely on the program implementation rules, which states that the release of BFP resources for registered families is automatized and based on municipality quotas estimated by the government. In an alternative identification strategy, we consider an instrumental variable, an observed proxy for the municipality effort to register vulnerable families.

These strategies help to solve the potential selection bias of families to the SR, and consequently to the treatment. Nonetheless, since the program selects the most vulnerable families, the threats to the identification suggest that the estimated effects are lower bounds.

Our main results show positive long-term effects on Schooling, and on the Formal Labor Market participation, while mixed results are observed for Earnings. Heterogeneity tests suggest that the effects are stronger for boys, for smaller cities, and for families with never formally employed parents.

THE CONTRIBUTION OF ECONOMIC ACTIVITY AND ENERGY CONSUMPTION TO CO₂ EMISSIONS

Fernando Barreiro-Pereira¹, Touria Abdelkader-Benmesaud Conde²

¹National University for Distance Education (UNED)-Faculty of Economics and Business Administration, 11 Paseo Senda del Rey, 28040-Madrid, Spain, fbarreiro@cee.uned.es; ²National University for Distance Education (UNED)-Engineering High School, 12 Juan del Rosal, 28040-Madrid, Spain, tabdelkader@madrid.uned.es

ABSTRACT

The pollutants that contribute most to environmental degradation are carbon dioxide emissions and PM10 particulate matter. Greenhouse gas emissions have doubled between 1971 and 2015, with CO₂ representing more than two-thirds of greenhouse gas emissions. The objective of this research is to analyze to what extent excess CO₂ emissions are directly associated with energy consumption or are due to imperfections in the production processes of goods and services. To carry out this analysis, a microeconomic specification has been developed and applied in the period 1995-2015 on 6 countries of the European Union plus 14 countries of the rest of the world, whose total population is equivalent to 61 percent of the world population. The application has been carried out using econometric techniques including panel data and the results indicate that imperfections in production processes generally contribute to emissions to a greater extent than energy consumption, suggesting a duty to improve production processes.

KEYWORDS

1. INTRODUCTION

Since the last decade of the 20th century, regions and countries have emphasized the negative effects on the environment caused by the maintenance of energy consumption patterns that often lead to emissions of gases and other polluting particles, which are also associated with economic activity and economic growth. Carbon dioxide (CO₂) in natural proportions is not harmful, but as a result of the combustion of fossil fuels, the concentration of this gas in the atmosphere has been increasing until it has become a greenhouse gas (GHG), which induces a greater absorption of infrared radiation that should escape from the earth but which ends up causing an increase in the temperature of the atmosphere and in the temperature of the earth's surface. The increase in the production of goods and services generates externalities, many of them negative, which add to the excesses in the use of environmental resources used to supply energy consumption and production. Many research results on the relationship between energy consumption and gross domestic product (GDP) indicate that energy consumption patterns have a positive impact on CO₂ emissions. CO₂ emissions are considered to be particularly responsible for global warming, as CO₂ is the most abundant greenhouse gas. Several World Bank reports claim that from 1971 to 2015 global greenhouse gas emissions have doubled, with CO₂ contributing 76 % of total greenhouse gas emissions. Other greenhouse gases, which not only affect health, but also promote environmental degradation are: i) carbon monoxide (CO), mainly associated with traffic and transportation; ii) sulfur dioxide (SO₂), associated with the combustion of coal and petroleum products; iii) nitrogen oxides (NO_x), associated with the combustion of fossil fuels; and iv) hydrocarbons (CH_x), substances that contain only hydrogen and carbon but influence the formation of photochemical smog. Finally, lead (Pb) suspended or diluted in water and suspended particles called aerosols, which are particles of different sizes that influence the formation of sulfur smog, also highly polluting. Dust, fiber, soot, fumes, fog, mist and smog overload the environment in such a way that these particles end up affecting, to a greater or lesser extent, not only the health of people, but also the degradation of the environment. Among the most polluting aerosols, PM10 (Particulate Matter) are small solid or liquid particles of dust, ash, soot, metal particles, cement or pollen dispersed in the atmosphere. The size of PM10 particles is less than 10 microns. The daily limit value for the protection of human health is 50 micrograms per m³ (µg/m³) of PM10, which must not be exceeded more than 7 times a year, with the average annual limit for the protection of human health being 20 µg/m³. Exceeding the permitted PM10 limit is very harmful to health and reveals a poorly developed production technology. The countries with the highest PM10 index are Pakistan, Bangladesh, Nigeria, Egypt, India, China, Saudi Arabia, United Arab Emirates and Kuwait, the latter related to fuel production and distribution. Table 1 shows the PM10 concentrations in the world's 44 agglomerations with more than 9 million inhabitants (megacities) and those exceeding the daily allowable limit, which are mostly Asian and African megacities, have been shaded.

Shaded megacities indicate that they exceed the permissible limits of PM10.

Source: own elaboration based on data from the International Energy Agency 2019.

Air pollution is a phenomenon that is aggravated when population density is high. Population density is very high in countries such as Bangladesh, South Korea, India, Japan or Bahrain and, in the case of megacities, in Manila, Lagos, Delhi, Bangalore, Cairo, Dhaka or Tehran. It seems clear that it is at the local level that pollution control should be most decisive. For these reasons, its regulation is very important for the governments of countries and cities. From the Kyoto protocol (1997) to the climate report (IPCC, 2018) through the Paris agreements¹³⁰ (2015) and the Marrakech Climate Change Conference (2016), many countries have set themselves targets to reduce pollution and greenhouse gases. On the other hand, all these pollutants can also end up being a source of conflict between neighboring countries, regions and even between neighboring cities, due to the emission of toxic gases over less polluted areas. In volume, the most important pollutants are CO₂ emissions and PM10 particulate matter. In this research, only CO₂ emissions related to energy consumption and production processes of goods and services are analyzed.

The aim of this paper is to analyze to what extent CO₂ emissions are directly associated with energy consumption or imperfections in the production process of goods and services. The analysis is conducted across 20 countries over the period 1995-2015 with annual data from the International Energy Agency (2019). The countries in which the analysis is conducted represent 61% of the world's population in 2018 and belong to four continents. In the case of the European Union (EU), they include Ireland, France, Germany, Portugal and Spain. Iceland and the United Kingdom are also listed as European countries. The Asian countries analyzed in this research are: India, Indonesia, Saudi Arabia, Iran, Japan and China. Russia is also included. Some American countries are included, such as the United States, Brazil and Mexico. And the African countries included in this analysis are Morocco, South Africa and Nigeria. The five most important emerging countries considered in this analysis are included in the BRICS bloc.

The structure of this article is as follows: Section 2 deals with the background and literature Review. Section 3 contains the methodology and performs the modeling of the equations that attempt to explain the causal relationship between energy consumption and production and between CO₂ emissions and energy consumption. Section 4 analyzes the emissions. Section 5 contains the results obtained from the estimations of the equations obtained in the second section for the 20 countries in the sample. Section 6 contains the discussion of the results and, finally, section 7 contains the most relevant conclusions and policy implications of this research.

2. BACKGROUND AND LITERATURE REVIEW

The relationship between emissions and energy consumption, as well as the relationship between energy consumption and production, or production growth, has been widely analyzed since the pioneering work of Kraft and Kraft (1978), from which numerous researches on this topic are derived, but there is still no precise consensus on the relationship between energy consumption and economic growth. In this regard, two opposing positions can be identified: the first

130 United Nations Conference on Climate Change (Paris, December 2015) whose agreements were ratified and approved by the Parliament of the European Union on October 4, 2016. This European action on climate change has its background in articles 17, 18 and 19 of EU Directive 2009/28 / EC of the European Parliament and Council in April 23, 2009.

holds that changes in energy consumption have no clear effect on economic growth, and the second that there is some relationship between energy consumption and the level of production. There are enough studies that have attempted to empirically demonstrate this relationship in economies such as the United States (Abosedra and Baghestani, 1989), Gardner and Joutz (1996) and Soyatas, Sari and Ewing (2007); Canada (Ghali, 2004); Mexico (Caballero and Galindo, 2007) and Gómez (2010); Central American and Caribbean countries (Apergis and Payne, 2009). Studies in Asian countries have been conducted by Razzaqi, et al. (2011) and specifically in Bangladesh (Alam, et al., 2012); in China (Zhang and Cheng, 2009) for the period 1960-2007; in Taiwan (Cheng, 1997) for the period 1980-2007; in Pakistan (Siddiqui, 2004); in Iran (Zamani, 2007); in India (Mallick, 2009); in Turkey (Jobert and Karanfil, 2007) and Halicioglu (2009) for the period 1960-2005; Ang (2007a) examines the relationship between GDP, pollutant emissions and energy consumption in Malaysia between 1971 and 1999. In Africa, Belloumi (2009) examines the causal relationship between per capita energy consumption and per capita GDP in Tunisia for the period 1971-2004. In European countries, studies have been conducted in France (Ang, 2007b), Greece (Tsani, 2010), Russia (Zhang, 2011) and in Spain (Labandeira et al. 2017a, b). Medlock and Soligo (2001) have conducted analyses in 28 countries at different levels of development; Pao and Tsai (2010) have examined the relationships between CO₂ emissions, energy consumption and GDP in BRICS countries over the period 1990-2005; Mehrara (2007) has examined the causality between per capita energy consumption and per capita GDP through panel data on eleven oil exporting countries; Luzzati and Orsini (2009) study the relationship between energy consumption and per capita GDP in 113 countries for the period 1971-2004 and Farhani and Ben Rejeb (2012) conducted a study on 90 countries. Other research argues that increasing GDP increases pollution until the country reaches a certain per capita income, after which pollution starts to decrease (Hettige, Mani and Wheeler, 2000). In addition to all these authors, Srivivasan and Siddanth (2015) also found relationships between energy consumption and production level, which is not the case in the research of Yu and Choi (1992) and Altinay and Karagol (2004).

3. METHODOLOGY

Energy is a consumption good for consumers and, at the same time, a production factor for firms. We can assume an economy in equilibrium where there is a small number F of firms in imperfect competition, usually in oligopoly, in charge of supplying energy to a population of H consumers and to a large number N of firms producing consumer goods, which for simplicity we assume in perfect competition. We assume the absence of political or governmental interventions and call e_H the quantity of energy demanded by consumers as a good and c and R respectively the quantities of consumer goods and factors of production other than energy; p_e , p_c and p_R are the respective unit prices. We assume that the unit price of energy (p_e) is the same whatever the use of this energy. Energy used as a factor of production will be denoted as e_N if it plays the role of a factor of production in the N firms producing consumer goods c and when energy appears as a factor of production for the F firms supplying energy it will be denoted as e_F . We have assumed that the economy is in equilibrium and we also assume that the supply of energy is equal to the demand for energy, i.e., that the supply of energy provided by the F firms is demanded entirely as a good by the H consumers and as a factor of production by the N plus F firms in the economy. Denoting as e_S the amount of energy supplied by each of the F firms and, assuming that the agents are representative, the equilibrium in the internal energy market can be expressed in this form:

$$e_S \cdot F = e_H \cdot H + e_N \cdot N + e_F \cdot F \quad (1)$$

where the first member is the total energy supply and the second member is the total demand. We will simply denote as e the energy consumption in the market equilibrium, which is the energy consumption corresponding to the equality between energy supply and demand.

3.1 Market structure.

We are assuming that the H consumers in the economy are a large number and are therefore competitive, i.e., the quantity of goods and energy demanded by each of them is very small relative to the overall quantities demanded in the market, so that each consumer individually cannot influence the market equilibrium price and are therefore price-accepting. The same is true for the N consumer-goods-producing firms, which we assume operate under perfect competition. But the F energy supplying firms are a small number of firms. The empirical application of the present theoretical model will be carried out on 20 countries in Europe, Asia, America and Africa, in each of which the number of energy supplying firms ranges from 2 (in Portugal) to 29 (in the United Kingdom). In general terms, therefore, these energy supply companies operate in imperfect competition, in an oligopoly regime, generally non-collusive. For the sake of simplicity, we assume that the product they offer is homogeneous: energy. In this sense, the simplest model to specify the operation of these companies is a Bertrand (1883)-type oligopoly, because its solution with homogeneous product is similar to that of perfect competition with few companies instead of infinite ones. Although it is an ideal model, there are some energy companies that compete, especially in the electricity market, according to the Bertrand oligopoly model. The Bertrand oligopoly model takes price as a strategic variable, i.e., companies compete on price. When the product is homogeneous, as in the case of energy, and under the assumption that all firms reach the same marginal cost in equilibrium, competition between firms ends up producing a price equal to the marginal cost, as in the case of perfect competition, even if there are only two firms in the market. Moreover, in equilibrium, zero profit for the firms ends up occurring, which is known as Bertrand's "paradox". To avoid the situation of zero profits, which does not usually occur in reality in the equilibrium of energy supply companies, we will also choose to analyze Cournot (1838)-type non-collusive competition in this type of companies. In applied studies of electricity markets, Cournot-type models are ubiquitous and are applied to a wide range of applications. The Cournot model takes quantities as the firm's strategy, i.e., firms compete on quantities, but not on prices as in Bertrand. The Cournot model is often well suited for application in the electric power market and are the

preferred choice when detailed modeling of technical characteristics, such as grid constraints, voltage stability, or start-up costs in the case of electric power, are needed. The impacts of congestion on prices and market power have also been analyzed with these models in several studies. Cournot models are easy to solve and provide, under the right conditions, a unique Nash equilibrium. An overview of the application of Cournot models in the analysis of market power issues can be found in Bushnell et al. (2008) and also in Palazuelos (2019) among others. Other applications of Cournot to energy markets, including the treatment of network problems in electricity supply, are discussed in Day et al. (2002) and Ventosa et al. (2005). However, following Klemperer and Meyer (1989), it is considered that the oligopolistic Supply Function Equilibria (*SFE*) model can represent power markets in a more realistic way than the Cournot model. *SFE* models assume that firms compete through continuous and fluid bidding in an oligopolistic market facing demand with uncertainty. And in the presence of uncertainty, firms take their supply function as a strategic variable. *SFE* models allow to find intermediate solutions located between Cournot and Bertrand and even collusion. These intermediate solutions occur in both equilibrium prices and quantities and are achieved by simply varying parametrically the hypothetical response of the supply function. The main drawbacks of supply function equilibrium models, as well as their derived models, are that they often have multiple equilibria, may have unstable solutions and require strong simplifications with respect to market and cost structures, all of which make *SFE* models difficult to compute, compared to Cournot models. Some authors such as Hu et al. (2004) conclude that, especially in the presence of congestion, the Cournot model is more efficient than the Supply Function Equilibrium (*SFE*) model. For all these reasons, in this paper we will alternatively use the Bertrand and Cournot models to explain the oligopolistic behavior of the *F* energy supply companies, in order to specify a relationship between energy consumption and the production of goods and services.

3.2 Consumers' energy demand:

Consumers maximize their utility conditional on their budget constraint. The utility function proposed for consumers, who choose between energy consumption (e_H) and other consumer goods represented by a composite good (c), is for simplicity of Cobb-Douglas type and has the following expression, for $0 < \alpha < 1$:

$$U(e_H, c) = e_H^\alpha c^{1-\alpha} \tag{2}$$

We assume that the prices of goods e_H and c do not vary with the quantity demanded by the consumer because, according to Mas-Colell et al. (1995), consumers are considered to be price-acceptors and cannot affect these prices because the quantity of energy (e_H) and consumer goods (c) demanded by each of them is insignificant in relation to the market, which implies that each consumer cannot influence it. Calling m the monetary disposable income per capita of the consumer, which we also assume constant in the short run, the behavior of the individual agents in each period will then be as follows:

$$\text{Max}\{U(e_H, c) = e_H^\alpha c^{1-\alpha}\} \text{ subject to: } e_H p_e + c p_c = m \tag{3}$$

Solving this maximization we obtain: $m = \frac{p_e}{\alpha} e_H$; considering that this consumer is representative, in the absence of taxes we know that: $H m = Y$ (monetary income or monetary *GDP* of the economy), i.e.: $Y = \frac{p_e}{\alpha} H \cdot e_H$. Therefore, the aggregate demand for energy by consumers, as a consumption good, will turn out to be:

$$H \cdot e_H = \frac{\alpha Y}{p_e} \tag{4}$$

3.3 Energy demand of firms producing consumer goods

In the economy there are N firms in perfect competition, firms that accept the price not being able to vary the price of c and that produce the consumer goods c maximizing profit. We assume that the goods c are, for simplicity, produced from a Cobb-Douglas type production function based on a series of production factors represented by a composite production factor (R), plus energy (e_N), which in this case functions as a production factor. That is:

$$c = A e_N^\beta R^{1-\beta} \tag{5}$$

with $0 < \beta < 1$. A is the coefficient of technical progress or technology which we assume to be neutral in the Hicks sense. The objective of each of these firms is to maximize profit $B = p_c c - p_e e_N - p_R R$. The demand for energy as a factor of production is a derived demand from profit maximization:

$$\text{Max} B = \text{Max} \left\{ p_c A e_N^\beta R^{1-\beta} - p_e e_N - p_R R \right\} \tag{6}$$

We assume that the markets for consumer goods c and factors R are in perfect competition, so that prices p_c and p_R appear as given.

Bertrand case: With respect to energy prices, p_e , in principle we assume that the F firms supplying energy to consumers and firms have non-collusive Bertrand (1883) type price competition among themselves, which implies that, although they form an oligopoly, their equilibrium is similar to that of perfect competition (for the F firms producing energy it must be satisfied: $p_e = C'_{eF}$) since the product they offer (energy) is homogeneous. The derived energy demand is obtained by maximizing profit (B) with respect to e_N : $B'_{eN} = 0 = \beta \cdot p_c \cdot A \cdot e_N^{\beta-1} \cdot R^{1-\beta} - p_e$, from where the energy demand of each firm is: $e_N = \frac{\beta \cdot p_c \cdot c}{p_e}$; and for the N firms the demand will be:

$$e_N N = \frac{\beta \cdot (p_c \cdot c \cdot N)}{p_e} \tag{7}$$

Cournot case: Now, if we assume that the F firms producing and supplying energy operate as a non-collusive Cournot-type oligopoly, then the price of energy p_e is no longer given, nor is it equal to the marginal cost of energy, but depends

on the quantity of energy, according to the energy demand function: $p_e = p_e(e_N)$. This implies that the profit maximization from which the derived demand for energy as a factor of production is now extracted, is:

$$B'_{eN} = 0 = \beta p_c A e_N^{\beta-1} R^{1-\beta} - \left(\frac{dp_e}{de_N} e_N + p_e \right) = \beta p_c A e_N^{\beta-1} R^{1-\beta} - p_e \left(1 - \frac{1}{\varepsilon} \right) = \beta p_c A e_N^{\beta-1} R^{1-\beta} - \frac{p_e}{\mu}$$

where ε is the elasticity of the derived energy demand faced by the firm and μ the mark-up on the marginal costs of the energy supplying firm. From this maximization it follows that the amount of energy as a factor of production (e_N) demanded by the firm is: $e_N = \frac{\mu \cdot \beta \cdot p_c \cdot c}{p_e}$; and for the N firms the demand will result:

$$e_N N = \frac{\mu \cdot \beta \cdot (p_c \cdot c \cdot N)}{p_e} \tag{8}$$

3.4 Energy demand of energy supplying firms

The F firms that supply the good energy offered (e_S) also use part of it as a factor of production (e_F), according to a certain production function that for simplicity we also assume as a Cobb-Douglas type and whose arguments are energy as a production factor (e_F) and the rest of production factors, represented by a composite factor R :

$$e_S = A e_F^\beta R^{1-\beta} \tag{9}$$

where e_S is the energy produced by each of the F companies and then supplied to the companies producing consumer goods and to consumers.

Bertrand case: The demand for energy is derived from the profit maximization by each of the F firms: $Max B = Max \left(p_c A e_F^\beta R^{1-\beta} - p_e e_F - p_R R \right)$ whose result, considering that the price p_e is given by the Bertrand equilibrium, is: $e_F = \frac{\beta \cdot p_c \cdot e_S}{p_e}$; and for the F firms the demand is:

$$e_F F = \frac{\beta \cdot (p_c \cdot e_S \cdot F)}{p_e} \tag{10}$$

Knowing that in an economy in equilibrium the income of sellers is equal to the expenditure of consumers and that the total annual nominal income of the economy (Y) is the sum of the annual income of all firms: $Y = (p_c c)N + (p_e e_S)F$, where we know that the energy supplied by each firm (e_S) is applied as a factor of production (e_N) in the firms producing consumer goods, in addition to meeting the needs of consumers as a good (e_H), the total derived demand for energy as a factor of production by the $N + F$ firms, when the F firms operate a la Bertrand, by (7) and (10) will be:

$$N \cdot e_N + F \cdot e_F = \frac{\beta}{p_e} [(p_c c)N + (p_e e)F] = \frac{\beta}{p_e} Y$$

And the total energy demand (e_D) of companies and consumers, taking into account (4), (7) and (10), will be:

$$e_D = H \cdot e_H + N \cdot e_N + F \cdot e_F = (\alpha + \beta) \frac{Y}{p_e} \tag{11}$$

where p_e is given. When the internal energy market is in equilibrium, the energy demand must be equal to the energy supply: $e_D = e_S \cdot F = e$, where e is the energy consumption in equilibrium.

Cournot case: Energy demand is derived from profit maximization by each of the F firms: $Max B = Max \left(p_c A e_F^\beta R^{1-\beta} - p_e e_F - p_R R \right)$ but now the unit price of energy, p_e , is not given, but depends on the quantity of energy demanded as a factor of production: $p_e = p_e(e_F)$. The profit maximization from which the energy demand function is derived as a factor of production for each of the F supplying companies will now have the following expression:

$$B'_{eF} = 0 = A R^{1-\beta} \left(\frac{dp_e}{de_F} e_F^\beta + \beta e_F^{\beta-1} p_e \right) - \left(\frac{dp_e}{de_F} e_F + p_e \right) = \left[A R^{1-\beta} e_F^{\beta-1} \left(\beta - \frac{1}{\varepsilon} \right) - \left(1 - \frac{1}{\varepsilon} \right) \right] p_e$$

where ε is the elasticity of demand for energy as a factor of production and $(1-1/\varepsilon)$ is $1/\mu$, where μ is the same mark-up previously defined since we have assumed that the unit price of energy is the same whether it is a consumer good or a factor of production. Solving the maximization, the quantity demanded of energy as a production factor by each of the F companies is: $e_F = [1 - \mu(1 - \beta)]e_S$. Therefore, the quantity of energy demanded by all the F companies will be:

$$e_F F = [1 - \mu(1 - \beta)]e_S \cdot F \tag{12}$$

And the total energy demanded by the economy will be: $e_D = H e_H + N e_N + F e_F$. That is to say:

$$e_D = \frac{\alpha Y}{p_e} + \frac{\mu \cdot \beta \cdot (p_c \cdot c \cdot N)}{p_e} + [1 - \mu(1 - \beta)](e_S \cdot F) \tag{13}$$

Since the total income of the economy or money income is $Y = (p_c c)N + (p_e e_S)F$, we have that $(p_c c)N = Y - (p_e e_S)F$ and substituting $(p_c c)N$ in (13) we obtain the total energy demand:

$$e_D = \frac{(\alpha + \mu \cdot \beta)Y}{p_e} + (1 - \mu)(e_S \cdot F)$$

where the unit price of energy is not constant, but depends on the overall energy demand: $p_e = p_e(e_D)$. If we assume that the economy is energetically closed, i.e., consumers and firms receive energy only from the F supplying firms, then all the energy the energy produced by the supplying firms is distributed in this way: $e_S \cdot F = e_F \cdot F + e_N \cdot N + e_H \cdot H$ where the first member is the total energy supply and the second member the total demand (e_D). In equilibrium: $e_S \cdot F = e_D = e$, where e is the energy consumption when the energy market is in equilibrium. Substituting, we finally have that:

$$e = \frac{(\alpha + \mu \cdot \beta)Y}{\mu \cdot p_e} \tag{14}$$

where p_e is not constant. To value p_e at equilibrium, the energy supply must be analyzed.

3.5 Energy supply

We have assumed that each of the F energy supplying firms produce according to a Cobb-Douglas production function of the type: $e_S = Ae_F^\beta R^{1-\beta}$, with a cost function: $C = p_e e_F + p_R R$, where e_F is the endowment of energy as a factor of production, R involves the other factors of production other than energy but necessary to produce it, A is the coefficient of technical progress or technology and e_S the quantity of energy produced and supplied. To the Cobb-Douglas production function mentioned (9) corresponds a variable cost function dependent on e_S , which is obtained by minimizing the cost function C subject to the production function:

$$\text{Min}(C(e_F, R) = p_e e_F + p_R R) \text{ subject to: } e_S = Ae_F^\beta R^{1-\beta} \quad (15)$$

Bertrand case: Minimizing by Lagrange considering factor prices as given, a relationship is established between the two factors of production that allows to put each of them as a function of output e_S . Once these results have been substituted in the expression of the costs (C), we can obtain the expression of the variable costs (Cv) as a function of e_S , corresponding to the production function (9):

$$Cv = \left(\frac{p_e}{\beta}\right)^\beta \left(\frac{p_R}{1-\beta}\right)^{1-\beta} \frac{e_S}{A} \quad (16)$$

to which corresponds the following marginal cost function (C') with respect to e_S :

$$C'_{e_S} = \frac{1}{A} \left(\frac{p_e}{\beta}\right)^\beta \left(\frac{p_R}{1-\beta}\right)^{1-\beta} \quad (17)$$

Function that in this case turns out to be constant for the F firms, because it does not depend on the quantity of energy and the prices p_e and p_R are constant. When the F oligoplastic energy supplying companies maintain a Bertrand-type competition, competing on prices, in equilibrium they will equal the selling price of energy to the marginal cost ($p_e = C'_{e_S}$) in a single market. Therefore, the market equilibrium can be expressed by equating price to marginal cost, from (11 and 17):

$$p_e = (\alpha + \beta) \frac{Y}{e} = \frac{1}{A} \left(\frac{p_e}{\beta}\right)^\beta \left(\frac{p_R}{1-\beta}\right)^{1-\beta} \quad (18)$$

from which we can obtain the total energy consumption in the market equilibrium (e):

$$e = (\alpha + \beta) \beta^\beta (1 - \beta)^{1-\beta} \frac{A \cdot p \cdot y}{p_e^\beta \cdot p_R^{1-\beta}} \quad (19)$$

equation in which monetary income Y has been broken down into its components, general price level p and real income y : $Y = p \cdot y$, where y is now income in real terms or GDP at constant prices. What is indicated in expression (19) is that energy consumption depends directly on real income and inversely on the price of energy and the prices of the other factors of production.

Cournot case: To perform the conditional minimization (15) with the idea of obtaining the variable cost function corresponding to the Cobb-Douglas production function, $e_S = Ae_F^\beta R^{1-\beta}$, we must use Lagrange's method taking into account that we assume the factor market R in perfect competition, i.e., we consider p_R as given. The same is not true for p_e , since $p_e = p_e(e_F)$. The Lagrangean function (\mathcal{L}) of the problem is:

$$\mathcal{L}(e_F, R, \rho) = p_e \cdot e_F + p_R \cdot R + \rho \cdot (e_S - A \cdot e_F^\beta \cdot R^{1-\beta}). \text{ First-order conditions:}$$

$$\mathcal{L}'_{e_F} = \left(\frac{dp_e}{de_F} \cdot e_F + p_e\right) - \beta \cdot A \cdot e_F^{\beta-1} \cdot R^{1-\beta} \cdot \rho = 0$$

$$\mathcal{L}'_R = p_R - (1 - \beta) \cdot \lambda \cdot e_F^\beta \cdot R^{-\beta} \cdot \rho = 0$$

Considering again that $1 - 1/\varepsilon = 1/\mu$, where in this case ε is the elasticity of demand for energy as a factor of production for a firm in the group of F firms and μ the mark-up that these firms put on marginal costs, equating the Lagrange multipliers (ρ) of the two first-order conditions and substituting the results in the production function, we obtain the relationship between factors of production and output, i.e. between e_F and e_S , and between R and e_S . Substituting these relationships in the variable cost function to be minimized, we obtain the variable cost function of the firm as a function of e_S :

$$Cv = p_e e_F + p_R R = \frac{p_e}{A} \left[\frac{(1-\beta)p_e}{\mu \cdot \beta \cdot p_R}\right]^{\beta-1} e_S + \frac{p_R}{A} \left[\frac{(1-\beta)p_e}{\mu \cdot \beta \cdot p_R}\right]^\beta e_S \quad (20)$$

Denoting now $X = \frac{1}{A} \left[\frac{1-\beta}{\mu \cdot \beta \cdot p_R}\right]^{\beta-1}$, and as $Z = \frac{p_R}{A} \left[\frac{1-\beta}{\mu \cdot \beta \cdot p_R}\right]^\beta$, the marginal cost function will be:

$$C'_{e_S} = (X + Z) \cdot p_e^\beta \cdot \left[\frac{\mu \cdot (1-\beta) + \beta}{\mu}\right] \quad (21)$$

3.6 Equilibrium

We will now assume, just for simplicity, that the F supplying firms have identical marginal cost in equilibrium. This implies that if the F firms compete in Cournot style, where competition is in quantities, the amount of energy that ends up being offered to the market by each firm is identical for all firms. We will assume, also for simplicity that the mark-ups imposed on marginal costs by the F firms are identical (μ). Since the energy supply companies are operating under imperfect competition, the relationship between the selling price and the marginal cost is: $p_e = \mu \cdot C'_e$. Taking into account the value of from (21), the unit selling price of energy for each company will be:

$$p_e = [(X + Z)[\mu(1 - \beta) + \beta]]^{\frac{1}{1-\beta}} \quad (22)$$

In a non-collusive Cournot-type oligopoly this price is the same for all firms. But we know that the market equilibrium price is given by equation (14). That is:

$$p_e = \frac{(\alpha + \mu\beta)}{\mu \cdot e} Y \tag{23}$$

where e is the energy consumption in the market equilibrium. Equating the prices given by relations (22) and (23), we finally have that if in the oligopoly formed by the F firms, these compete in Cournot style, the energy consumption of the economy will then be:

$$e = \left(\frac{\alpha + \mu\beta}{\mu}\right) \left(\frac{1-\beta}{p_R}\right) (\mu\beta)^{\frac{\beta}{1-\beta}} \left[\frac{A}{\beta(1-\beta)(\mu-1)^2 + \mu}\right]^{\frac{1}{1-\beta}} p y \tag{24}$$

Where monetary income Y has been broken down into its two components: general price level (p) and real income (y). If a regression line could be fitted to the overall energy demand function faced by each firm then the mark-up on marginal costs imposed by each of the F firms competing in Cournot can be approximated as: $\mu = \frac{F+3}{F+1}$, where F is the number of firms composing the oligopoly, obviously for $F > 1$, because it is an oligopoly. If $F = 1$ it would be a monopoly and the mark-up would then be $\mu = 2$. When $\mu = 1$ we have Bertrand's solution, for which, the energy consumption will be:

$$e = (\alpha + \beta) \left(\frac{1-\beta}{p_R}\right) \beta^{\frac{\beta}{1-\beta}} A^{\frac{1}{1-\beta}} p y \tag{25}$$

It can be verified that energy consumption in equilibrium is higher when firms compete on prices (Bertrand), according to equation (25), than when they compete on quantities (Cournot), according to equation (24). Calling λ_0 the term $\left(\frac{\alpha + \mu\beta}{\mu}\right) (1 - \beta)(\mu\beta)^{\frac{\beta}{1-\beta}} \left[\frac{1}{\beta(1-\beta)(\mu-1)^2 + \mu}\right]^{\frac{1}{1-\beta}}$, and taking natural logarithms in (24), but also considering (19) and (25) we can obtain a first explanatory linear expression of energy consumption in an economy; but when regressing the equation along a database, most probably the coefficient λ_0 would be highly significant, manifesting the existence of omitted variables. One of them may be related to the population level (PO) of the economy since it seems evident that higher population may correspond to higher energy consumption, so a more complete specification of equilibrium energy consumption to be regressed could be:

$$\log_e e = \lambda_0 + \lambda_2 \log_e A + \lambda \log_e y + \lambda_3 \log_e p + \lambda_4 \log_e p_e + \lambda_5 \log_e p_R + \lambda_1 \log_e P O + \varepsilon \tag{26}$$

where ε is a random disturbance.

3.7 Emissions

Energy production and consumption processes involve emissions of gases and particulates, but a good part of the emissions seem to come from heating and air conditioning of dwellings and buildings.

Therefore, we can assume that a certain percentage of the total pollutant emissions (Em) are a by-product of energy consumption specifically dedicated to heating and cooling (e_{cr}), so in principle we can express:

$$Em = \rho \cdot e^\gamma \cdot e_{cr}^{\gamma_1} \tag{27}$$

where ρ , γ and γ_1 are parameters. Some of the variables that explain the emissions caused by e_{cr} consumption may be related to environmental conditions, specifically variations in ambient temperature that affect heating and cooling consumption, as well as wind or rainfall, which can affect the dispersion of gas and particle emissions associated with energy production and consumption. From Joule (1850) it is known that the amount of heat required to raise or lower the temperature of a body of mass M is: $Q = s \cdot M \cdot \Delta T$, where Q is heat, s a constant called specific heat and ΔT the temperature increase in Celsius degrees ($^{\circ}C$); at the same time it is established that the accumulated heat energy (E) is: $E = J \cdot Q$, where J is a universal constant called the mechanical equivalent of the kilocalorie. Therefore $E = J \cdot s \cdot M \cdot \Delta T$ is the extra energy consumption caused by variations in ambient temperature. Since we have assumed that this consumption is basically due to heating and cooling (e_{cr}), we can express that: $e_{cr} = \theta \cdot J \cdot s \cdot M \cdot \Delta T$, where θ is a parameter reflecting a proportionality. Therefore, the expression (27) will now take the following form.

$$Em = \rho \cdot e^\gamma (\theta \cdot J \cdot s \cdot M \cdot \Delta T)^{\gamma_1} \tag{28}$$

Which indicates that emissions caused by energy consumption are amplified or reduced by the effect of environmental conditions. Taking natural logarithms in (28), concentrating the constant terms in γ_0 and being ε a random disturbance, the equation to be estimated to explain emissions will finally have the following expression:

$$\log_e E m = \gamma_0 + \gamma \log_e e + \gamma_1 \log_e (M \cdot \Delta T) + \varepsilon \tag{29}$$

4. DATA AND EMPIRICAL RESULTS

As mentioned above, the objective of this research is to determine whether CO₂ emissions to the atmosphere are primarily due to energy consumption or imperfections in the countries' production process, or both, and in what proportion. To find out, equations (26) and (29) have been regressed over 20 countries during the period 1995-2015 with annual data. The 20 selected countries belong to consolidated economic blocs: on the European Union side are Ireland, France, Germany, Spain and Portugal. One non-EU European country are Iceland and United Kingdom. The BRICS countries include India, China, Russia, Brazil and South Africa; other Asian countries include Indonesia, Japan, Saudi Arabia and Iran; other American countries include the United States and Mexico; and finally there are other African countries in the sample, such as Nigeria and Morocco. The application has been carried out with data from the International Energy Agency (2019) and equations (26) and (29) have been adapted to perform the regressions according to the data. In order to have sufficient degrees of freedom, the prices of goods and factors, which, together with technology, have been included in the regression intercept, have been left out. In this way, equation (26), which explains energy consumption (e), has been simplified, finally estimating the following equation:

$$\log_e e = \lambda_0 + \lambda \log_e y + \lambda_1 \log_e P O + \varepsilon \tag{30}$$

where ε is a random disturbance and e is the annual energy consumption¹³¹ measured in thousands of tons of oil equivalent (ktoe¹³²). PO is the population of the country measured in millions of inhabitants, and y is the real output of the economy measured at power parity purchasing in billions of constant 2010 US\$. Equation (29), which explains CO₂ emissions, will be estimated considering that the following considerations will be made regarding the term $M \cdot \Delta T$: ΔT is the difference between the annual average maximum and minimum temperatures measured in Celsius degrees (°C) with respect to an ideal temperature, which in our case has been taken as 19 °C. M is the mass of the bodies to be heated or cooled. In this research, M has been taken for simplicity as the total population (PO) of the country¹³³ measured in millions of inhabitants. And calling $PO \cdot \Delta T$ as TPO , the equation (29) to be finally regressed will be:

$$\log_e Em = \gamma_0 + \gamma \log_e e + \gamma_1 \log_e(TPO) + \varepsilon \tag{31}$$

where ε is a random disturbance, e the annual energy consumption and Em the annual CO₂ emissions discharged by each economy.

To detect whether or not there is spatial dependence in energy consumption and emissions across the 20 countries in the sample, the I-test (Moran, 1950) was applied. The results in Table 2 show a slight spatial dependence in energy consumption and no spatial dependence in emissions. To verify whether the possible spatial dependence is due to dependence on the endogenous variables (lag dependence) or on the disturbances (error dependence), other tests based on the Lagrange multiplier applied to the residuals of an OLSQ regression have been used: Burrige's (1980) LM(err) and robust RLM(err) tests, which measure the spatial dependence in error, and Anselin's (1998) LM(lag) and robust RLM(lag) tests, which measure the spatial dependence of the endogenous variables. None of these last four tests shows any evidence of spatial dependence in either energy consumption or emissions, possibly due to the dispersion of the countries selected in the sample. Table 2 shows the results of the estimations of the equation (30) -regressions I to XII- and of the equation (31) -regressions XIII to XIV- for half of the countries in the sample, plus the overall regression on the 20 countries with panel data (models XII and XIV).

Table 2. Estimates of energy consumption and CO₂ emissions by country

131 Total final consumption: residential energy consumption, transportation, industrial, services and primary sector, but energy consumption in transportation, industrial and primary sector are considered associated in this work to the "Economic Activity". Residential energy consumption and services are assumed as "Consumption".

132 1 ktoe = 11630000 kWh.

133 Strictly speaking, it would have been necessary to multiply for each country each inhabitant by its mass or by the average mass of the inhabitants but, assuming that on average the inhabitants of the countries have a similar mass, it was preferred to normalize the mass of each inhabitant to the unit.

From these regressions we extract the coefficients of $\log_e y$ and of $\log_e e$, respectively coefficients λ and γ from equations (30) and (31). According to the estimates, these coefficients turn out to be significant at 99 % in general, except in regressions IV, V, VI and XVII where the significance of the estimators is somewhat lower. The regressions for the countries have been performed by ordinary least squares (OLS) method, correcting as far as possible for autocorrelation by assuming that the residuals follow a first-order autoregressive process (AR1), although in some of the estimates there is still temporal autocorrelation of the residuals. All regressions have high or acceptable R²-adjusted coefficients of determination. Table 2 does not report the regressions for the entire sample of countries, only for ten of them, but the remaining coefficients λ and γ not reported in Table 2 are reported below in columns IV and V of Table 5. Regression XII in Table 2 shows the panel estimate for the 20 countries in the sample over the 1995-2015 period in terms of the relationship between the log of energy consumption and the log of the real output (equation 30), with the best panel estimate being the Random Effects (Random Effects) estimate, since the p-value of the Lagrange multiplier test (Breuch and Pagan, 1980) is less than 0.05, which rejects the OLSQ-plains estimation, while the p-value of the Hausman (1978) test is greater than 0.05, which rejects the Fixed Effects estimation. As for the panel estimation of the logarithm relationship between CO₂ emissions and energy consumption (equation 31), the results indicate that the best panel regression is the Between Groups estimation, reported in regression XIV.

To verify whether the series involved in the regressions in Table 2 do not have unit roots, i.e., whether they are stationary, the Harris and Tzavalis (1999) test for panel data was used. The results of this test indicate that all the series involved are stationary, as can be seen in Table 3 in which the Rho parameters of the lagged variables are all less than unity. Given that they are all stationary, it is of interest to know whether there are causal relationships between the exogenous and endogenous variables of the two regressions in Table 2. For this purpose, the Granger causality test (1969) has been used, the results of which are shown in Table 3.

Source: own elaboration. Note: FE (Fixed Effects); RE (Random Effects).

It can be seen from this table that there is Granger causality between real income (y) and population (PO) on energy consumption (e); and there is also Granger causality between the variable TPO (temperature multiplied by the population) and energy consumption (e) on the volume of emissions (Em), because the respective regressions with lagged explanatory variables imply a higher prediction of the endogenous variable.

The economic interpretation of the λ estimators is relevant, since: $\lambda = \frac{\partial \log_e e}{\partial \log_e y} = \frac{\Delta e}{\Delta y} \cdot \frac{y}{e}$, i.e., they are energy-income elasticities, from which we can know how much energy consumption varies when the country's production varies:

$$\frac{\Delta e}{\Delta y} = \lambda \cdot \frac{e}{y} \tag{32}$$

The term (e/y) is called energy intensity and is an indicator of the energy efficiency of each country. Columns III and IV of Table 4 show the countries in the sample ordered from lowest to highest energy intensity for 2015 data.

Table 4. CO₂ emissions, Energy Intensities and fossil energies (2015)

Source: own elaboration based on data from the International Energy Agency 2019

Lower energy intensity generally corresponds to higher energy efficiency. Columns I and II of the same table show the countries ordered by amounts emitted of CO₂ per ktoe of energy consumed, from lowest to highest emission. There seems to be a certain correlation between the two parts of the table and also between the massive use of fossil fuels (column V) in the last countries in column III and the higher proportion of renewable energy use in the first countries in this column. The evolution of energy intensity by blocks of countries in the sample from 1995 to 2015 can be seen in Figure 1. This figure shows that the lowest energy intensity is in the European countries and the highest in the BRICS countries. It can also be observed how energy intensity decreases over time in the four blocks of countries, probably due to the increase in efficiency in energy consumption, due to the progressive substitution of fossil energy for renewable energy.

Figure 1. Evolution of the energy intensity by block of countries (1995- 2015)

Source: own elaboration based on data from the International Energy Agency 2019.

From equation (20) we can deduce that $\gamma = \frac{\partial \log_e(Em)}{\partial \log_e e} = \frac{\Delta(Em)}{\Delta e} \cdot \frac{e}{Em}$, from which we can infer how much emissions increase by energy consumption:

$$\frac{\Delta Em}{\Delta e} = \gamma \cdot \frac{Em}{e} \tag{33}$$

We want to know to what extent the increase in CO₂ emissions, when energy consumption increases, is greater or smaller than the increase in CO₂ emissions, when GDP increases. The term $\lambda \cdot \gamma = \left(\frac{\partial \log_e e}{\partial \log_e y}\right) \left(\frac{\partial \log_e Em}{\partial \log_e e}\right) = \frac{\Delta Em}{\Delta y} \cdot \frac{y}{Em}$, therefore, the increase in emissions when real income (real GDP) increases is:

$$\frac{\Delta Em}{\Delta y} = \lambda \cdot \gamma \cdot \frac{Em}{y} \tag{34}$$

From (33) and (34) we can see which emits more, whether the production process of y or the energy consumption process (e), i.e., how much the difference is worth: $\frac{\Delta Em}{\Delta y} - \frac{\Delta Em}{\Delta e}$. The results, with 2015 data are shown in column VII of Table 5. When this difference is positive, the increase in production emits more CO₂ than the increase in energy consumption, which would indicate the need to reduce emissions caused by the production process.

5. RESULTS AND DISCUSSION

From the estimates for the 20 countries in the sample, of which for 10 of them are shown in Table 2, we obtain the corresponding estimators of λ and γ for each country, which are collected in columns IV and V of Table 5. Using expressions (33) and (34) with 2015 data we obtain the results in column VII. Considering the coefficients λ and γ obtained in estimations XII and XIV with panel data from Table 2 we obtain that the average difference $\frac{\Delta Em}{\Delta y} - \frac{\Delta Em}{\Delta e}$ is 0.165 which shows that overall $\frac{\Delta Em}{\Delta y} > \frac{\Delta Em}{\Delta e}$. That is, as seen in column VII, what emissions increase when real GDP increases in general is more than what emissions increase when energy consumption increases. This implies that in the economies where this is the case, there are emitting production processes suggesting that an improvement in these production processes could cause emissions to decrease. There are only four countries in the sample, Mexico, Brazil, Japan and Germany, in which the increase in CO₂ emissions related to energy consumption are greater than those associated with economic activity, implying that the marginal productivity of energy is greater than one¹³⁴ (Brazil and Mexico) or that emissions decrease when production increases due to the Kuznets¹³⁵ effect (Germany and Japan). Countries whose difference is greater than the average provided by the panel data estimation (0.165) should improve their production processes. These countries are shaded in column VII of Table 5. Column VI shows the countries whose CO₂ emissions per capita are higher than the sample average (6.19 tons of CO₂ per capita), from which Ireland, Japan, Germany, Iran and Russia should reduce energy consumption while the United States, Saudi Arabia, South Africa and China should incorporate less polluting production processes, comparing the results of columns VI and VII. Columns II and III of Table 5 relate to the efficiency in the use of production factors, including energy, relative to 2015. Assuming that the production functions of the firms in the economy are homogeneous of degree one, as corresponds to the production functions (5), whose arguments are energy as a production factor (e_N) plus a series of production factors (R), some of which we assume

134 If (ΔEm / Δe) > (ΔEm / Δy) then (1 / Δe) > (1 / Δy), that is: (Δy / Δe) > 1. See Table 5, column III.

135 From a high level of per capita income, emissions decrease as production increases.

fixed during 2015, then if we consider energy as a variable factor all production factors are efficiently used by the firm when production is between the technical optimum¹³⁶ and the technical maximum of a productivity function where energy acts as a variable factor. At that stretch the average productivity function of energy lies above the marginal productivity function of energy as a factor of production. Aggregating the productivity functions of the firms in the economy it can be deduced that the efficient use of all factors of production, including energy, is obtained when over the aggregate productivity function, the average productivity of energy (Table 5, column II) is equal to or greater than the marginal productivity of energy (Table 5, column III) the latter being non-negative: $(y/e) \geq (\Delta y/\Delta e) \geq 0$. Therefore the shaded results in columns II and III belong to countries that probably did not efficiently use energy as a factor of production in 2015. According to the results in Table 5, it can be assured under the assumption of aggregate production functions with constant returns to scale but decreasing returns to capital factor that, of the 20 countries analyzed only Spain, Portugal, France, India, the United States, Saudi Arabia, China and Iceland used energy efficiently in 2015 since, in relation to energy, their average productivities are higher than the marginal ones.

From the results obtained in the previous epigraph, the following considerations can be established corresponding to the situation reached in 2015 by the twenty countries analyzed: 1) In general, the increases in CO₂ emissions related to the productive processes of goods and services are greater than those associated with energy consumption: $\Delta Em/\Delta y > \Delta Em/\Delta e$. 2) Only the increase in CO₂ emissions associated with energy consumption are greater than those associated with the productive processes of goods and services ($\Delta Em/\Delta e > \Delta Em/\Delta y$) in Germany, Japan, Brazil and Mexico. 3) The countries where the difference between the increases in CO₂ emissions related to the productive processes of goods and services are greater and the increases in CO₂ emissions associated with energy consumption turn out to be greater than the average ($\Delta Em/\Delta y - \Delta Em/\Delta e > 0.165$), are: Spain, France, India, United States, Saudi Arabia, South Africa, and China. 4) The countries in the sample whose per capita CO₂ emissions are above the sample mean ($Em/PO > 6.19 \text{ Tn CO}_2 / PO$), are: Ireland, Japan, Germany, United States, Saudi Arabia, China, Iran, and Russia. 5) The blocks of countries represented in the sample that use energy more efficiently, according to the inverse order of energy intensity are, in order from most efficient to least: Europe, America, Asia and BRICS. And 6) The countries that manage to user energy efficiently considered as a factor of production together with other factors, i.e., countries where the average energy productivity is greater than the marginal energy productivity [$y/e \geq y'(e)$], are: Portugal, Spain, France, India, the United States, Saudi Arabia, China and Iceland.

According to these considerations established for 2015, the situation of the twenty countries in the sample with respect to the incentives they have or do not have to curb CO₂ emissions is shown in Table 6. From the results of Table 6 and the previous headings it can be seen that in 2015: 1) The United States, Saudi Arabia, China, Portugal, Iceland, Spain, France and India do not have sufficient incentives to reduce CO₂ emissions because energy use in these countries is already efficient. 2) Even so, the United States, Saudi Arabia, China, Spain, France and India must reduce CO₂ emissions from production even if energy use is already efficient. 3) But according to the results, South Africa should reduce CO₂ emissions from its production processes, because its current energy use is not efficient and it could improve efficiency by implementing innovations in the production processes of goods and services. 4) Undoubtedly Ireland, Russia, Japan, Germany, Iran, United Kingdom, Brazil, Morocco, Indonesia, Nigeria and Mexico must reduce CO₂ emissions from energy consumption.

Table 6. CO₂ Emissions from Production and Energy Consumption (2015)

	Emissions and energy efficiency (2015)	Countries
1	<u>Emissions per capita above the sample mean.</u> Energy could be more efficient if production emissions are halted.	SOUTH AFRICA.
2	<u>Emissions per capita above the sample mean.</u> Energy could be more efficient by curbing energy consumption emissions.	IRELAND, JAPAN, IRAN, GERMANY, RUSSIA.
3	<u>Emissions per capita above the sample mean.</u> Production emissions must be halted, but energy use is already efficient.	US., SAUDI ARABIA, CHINA.
4	Emissions from energy consumption must be stopped, but energy use is already efficient.	PORTUGAL, ICELAND.
5	Better production processes must be implemented, but energy use is already efficient.	SPAIN, FRANCE, INDIA.
6	Energy consumption must be halted.	UK., MOROCCO, NIGERIA INDONESIA, BRAZIL, MEXICO

Source: own elaboration.

To curb CO₂ emissions, the production processes of goods and services must be improved in order to reduce the emissions they produce, and emissions from energy consumption must be reduced, either by improving energy consumption processes or by reducing energy consumption. According to Table 6, the countries in rows 2, 4 and 6 should curb energy consumption, albeit with greater or lesser incentives to do so. In total there are 13 of the 20 countries in the sample.

6. CONCLUSIONS AND POLICY IMPLICATIONS

This research has proposed a microeconomic model that explains the supply and demand of energy, energy consumption and emissions produced by energy consumption and economic activity in the economic equilibrium. The objective of this

¹³⁶ Maximum of the average productivity function. Technical maximum is the maximum of the productivity function.

model is to find from the economic theory causal relationships between energy consumption and economic activity and between emissions and energy consumption. The emissions covered by this research are exclusively those of carbon dioxide, which was selected as the most abundant greenhouse gas and supposedly the most responsible for global warming and therefore of the possible long-term environmental degradation. The most important purpose of this research is to analyse what part of the total carbon dioxide emissions is associated with energy consumption and which part is associated with economic activity, regardless of energy consumption. The model has been applied econometrically on a sample of 20 countries in the period 1995-2015 with data from the International Energy Agency. Six of these countries belong to the European Union and the rest of the countries in the sample belong to Europe, Asia, America and Africa. The total population of these countries accounts for 61% of the world's population. The results of the application indicate that, in general, the process of carrying out economic activity, measured by gross domestic product in real terms, emits more carbon dioxide than the process of energy consumption. This seems to indicate the existence of certain imperfections in the productive processes of most of the countries in the sample. The results also indicate that Ireland, Japan, Germany, Iran and Russia should be able to reduce their energy consumption while the United States, Saudi Arabia, South Africa and China should incorporate less polluting production processes. The carbon dioxide emissions per capita of these nine countries are above the average of the sample. In relation to the productivity of energy in the production processes, only Spain, Portugal, France, India, the United States, Saudi Arabia, China and Iceland used energy efficiently in 2015, while only Portugal and Iceland, in addition to appearing efficient, did not exceed the average energy emissions per capita and the the difference between emissions caused by their production processes and those caused by their energy consumption does not exceed the sample average. Regarding the relationship between energy efficiency and the inverse of energy intensity, it can be ensured that during the period 1995-2015 together the European countries in the sample are those that show less energy intensity, and therefore probably more energy efficiency, followed of the American countries; then there are the Asian countries and finally the BRICS. The analysis and the results contained in this research could be useful for the correction of trends in some environmental degradation processes.

THE SPATIAL DIMENSIONS OF GREENHOUSE GAS REMOVAL TECHNOLOGIES TO ADDRESS CLIMATE CHANGE: A CRITICAL ASSESSMENT

Nazmiye Balta-Ozkan¹, Adrian Williams¹, Khaled Abdou¹, Pietro Goglio²

¹Cranfield University, United Kingdom. ²Wageningen University, United Kingdom

ABSTRACT

The complex socio-technical challenges associated with meeting the goal of Paris agreement to limit global temperature increase to 1.5 °C create a policy and academic interest for the development of large-scale solutions to remove greenhouse gas (GHG) emissions from the atmosphere. These so-called GHG removal technologies (GGRT), also known as negative emissions technologies (NETs), represent a potential climate engineering method to remove GHGs from the atmosphere through enhancing and expanding existing natural (land or ocean) carbon sinks or creating new sinks and carbon sequestration options (IPCC, 2014; Royal Society, 2018). The environmental performance of GGRTs to date have been analysed using different methods such as material flow analysis and life cycle analysis (for a recent review, please see Goglio et al. (2020)). Life cycle analysis (LCA) is a standardized framework by ISO-14000 (ISO, 2006a, 2006b) and by the International Reference Life Cycle Data System (ILCD) handbook (European Commission, 2010) to assess potential environmental impacts and quantify resource use related to a product or a service their supply chain and entire life cycle of the product, “from cradle- to-grave” (Guinée et al., 2002). Using an inventory of inputs (resources required such as energy and materials) and outputs (products, waste and pollutants emitted) through all stages of the production cycle, it is considered as a powerful tool to assess the environmental performance of GGRTs (Klein et al., 2015; Plevin, 2017). A variant of LCA, consequential LCA (CLCA), takes into account the interdependencies between environmental performance of a technology/ product and the market dynamics. CLCA describes changes in physical flows and it predicts how environmental performance would evolve in response to market changes (e.g. increase or decrease in demand) within the system boundaries (Weidema, 2003). It consists of analysing substituted systems rather than just the actual system under study. Whilst capturing these feedback effects between a technology’s whole life cycle and economy are important, how these interactions evolve as a technology matures is largely ignored. Drawing from innovation studies and using a selection of GGRTs, the aim of this paper is to address this gap. More specifically, the objectives of this paper are three-fold: i) provide a brief description of the contribution of selected GGRTs to address climate change; ii) identify the supply chain of the selected GGRTs, and iii) offer a critical assessment of how supply chain and maturity of these technologies are characterised in CLCA approaches. Taking into account their differences in technology readiness levels, the analysis focus on the following GGRTs: Soil carbonation, enhanced weathering, bioenergy with carbon capture and storage (BECCs) and direct air capture.

**'GONE WITH THE WIND'. ORGANISED CRIME AND THE GEOGRAPHY
OF WIND AND SOLAR FARMS IN ITALY**

Daide Luca¹, Alessio Romarri²

¹University of Cambridge, United Kingdom. ²University of Barcelona, Spain

ABSTRACT

The transition to low-carbon energy sources is considered as one of the key policies to tackle climate change and, to this aim, many European governments have been supporting the transition to renewable energy through subsidies. Growing anecdotal evidence suggests that the generosity of incentives has attracted the interests of corrupt politicians and criminal organisations, as the wind and solar energy sector offer attractive opportunities for mafias to benefit from public subsidies and to launder illegal money via legal business structures. Yet, no academic research has systematically explored the link between organised crime and the renewable energy sector at the local level. Our project aims to fill this gap. The analysis features innovative GIS data on the geo-location of wind and solar farms across Italy and on the local presence of mafia groups. Preliminary findings confirm how, in mafia-ridden regions, local criminal presence is strongly associated with a higher likelihood of hosting at least a plant.

FINDINGS AND LESSONS OF THE PROGREEN RENEWABLE ENERGY ASSESSMENT IN BURKINA FASO

Lin Da

ProGREEN, Burkina Faso

ABSTRACT

In Burkina Faso, communities and industries find many obstacles relating to insufficient supply and access to energy (i.e. 18.83% coverage in urban areas compared to 3.06% in rural areas). These obstacles are intricately linked to the agricultural sector and to water, health, social equity and the economy. Agriculture occupies more than 86% of the population with 34.4% of share in the GDP. Despite its importance in the economy, this sector faces challenges including low agricultural productivity linked to poor water control, poverty of arable land, low rate of use of improved varieties, etc. Approaching these challenges through an Energy, Water and Agriculture Nexus framing is essential for understanding the adaptation and resilience of the agricultural and other sectors in the face of global environment challenges and the energy transition. The Promoting Gains in Renewable Energy (ProGREEN) project with the collaboration of Burkinabe experts is carrying out an in-depth assessment of one facet of this framing, small-scale renewable energy (RE) systems in Burkina Faso. This evaluation aims to identify the factors enabling and constraining factors of the development of RE as well as their impacts on rural communities. The method adopted is based on a participatory approach starting from a literature review of renewable energy projects initiated in Burkina Faso, followed by interviews with project managers and interviews and group discussions with beneficiaries of these projects. In this presentation, I will detail the results of this assessment including how small-scale energy systems such as solar pumping and especially biodigesters support the different Sustainable Development Goals in Burkina Faso in particular through improving food security, community health, gender mainstreaming, job creation in rural areas etc. Enablers and barriers to the spread of renewable energy, notably the political and regulatory framework, the investment costs, the access to finance and the national norms and standards will also be presented.

EXPLORING RENEWABLE ENERGY IN SENEGAL: THE PROGREN WEST AFRICA ASSESSMENT

[Khoudia Kane](#)

Direction des Financements verts et des Partenariats/Ministère de l'Environnement de l'Environnement et du Développement Durable, Senegal

ABSTRACT

Access to energy plays an essential role in the growth and economic performance of Senegal, mainly through its key development sectors agriculture, industry and trade. Agriculture occupies a strategic place in national policy (development of the green economy, support food security, empowerment of young people and women, etc.). However, the sector faces many barriers linked to lack of energy access, poor quality supply, weakness of mechanization, inadequacy of harnessed water, insufficiency of fertile lands, difficulties in accessing improved and resistant varieties, weakness of the value chain, and others. To address these challenges, the government is investing in efforts to promote renewable energy access with the installation of large Photovoltaic (PV) on-grid plants. Decentralized off-grid renewable energy systems are also gaining greater interest. These off-grid operations have contributed significantly to our understandings of integrated systems, which are the focus of the Energy-Water-Agriculture Nexus approach. This framing examines not only access to clean and affordable energy in rural areas, but also looks at impacts of this on agricultural production, food security, income generation and the security of women and young people. In this context, the Promoting Gains in Renewable Energy (ProGREEN) project explores with a multidisciplinary team of Senegalese experts the main factors that revolve around the development of small-scale renewable energy systems as well as the impact of access to sustainable and affordable energy on the livelihoods of communities in rural and peri-urban areas. This presentation will provide the results of the ProGREEN assessment in Senegal, which demonstrates that the interactivity between access to energy (e. g. solar or bioenergy) and water control enhances economic growth in rural areas and substantially improves social equity, the quality of education, the performance of health services, the development of income-generating activities such as fish farming, gardening, the production of forest fruit plants, transformation of agricultural products, and more. The results also show the needs and difficulties encountered by the beneficiaries of the projects as well as the prospects to promote Renewable Energy access, especially in ways that benefit vulnerable groups.

UNDERSTANDING SMALL-SCALE RENEWABLE ENERGY TRANSITIONS IN WEST AFRICA, THE PROGREEN PROJECT

[Mariama Camara](#)

START International, Burkina Faso

ABSTRACT

Despite large untapped potential for renewable energy, a limited supply of affordable and reliable energy remains a persistent barrier to development in West Africa. Indeed, despite substantial investments in fossil fuels, the region has some of the lowest rates of electricity access in the world. Only about 42% of the total population is connected, and in the rural areas that rate is much lower at 8%. In addition, rural populations depend heavily on fuelwood for cooking and lighting. This energy vulnerability negatively impacts local economies and social development including health services, agricultural productivity and food security, control of water, agricultural value chains, youth and women empowerment, etc. Knowing the essential role energy plays for economic growth and performance and social equity in the region, countries are increasingly implementing efforts to attain international targets like the Paris agreement, as well as regional policy objectives such as the Regional Roadmap, ECOWAS Renewable Energy Policy (EREP), National Renewable Energy Action Plans (NREAPs), National Energy Efficiency Action Plans (NEEAPs), and National SE4ALL Action Agendas. The ECOWAS Centre for Renewable Energy and Energy Efficiency (ECREEE) was also created to support governments in developing and implementing their national engagement towards 2030. As concrete actions to meet this agenda and objectives, countries like Senegal and Burkina Faso installed large scale solar plants to increase the share of renewable energy in the national energy supply. To reach populations in remote areas, a focus has also been placed on the promotion of small-scale renewable energy with the hope of reaching vulnerable groups and bringing significant changes in the livelihoods of local communities. In this context, the Promoting Gains in Renewable Energy (ProGREEN) project has been undertaking an assessment of barriers and enablers to more widespread transitions to renewable energy in Burkina Faso and Senegal and of development impacts of such transitions. In this presentation, I will provide details on the ProGREEN project and an overview of the small-scale renewable energy transitions in both countries.

**DETERMINANTS OF MANUFACTURING MICRO FIRMS' PRODUCTIVITY
IN ECUADOR. DO INDUSTRY AND CANTON WHERE THEY OPERATE
MATTER?**

[Carolina Guevara](#)

Department of Quantitative Economics, Escuela Politécnica Nacional, Ecuador

ABSTRACT

This study aims to identify the productivity determinants of manufacturing micro firms, emphasizing on regional and industrial factors. A cross-classified multilevel model is employed using the Economic Census of 2010 from Ecuador. Results evidence that the heterogeneity of the total factor productivity of micro formal firms of the manufacturing sector is mainly due to differences across firms in 90.1%. The remaining variation of the TFP is explained to a larger extent by the industrial context (5.8%) than the geographical context (4.1%). Among firm characteristics, information and communication technologies, credit and training are important drivers of productivity. Despite of this, very few micro firms use internet, have credit access or engage in training in Ecuador. Moreover, micro firms benefit from agglomeration economies derived from specialization, diversity and density that they themselves generate.

SUBNATIONAL POVERTY DYNAMICS IN DEVELOPING COUNTRIES: THE CASES OF ECUADOR AND URUGUAY

Obaco Moises¹, Nicola Pontarollo², Rodrigo Mendieta³

¹Universidad Católica del Norte, Chile. ²Department of Economics and Management University of Brescia, Italy. ³GIER, Universidad de Cuenca, Ecuador

ABSTRACT

This paper analyses subnational dynamics of a novel composite indicator, called Local Multidimensional Poverty Index (LMPI), accounting for multidimensional poverty at subnational level in Ecuador and Uruguay between the last two census, 1990 and 2010 and between 1996 and 2011, respectively. As a first step, using censuses microdata, we construct the LMPI at municipal level for both countries. Then, through a set of tools like probability transition matrix, Moran's I and Moran scatterplot, spatial probability transition matrix and spatial regressions, we explore the spatial and time dynamics of the LMPI. Results indicate that, compared to Ecuador, Uruguay is initially in a better position in terms of LMPI. However, Ecuador achieved a generalized reduction of LMPI during the period of analysis, reaching the levels of Uruguay. Probability transition matrices point to a convergence toward low levels of LMPI for both countries, while spatial probability transition matrices based on Moran scatterplots highlight a tendency toward clusters of municipalities with low levels of LMPI. Finally, divergence due to spatial spillovers is observed for Ecuador, while in Uruguay convergence is due to a leapfrogging phenomenon.

POST-EARTHQUAKE SHORT-RUN LABOR INCOME SHIFTS. WHAT HAPPENS WITH THE DISTRIBUTION OF WAGES AFTER AN EARTHQUAKE?

[César Andrés Mendoza](#)¹, [Benjamin Jara](#)²

¹Universidad de Cuenca, Ecuador. ²Gran Sasso Science Institute, Italy

ABSTRACT

In this article we explore whether a strong earthquake (Manabí and Esmeraldas provinces, Ecuador, April 16th, 2016) had a distributional effect in labor income. We use survey micro-data and exploit the exogenous nature of the shock with an empirical strategy based on a combination of matching, difference in difference (DD) and quantile regression (QR) methods using three earthquake intensity measures (Peak Ground Acceleration, PGA; Peak Ground Velocity, PGV; and Modified Mercalli Intensity, MMI). We find a short-run distributional effect for the poorest workers in the most seismic areas. Compared to our control group, workers located in the lower income percentiles in the most affected zones earned more in the short run (between 17.6 and 20.3 percent in percentile 0.1, and 15.5 and 19.4 percent in percentile 0.2). Our results suggest that although some disasters could create opportunities for poorest workers, the assumption that proper public policies and support networks do exist is strong, and there is a need for specific policies to avoid gender gaps and help the most vulnerable workers in a disaster scenario.

**OIL ROYALTIES AND MULTIDIMENSIONAL POVERTY IN ECUADOR:
HAVE THE EXTRACTION REGIONS IMPROVED THEIR LIVING
STANDARDS?**

ABSTRACT

In this work we check for the causal effect of the introduction of a regulatory change on oil royalties happened in 2008 in Ecuador. This law established conditionalities on the transferences of money to extractive municipalities, that have to spend these resources in sectors such as education and public services, which should reduce unsatisfied basic need poverty. Our estimates, based on a difference in differences approach, are robust to different specifications and show a lack of positive effects in the improvement of education, provision of public services and poverty reduction. These results have various public policy implications related to the quality of local and national institutions, the way in which the oil resources are management and the population audit of way in which the local authorities spend this royalties.

ABSTRACT

Currently, companies are changing from a concept of income generation just for their own benefit, to one where the generation of economic development promotes improvements in the quality of life and the environment of a community where these are located. These companies with a social purpose have stood out for using the force of the market to solve problems faced by humanity such as education, health, economic and environment. This type of companies that stand out have a B certification. Type B companies have a very clear mission of generating a long-term impact that contributes to development in urban and rural areas. The objective of this article is to present the experience of an organization that works with artisan warpers and represents an opportunity for the contribution of sustainable community development in Mayapan, Yucatan. For this research a literature review was conducted. The purpose of this literature review was to find concepts related to understand the empirical approach of a B company in regards to sustainability. Four thoroughly interviews were carried out to analyze how B companies have been able to respond to social, economic and environmental demands, in order to demonstrate their viability as a sustainable alternative, in a world where social and ecological problems predominate. The complexity of reality, detail and context of Cielo Hamacas as a case study was examined from a systemic perspective. The results revealed that there is still a lack of actions aimed at a good economic and social development of the group of community warpers. So, it is necessary to promote greater economic and education capacity of the stakeholders that participate in conjunction with this type of companies, since their culture and social level do not make them see themselves as main actors of their communities development. For this reason, the transition to a new sustainable rationality of doing business is essential. Regarding the environment, the B company has good practices, and these have been reflected in the work that leaders and artisans are doing to take care of their environment.

KEYWORDS

Community development, Social enterprise, Socio-environmental impact, Sustainability, Type B enterprise.

1. INTRODUCTION

Community development has achieved a strategic scope in different nations and regions, acquiring an important role as a means of participation in the conduction of social and economic development, as well as a unifier of different actors to carry out plans to achieve social change (Pérez, 2016). This is developed on a medium and long-term time scale, it is not a program subject to a closed planning in time but to a process, understood with a pedagogical sense that aims to become an element of self-learning, of a citizenship school and democracy, with a vision of continuous transformation in the sense of improving the living conditions of citizens (Camacho, 2014).

Currently, both the government, civil organizations and some companies have designed and executed plans for community development with the aim of reducing poverty, generating production and income alternatives in order to promote comprehensive and sustainable development (Rosales, 2012). In our country public policies have only provided partial and short-term solutions to the socio-environmental problems that are experienced in the communities (Vázquez, 2010).

The social, economic and environmental crisis that humanity is experiencing, has made several people feel disillusioned that the financial profits generated by their companies have not been able to improve people's quality of life, address

social problems, improve conditions environmental, among others (Deloitte, 2018). This is why several companies have moved from a traditional model to one that can respond to social and environmental problems.

Today, many organizations are no longer evaluated on financial metrics; on the contrary, they are judged on the basis of their relationships with their workers, clients and communities, that is, on the impact they are generating on society (Deloitte, 2018). To achieve this, it is necessary to focus on the perspectives and evaluations of the reality of the region to identify the different meanings of the various actors who live the same situation, the main reason, as well as the social relations that are important, with the purpose of planning comprehensive, solid and long-term solutions that seek social, economic, cultural and environmental satisfaction, among others (Vázquez, 2010).

Businesses with a social purpose can also contribute to the community development of a region or country and positively impact rural communities. Therefore, the purpose of this article is to present the experience of a company with B certification for the contribution of community development in Yucatán, through a literature review to understand the empirical approach of a B company in regards to sustainability, and four thoroughly interviews that evaluates the three aspects of sustainability (social, economic, and environment). For this reason, it was necessary to know the experiences and perceptions of the artisan leaders, mayor and owner of the company; with the aim of analyzing how the company has contributed to the economic and human development of the weavers in the town of Mayapan.

2. LITERATURE REVIEW

2.1. Social enterprise

Alvarado, Auxiliadora and Agafanow (2016: 14) define a social enterprise as one whose mission is aimed at addressing social problems and meeting the needs of the population, through the provision of goods or services of general economic interest. They are financially sustainable entities and their profit margins are reinvested entirely or mostly in the production of goods or services for a disadvantaged population. Likewise, Deloitte (2018) mentions that it is an organization whose mission combines the growth of income and obtaining benefits with the need to respect and support its environment and the network of stakeholders.

Díaz, Marcuello and Marcuello (2012) indicate that the definition of social enterprise requires a multidimensional approach in which traditional elements of the enterprise and the social economy are related that affect the social objective, economic motivation and the management models. Similarly, the European Commission (2013) mentions that the main objective of a social enterprise is to achieve a social impact, beyond generating benefits for owners and shareholders. It operates in the market through the production of goods and services in an innovative and entrepreneurial way, which uses surpluses to achieve these social objectives, and it is managed by social entrepreneurs in a transparent and responsible manner. In the same way, it tries to help civil society and business organizations to increase their capacity to produce goods and services, or to serve their own beneficiaries (Valor, 2013).

The rise of different types of social enterprises requires a determined focus on building social capital through the participation of diverse stakeholders, creating a sense of mission and purpose throughout the organization, and devising strategies that address social expectations; which is related to reputation, relationships and the success or failure of a company (Deloitte, 2018).

The social enterprise sector in Mexico, known locally as the social economy, is relatively well established. Furthermore, the Mexican higher education system plays a key role in promoting social change; being one of the few countries that has a compulsory service component for students enrolled in higher education (British Council, 2016). However, the country lacks a consensual concept among different actors, and the use of synonyms is frequently. In this regard, the National Institute of Social Economy (2013) pointed out *that in practice it is very complex to have a worldwide definition of social enterprise, largely because the legal figures vary from one country to another and for different reasons, although it is not the same as cooperatives* (Cited in Conde, 2016).

Social enterprises have arisen long ago from a cooperative tradition; however, Mexico strongly advocates social entrepreneurs, innovation, and earned income strategies as solutions to social problems. In turn, more Mexican non-governmental organizations are changing to a hybrid business model to obtain financial sustainability through the creation of income streams (Wulleman and Hudon, 2015).

2.2. Type B company

Company B is an emerging phenomenon. It is known as hybrid company or companies with a purpose, the result of the convergence process among various actors that seek to use market instruments to build goods of public interest (Abramovay, Correa, Gatica and Van Hoof, 2013). A company B is one that is distinguished by two essential characteristics: a) it measures the social and environmental impacts of the entire company, using a rigorous evaluation that is Impact Evaluation B; and b) it is committed in its corporate constitution contract, in order to achieve positive impacts for society and for nature, while offering financial results to its shareholders (FOMIN, 2017). Impact evaluation

B measures the general impact of a business on all stakeholders (workers, suppliers, customers, community and environment), through an online platform (Troncoso, 2014).

This new business model is promoting the formation of an emerging sector or fourth sector that does not pretend to be another niche within the ecosystem, but to transform the conception of business success. The so-called fourth sector incorporates the private sector, regular participation in the markets; from the public sector, the nature associated with the generation of public value; and from the social sector, the orientation to its mission (FOMIN, 2014). This type of company is clear about its objectives, mission and vision, constantly contributing to build a new economy, where social and environmental issues correspond to the main axis and the way forward when making business decisions (Tapia and Zegers, 2014).

Being a B company is not determined by category, size or turnover; it is a type of company committed to generating change, considering consumers, workers, the community, investors and the environment in decision making (Bianchi, 2016). Likewise, they work together to achieve a unified goal: to redefine business success with the aim of companies competing not only to be the best in the world, but also the best for the world (Honeyman, 2015).

In the FOMIN report (2014), the triple impact that these companies pursue is:

1. Solve social and environmental problems with the products and services they sell, and also through their professional and environmental practices, their relationship with the community, suppliers and different stakeholders.
2. Pass a rigorous certification process that validates compliance with minimum performance standards, the exercise of its tasks with transparency, through the publication of its results and the impact of its social and environmental results.
3. Incorporate legal modifications to protect its mission or business purpose in which the public and private interest are combined.

B Companies matter because they are a global movement that seeks to redefine the concept of business success, so that society can enjoy shared and lasting prosperity. As a result, they have made progress in reducing poverty, building stronger communities, creating good workplaces, and restoring the environment for generations to come (Honeyman, 2015). In addition, being registered and certified as a B company is important to impact investors in the commitment of a corporation that creates social impact, as well as profits (Fierro, Miller and Johnson, 2016).

Today, there is a community of more than 3,000 certified B-companies in 70 countries and more than 130 industries focused on redefining business success. In Latin America, countries such as Chile, Colombia, Argentina, Brazil, Uruguay, Peru, Ecuador, Mexico and Paraguay have already joined this movement (Bautista y Cámara, 2018). In Mexico there are more than 50 B companies that cover different business sectors, whether consulting, restaurants, electronic commerce, product sales, media, and crowdfunding, among others.

2.3. Community development

To understand the concept of community development, it is first necessary to recognize what the notion of development and community refers to. Oteiza (1983) defines development as a process of social change based on a creative and participatory effort of the peoples themselves, and on the mobilization of the resources at their disposal, in order to eliminate poverty and marginalization, overcoming exploitation and internal or external socio-political domination and the continuous unfolding of the human personality through its own expression (Cited in del Moral, 1991: 153). Within this construction, the conception of the centrality of the subject that is claimed as the guiding principle of any development project is basic, so, in this approach what is important is people and not things; for a long time, the predominance of the economic vision of development has led to the forgetting of the human, cultural and environmental aspects that are now trying to recover (Carvajal, 2011: 30). Hence, Alguacil (2000) emphasizes the need to refer to the term as human development, sustainable development, local development, community development, among others; with the idea of highlighting those dimensions of development that are considered fundamental to be able to speak properly about it (Cited in Camacho, 2014: 207).

Regarding the concept of community, Marchioni (2002) mentions that it is a specific territory, with a specific population, resources and it has certain demands. In the same way, Ander-Egg (2005) points out that it is a group of people who inhabit a delimited geographical space, whose members are aware of belonging or identification with some local symbol and that they interact with each other intensely, operating communication networks, interests and mutual support, in order to achieve certain objectives, satisfy needs, solve problems or perform relevant social functions at the local level (Carvajal, 2011: 12).

Camacho (2014: 209) defines community development as an intervention method that incorporates all the agents that make up the community, establishing processes of participation and articulation between the population and the institutions that, enhancing a pedagogical process, and the participatory capacities of the actors and of the mediating

structures, it is then possible to pursue common and predetermined objectives to improve the socio-economic, social and cultural conditions of the communities, which the results can be evaluated. Likewise, Lopez and Cruz (2003: 60) point out that it is a process that combines the efforts of the inhabitants of a region, interest groups and the government to improve the economic, social and cultural conditions of the communities, through the diagnosis, plan, execution and evaluation of programs for this purpose. Finally, Nogueiras (1996) presents some characteristics that define community development: a) represents an educational process destined to achieve qualitative changes; b) a technique of social action, since it requires the intervention or collaboration of various agents; c) aimed at those communities that are in a situation of insufficient use of resources; d) a primary objective is to achieve social well-being and to improve the quality of life of the community; e) requires the voluntary, conscious and responsible participation of individuals in solving problems (Cited in Carvajal, 2011).

2.4. Sustainable development

Sustainable development or sustainability has two approaches. The first approach is ecological sustainability, which the authors Pearce and Turner define as ensuring that substitute products are accessible as non-renewable resources become physically scarce, and means ensuring that environmental impacts resulting from the use of these resources are kept within the support capacity of the earth to assimilate them (Foladori and Tommasino, 2000). In this approach, only the relationship between human beings and nature is discussed; social relationships are not included.

The second approach to sustainable development is social-economic sustainability. Social-economic sustainability is commonly considered an increase in population and poverty (when speaking of poverty, the authors also refer to hunger, health, lack of housing, drinking water, education, among others). These problems give a social inclination to sustainability. Poverty generates environmental problems because the poor do not have the resources for a sustainable productive strategy, or because the population growth that the poor promote implies a greater demand for resources and pressure on ecosystems (Foladori and Tommasino, 2000).

In this research, companies can use the Sustainable Development Goals (SDGs) as a general framework to shape, direct, communicate and inform about their strategies, goals and activities, which allows to capitalize on a series of benefits such as: 1) Identifying future business opportunities, and can offer innovative solutions and transformative change; 2) enhancing the value of business sustainability, the SDGs can reinforce economic incentives for businesses to use resources more efficiently as externalities become increasingly internalized; 3) strengthen relationships with stakeholders and stay up to date with policy development, companies that align their priorities with the SDGs, can strengthen their commitment to customers, employees and other stakeholders (SDG Compass, 2016).

2.5. Context characteristics: Mayapan

For this research, it was necessary to know the perspectives and experiences of the artisan leaders who have worked with the company, and for a convenience of the company, the Mayapan community was chosen. The municipality of Mayapan (located between parallels 20 ° 26 '- 20 ° 31' N and 89 ° 09 '- 89 ° 15' W) has a population of 3,700 inhabitants and 2,785 people over five years of age speaks the Maya language (INEGI, 2015). The main craft activity is hammock weaving. Furthermore, 89.80% of the total population suffers from poverty and the rest suffer from vulnerability due to social deprivation. On the issue of social backwardness and marginalization, it is classified as high and very high, respectively. In addition, the deprivation index is alarming in terms of access to social security and basic services in housing (H. Ayuntamiento Mayapan, 2015). Due to their levels of marginalization, the government agencies responsible for health and social development have applied various programs and projects to improve the social and economic conditions of the population, including the construction of roads and infrastructure for the community, alternative work options and programs focused on child nutrition and reproductive health (Robles, 2009).

3. METHODOLOGY

The unit of analysis for this research was a type B company that works with hammock weaving artisans in different communities and the population studied is the Mayapan community, its main activity is hammock weaving (H. Ayuntamiento Mayapán, 2015). Two methodological instruments were used, literature review and deep interviews. The sample was determined in a non-probabilistic way, the samples are not representative by the type of selection, they are informal or arbitrary (Pimienta, 2000). The different study actors for this research are described:

- An interview was conducted with two community artisan leaders from Mayapan and Chumayel.
- An interview was carried out with the general director of the company.
- An interview was conducted with the municipal mayor.

The reason for interviewing these actors was to learn about the company's perspectives and experiences towards sustainable community development through the hammock weaving activity. In addition, the interview with the owners was to find out their opinions of the impact they have generated in the community.

The information obtained was transcribed using a word processor. Subsequently, all the information was manually analyzed to examine similar and different opinions; where a classification and interpretation of the results was obtained. Then, we proceeded to create the aspects based on sustainable development in order to identify if the company contributes to the community development of the town. It should be noted, the economic aspect is within the category of social sustainability.

4. RESULTS

The results are presented for each of the three aspects of sustainable community development through the opinions of different actors who participated in the research.

4.1. Social and economic sustainability

It was observed some social and economic problems in the communities. This was according to the opinion of the municipal mayor:

With regard to the social is the lack of employment; it had to be managed before the state government and some civil associations training people, such as temporary jobs (Mayor)

Lack of employment is one of the social problems that can trigger other stronger complications in communities. Therefore, the company by providing a source of work to the artisans can reduce the difficulties in which they live and preserve an artisanal technique that has been transmitted from generation to generation. In this regard, the mayors mentioned the importance of hammock weaving crafts:

It is of great importance, today there is not so much work in the field. So, the peasants are dedicated to making hammocks. Practically, in most of the houses of the town they are dedicated to making hammocks as a source of extra income. It is quite a lot because people live on it, but not in its entirety. This is due to the cost that it has, speaking by hand, people suddenly no longer want to continue concocting and they better go to work in the city because they earn more, women work as domestic servants and men as barns, bricklayers or porters. I feel that attention and resources must be given at the time to encourage artisans, because if we do not do it, this traditional practice will be lost little by little (Mayor).

Faced with this situation, the social and economic impacts that one of the owners of the company has seen in the communities are:

In the social part, the first study we carried out, showed us that the warpers feel more financially secure, finishing a hammock and there is an immediate and cash payment. They spend more time with the family because they do not have the need to go to work or to look for work elsewhere or to travel to the city. We are sponsoring the local baseball team, we started to create a sense of community. Also, our environmental actions begin to influence some leaders, there is one who no longer uses plastic bags and recycles. In the economic part, we make loans without interest so that artisans acquire equipment and tools, this helps them to be more efficient (Owner).

In addition, the activity carried out by the company when employing warpers (especially women) is commendable and of the utmost importance for the ancestral warping knowledge to continue to be preserved. In addition, some artisans who were interviewed (45%) mentioned that they want to teach their children hammock weaving; likewise, a leader of artisans expressed himself as follows:

It is important to teach warping to subsequent generations; for my part, I am going to teach my daughter to weave (Artisan leader).

Mayor is happy with the work conducted by the company in the community, expressing how the company contributes: *They seek the participation of all: it involves society, it takes women and their coexistence very much into account. Above all, it provides sources of work. Also, company helps the community baseball team a lot. It helps us by paying fair prices to the artisan and giving them loans, which is something that would help a lot (Mayor).*

In turn, the owners of the company have observed a positive impact on the artisans of the different communities:

We have improved in the standard of living and in educational matters, especially in the children of the warpers. Our impact is very focused on women; it is only invested in women because they spends and will spend in her family. In addition, we have leaders who finance a truck and end up paying for it.

From one study, it was perceived that the warpers feel more financially secure, finishing a hammock and there is an immediate and cash payment. They spend more time with the family because they do not have the need to go to work or to look for work elsewhere. We are sponsoring the local baseball team, we started to create a sense of community (Owner).

Additionally, a large part of artisans do not allocate a portion of their income to savings, which is why few initiatives at the family or community level are difficult to achieve. But, they feel happy with the work they do and belonging to a group of artisans.

On the other hand, artisan leaders expressed how their well-being and that of their family has changed with the arrival of the company in the communities:

In the family the economic income has improved. For artisans, it is a complement or help. In social welfare, not much has been done, there have not been scholarships or health campaigns, only missions have been carried out where women arrive and play with children (Artisan leader one)

Regular, when there is work there are changes. Even so, I am very satisfied with the changes that have taken place with the arrival of the company in the community (Artisan leader two).

Also, the artisan leaders expressed what is needed for the company to improve:

If there were more requests, that would help a lot (Artisan leader one).

Training for artisans, distribute a pantry and have the price of the hammock raised a little, so that the artisans feel more motivated to work (Artisan leader two).

In a similar way, the company expressed their opinion about the improvement of their work.

The company contributes to the 2030 Agenda because they work with 7 of the 17 sustainable development goals: 1. End of poverty: generating sources of employment in the most marginalized areas of the state; 4. Quality education; 5. Gender equality: gender equality is promoted, with special emphasis on women; 8. Decent work and economic growth: artisans work from home, offering favorable working conditions. With the leaders we promote economic development, since they are like small entrepreneurs; 10. Reduction of inequalities: holistic business model, transforming the artisan product into a product that can be massively consumed; 12. Responsible production and consumption: the only hammock company certified as Fair Trade and company B; 17. Alliances to achieve the objectives: there are alliances with local institutions, governments, health institutions and non-governmental organizations (Owner two).

In the same way, the mayor expressed in what way the artisan activity contributes to sustainable development:

Because through handicrafts people have capital or something to survive, even if it is little, but they seek to have one more resource to help the family.

I think that if our Yucatecan countryside, our smallholders, our artisans had the way to work in an organized way, to have resources and to have a market, we would be a municipality everywhere that we would not have to depend much on the income of others, since we would produce what we consume and we would give what we spend (Mayor).

4.2. Environmental sustainability

There are some environmental problems faced by the community. For instance,

Environmental problems have to do with urban solid waste, there is no culture of classifying garbage. We have the problem with our own culture and society that does not lend itself to working with the municipality, with more that we have a free collection service but people go to the periphery and leave their garbage bag; as a result such place is a source of infection that can expand (Mayor).

In this regard, mayor has carried out garbage collection campaigns for people to clean their houses and their surroundings. Mayor expressed himself as follows:

If society is not geared to the government, the change will be minimal. I think we should change that way of thinking and start with our young people, I feel that they are the base right now; If they change their way of thinking, the country can also change. But if we do not instill good values in him, we will continue the same (Mayor).

The actions carried out by the company in favor of the environment, such as stopping the use of plastic bags, PET bottles and Styrofoam cups; have influenced community leaders to change their attitude towards caring for nature:

I have seen how the company is taking care of the environment, like when they use biodegradable bags. Also, I always take my sabucan¹ to the store so they don't give me a plastic bag (Artisan leader one). I avoid wasting water and in the house I separate organic from inorganic waste. Also, the rest of the meals I use to feed my animals (Artisan leader two).

In addition, the artisan leaders mentioned that most artisans avoid wasting water, recycle PET and cardboard, reuse an object, and use the rest of the food for animals and plants. On the other hand, the owner talked about what the environmental impacts of the company's future projects would be:

Our processes are very friendly to the environment, since no water or any pollutant is used. We try to use the least amount of non-recyclable products in our final product. In addition, we are looking at the possibility of a Leed Certification for the new factory. With the new plant that was built, it is intended to reforest the areas where trees were removed for the construction of the factory, with the help of some environmental foundations. As well as getting rid of the use of plastics and using solar panels (Owner).

In general, most of the people are concerned about caring for the environment and consider, they consider that the hammock warping activity does not contaminate very much the environment because they reuse the scraps of yarn that are left over from the warp, to make candles or to make moorings.

5. DISCUSSION

Community development has the objective of improving the social, economic, cultural and environmental conditions of a population. Currently, it is viewed as a way to sensitize and motivate people to participate in solving their problems (Lopez and Cruz, 2003). This is consistent with the purpose of a Type B and social enterprise, which is to generate an impact that benefits stakeholders by solving social and environmental problems so that society can enjoy shared and more lasting prosperity (Honeyman 2015; European Commission, 2013). From this study, it was observed some needs in the community such as lack of employment, low level of education, vulnerability of women, low access to health services and problems with garbage.

It can be seen that community development aims to improve economic, social and cultural conditions through different actors (organizations, government, companies and society) for a better quality of life of the community and the empowerment of the inhabitants. An example is the type B company as a member of the Fair Trade Federation, committed to the economic and human development of the artisan communities in the region. This company promotes the empowerment of women as heads of families and also as entrepreneurs and an instrument of change in their communities. They have a business model with a holistic component that provides fair jobs and helps to improve living conditions.

Vázquez (2010) emphasizes that proposals to achieve community development must be based on local perceptions in order to plan comprehensive, solid and permanent solutions based on the determination of the causes of problems, and their consequences in different areas of life community; the actors must be involved and able to transform current conditions; and the participatory construction of long-term strategies that seek to satisfy material, cultural, spiritual, recreational, and environmental needs, among others.

However, the company needs to have a significant impact on the economic side. This is because the warpers feel that the payment for hammock warping is very little; therefore, they do not cover their health, basic services and expenses. Arvizu and Borbón (2017) point out that the community where a social enterprise is installed plays an important role, since its purpose is to increase the utility and benefit of those involved in the process to create a spatial and cultural link, in a way that a joint value creation is generated between the different groups that make up the company and an equitable distribution of such maximization.

In a FOMIN report (2014) emphasizes that the purpose of type B companies is to create a favorable environment for solving social and environmental problems. This could be seen in the impact that the company has had on job satisfaction issues, the communication with the leader and the unity that exists among the artisans is favorable. Above all, in responding to a problem that affects most communities, which is the lack of employment.

On the environmental side, the company has shown interest in this issue. The actions carried out in favor of the environment such as stop using plastic bags and use biodegradable bags to deliver hammocks, zero disposable products, as well as the use of a water purifier. This has influenced the way of thinking of some artisans and they have adopted some conservation practices that they carry out from home. In this regard, Honeyman (2015) indicates that supporting the environment can help retain both artisanal and professional talent, as well as establish more lasting relationships with its suppliers and increase trust with consumers.

Business, for better or for worse, is one of the most powerful forces on the planet. When companies are positive they promote collaboration, innovation and mutual well-being, and help people to live more vibrant and fulfilling lives. When they are negative, they can lead to significant social and environmental damage (Honeyman, 2015). Alonso (2013) mentions that to achieve a change in communities, it is necessary to assume people as subjects capable of achieving the change they need on their own. This implies promoting symmetrical links between people and human groups, that is, fostering union and meeting, so that this translates into a better quality of life (Cited in Pérez, 2016).

6. CONCLUSIONS

Companies with type B certification represent an alternative to solve the economic, social and environmental problems that society is currently experiencing; as well as support to achieve sustainable community development. But, it must be taken into account that certification is a change of mentality to redirect businesses towards the concern for the well-being of people and the environment, that is, increasingly sustainable.

The company's activities towards achieving sustainable community development in the Mayapan community are still incipient. Actions are needed to achieve good economic development, to improve the quality of life and to generate changes in the perception of caring for the environment in community artisans. Also, it is important that the company

establish short and medium term goals; in turn, observe that these results are aimed at achieving a significant impact on the social, economic and environmental aspects of the Mayapan community.

In the economic aspect, an analysis is required for the possibility of making changes in the income received by the warpers, since the majority are not satisfied with it, and it is not enough for basic and health services. Once the above is resolved, the social impact may increase. In the environmental aspect, it is necessary to raise awareness of how to manage the garbage. Finally, type B companies can contribute to sustainable community development, influencing a systemic and paradigm change at the local level and making it possible to scale globally.

THE ROLE OF PUBLIC MANAGEMENT IN THE PROMOTION OF INTELLIGENT TOURIST DESTINATION: THE CHALLENGE FOR COZUMEL, QUINTANA ROO, MEXICO

Alex Adiel Cano Herrera, Crucita Aurora Ken

University of Quintana Roo, Mexico

ABSTRACT

The smart tourist destination (STD) model has become a tool with advantages to analyze the role of public management of tourist destinations. This is because the model highlights the situation of sustainability of the tourist sector, its adaptation to the digitization and the progress towards connectivity. The STD model, in addition to promoting the development of the destination, it endorses inclusiveness and other dimensions, such as benefits to the local population and the role played by public management in its establishment. Through a compilation of documents such as plans, programs and regulations, we analyze the STD model and dimensions as applied in the tourist island of Cozumel, Quintana Roo, Mexico. This study intends to capture the current panorama of the smart model, at the federal, state and municipal levels in Cozumel. This allows us to point out the challenges that this island faces as a tourist destination in its route to becoming a STD. Above all, we measure the performance of public management in achieving this objective. We perceive that the challenges for the public administration is great due to the absence of a plan to promote, expand and to include the population at large, through actions that lead to the island's classification as a STD.

GENDER BASED POLITICAL VIOLENCE AGAINST WOMEN IN MEXICO: A MULTIDISCIPLINARY RESEARCH MODEL PROPOSAL

Serena Eréndira Serrano Oswald

CRIM-UNAM, Mexico

ABSTRACT

Gender Based Political Violence against Women is one of the main forms of political discrimination. It violently affects women, obstructing social justice for all and hindering parity democracy. In Mexico, the Constitution and the legal framework has been greatly reformed over the past two decades in order to enable women to fully exercise their political rights and have formal power in the political arena. Results are visible, if we consider that Mexico went from having 14 to 49 per cent of female representation in federal chambers from 1995 until 2018. In April 2020, the federal law of Gender Based Political Violence against Women was approved.

On September 7th, 2020 and until June 6th, 2021, in the midst of the Covid-19 pandemic, the biggest and most complex electoral process in Mexico began. IT will be the first electoral process under the federal law sanctioning Gender Based Political Violence against Women. It includes 95 million registered voters with 21,368 elected positions in dispute and elections on almost half of the states that make up the republic. For the first time in history, gender parity has been established by a strict quota system at municipal, state and federal level. This has exacerbated all forms of political violence, political violence against women and gender based political violence against women.

Gender Based Political Violence against Women is one of the least researched emerging topics in the social sciences, and it is mostly absent in regional science debates. It is relevant to consider that the 2017-18 electoral process was the most violent in Mexican history (in terms of total aggressions and homicides), narcopolitics have become a defining feature of Mexican politics, and the present Covid-19 crisis has exacerbated long-lasting inequalities and intersectional violence. It follows an in-depth study of Gender Based Political Violence against Women in Mexican history, encompassing a research team of over twenty academics primarily developed and led by the presenting author. The paper seeks to discuss a triangulated multidisciplinary research methodology proposal, with quantitative and qualitative indicators, to research the prevalence and impact of Gender Based Political Violence against Women in the 2020-21 electoral process with a transversal social justice and regional lens, presenting some preliminary research findings.

THE SYSTEM OF SEAPORTS IN THE SOUTHERN AFRICAN CONE: HINTERLANDS AND SHIPPERS CHOICES

Jean-Claude Thill

University of North Carolina at Charlotte, USA

ABSTRACT

Ports have historically been critical points articulating shipping and commercial activities between countries and regions. Their importance today is no less than it was centuries ago, but it may have morphed to some extent. Today, ports should not be regarded as isolated assets, but as nodes on shipping networks that may stretch over long distances, across oceans and supporting the global trade activities of territories. Africa, and Southern Africa in particular, has attracted the attention of the international business community as a frontier with great opportunities. Infrastructure is known to be rather deficient and widely believed to hold back the economic potential of the region. Transportation infrastructure has been a particularly weak in this respect. In this paper, we study the port system of the Southern African Cone. We aim to identify the hinterland of ports of the region for the purpose of export to another world region. Focus is on the capacity to handle containerized freight in particular. The analysis includes the econometric modeling of port choices by shippers seeking to export from the region. The model is estimated on data reflecting current logistical operations and trade realities. Factors include ports infrastructure elements, landside transportation systems, oceanside connectivities, and barriers associated with the crossing of national borders. A disaggregated choice model is used to this effect. Results underscore the core drivers of port choice in the region and are intended to serve as a decision-support tool to evaluate the possible responses of the freight transportation systems of the region to alternative future investment scenarios and enhancements of the level of service on a geographically disaggregated basis.

SUBWAY EXPANSION, JOBS ACCESSIBILITY IMPROVEMENTS AND HOME VALUE APPRECIATION IN FOUR GLOBAL CITIES: CONSIDERING BOTH LOCAL AND NETWORK EFFECTS

Adriano Borges Costa, Camila Ramos, Siqi Zheng

MIT Center for Real Estate, USA

ABSTRACT

We explore the potential of incorporating accessibility analysis in studying the impact of subway expansions on the real estate market. We first demonstrate that using increases in accessibility to firms as a continuous treatment variable instead of its binary alternative, the station-dummy approach, yields better goodness-of-fit in a quasi-experimental econometric analysis. We show that the dummy treatment variable consistently reported overestimated coefficients of impact for new subway stations. Furthermore, accessibility measures allow the exploration of impacts beyond the local effects around new subway stations, shedding light on network impact that has been largely overlooked in the literature. To provide greater external validity to our results, we apply the same analysis to the cities of Santiago (Chile), São Paulo (Brazil), Singapore, and Barcelona (Spain) and explore the common results. We argue that the integration of urban economics and transportation analysis can bring innovation to the empirical approach commonly adopted in the literature, and the use of accessibility measures in causal empirical studies on transportation impacts can produce more robust and comprehensive results and capture the nuanced spatial heterogeneity effects.

EMISSIONS IMPACT OF PORT ACTIVITIES ON AIR QUALITY AND PUBLIC HEALTH: EVIDENCE AND IMPLICATIONS FOR ENVIRONMENTAL JUSTICE

[Yeonkyeong Park](#)
Cornell University, USA

ABSTRACT

Over the past decade, many studies have explored various spatial dimensions of long-term emission impacts by pollutants and discovered associations to public health. However, there has been lack of scholarly attention on the environmental justice in those studies. Using the case of the Port Authority of New York and New Jersey, this paper aims to identify the spatial footprints of long-term emissions from port industrial activities on the ambient air quality of near-port communities, their expected outcomes on the public health, and implications for environmental justice.

Assuming a general higher preference to a cleaner environment for a higher quality of life, it is hypothesized that the residents living around the port areas of New York and New Jersey are those whose income levels are below average compared to other neighborhoods. Ports, as public infrastructure, are accountable for upholding principles of environmental justice and to protect marginalized and vulnerable groups of people for their fundamental right to live in a clean and healthy environment. While emission contributions vary by pollutants and locations within the states, PANYNJ's biggest contribution in local air pollution comes from its nitrogen dioxide emission in the Union county, NJ, accounting for 16 percent of the entire local air emissions in the New York and New Jersey area. Hypothetically, it is explained by the port truck operations from the three biggest terminals within the Union county. However, can the inference be scientifically proven? How can the trajectory of long-term emissions be spatially illustrated? What are the implications for the health outcomes of local communities? What does the spatial distribution of long-term port emission explain about environmental justice?

In terms of its research methodology, the paper conducts spatial analyses to test the hypotheses using the following multiple maps: 1) air pollution concentration map, 2) socioeconomic demographic map, and 3) respiratory diseases map. Data is combined from three sources: the C-PORT model, a web-based screening tool to estimate the long-term near-port air quality by four main air pollutants (NO_x, PM_{2.5}, SO₂, CO) in census tracts scale, socio-economic data for near-port residents in New York and New Jersey from the U.S. Census Bureau of 2019, respiratory illnesses from the Centers for Disease Control and Prevention (CDC) for Chronic Obstructive Pulmonary Disease (COPD) prevalence. By spatially joining the three datasets, the paper attempts to validate the hypotheses on the port emission impact of air quality and public health of the near port residents.

Contributions from the study will include recommendations for local environmental policies specifically targeting the identified pollutant sources matched to the demographic profile and respiratory diseases to stir up more local dialogues between municipalities and communities. Furthermore, the study contributes to port hinterland studies which have been neglected in a scholarly context, by providing evidence of ports industrial risks and environmental justice across countries, and suggesting future guidelines for the developing countries with similar motivations. Lastly, the research will give a preliminary result for larger research questions on the sustainability of freight movements for both local communities and economic development.

DO MOBILE DEVICES RENEW URBAN TOURISM PRACTICES? THE CASE OF THE CHAMPS ELYSEES IN PARIS

[Leila Kebir](#)¹, [Marie Delaplace](#)²

¹University of Lausanne, Switzerland. ²University Paris Est, Lab'Urba, France

ABSTRACT

The digital revolution and what are called E-tourism modify urban tourist behaviors. With a computer and an internet connection, booking a room or building a tourism circuit is now easy to do by internet before the departure. But mobile devices can also be used in tourism during the tourism trip and inside the destination. What is called M-tourism is different from e-tourism. Indeed, mobile devices might allow changing behavior in-situ, i.e. in the destination. The changes induced by the increasing and widespread use of mobile device for tourism purpose affect these behaviors in a more important manner during their stay. M-tourism allows for last-minute booking for accommodation but also for different activities (museum, restauration, etc.). It can allow to changing instantly access, itinerary in the destination. It can also change the experience of the destination when tourism stakeholders are developing some new applications that are providing for instance geo-localization, augmented reality, etc. They also allow tourists for sharing experiences through social media (Munar and Jacobsen, 2014). The growing use of digital technologies offers many opportunities for innovation to build the destination of tomorrow, a smart destination (Gretzel et al., 2015), that is a destination in which the tourism experience will be central, and where the actors of the offer will be many, some of them even new to the tourism activity. The aim is to investigate, how mobile devices are used and how they eventually change urban tourism practices, taking into account a French case, the Champs Elysees in Paris. We have identified if the tourists own a smartphone, for what purpose M-tourism is used in-situ (transportation, hotel booking, restauration, meteo, activities, etc.). What other tools are used to prepare the trip (TV, mouth of word, touristic guide, etc.), what kind of mobile applications have been downloaded for what type of services (geolocation, trip, practical information, user reviews, etc.), if they are using augmented reality. The aim of the survey is also to identify if tourists but also inhabitants share photography or other information via mobile applications and what kind of information. For that purpose, a survey was conducted during May and June 2018 on the Champs Elysées in Paris. This paper starts by presenting the main digital technologies used in tourism and the way they may modify tourist's behavior and practices. It then presents the case of the Champs Elysées.

SPATIAL MOBILITY AND CRUISE PASSENGERS' EXPENDITURE: AN INVESTIGATION USING GPS TECHNOLOGY

[Mauro Ferrante](#)¹, [Caterina Sciortino](#)², [Stefano De Cantis](#)², [Szilvia Gyimóthy](#)³

¹Department of Culture and Society - University of Palermo, Italy. ²Department of Economics, Business and Statistics, University of Palermo, Italy. ³Department of Marketing, Copenhagen Business School, Denmark

ABSTRACT

This paper aims at analyzing the relationship between tourists' spatial behaviour and expenditure at the destination by means of an integration of traditional questionnaire-based survey and GPS technology. The complex information derived from GPS tracking device are analyzed through the implementation of various algorithm in order to synthesize key-characteristics of the itinerary undertaken. As a case study cruise passengers' behaviour in the city of Copenhagen are analyzed thanks to the availability of information collected in 2018 and 2019. The relationship among cruise passengers' expenditure at the destination, socio-demographic characteristics and mobility is analyzed through logistic regression models. The results show the relevance of spatial behaviour on expenditure. More in particular, stop activities are strongly associated with expenditure. Consequently, an analysis of stop locations is performed in order to highlight locations in which is likely that most of the expenditure is concentrated. The proposed approach is of relevance both from the methodological perspective, related to the analysis and synthesis of complex information derived from GPS tracking data, and from the applied point of view, with reference to destination marketing and management implications.

COVID-19 AND THE SILENCE IN THE STREET: REGIONAL ECONOMIC IMPACTS OF A BRAZIL WITHOUT CARNIVAL

Cláudio Eurico Seibert Fernandes da Silva¹, Thaís Diniz Oliveira², Rayan Wolf³, Fernando Salgueiro Perobelli¹, Victor Eduardo de Mello Valério⁴

¹Federal University of Juiz de Fora, Brazil. ²Instituto I17, Brazil. ³Federal University of Viçosa, Brazil. ⁴Federal University of Itajubá, Brazil

ABSTRACT

The outbreak of pathogenic viruses and their interactions with humans and animals have resulted in severe acute respiratory syndromes over time. The emergence and rapid spread of Corona virus disease (COVID-19) has posed a major public health and governance challenges worldwide. The new SARSCoV-2 infection was first reported in Wuhan (China) but quickly reached a global pandemic status due to its high transmissibility characteristic. The COVID-19 pandemic has led to numerous sanitary restrictions that affected both the economy and individuals. The primary measure commonly adopted to prevent the transmission of the virus involves social distancing. The tourism sector has been by far the hardest hit, with postponements and cancellations of previously scheduled travels and public events in an attempt to avoid large gatherings of people. The negative effects on tourism activities are set to persist more than those on other economic activities since recovery will require a massive vaccination. In developing economies like Brazil, the total supply of tourism activities results from a mix of formal and informal activities and workers, which help shield important economic and social indicators. This research aims to estimate the regional economic impact of a Brazil without Carnival due to COVID-19 in 2021. Carnival is the most important and well-known tourist event in Brazil. This popular cultural celebration occurs annually and attracts people from different regions, promoting various economic gains from taxes collection and employment creation, for instance. The last Carnival before the first case of COVID-19 generated approximately US\$1.5 billion from tourism activities such as restaurants, accommodation, transportation, artistic and leisure activities, and travel agencies. Those are the activities supposedly most affected by the silence of the streets during Carnival this year. The analysis is focused on the six main Carnival states, namely Rio de Janeiro, São Paulo, Bahia, Minas Gerais, Pernambuco and Ceará. Using an unprecedented interregional input-output modelling for the population arrangements of each state, we simulated the contraction in touristic demand of each region under scrutiny to estimate the effects of cancelling Carnival. To account for such contraction, we use the relative share of each tourism activity in total earnings from Carnival 2020. With the method of total hypothetical extraction, we also identify the underlying relevance of the value chain linked to carnival tourism in creating both formal and informal jobs. The implications of this employment variation differ among the regions. Preliminary results show that more than 190 thousand jobs would have been created in Brazil if Carnival had not been cancelled in those states. Moreover, the government could have collected approximately US\$102 million of taxes. This Carnival chain represents, on average, 18.6% of job creation in these states. Given the substantial economic relevance of Carnival, public policies should encourage similar touristic events in the post-COVID context as a measure to stimulate both sectoral and overall economic recovery through employment generation and taxes collection.

Regular Session: RS18.4 - Resilience and Risk Management

ANALYSIS OF DROUGHTS AND THEIR IMPACTS ON THE NATURAL AND SOCIO-ECONOMIC ENVIRONMENTS OF THE RURAL COMMUNITY OF EL FAID

Abdellatif Khattabi, Mohamed Koulsi
Ecole Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

The rural commune of El Faïd, which is part of the Souss region, has experienced alternating wet and dry periods. This evolution will certainly have negative impacts on the natural resources of the commune (Forests, water resources, soil,...), as well as on the socio-economic activities (Agriculture, breeding, ...). These climate trends are an important element for the assessment of the impact of climate change. The objective of the present work is to analyze precipitation data in order to characterize dry periods in the municipality and their succession over time. The analysis of rainfall data covers a period of 38 years (1981-2018) by calculating the values of the Standardized Precipitation Index (SPI) on an annual basis. The precipitation data used are taken from CHRIPS (Climate Hazards Group Infra Red Precipitation With Station Data). The results obtained show rainfall variability with a succession of dry periods and wet periods with a dominance of dry years. Indeed, there were several successive years of significant and moderate droughts during the periods 1981-1986, and during the period 1990-2008, with a severe drought year in 2001. Diachronic vegetation index analysis showed a variation on vegetation density and a survey among farmers has provided substantial vulnerability of the agriculture sector.

A PROBABILISTIC ASSESSMENT OF ECONOMIC IMPACTS CAUSED BY EARTHQUAKES BY USING SEISMIC RISK MODELS AND SPATIAL CGE MODELING

José Antonio León Torres¹, Mario Ordaz², Eduardo Haddad³, Inácio Araújo⁴

ABSTRACT

This paper presents a probabilistic approach to estimating economic losses caused by the propagation of catastrophe-induced disruptions through the economy of an entire country and its regions. Our proposal connects a spatial Computable General Equilibrium model (CGE) with a probabilistic model for seismic risk assessment both robust and well-known models, used worldwide in their respective fields. We use a spatial CGE model based on a bottom-up approach to describe economic relations that consider the geographic location of the economic components and to propagate losses caused by earthquakes throughout the economy. The seismic risk model is used to estimate the physical loss of all economic components during a seismic event and the frequency with which it occurs. We estimate the physical losses not only for a particular event but also for a vast collection of events that collectively describe the entire seismic hazard of a country. To integrate the models, the assumption is that physical losses are directly proportional to the reduction of capital stocks that make up the assets inventory of an economy. Our approach allow us to present for the first time a set of probabilistic risk indicators regarding losses of production, employment, GDP, gross regional product, export volume, inflation, tariff revenue, among others, due to earthquakes. All indicators are computed by using a systematic probabilistic approach, which considers a vast collection of earthquakes, each of which has a particular frequency of occurrence. We illustrate this novel approach with an example developed for Chile. Results reveal that the Average Annual Loss (AAL) of production, GDP and export volume in Chile are 583, 305 and 62 million dollars, while the employment AAL is 7,786 workers. We also present for the first time the loss exceedance curves of production, employment, exports and for other different components of the Chilean economy at country and regional levels caused by the earthquake hazard.

KEYWORDS

Economic impacts, CGE modelling, disaster risk management indirect impacts, seismic risk.

1. INTRODUCTION

We have witnessed recent catastrophic events that have made evident the economic implications and new features brought by disaster occurrence. The 2004 Indian Ocean earthquake and tsunami, hurricane Katrina in 2005, the 2010 Haiti earthquake, and the 2011 Japan earthquake and tsunami highlighted the importance of matters as disaster risk governance, reconstruction strategies, vulnerability of the economy of developing countries, the multinational disaster aspects and how disasters can cascade. The importance of accounting for indirect losses in risk is crucial and becomes larger as the supply-chain complexity increases in the age of globalization shown even in occasions, losses larger than those produced by physical damage (GFDRR 2014). However, it is not easy to account for the economic consequences of earthquakes with historical information alone, because these catastrophic events are infrequent, so relevant information is scarce, and it is not always easy to distinguish between direct and indirect losses.

Catastrophe modeling of physical damage caused by earthquakes is today a well-developed technique, to the point that it is possible to estimate, in a probabilistic manner, the seismic risk of individual assets (Marulanda et al., 2013) as infrastructure, buildings, contents, machinery, equipment, etc. Modeling of indirect losses, in comparison, lags far behind, mainly due to the difficulties in empirically translating property damage into indirect losses and due to the lack of adequate models that relate these two kinds of losses. Usually, indirect losses are estimated roughly as a percentage of physical losses, establishing this percent with empirical information obtained from a very limited historic database of events occurred around the world; this is clearly unsatisfactory.

However, there is a well-developed literature on the economic impact of natural and man-made disasters, whose most recent advances have been compiled by Okuyama and Rose (2019). On one hand, efforts have been focused on improving and extending the quantitative models used for disaster impact analysis, such as cyber-attacks, extreme weather events, earthquakes, flooding, climate change, and terrorist attacks, amongst others. On the other hand, researchers have devised

tools to directly estimate economic damages and/or losses based on some physical data of natural hazards, or to evaluate, for instance, the changes in economic activities with a set of satellite data on annual difference in nighttime light intensity. In spite of the existence of this large and rich analytical framework to study the impact of disasters into the economy, efforts have concentrated in the analysis of individual, without appropriate consideration of their frequency of occurrence. But frequency of occurrence matters. Clearly, decisions and policy would be very different if one knew that the economic impacts of a certain size are to be expected, on average, once every 100 years or once every 1000 years. Further, it would seem that little attention has been given to linking physical damage to infrastructure or economic components with higher-order economic losses.

In view of this, we present here a probabilistic approach to the estimation of higher-order losses that takes into account that: 1) natural events –earthquakes in our case– take place as a stochastic process in time; 2) frequency of occurrence of events matters for measuring risk; and 3) there are links between the level of physical damage to economic components and the reduction of capital stock. In our approach, we start with a Computable General Equilibrium (CGE) model of the economy, specified as a fully integrated interregional system. This model describes the economic interactions among regions and industrial sectors, and is in equilibrium under a certain level of inputs, outputs and prices. Then, an earthquake happens, and produces physical damage (direct losses) to the economic components associated with the available capital stock (e.g. buildings, factories and infrastructure) of the affected portion of the region; these losses are estimated with conventional seismic risk techniques (Cardona et al., 2012). Direct losses, in turn, produce partial reductions in some inputs to the CGE model, namely regional-sectorial capital stocks, which attains a new equilibrium after proper adjustments, reaching new levels of outputs and prices. The result is that the occurrence of the earthquake produces direct losses plus other types of indirect losses that result from the propagation of the reduction of available primary factors through the economy described by our CGE model. As in the case of conventional seismic risk models, the analysis is then repeated for a vast set of earthquakes (44,350 events for our case of study) with known occurrence frequencies, that collectively describe the hazard of the region under study. Results for all earthquakes allow for various probabilistic risk metrics to be computed, now including the effect of indirect losses as well.

This work is the first effort to join, in a systematic way, the probabilistic seismic risk and the CGE modeling frameworks, both robust and well-known models used worldwide in their respective fields. CGE models are used widely for studying and simulating economic effects within an economy, given the occurrence of different types of shocks, such as economic policies, taxes, financial crises, terrorist attacks, natural disasters, etc. We make use of a special type of CGE models, known as spatial CGE models (Haddad 2009), which have the ability to take into account the geographic location of economic agents and endowments.

Our modeling approach is fully probabilistic on the earthquake occurrence side, but for now is deterministic on the CGE side. We assume that the physical damage produces a proportional reduction on the value of the capital stock of components hit by the earthquake, which initially causes a direct reduction on production and later propagates into the economy in ways dictated by the interactions contained in the CGE model.

Besides dealing with the estimation of indirect monetary losses, our approach allows for a better glance of the likely consequences of the earthquake occurrence into the full economy. As we will see, the richness of the CGE modelling allows for carrying out risk assessment referred to different economic variables, such as employment, GDP, GRP, wages, tariff revenue, consumer price index, export volume, and so on. Furthermore, we have observed the capacity of the CGE model to catch positive economic impacts of earthquakes on certain sectors and regions, through substitution effects. The new methodology is applied to Chile, a country that is frequently affected by large earthquakes and with one of the most dynamic economies of Latin America, economy that in addition shows remarkable regional disparities. These characteristics make Chile an ideal place to exemplify our approach.

2. SEISMIC RISK MODEL

First, the seismic risk model contains an exposure database (ERN-AL 2010) that includes all assets at risk that are relevant for the analysis. In our case, the relevant assets are buildings, factories, infrastructure and, in general, all assets that provide input of some kind to the economic model. In other words, all assets whose damage might have a potential impact in the economic flows. Each asset must be identified by its location, seismic vulnerability characteristics and, particularly relevant for our present purposes, the economic sector to which it belongs. Exposure database can be built from cadastral and local data or by using proxy methodologies as suggested by Gunasekera et al., (2015), Aubrecht & León Torres (2016) that harnesses global geo-referenced datasets and census data.

At random instants, with all assets intact, and following a Poisson process, the economic equilibrium is perturbed by the occurrence of an earthquake with known focal characteristics (magnitude, hypocentral location, orientation of the rupture plane), which in turn will produce a spatial random field of intensities (peak ground acceleration, spectral values). In contemporary seismic risk models, this information is provided by its hazard component (Esteva 1967), (Ordaz et al., 2014). This component provides a potentially very large event set, each one associated to an annual frequency of occurrence and to one or more intensity random fields. Therefore, the hazard component provides information about how frequently different kinds of earthquakes take place and gives probabilistic indications of the intensities it produces. In principle, the hazard component should contain information about occurrence frequencies and intensity distributions of all earthquakes that could take place in the future. In other words, the event set must be collectively exhaustive. For the case of Chile, we have used a seismic hazard model developed by consulting company ERN (Salgado-Gálvez 2018).

Once a hypothetical earthquake has taken place and its intensities are known –or, more precisely, the probability distributions of the intensities are known–, the seismic risk model (Ordaz et al., 2000) provides tools to assess, in probabilistic terms, the level of direct losses suffered by each one of the assets contained in the exposure database; this part of the model is usually referred to as the loss component. The level of damage sustained by an asset depends on its location, the size of the intensity and its vulnerability characteristics. Thus, once a hypothetical event has taken place, we have means to determine the probability distribution of the losses sustained by each one of the assets at risk. For this issue, we computed a set of functions, called vulnerability functions (ERN-AL 2010) that characterize the seismic vulnerability of any asset.

In general, and in view of the lower geographical resolution of the CGE models compared to that of the seismic risk models, a loss aggregation is required in order to sum all the losses that correspond to the same economic sector at the same economic region. Since the losses at the various assets are not numbers but correlated random variables, the aggregation process is not trivial, because of the correlation among losses for the same event. We will not discuss in detail how this aggregation process is handled; we just call the readers’ attention to this complexity.

Therefore, as it can be noticed, the seismic risk model is used in our approach to determine two important pieces of information for each one of the members of the event set: 1) the probability distributions of the losses incurred by assets belonging to all economic sectors and regions, that is, the severity of the direct losses; and 2) the annual frequency with which that particular loss scenario takes place. We will see later how this information is used in the overall risk calculations.

3. CGE MODELLING

We use the BMCH model, a fully operational spatial CGE model for Chile. The model uses an approach similar to Peter et al., (1996), Haddad (1999), Haddad & Hewings (2005) to incorporate the interregional economic structure. We use an absorption matrix as the basis to calibrate the CGE model, together with a set of elasticities borrowed from the econometric literature applied for Chile. This database allows capturing economy-wide effects through an intricate plot of input-output relations. Table 1 shows the regions and economic sectors that constitute our model.

Table 1: List of regions and sectors used for Chile

Code	Name of the region	Code	Name of the economic sector
R1	Region of Arica and Parinacota	S1	Agricultural-forestry and fishing
R2	Region of Tarapacá	S2	Mining
R3	Region of Antofagasta	S3	Manufacturing industry
R4	Region of Atacama	S4	Electricity, gas and waste management
R5	Region of Coquimbo	S5	Construction
R6	Region of Valparaiso	S6	Commerce, hotels and restaurants
R7	Metropolitan Region of Santiago	S7	Transport, communications and information services
R8	Region of Libertador General Bernardo O'Higgins	S8	Financial intermediation
R9	Region of Maule	S9	Real state and housing services
R10	Region of Biobío	S10	Business services
R11	Region of La Araucanía	S11	Personal services
R12	Region of Los Ríos	S12	Public administration
R13	Region of Los Lagos		
R14	Region of Aysén Del General Carlos Ibáñez del Campo		
R15	Region of Magallanes and Chilean Antarctic		

The current version of the BMCH model recognizes the economic structures of the 15 Chilean regions. Results are based on a bottom-up approach – i.e. national results are obtained from the aggregation of regional results. The model identifies 12 production/investment sectors in each region producing 12 commodities, a representative household in each region, regional governments and a Central government, and a single foreign area that trades with each domestic region. Two local primary factors are used in the production process, according to regional endowments (capital and labor). Special groups of equations define government finances, accumulation relations, and regional labor markets. The BMCH model qualifies as a Johansen-type model in that the solutions are obtained by solving the system of linearized equations of the model, following the Australian tradition. A typical result shows the percentage change in the set of endogenous variables, after a policy is carried out, compared to their values in the absence of such policy, in a given environment. Interregional linkages play an important role in the functioning mechanisms of the model. These linkages are driven by trade relations (commodity flows), and factor mobility (capital and labor migration). In the first case, interregional trade flows are incorporated; interregional input-output relations are required to calibrate the model, and interregional trade elasticities play an important role (Haddad 2009).

When an earthquake takes place it produces direct losses, whose probability distributions were determined with the seismic risk model described succinctly in the previous subsection. Once aggregated, the direct losses by sector and by region are entered into the CGE model as “shocks” to the capital stock component of the sector/region combination. These shocks are nothing more than exogenous capital stock reductions, which are usually calculated as the ratio between physical loss and the total cost of the capital stock. When entering the set of shocks to the CGE model, the equilibrium conditions of the model are lost, so that we need to run the CGE model again in order to reach a new equilibrium that reflects how the economy adjusts to the received shock. The new equilibrium condition is obtained with a new value-set of the endogenous variables, which are the results of the model.

A CGE model can be made of hundreds or even thousands of variables (exogenous and endogenous); each one of them can provide us with a different type of result, either of economic or social interest. The richness of the CGE model in terms of the amount of results is extraordinary, allowing for the possibility of developing a broad range of analyses. Initially, we will focus on the variables that quantify the total production of the industries; later, however, we will analyze other, non-economic types of losses.

We will define the *production loss* of sector i in the spatial region j , L_{pij} , as the difference between the production before and after the earthquake, for the same sector/region. In other words, as a consequence of the decreased capital stock in certain sectors and regions, hit by the earthquake, the economy attains a new equilibrium in which the production at that sector/region is smaller (or higher...) after the earthquake than before. We regard this difference as a production loss, and this will be our initial measure of indirect losses, although we will later explore the use of results related to other variables.

At this initial phase of our research, the behavioral parameters and structural coefficients of the CGE model, that is, the parameters and coefficients required to establish the relations between exogenous and endogenous economic variables, are considered deterministic. In spite of this, the outputs of the CGE model – the indirect losses – are not numbers, but random variables, because some of the inputs were also random variables. We do not distract the attention of the reader with details on how the probability distributions of the CGE model outputs are determined. For the time being, it suffices to say that it is possible – although computationally challenging – to obtain the probability distributions of all relevant CGE model outputs, either at the sector/region level or for any required aggregation.

At this point, we are able to compute, for each event of the event set, probabilistic direct and indirect losses. In the following section we will illustrate the way in which the most common risk measures can be obtained with the results presented so far.

4. RISK ASSESSMENT

The most common risk measures, both in the disaster risk management world as well as in the insurance sector, are: 1) the average annual loss; and 2) the loss exceedance curve, which indicates the average frequency with which given values of loss would be exceeded. We will focus only for illustration purposes, on the total direct and indirect losses. The total losses are, of course, the sum of the losses for all assets, in the case of the direct losses, and for all sectors and regions, for the case of the indirect losses.

For instance, the k -th event of the event set produces probabilistic direct and indirect losses Ld_k and Lp_k , respectively. Then, the corresponding average annual loss, AAL_d would be given by:

$$AAL_d = \sum_{k=1}^{Events} E(Ld_k) F_k \tag{1}$$

$$AAL_p = \sum_{k=1}^{Events} E(Lp_k) F_k \tag{2}$$

where $E(.)$ denotes expected value and F_k is the annual frequency of occurrence of event k . AAL_d is a quantity that is routinely computed in conventional risk analyses; AAL_p is introduced in this paper.

The loss exceedance curves, $v_d(.)$ and $v_p(.)$ of direct and indirect loss, respectively, are computed with the following expressions:

$$v_d(l) = \sum_{k=1}^{Events} Pr(Ld_k > l) F_k \tag{3}$$

$$v_p(l) = \sum_{k=1}^{Events} Pr(Lp_k > l) F_k \tag{4}$$

where $Pr(Ld_k > l)$ and $Pr(Lp_k > l)$ are, respectively, the probabilities of direct and indirect losses exceeding a given value, l .

4.1 New complementary risk indicator

The procedure for the computation of the probabilistic risk measures regarding employment, GRP, consumer price index, export volume and any other economic variable of the CGE model, is exactly the same but for the corresponding economic variable instead of that of production one. In the case of positive economic effects, the procedure for the computation is again the same, with the difference that, in this case, we only account for the positive effects that each earthquake triggers in the CGE model.

The risk calculations shown in this paper have been carried out with program DIRAS2020, developed at the Instituto de Ingeniería, UNAM. This piece of software has been specifically created to join and process the information coming from a conventional seismic risk model and a spatial CGE model.

4.2 Calibration of the model

Empirical validation of catastrophe models is, by definition, a difficult task. Fortunately, catastrophes are relatively rare events (otherwise, they would not be catastrophes) so observed values of losses are never a sample big enough to allow for empirical validation. Even if we had observed losses for a long time, cities change, construction materials change as well, so the loss information of events that took place more than a few decades ago is not very useful. In a way, the reason

to start developing catastrophe models, back in the 1990s, was precisely the need to compensate for this data shortage. So direct validation of the models, in the sense of empirically establishing the exceedance frequency of losses of various sizes, is never possible.

Nevertheless, efforts are made to carry out partial validations of different kinds. First, the rate of occurrence of earthquakes of various magnitudes, as well as their spatial distribution, is estimated from appropriate earthquake catalogs and knowledge of the regional tectonic setting; this guarantees that the model for future occurrences will not be introducing too many or too few events, and also that the spatial distribution of future, hypothetical events, will be coherent with the observed distribution and coherent also with geological science.

Additional validations are made regarding the relation between earthquake source characteristics (magnitude, hypocentral location, rupture plane orientation, etc) and the ground acceleration field produced by the event. This guarantees that, on average, the observed ground accelerations and the accelerations predicted for future events will be unbiased.

In some cases, it is possible to compare the real losses produced by an event with those computed with the model for a synthetic event of similar characteristics. We present an example of this comparison with the Maule earthquake of 2010 (section 5.3), finding that the modelled losses are coherent with those observed. In some cases, several loss-producing events can be used in this validation phase but, in our case, the last big event before the Maule earthquake took place in 1985, which was considered to be too far away in the past. Although it is no possible to use for validation proposes, in results sections we have included the losses obtained for simulations of the 1985 Valparaiso and the 1960 Valdivia Earthquakes in order to estimate what would be the economic consequences if those earthquakes took place today.

5. HAND-ON CASE OF STUDY

As we have mentioned before, this is the first time in which a robust, probabilistic and systematic connection between entire seismic risk and large-scale economic models has been attempted. Therefore, we have not been able to collect all data required to carry out a full joint calibration of the models, in particular the proportional relation between the reductions of the capital stock and the direct losses in non-residential buildings. In this sense, our example should be considered a proof-of-concept rather than a final product. In spite of this, we believe that the results obtained in this example are quite reasonable and can be used to gauge the power of the approach, within, of course, its assumptions and limitations. In what follows we will present the main results of our example, highlighting some of the most interesting findings.

Table 2 presents general descriptors of the Chilean economy and some of the more aggregated results of our analysis. Direct losses computed refers exclusively to non-residential buildings. The reason for this restriction is that we are trying to model damages only in capital stocks used in the production process, in the sense that their physical disruption is susceptible of being propagated in the economy of the country.

5.1 General results

Table 2 presents general descriptors of the Chilean economy and some of the more aggregated results of our analysis. Direct losses computed refers exclusively to non-residential buildings. The reason for this restriction is that we are trying to model damages only in capital stocks used in the production process, in the sense that their physical disruption is susceptible of being propagated in the economy of the country.

Table 2: general value of the Chilean economy (2014) and main aggregated results

Item	Total Value	Average annual loss
Total value of non-residential buildings	103,720 million USD	302 million USD
Total value of yearly production	442,805 million USD	583 million USD
GDP	251,020 million USD	305 million USD
Total employment in Chile	6,671,072 workers	7,786 workers
Total export volume	83,102 million USD	62 million USD

We will express seismic risk, due to direct or indirect losses, in terms of a few standard risk metrics. We will use the average annual loss (Methods, equations 1-2) and the loss exceedance curve (LEC; Methods, equations 3-4). Let us start presenting the results at the country level.

Figure 1 shows the loss exceedance curve of Chile’s direct and production losses. It must be noted that we are representing the LEC with the return period (the inverse of the exceedance rate) in the horizontal axis and the loss values in the vertical axis. The LEC for physical losses is a common metric within the risk assessment world; however, the LEC for production losses is introduced for the first time in this paper. The production loss associated to 250 years of return period for Chile was estimated in 15,870 million dollars (3.58% of the total yearly production) while direct losses were 5,025 million dollars, that is 4.9% of the total value of non-residential buildings. For 1,000 years of return period, the production and direct losses were 28,760 and 9,835 million dollars, respectively.

Figure 1: Loss Exceedance curves of direct and production losses.

It is shown the LECs expressed in million dollars. Direct losses refer exclusively to non-residential buildings of the country

In the case of the AAL for the whole country, that of direct losses has been estimated as 302 million dollars, which is 0.29% of the total value of non-residential buildings. In turn, the AAL of production losses reaches 583 million dollars, that is, 0.132% of the total yearly production of the country.

Figure 2 shows the AAL for Chile grouped by economic sector, both for direct and production losses. We present the AAL results: 1) as a percentage of its total value, in order to see the influence of each sector in the total AAL; and 2) as a fraction (per thousand) of its exposed sectorial value of assets and yearly production, respectively, in order to see how risky each sector is. Clearly, we can see in Figure 2 that both the AAL distribution by sector and the risk rank of economic sectors are different for direct and indirect losses. Similarly, Figure 3 depicts the AAL by region of the country for both types of losses, together with an indication of the seismic hazard level, expressed in terms of the peak ground acceleration (PGA). Figure 3 shows for instance that regional risk indicators of direct losses are not proportional to their corresponding ones of production loss. We have found that the riskiest region (highest value of relative AAL) in terms of direct losses are Region of Atacama (R4) while in terms of production losses the riskiest is Region of Valparaiso (R6). This clearly demonstrates the importance of taking into account the high-order economic losses since, while there are regions most physically affected by the earthquake hazard, there are other regions that suffer the largest effects in terms of loss of production.

Figure 2: Average annual loss for Chile by economic sector

Panel a shows the production AAL as a percentage of its total value (gray) and as a fraction (per thousand) of its sectorial yearly production (orange). Panel b shows the direct AAL as a percentage of its total value (grey) and as a fraction (per thousand) of the corresponding sectorial value of non-residential buildings (red)

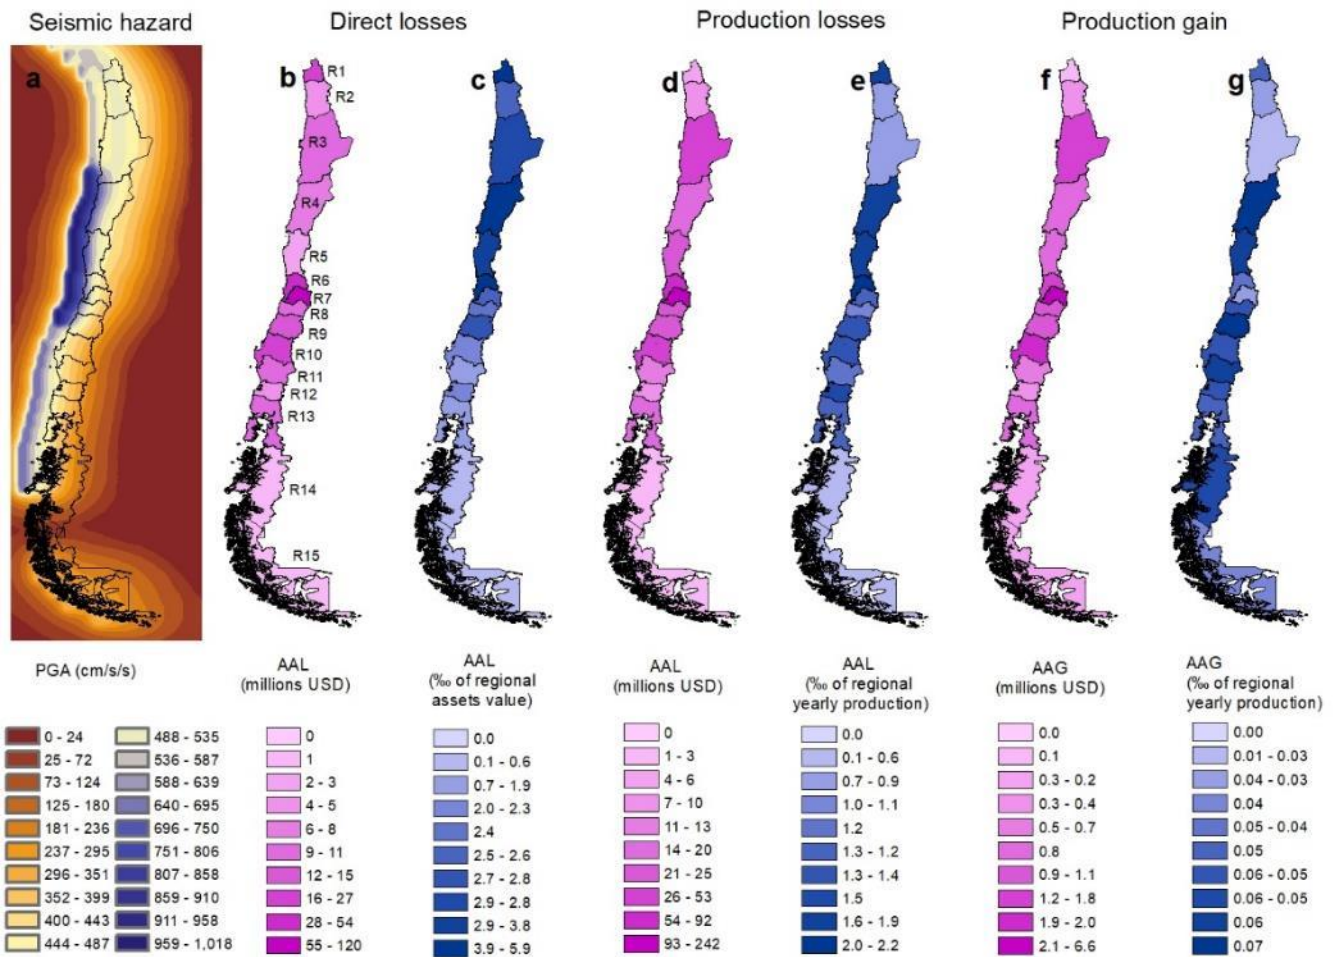

Figure 3: Distribution of AAL in Chile

Panel a shows the seismic hazard for Chile, expressed in terms of the peak ground acceleration (PGA) associated to 475 years of return period. The average annual loss due to physical damage of non-residential buildings (direct losses) by region is shown in panel b in millions of USD and in panel c as a fraction (per thousand) of its regional exposed value. The average annual loss in production by region is shown in panel d in millions of USD and in panel e as a fraction (per thousand) of the corresponding regional annual production. Finally, panels f and g present the annual average gain (AAG) of production by region in millions of USD and as a fraction (per thousand) of the corresponding regional annual production

Our approach also allows us to obtain the LEC of production for individual regions or economic sectors, as shown in Figure 4. The Metropolitan Region of Santiago, R7, presents the highest losses in absolute terms. For example, for a return period of 250 years, region R7 shows a loss of 10,674 million dollars, which is 5.45% of its total yearly production. In the case of economic sectors, manufacturing industry, S3, presents the highest losses in the country in absolute terms, and, transport, communications and information services, S7, the highest losses in in relative terms to its sectorial production, for any return period.

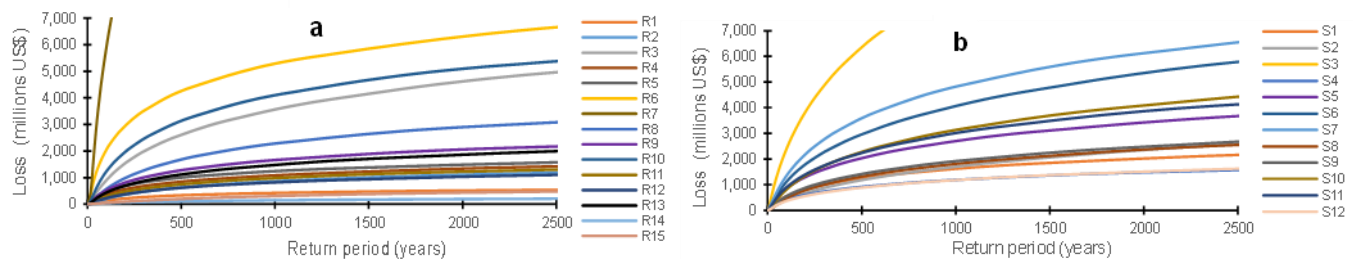

Figure 4: Production loss exceedance curve of Chile by region

Panel a by region of the country, Panel b by economic sector.

5.2 New risk indicators

The richness of CGE modelling regarding the amount of interesting output variables, each one of them reflecting a different aspect of the economy, allows for the computation of many interesting and useful risk measures. Besides calculating the risk measures in terms of production loss, it is possible to compute risk measures for losses of

employment, GDP, GRP, tariff revenue, consumer price index, export volume, among others. These novel indicators can be useful for seismic risk management, as they provide a way to measure the losses in various aspects of an economy facing earthquake hazard.

For instance, the employment AAL and the employment loss associated to 250 years of return period for Chile are 7,786 and 237,165 workers. In the case of AAL in GDP and the loss associated to a return period of 250 years due to seismic hazard, losses have been estimated in 305 and 9,415 million dollars, those are, 0.122% and 3.77% of the total Chilean GDP. GDP loss do not include direct losses (physical damage). Figure 5 exemplifies some of the results obtained in term of the AAL for several economics variables.

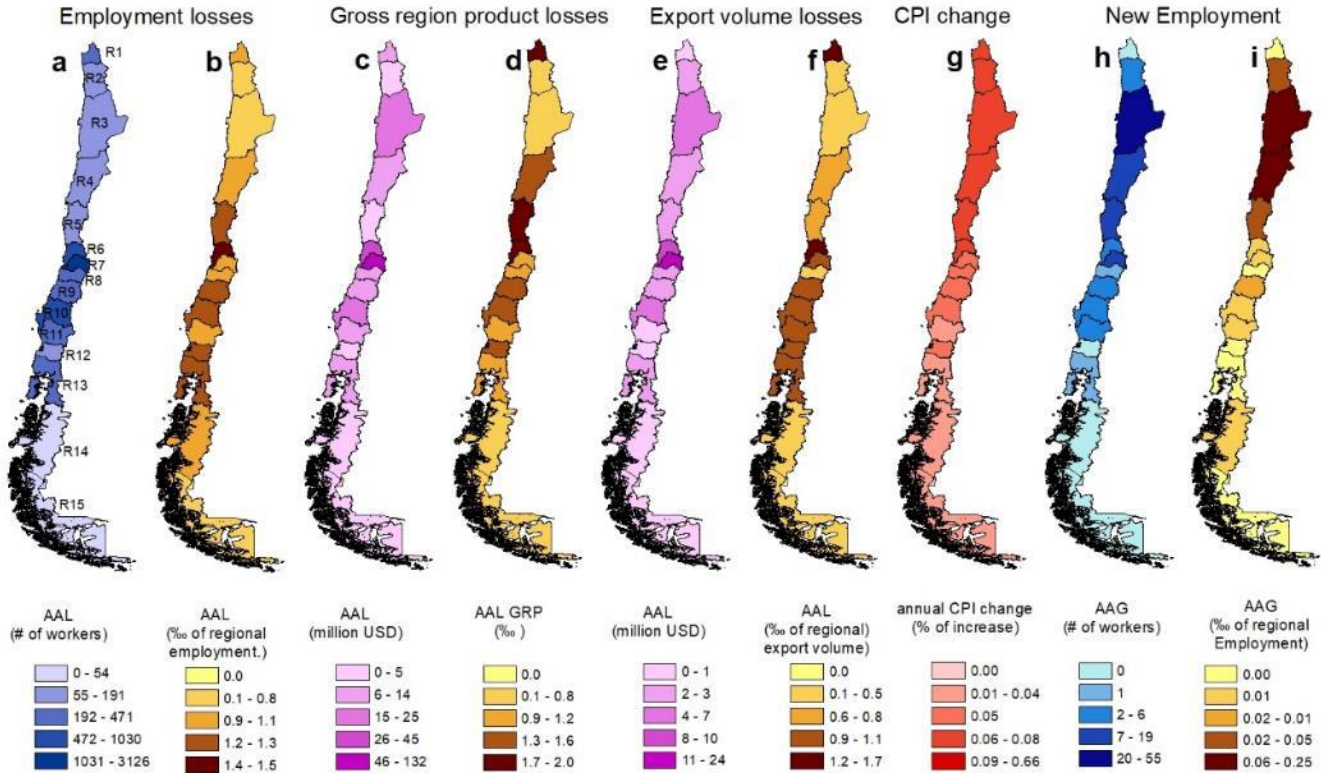

Figure 5: New risk indicator for Chile

Panel a and panel b show the average annual loss (AAL) of employment by region of Chile in number of workers and as a fraction (per thousand) of the corresponding regional employment. Panel c and panel d show the AAL of gross regional product in millions dollars and in relative terms. Panel e and panel f show the AAL of export volume by region in million dollars and as a fraction (per thousand) of the regional export volume. Panel g shows the average annual change of the consumer price index by region of Chile. Panel h and i show the average annual gain of employment by region in number of workers and as a fraction (per thousand) of the regional employment.

Because of an earthquake, economic losses usually occur; however, in certain regions one or various economic sectors can have positive effects, like production increases given the decrease of production in other regions. In fact, we are able to measure, using the same indicators, the positive effects in the same components of the economy for which we calculated the negative impacts. These novel probabilistic indicators of positive effects can be also useful for a better understanding and management of the seismic risk. Similar to economic losses, positive effects are captured for a vast collection of events that collectively describe the seismic hazard of the country. Figures 3 and 5 in the most-right panels present a couple of examples of the positive results obtained. By now, we are not considering recovery and reconstruction processes of the lost capital stock, reason why, on average, positive effects are much smaller than the negative effects and mainly due to substitution effects.

5.3 By-scenario analysis and calibration of the model

Production losses, employment losses, CPI changes, and so on, can also be computed for any particular stochastic earthquake coherent with a seismic hazard model for the region over study. Figure 6 presents the direct losses and GRP reductions estimated for simulations of three large earthquakes occurred in Chile. Earthquake. For instance, we found that for the 2010 Maule Earthquake, the maximum price increase take places in Region of Biobío (R10), with a 1.9% and would cause an average production loss of 1.7% of the total yearly production of Chile.

By-scenario loss analysis is also useful to calibrate y/o validate catastrophe models, when information of real losses of recent events are available. In our case, official information of direct and indirect losses of 2010 Maule Earthquake are available.

According to estimations of the Central Bank of Chile, The Maule 2010 Earthquake caused a 3% of losses in the total net capital stock of Chilean economy, 3.2% in the residential buildings and 2.6% in non-residential infrastructure (Banco de

Chile 2010). Our model estimate direct losses in non-residential buildings of 2.5% of its total value. Furthermore, Chilean Government (Gobierno de Chile 2010), estimated a GDP decrease of 7,600 million dollars for the next four years after the 2010 Maule Earthquake. Our simulation for this event estimates a yearly GDP contraction of 1.65%, which is coherent with the official estimation assuming that the first year after the earthquake, at least, half of the total 7,600 million loss will take place, it is, a 1.74% GPD contraction (Total Chilean GPD 2010: 218,500 million dollars).

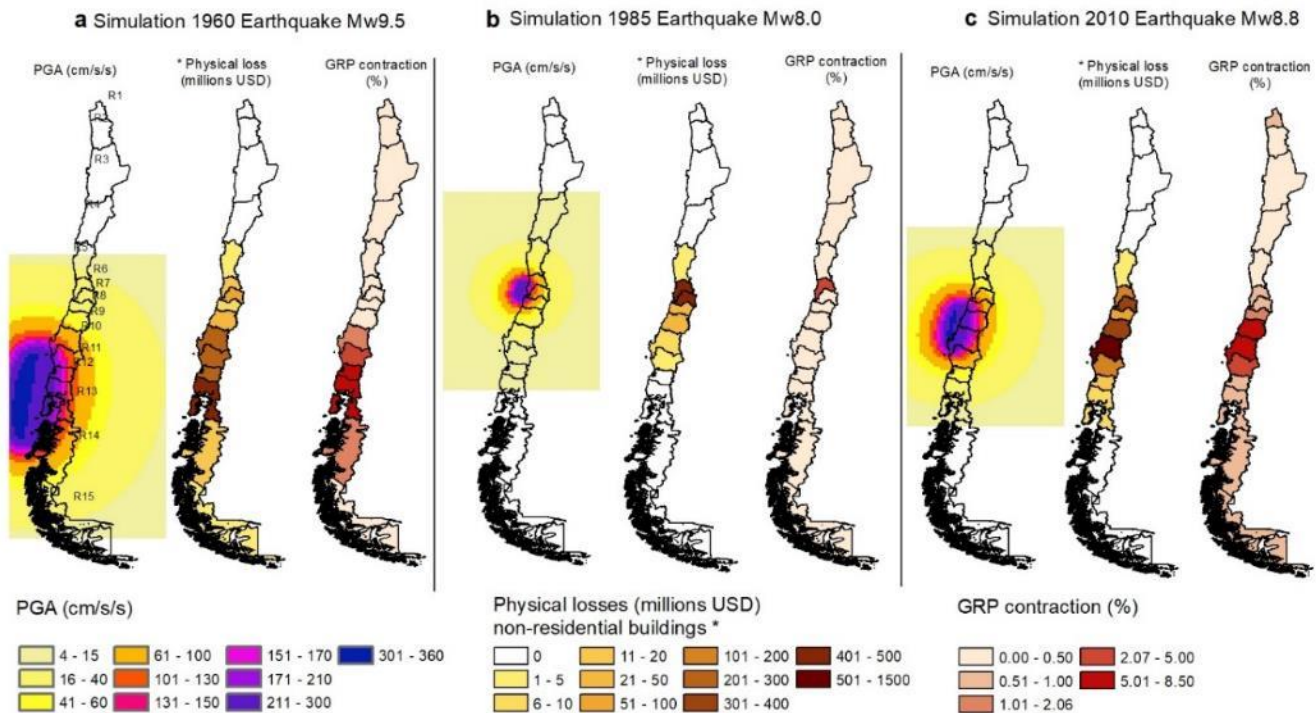

Figure 6: Physical losses and GRP contraction caused in Chile by three simulated earthquakes

Each panel present the PGA intensity field generated by the earthquake and both the physical losses in non-residential buildings and the Gross Regional Product (GRP) contraction caused the earthquake. Panels a, b and c show results for simulated earthquakes similar to 1960 Mw9.5 Valdivia Earthquake, 1985 Mw8.0 Valparaiso Earthquake and for 2010 Mw8.8 Maule Earthquake.

6. CONCLUSION

Our approach has shown how the Computable General Equilibrium model and the probabilistic model for seismic risk assessment are able to work together, allowing for a robust and systematic probabilistic glance of the consequences of the earthquake disturbance into the full economy. We were able to successfully deal with the production losses, exemplifying our methodology with the computation of the standard risk metrics respect to production losses, that is, the average annual production loss and the production loss exceedance curve, both at country and regional levels, and computed by considering a vast collection of earthquakes, with known annual occurrence frequencies, that collectively describe the entire seismic hazard of a country. We also have shown how our approach can go beyond production losses and, harnessing the richness of the CGE modelling, we have computed the standard risk metrics for different economic variables, such as losses of employment, GDP, GRP, export volume and consumer price index. We believe that these new risk measures are useful and complement well the usual risk indicators of physical damage, and can contribute for a better integral disaster risk management as well as in designing financial hedging instruments for governments and the insurance industry. Our model captures not only the negatives consequence of earthquakes but also some positive effects on the economy proposing new probabilistic measures of these gains. Our methodology is not exclusive for earthquakes and can be easily extended to other natural disaster as flooding, hurricanes, drought, etc.

For the case of Chile, we find that the average annual loss (AAL) and the production loss associated to a return period of 250 years, for the whole country, were 0.132% and 3.58% of its total yearly production, respectively. From the authors' experience, these results look reasonable in comparison with the direct economic losses obtained (0.29% of the total value as AAL of non-residential buildings). We also find that the employment AAL in Chile is 7,786 workers and the AAL in the GDP and export volume are 305 and 62 million dollars, corresponding to 0.122% of the GDP and 0.08% of the annual export volume, respectively. Metropolitan Region of Santiago concentrates ~41% of the total production AAL while Region of Valparaiso is the riskiest, with a regional production AAL of 0.22%.

HEALTH INTERVENTIONS IN A POOR REGION AND RESILIENCE IN THE PRESENCE OF A PANDEMIC

[Amitrajeet A. Batabyal](#)¹, [Hamid Beladi](#)²

¹ Department of Economics, Rochester Institute of Technology, 92 Lomb Memorial Drive, Rochester, NY 14623-5604, USA. E-mail: aabgsh@rit.edu; ² Department of Economics, University of Texas at San Antonio, One UTSA Circle, San Antonio, TX 78249-0631, USA. E-mail: Hamid.Beladi@utsa.edu

ABSTRACT

We focus on a poor region and analyze the connections between health interventions undertaken by a regional authority (RA) and this region's resilience in the presence of a pandemic such as Covid-19. First, we show how a health intervention by the RA stochastically impacts an appropriately defined health indicator for this region. Second, we compute the probability that the health status of this region's population falls below a minimum acceptable level in the presence of the health intervention. Third we solve an optimization problem in which the RA maximizes the likelihood that the health status of this region's population stays above a minimum acceptable level at a given economic cost. Finally, we discuss the nexus between a health intervention, our region's health status, and its resilience by presenting two applications of our theoretical framework.

1. INTRODUCTION

1.1. Preliminaries

In early December 2019, a physician by the name of Li Wenliang from the city of Wuhan in China commented in a group chat that he had observed a series of patients demonstrating signs of an ailment that was similar to severe acute respiratory syndrome (SARS). As pointed out by Lango (2020), this ailment was then reported to the World Health Organization (WHO) country office in China on 31 December 2019. On 12 January 2020, Chinese scientists published the genome of the virus and the WHO asked a team in Berlin, Germany to use the information provided to develop a diagnostic test to identify any active infection. This was developed a few days later. The work of Chaplin (2020) and that of many others tells us that the cause of the SARS-like ailment that subsequently became known as Covid-19 was a novel coronavirus, specifically, the SARS-CoV-2. On 30 January 2020, Covid-19 was declared by the WHO to be a Public Health Emergency of International Concern (PHEIC). The first case of Covid-19 stemming from local person-to-person spread in the United States (U.S.) was confirmed in mid-February 2020. On 11 March 2020, the WHO declared COVID-19 a pandemic.

It is important to recognize that the *regional* impacts of Covid-19 thus far have been very different. For instance, China and Italy, the two nations in which the adverse impacts of Covid-19 were felt very strongly early on in the spread of the coronavirus---see Perez-Pena (2020)---are now doing much better as far as the management of the virus is concerned. In contrast, Londono (2020) tells us that initially little affected nations such as Brazil are now seeing some of the worst outbreaks of the virus. Even within a single nation such as the U.S., there are substantial regional differences. Northeastern states such as Connecticut, New Jersey, and New York were all initially hit hard by Covid-19 but now have few new cases or deaths (Anonymous, 2020). In contrast and as noted by Findell *et al.* (2020), states such as Arizona, Florida, and Texas that were relatively unaffected by Covid-19 during the early days of the outbreak in the U.S. are now seeing large increases in both new cases and deaths.

Given the clear regional dissimilarities in the impacts of Covid-19, it is pertinent to explore what regional scientists have written about the connections between the health and the well-being of regions. We now discuss this topic briefly.

1.2. Literature review

Eibich and Ziebarth (2014) use hierarchical Bayes models to analyze spatial health effects in Germany. They show that more than twenty years after the reunification of Germany, there exists a clear spatial east-west health pattern that equals an age impact on health of up to five life-years for a 40-year old individual. Dorfman and Mandich (2016) use a Bayesian estimation strategy to study migration for amenities by “later-life migrants.” Their analysis shows that there is a positive association between access to healthcare and the migration decisions of older individuals.

Looking at the Massachusetts healthcare reform of 2006, Alm and Enami (2017) ask whether governmental subsidies to low-income persons influences them to move to a state with better health subsidies. Their analysis reveals that the reform did not lead to a “global effect” meaning that there was no movement of low-income persons across all cities in Massachusetts. Even so, there was a “local effect” meaning that there was a noteworthy movement of low-income persons into the border cities of Massachusetts. Goodman and Smith (2018) study the regional location of health professionals by examining 373 metropolitan statistical areas (MSAs). They show that spatial agglomerations raise factor productivity and therefore the rents paid and the wages earned by health professionals.

Moving on to natural disasters, Skoufias *et al.* (2017) construct damage indices for individual districts in Indonesia and show how these indices can be used for budgetary planning. For instance, they contend that *ex ante* or before the occurrence of a natural disaster, these indices can be used to ascertain the size of the annual fiscal transfers that will need to be made from the central government to the affected subnational governments. Looking at the impact of natural disasters on the growth of population densities across U.S. counties in 1960-2000, Wang (2019) finds no significant adverse long-term growth effects.

The last four decades have given rise to a burgeoning literature on the topic of the nexuses between the concept of *resilience* and the well-being of a region. The modern or post-World War II usage of the term resilience in the academic literature is due to the prominent but now deceased ecologist Buzz Holling (1973). The Holling resilience of an ecological-economic or a socioeconomic system is “the capacity of [this] system to absorb disturbance and reorganize while undergoing change so as to still retain essentially the same function, structure, identity, and feedbacks” (Walker *et al.*, 2004).¹³⁷ The ways in which the notion of resilience has been studied in the regional science literature and some of the problems stemming from this kind of study have been discussed in detail by Batabyal (2020) and by Batabyal and Kourtit (2020).¹³⁸

That said, we would now like to emphasize two points. First, the extant regional science literature has studied the connections between a region’s health and its well-being in a variety of ways. Second, this literature has also shed light on how alternate policies and a region’s functioning affects and is affected by its resilience. Even so, our central claim is that to the best of our knowledge, there are *no* theoretical studies in regional science that analyze how a pandemic such as Covid-19 influences a poor region’s welfare and how policies adopted to combat the ill effects of the pandemic influence this same region’s resilience. Given this lacuna in the literature, we now discuss our main objective in this paper.¹³⁹

1.3. Our objective

We concentrate on an economically disadvantaged region and analyze the links between health interventions undertaken by a regional authority (RA) and this region’s resilience in the presence of a pandemic such as Covid-19. Consistent with the work of Paul-Sen Gupta *et al.* (2007), Adler and Newman (2002), and Choksi (2018), we take it as given that the population of an economically disadvantaged region also has poor health. In this setting, we first demonstrate how to connect the RA’s health intervention or action¹⁴⁰ to the evolution of a suitably defined regional health indicator in an environment of uncertainty. Second, we compute the probability that the health status of this region’s population falls below a minimum acceptable level in the presence of a health intervention. Third, we solve an optimization problem in which the RA maximizes the likelihood that the health status of this region’s population stays above a minimum acceptable level at a given economic cost. Finally, we discuss the nexus between a health intervention, our region’s health status, and its resilience by presenting two applications of our theoretical framework.

The remainder of this paper is organized as follows. Section 2 describes the theoretical model of an economically disadvantaged region that is adapted from Batabyal *et al.* (2003). Section 3 shows how to link the RA’s health intervention

137 In the remainder of this paper, we shall drop references to Buzz Holling’s name when we talk about resilience. The reader should understand that even though there are two senses in which the term resilience is used in the ecology literature---see Batabyal (2020) and Batabyal and Kourtit (2020)---all mentions of resilience in this paper are to the Holling interpretation of this term.

138 See Di Caro (2018) and Ezcurra and Rios (2019) for a discussion of related issues.

139 This objective is consistent with the perspective of Bailly and Gibson (2017, p. 58) who note that “[r]egional scientists have certainly contributed to discussions on [health care] but there is clearly still work to be done.”

140 In the remainder of this paper, we use the terms “action” and “health intervention” interchangeably.

to the behavior of an appositely defined regional health indicator in an environment of uncertainty. Section 4 calculates the probability that the health status of this region's population falls below a minimum acceptable level in the presence of the health intervention. Section 5 solves an optimization problem in which the RA maximizes the likelihood that the health status of this region's population stays above a minimum acceptable level at a given economic cost. Section 6 discusses the nexus between the RA's health intervention and this region's resilience by presenting two applications of our theoretical framework. Finally, section 7 concludes and then discusses two ways in which the research delineated in this paper might be extended.

2. THE THEORETICAL FRAMEWORK

Consider a poor region in a particular country. An example of such a region in a poor (wealthy) country would be Chhattisgarh (Mississippi) in India (the United States). In practice, it is common to find one or more health indicators that provide a researcher with information about the health status of those residing in this region. So, for instance, if the region under consideration is New York State in the U.S. then we know that there exist "The New York State Community Health Indicator Reports (CHIRS)" that are annually updated to consolidate and provide information regarding health indicators in the so called County Health Assessment Indicators (CHAI) for all communities in New York.¹⁴¹ The CHIRS dashboard tracks about 350 indicators organized by 15 health topics and hence an analyst can easily obtain information about the incidence of, for instance, cancer, cardiovascular disease, and communicable diseases.

Similarly, if we were to focus on what the WHO calls the "European region," then we could use information published by this organization in the "Core Health Indicators" to monitor progress towards the attainment of specific health targets in the 53 member states of the WHO European region.¹⁴² Finally, the Ministry of Health and Family Welfare in India, in cooperation with the World Bank, publishes information about different health indices for states in India.¹⁴³

Since we are interested in studying the effects of a pandemic such as Covid-19 on the health of people living in our economically disadvantaged region, suppose that a relevant health indicator (H) which tells us the proportion of the regional population with *no* respiratory disease, has a stable, steady-state value denoted by H_0 . When the stochastically arriving coronavirus begins to spread in our region, *ceteris paribus*, the virus tends to *lower* the value of the health indicator (H) to some fraction below H_0 . Note that this lowering of the indicator means that the proportion of the regional population that now has a respiratory ailment of some sort has *risen*.

To combat this insalubrious state of affairs, an appropriate regional authority (RA) takes action (A) to raise the value of the indicator from H_0 to $H_0 + \beta A$, where $\beta > 0$ is a parameter. Taking action is costly and therefore we suppose that the cost of taking action A is given by the cost function $c(A)$. We assume this cost function is both strictly increasing and strictly convex. In terms of the derivatives of the cost function, we have $c'(A) > 0$ and $c''(A) > 0$.

Examples of an action A taken by the RA include, but are not limited to, a lockdown, a mandatory mask wearing requirement, an increased level of testing, a decision to quarantine visitors and those testing positive for Covid-19, and contact tracing. The action A can be viewed as a single action or it can also be viewed as a set of actions. When viewed as a set, we would let A_i denote the *ith* possible action, N denote the total number of actions that may be taken by the RA, and the composite action A would be, for instance, a linear combination of the individual actions. Mathematically, we would then have $A = \sum_{i=1}^N \alpha_i A_i$ where the weights $\alpha_i \in (0, 1)$ would denote the relative importance the RA assigns to each of the individual actions.¹⁴⁴ We now demonstrate how to connect the RA's action A to the behavior of our regional health indicator H in an environment of uncertainty.

3. LINK BETWEEN AN ACTION AND THE HEALTH INDICATOR

At any time t , let $Z(t) = \{H(t) - H_0 - \beta A\}$ denote the deviation in the value of our health indicator from the steady-state value H_0 when the RA's action or control variable is A . To account for the point that a pandemic such as Covid-19 almost certainly affects the value of the health indicator H stochastically, we model the evolution of the $Z(t)$ deviations with a stochastic differential equation.¹⁴⁵

The next question concerns what kind of stochastic differential equation we ought to use to model the $Z(t)$ deviations. Here, we are guided by two considerations. First, because there is no evidence to suggest otherwise, we assume that a

141 Go to <https://www.health.ny.gov/statistics/chac/indicators/> for more information about these indicators. Accessed on 5 August 2020.

142 Go to <https://www.euro.who.int/en/data-and-evidence/evidence-resources/core-health-indicators-in-the-who-european-region> for more information. Accessed on 5 August 2020.

143143 Go to https://smartnet.niua.org/sites/default/files/resources/healthy-states-progressive-india-report_0.pdf for more details. Accessed on 11 August 2020.

144 In what follows, in order to avoid algebraic clutter and to keep the mathematical analysis tractable, we shall proceed with the assumption that the action A is a single action and not a set of actions. That said, the reader should understand that an analysis of the "set of actions" case would proceed in a manner that is very similar to what we illustrate in the subsequent sections of this paper.

145 Here Z denotes the deviation random variable and z denotes a particular realization of this random variable.

linear approximation around the steady-state is valid. Second, because of the way in which we have defined the deviation random variable, we expect this variable to display some degree of mean reversion over time. Putting these two considerations together, we contend that it is reasonable to model the evolution of $Z(t)$ with the Ornstein-Uhlenbeck process.¹⁴⁶ This means that $Z(t)$ satisfies the linear stochastic differential equation

$$dZ = -\zeta Zdt + \sigma dW, \tag{1}$$

where $\zeta > 0$ is the speed of reversion, $\sigma > 0$ is the variance parameter, and dW is the increment of a standard Brownian motion or Wiener process.

We wish to analyze the steady-state behavior of the deviation in the value of our health indicator from the steady state value H_0 . From Proposition 5.1 in Karlin and Taylor (1981, p. 219), it follows that the steady-state probability distribution function of $Z(t)$ is given by

$$f_{SS}(z) = \sqrt{\frac{\zeta}{\pi\sigma^2}} \exp\left(\frac{-\zeta z^2}{\sigma^2}\right). \tag{2}$$

When we study nutritional health indicators, particularly those for children, we find that the notion of a “Minimum Acceptable Diet (MAD)” is one of eight core indicators developed by the WHO. Other similar indicators include the related concepts of “minimum dietary diversity (MDD)” and “minimum meal frequency (MMF).” In fact, the MAD indicator itself is a composite indicator that is constructed by using the MDD and the MMF indicators.¹⁴⁷ In addition, Xing and Batabyal (2019) tell us that in the natural resource and environmental economics literature, it is now understood that when uncertainty and irreversibility are issues in natural resource management, the management function ought to pay attention to the notion of a “safe minimum standard (SMS).” The idea here is to manage an ecological-economic system¹⁴⁸ so that this system’s ability to provide humans with a flow of ecosystem services does not fall below a particular level, namely, the SMS.

This discussion suggests that it would be reasonable for our RA to focus on some *minimally* acceptable value of the health indicator H when pondering how this authority might combat the onset of a pandemic such as Covid-19 in our poor region. Since $H(t)$ tells us the proportion of the population in our region that has *no* respiratory disease at time t , concentrating on a minimum value of H is equivalent to taking an action A so that the fraction of people in our region with no respiratory disease does *not* fall below this minimum acceptable threshold. Let us denote this threshold by H_M . Note that the threshold does *not* depend on time. By making H_M be time-independent, we are seeking to capture the idea that when combating a pandemic such as Covid-19 in a region where the population has poor health, the choice of the *threshold* proportion of the population in our region that has no respiratory disease ought not to depend on how virulent the pandemic is at any particular point in time. Our next task is to compute the probability that the health status of this region’s population falls below the minimum acceptable level H_M in the presence of the health intervention.

4. A LIKELIHOOD FUNCTION

To compute the above probability, let

$$f(h)dh = \text{Prob}\{\text{steady} - \text{state health status value} \in (h, dh)\}. \tag{3}$$

The probability on the right-hand-side (RHS) of equation (3) can also be written as

$$f(h)dh = \text{Prob}\{\text{steady} - \text{state deviation value} \in (h - H_0 - \beta A, h - H_0 - \beta A + dh)\}. \tag{4}$$

Now, using equation (2), the probability on the RHS of equation (4) can be simplified. This simplification gives

$$f(h) = \sqrt{\frac{\zeta}{\pi\sigma^2}} \exp\left\{\left(\frac{-\zeta}{\sigma^2}\right) (h - H_0 - \beta A)^2\right\}. \tag{5}$$

Note that equation (5) provides us with an explicit way of calculating the probability density of the deviation from the raised health indicator value $H_0 + \beta A$. We are now in a position to state and then solve an optimization problem in which the RA maximizes the likelihood that the health status of this region’s population stays above the minimum acceptable level H_M at a given economic cost $c(A)$.

5. AN OPTIMIZATION PROBLEM

The RA chooses the control (action) A , incurs cost $c(A)$, and maximizes the probability that the health status of our region’s population stays above the minimum acceptable threshold H_M . The reader will note that this is an unconventional objective function in the sense that it is partly focused on public health and partly on economic considerations. We say this because the probability part of the objective function is a public health criterion whereas the cost part is clearly an economic yardstick.

Using equation (5) and the cost function $c(A)$, mathematically, our RA solves

146 See Karlin and Taylor (1981, pp. 170-173) or Taylor and Karlin (1998, pp. 524-534) for more on the Ornstein-Uhlenbeck process.

147 Go to <https://index.nutrition.tufts.edu/data4diets/indicator/minimum-acceptable-diet-mad> for more details. Accessed on 6 August 2020.

148 Examples of ecological-economic systems include fisheries, forests, and rangelands.

$$\max_{\{A\}} \int_{H_M}^{\infty} \left[\sqrt{\frac{\zeta}{\pi\sigma^2}} \exp \left\{ \left(\frac{-\zeta}{\sigma^2} \right) (h - H_0 - \beta A)^2 \right\} \right] dh - c(A). \tag{6}$$

Let us now make the substitution $k = h - H_0 - \beta A$. Using this substitution, the RA's maximization problem in (6) can be written as

$$\max_{\{A\}} \int_{H_M - H_0 - \beta A}^{\infty} \left[\sqrt{\frac{\zeta}{\pi\sigma^2}} \exp \left\{ \frac{-\zeta k^2}{\sigma^2} \right\} \right] dk - c(A). \tag{7}$$

Differentiating the maximand in (7) with respect to the control variable A , the first-order necessary condition for an optimum is

$$\beta \left[\sqrt{\frac{\zeta}{\pi\sigma^2}} \exp \left\{ \left(\frac{-\zeta}{\sigma^2} \right) (H_M - H_0 - \beta A)^2 \right\} \right] = c'(A), \tag{8}$$

and the second-order sufficiency condition is

$$\sqrt{\frac{\zeta}{\pi\sigma^2}} \exp \left\{ \left(\frac{-\zeta}{\pi\sigma^2} \right) (H_M - H_0 - \beta A)^2 \right\} \left\{ \left(\frac{2\beta^2\zeta}{\sigma^2} \right) (H_M - H_0 - \beta A) \right\} - c''(A) \leq 0. \tag{9}$$

The first-order necessary condition in equation (8) tells us that optimality requires the RA to choose the action A so that the marginal economic cost to the poor region from the use of this action designed to fight the pandemic's ill effects (the RHS of equation (8)) is equal to the marginal increase in the likelihood that the health status of our region's population will be above the minimum acceptable level H_M . We now proceed to show how our analysis thus far can be used to figure out the resilience of the region under study and to demonstrate the connection between the RA's action and the resilience of this region.

6. A HEALTH INTERVENTION AND REGIONAL RESILIENCE

Let A^* be the solution to equation (8). To find a closed-form expression for A^* and to compute our region's resilience in the face of a pandemic, it will be necessary to impose more structure on the problem by positing explicit values for (H_0, H_M) and by working with a specific functional form for the cost function $c(A)$. Before we do this, let us emphasize two points. First, we shall focus on two applications of our analysis thus far. In both applications, we shall make use of a key finding in the extant literature---see Paul-Sen Gupta *et al.* (2007), Adler and Newman (2002), and Choksi (2018)---that the residents of economically disadvantaged regions also tend to have poor health. This means that the population of the region we are studying is unhealthy as far as the proportion of the population that has one or more respiratory diseases is concerned. Second, in the first (second) application, the region under study is more (less) healthy. We model this feature by supposing that $H_0 = 0.6$ (0.5) in the first (second) application. In words, when $H_0 = 0.6$ in the first application, when a pandemic such as Covid-19 hits this region, 60 percent of the region's population has no respiratory ailments of any kind and hence 40 percent do have one or more respiratory ailments. Similarly, when $H_0 = 0.5$ in the second application, upon the onset of Covid-19, 50 percent of the regional population has no respiratory ailments and therefore 50 percent of this population is afflicted with some kind of respiratory disease.

Note that since we are conducting two "thought experiments" for the *same* underlying regional population, in the following two applications, the initial value of the steady-state level of the health indicator H_0 is different. That said, the purpose of the RA's health intervention is to act forcefully to improve the health status of the relatively unhealthy regional population. As such, in both the following applications, we suppose that the RA's goal is to determine a stationary or constant value of the action A to maximize the likelihood that the health status of our region's population is above the minimum acceptable threshold or $H_M = 0.8$ at minimum cost. Finally, the cost of taking action A is represented by the exponential cost function.

6.1. Application 1: More healthy regional population

Suppose that the cost function $c(A) = \exp(A)$. Clearly, this means that $c'(A) = \exp(A)$. Let us now substitute $c'(A) = \exp(A)$ in equation (8). After several steps of algebra, equation (8) can be simplified to give

$$\beta \sqrt{\frac{\zeta}{\pi\sigma^2}} \exp \left\{ \left(\frac{2\zeta H_0 H_M - \zeta H_M^2 - \zeta H_0^2}{\sigma^2} \right) + \left(\frac{2\beta\zeta H_M A - \beta^2\zeta A^2 - 2\beta\zeta H_0 A}{\sigma^2} \right) \right\} = \exp(A). \tag{10}$$

Taking the natural logarithm of both sides of equation (10) and then rewriting the resulting expression gives us a quadratic equation in the control variable A . That equation is

$$\left[\frac{\beta^2\zeta}{\sigma^2} \right] A^2 + \left[\frac{2\beta\zeta H_0 + \sigma^2 - 2\beta\zeta H_M}{\sigma^2} \right] A + \left[\left\{ \frac{\zeta H_M^2 + \zeta H_0^2 - 2\zeta H_0 H_M}{\sigma^2} - \log \left(\beta \sqrt{\frac{\zeta}{\pi\sigma^2}} \right) \right\} \right] = 0. \tag{11}$$

Inspecting equation (11), if we denote the coefficient of A^2 by Γ , the coefficient of A by Δ , and the constant term by E , then the solutions to equation (11) are given by

$$A_i^* = \frac{-\Delta \pm \sqrt{\Delta^2 - 4\Gamma E}}{2\Gamma}, i = 1, 2, \tag{12}$$

with $\Delta^2 \geq 4\Gamma E$ for obvious reasons. Which of these two values¹⁴⁹ of the action A makes most sense for the optimization problem that we are analyzing depends on the parameters of the stochastic differential equation describing the evolution of the $Z(t)$ deviations and on the exogenously given health indicators levels H_0 and H_M . We already know that in this first application, $H_0 = 0.6$ and $H_M = 0.8$. Therefore, to illustrate the working of our model, suppose that $\beta = \zeta = 2$, and $\sigma^2 = 4$. In this case, tedious but straightforward computations show that the quadratic equation in (11) has two real roots given by $A_1^* = 0.1191$ and $A_2^* = -0.1691$. To see which of these two solutions maximizes the objective function in equation (7), we substitute the above two candidate maximizers into equation (7) and then perform the necessary computations.¹⁵⁰ This tells us that when $\beta = \zeta = \sigma^2 = 2$, $H_0 = 0.6$, and $H_M = 0.8$, $A_1^* = 0.1191$ maximizes the RA's objective function.

To see the link between the RA's maximization problem and the notion of resilience that we have discussed in section 1.2, recall that the resilience of a socioeconomic system is "the capacity of [this] system to absorb disturbance and reorganize while undergoing change so as to still retain essentially the same function, structure, identity, and feedbacks" (Walker *et al.*, 2004). The socioeconomic system that we have been studying is the poor region and our specific focus has been on the health status of the population in this poor region. The disturbance alluded to in the definition above is the onset of a pandemic such as the Covid-19. So, when will our poor region be able to withstand the Covid-19 induced disturbance and still retain its function, structure, identity, and feedbacks? This will happen if, as a result of the RA's health intervention, the health status of our region's population is *above* the minimum acceptable threshold $H_M = 0.8$. However, since we are analyzing a stochastic environment, we *cannot* be sure about whether the RA will succeed in enhancing the regional population's health status to at least $H_M = 0.8$. That said, in the stochastic environment that we are studying, we can compute the *probability* that the RA's health intervention will improve the regional population's health status to at least $H_M=0.8$. This probability is given by the integral in the first part of the maximand in equation (7). Using $A_1^* = 0.1191$ and the other parameter and indicator values given in the preceding paragraph, we can evaluate this integral and determine that the probability we seek is 0.5215.

In words, the probability that the RA's action will succeed in maintaining the health status of the population in our poor region above the threshold $H_M = 0.8$ is 52.15 percent. Put differently, the likelihood that our poor region will be resilient when faced with an adverse stochastic shock from the Covid-19 pandemic is 52.15 percent. Since our analysis is long-run in nature, consistent with the previous work of Batabyal (1999) and Batabyal and Beladi (1999), we can think of the resilience of our poor region as a probability and, more specifically, as the probability 0.5215. This way of thinking about resilience has two distinct advantages. First, since it is a probability, resilience is bounded from above and below. Second, it is integrally tied to our RA's health intervention and this is as it should be because we are studying a socioeconomic or social-ecological¹⁵¹ system whose behavior in the presence of a pandemic is governed partly by natural and partly by human forces. We now proceed to discuss the second application of this paper.

6.2. Application 2: Less healthy regional population

In this instance, $H_0 = 0.5$. This means that only 50 percent of our poor region's population has no respiratory ailments and hence 50 percent do when a pandemic such as Covid-19 strikes the region. This is the sense in which the regional population now is *less* healthy than the case studied in section 6.1. The cost function and the remaining parameter and threshold values are all as in section 6.1. Therefore, we have $c(A) = \exp(A)$, $\beta = \zeta = \sigma^2 = 2$, and $H_M = 0.8$. Also, the methodology we employ in this section is identical to that employed in section 6.1.

Let us plug the various values given in the preceding paragraph into equation (11) and then solve the resulting quadratic equation in the RA's control variable A . This gives us two real roots and they are $A_1^* = 0.116$ and $A_2^* = -0.066$. Next, let us substitute these two candidate maximizers into equation (7). After performing the necessary computations using the method delineated in section 6.1, we infer that when $\beta = \zeta = \sigma^2 = 2$, $H_0 = 0.5$, and $H_M = 0.8$, $A_1^* = 0.116$ maximizes the RA's objective function.

As in section 6.1, to see the link between the RA's maximization problem and the notion of resilience, let us compute the *probability* that the RA's health intervention will improve the regional population's health status to at least $H_M=0.8$. This probability is given by the integral in the first part of the maximand in equation (7). Using $A_1^* = 0.116$ and the other parameter and indicator values given in the preceding paragraph, we can evaluate the relevant integral and conclude that the probability we seek is 0.4617. In words, the probability that the RA's action will succeed in maintaining the health status of the population in our poor region above the threshold $H_M = 0.8$ is 46.17 percent. In accordance with the

149 It is understood that there will only be one value if $\Delta^2 = 4\Gamma E$.

150 We used the tables in Beyer (1991, p. 486) and the complementary error function calculator given in <https://keisan.casio.com/exec/system/1180573449> to perform the necessary computations. Accessed on 11 August 2020.

151 See Walker *et al.* (2004) for additional details on this point.

reasoning employed in section 6.1, we contend that the resilience of our economically disadvantaged region is also given by the probability 0.4617.

As an intuitive check on one of our key findings, note that when confronted with a relatively healthy (unhealthy) population, it should be easier (harder) for the RA to improve the health status of the population to the desired threshold of $H_M = 0.8$. However, since we are analyzing a stochastic environment, this means that the probability of being successful when the RA uses action A should be higher (lower) when working with a relatively healthy (unhealthy) population. This is indeed what happens in the two applications that we have presented. Specifically, in the more healthy population case analyzed in section 6.1, the RA's probability of being successful is 0.5214 which is clearly *larger* than the corresponding probability of 0.4617 which arises when the RA works with the less healthy regional population. This completes our discussion of health interventions in a poor region and resilience in the presence of a pandemic.

7. CONCLUSIONS

In this paper, we concentrated on a poor region and studied the connections between health interventions undertaken by a regional authority (RA) and this region's resilience in the presence of a pandemic such as Covid-19. First, we showed how a health intervention by the RA stochastically affected an appositely defined health indicator for this region. Second, we computed the probability that the health status of this region's population would fall below a minimum acceptable level in the presence of the health intervention. Third, we solved an optimization problem in which the RA maximized the likelihood that the health status of this region's population would stay above a minimum acceptable level at a given economic cost. Finally, we discussed the nexuses between our region's health status and its resilience by presenting two applications of our theoretical framework.

The analysis conducted in this paper can be extended in a number of different directions. In what follows, we suggest two possible extensions. First, it would be useful to study a scenario in which the minimum acceptable health threshold H_M is not exogenously specified but determined endogenously in an appropriately specified model. Second, it would also be instructive to study a scenario in which it is not possible---or possible only at great cost---for a RA to reverse the adverse impacts of one or more respiratory ailments suffered by the people living in the region under study. Studies of health interventions that incorporate these aspects of the problem into the analysis will provide additional insights into the nexuses between optimal health interventions and the resilience of economically disadvantaged regions.

THE PERSISTENT EFFECTS OF NATURAL DISASTERS ON OPIOID DEATHS

[Meri Davlasheridze](#)¹, [Stephan Goetz](#)²

¹Texas A&M University at Galveston, USA. ²The Pennsylvania State University, USA

ABSTRACT

Catastrophic natural disasters have been increasing worldwide in recent decades, among which floods and coastal storms (e.g., cyclones, hurricanes) have been recognized as the most consequential in terms of economic and human tolls. The two types have been responsible for the most economic losses and human impacts in the United States as well. Up to date, the research has focused on understanding disaster vulnerability measured by the number of fatalities at the onset of the event. Much less is known about the long-term health implications of disasters. Disasters can have health implications and potentially result in deaths in the long term potentially due to the debilitating consequences of post-traumatic stress disorder, as well as the overall decline in general mental or behavioral and physical health. Moreover, languishing health problems could lead to other more serious issues such as substance abuse and dependence and possible drug-related fatalities. This is a concern considering especially the already dire US opioids crisis coupled with the preponderant scientific consensus that climate change will likely increase the frequency and severity of extreme weather events in the future.

In this paper, we focus on understanding how individuals' exposure to extreme disaster events may linger over time and contribute to drug-related mortality in the United States. We also explore how federal disaster response specifically addressing the immediate needs of households in terms of temporary housing (e.g., shelters, hotels) accommodation and quick repair of homes, short-term counseling and legal services could mitigate substance-related fatalities of disasters.

Results of our county-level analysis covering the entire US over the period 1970-2016 suggest a significant rise in drug overdose mortality in areas experiencing damaging flooding events. Interestingly, our results indicate that impacts of floods on deaths (as opposed to opioids abuse, which may have started immediately after the disaster) start to emerge two years after the incident and linger over the long-term, with a significant rise in death rates seen even 9 years after the catastrophic disaster experience. Meanwhile, we also find that increased support for housing and other household needs made available by the Federal Emergency Management Agency (FEMA) in the aftermath of disasters is important in terms of reducing opioid-related mortality.

Our results are important and have significant policy implications both for the disaster risk and ongoing opioid crisis management.

ABSTRACT

Guinea-Bissau has been facing socioeconomic development challenges since it became in the late 1970s. The challenges concerns reconciling import tariff and export taxes reductions to promote national economy integration and to use resources from trade gains to fight against extreme poverty. This study uses a dynamic recursive micro-simulated computable general equilibrium model to analysis the macro-micro level long-term outcomes of two trade reforms scenarios in this least developing country, which are imports tariffs and export taxes cuts. We observe that negative import tariffs shocks adversely affected the overall output, investment, and government consumption. Although real product does not decrease at the end of simulations period, the small recovery over time is not enough to counteract the initial negative effects, since the accumulated result is negative. Conversely, export taxes reductions positively affect macroeconomic aggregates and sectoral level performances, as well as rural and urban households' income, with stronger impacts for poorer ones. Our results suggest the relevance of accumulated wealth in mitigate long-term poverty as it plays an important role in households' income gains and hence in their long-term consumption.

1 INTRODUCTION

Guinea-Bissau is one of the former Portuguese colonies in Africa, which became independent in 1973. It borders to the North with the Republic of Senegal, East and the South with the Republic of Guinea, and to the West by the Atlantic Ocean. The country's total population is approximately 2 million, of which 60% lives in rural areas and 40% in small urban cities. Guinea-Bissau is one of poorest country worldwide. For instance, in 2017, its Human Development Index (HDI) stands at 0.420, with 67% of the population considered poor or extremely poor. The average life expectancy at birth is 55 years (48.9 for women and 53.1 form men), with the infant mortality rate of 92 per 1000 born (World Bank Development Indicators - WBDI, 2018).

The country economy is supported by a variety of sectors and products. However, this is a typical example of a small and undeveloped agriculture-based-economy, in which only a few products play an important role for gross domestic product (GDP) of US\$ 100 million in 2017. In the total of 68% of the population over 15 years employed, 61% correspond to employment in the agricultural sector, 5.8% industrial employment and 34.1% employment in the services sector (ILO, 2017).

Employment opportunities reflect each sector production capacity in which agriculture represents 53 % of the total added value, the industrial sector 12% and the services sectors 35 % (WBDI, 2018). Agricultural most relevant products include the production of sorghum, maize, rice, sorghum, cashew nuts, and others. Cashew nuts became the main production and export product since 1990s when increasing demand from Asian countries, such as India and Singapore, boosted activities related to chestnuts. As the country does not export intermediate and capital goods, 99 percent of exports of Guinea-Bissau are mostly raw materials, of which the share of cashew nuts reach 90 percent.

To face the challenges of fighting persistent poverty, governments have relied on trade policies to improve the households' conditions as well as to find ways to increase budget to fund their development policies. The first trade measure was an initiative to the economy openness in mid-1986, having been cemented with the country's entry into the WTO (World Trade Organization) in 1995 and the consequent participation in the Doha Round, formally known as Doha Development Agenda (henceforth DDA), in 2001.

However, as the government agreed to reduce the import tariffs during the DDA, it also adopts the so-called exportable taxes to increase its revenue. This policy consists of a percentage of taxes set on export products. Such percentage is determined once a year during high harvest seasons between April and June and remains invariant for the remaining 9 months. Each product is taxable according to its sector classification and therefore its share on total output. The government charges higher export taxes to the agricultural products, represented primarily by cashews. Tax less products from other sectors allows disintegrating the export grid. However, exporters increase complains about the high taxes charged by arguing that the government has committed in the DDA to reduce import taxes, while failing to relieve

national exports. To mitigate these complaints, in May 2019, the government adopted a compensatory policy, reducing exports taxes by 2.5 percent.

The purpose of this study is to provide macro and micro level evidence of current trade reforms in Guinea-Bissau. The study is based on two development policies: the import tariff reduction agreement signed in DDA, that government effectively put into practice in 2007, and the government decree to reduce export taxes by 2.5 percent in 2019, as to mitigate the above exporters complaints, deepen economic openness, and explore the country's comparative advantages. We seek to answer the following questions: Is the agreement formalized in the DDA capable of promoting the performance of the economy of a small poor country like Guinea-Bissau? Are there gains from trade liberalization? If so, who earns or lost more? Do imports tariffs and exports taxes cuts have the same effects on rural and urban households living standard?

This study aims to analyze the DDA long-term impacts on socioeconomic outcomes, We analyze both the exports taxes and imports tariffs reductions proposal formalized in the Doha agreement on the economy of Guinea-Bissau and their implications for development, particularly discussing their effects on macroeconomic aggregates and household's income and consumption and more generally on poverty.

Our study fits in the context of the growing economic literature that analyzes impacts of trade liberalization on socioeconomic outcomes (see, for example, Davies et al.1994; Krishna and Mitra, 1998; Diao, Somwaru and Roe, 2001; Beghin, Roland-Holst and der Mensbrugge, 2002), particularly those evaluating the long-run effects of trade reforms on the households living conditions in developing countries (Chitiga, 2000; Cockburn, 2001; Mabugu, R. 2001; Chitiga, Kandiero and Mabugu, 2005; Chitiga and Mabugu, 2008; Cockburn, Decaluwé and Robichaud, 2008; Annabi et al.; 2005a,b).

We focus on analyzing the long-term effects of trade reforms for rural and urban households with different conditions, that is, poor and not so poor. Understanding the effects of such policies is important for several reasons for the country to find socioeconomic development options. First, economic policies might affect these households differently once they are exposed to the different challenges and opportunities arising from trade liberalization. These opportunities involve the diversification of consumption and job opportunities that openness can bring up. Suppose that a political measure ultimately resulted in the economic activity improvement. Suppose further that this improvement was due by faster production growth in the industrial sectors than in any other sector. *Ceteris paribus*, employment of (skilled) urban workers is expected to grow faster than employment of rural workers. This can increase the income of the former more quickly and then leading to income gap. So, by concentrating on different rural and urban households with different initial conditions, we will be able to provide instructive evidence for the elaboration of public policies consistent with the reality of each household.

Second, this study differs from those that simulate joint policy effects for regions or economic blocs (e.g., see Achterbosch *et al.*, 2004). In such studies, the country-specific characteristics and their potential effects may be not well captured, or they are ignored. However, the generalizations of the conclusions based on the simulated data could eventually fail when the block-based evaluations suffer greatly from the effects of the entities. For instance, besides striking difference in the size of economies, Sub-Saharan Africa has several countries, each with its own agricultural culture. Some have chestnuts-based economies and others have economies entirely based on cotton and therefore their interests must be in line with the characteristics of their economies, which suffer differently from the consequences of liberalization agreements. By focusing on one country, this study has the advantage of considering the national strategic interests and the effects of trade policies on different economic outcomes.

Third, we deal with an axis that has been the central focus of the government, which is to encourage trade on agricultural products, and \$ billions have been spent as better the condition of national production as well as the households' standard of living that suffer from extreme poverty. Fourth, evidence shows that trade impacts macroeconomic activities, and resources from a growing economy could be used to fund policies to fight against poverty (e.g., Bhagwati, Panagariya, and Srinivasan, 1998), but no empirical studies have been done for Guinean economics so far. As to fill this empirical gap, we apply a micro-simulated dynamic CGE model for Guinea-Bissau economy using 2014 updated SAM. For the best of our knowledge, this is the first CGE model for this economy.

Finally, although developing countries have increased participation in world trade, which has changed from 33 percent in 2000 to 48 percent in 2017, has contributed to a reduction in half the world's poverty, according to the World Bank (World Bank Report, 2018), it is still unclear how households in Guinea-Bissau with a monocultural economy will benefit from the trade liberalization. Evidence from our study therefore may guide current integration policies as well as to design development policies to fight against the prevailing extreme poverty.

The rest of the study is structured as follows: Section 2 shows the general characteristic of economy Guinea-Bissau. Section 3 provides a brief incursion into the applied related literature. Next section presents the methodology, including the database, while Section 5 discusses the results of the policy scenarios. Section 6 concludes the discussions.

2. OVERVIEW OF GUINEA-BISSAU ECONOMY AND MACROECONOMIC CONTEXT OF TRADE

The Guinea-Bissau economy is supported by a variety of sectors and products. Fishing is one of the most important economic activities, with the sale of industrial fishing licenses for the European Union and China been one of the main sources of government revenue. Since the economic openness in the mid-1980s this country has experienced significant economic growth and it is currently 20 times greater than it was in the 1970s, with GDP around US\$ 100 million (FCFA 50 billion). Private final consumption expenditure represents the largest cumulative share among GDP components (Table 1).

Table 1 – Macro aggregates (% of GDP)

Variable	1970-1989	1980-1989	1990-1999	2000-2009	2010-2017
Households consumption	95.476	85.623	91.948	87.637	89.106
Government consumption	26.710	11.854	8.1882	12.548	9.920
Investment	11.724	38.353	21.189	10.241	8.794
External balance	(33.910)	(5.831)	(21.325)	(10.427)	(7.820)
Total	100.00	100.00	100.00	100.00	100.00

Source: Authors' calculations. World Development Indicators: World Bank data, 2018.

Free trade practices were initiated in mid-1986 with the adoption of structural adjustment measures aimed at carrying out internal reforms that allow the country's international integration. The 1990s represented a decade of intensification of the process of integration into international markets. During this period, the country joined the West Africa Economic and Monetary Union (WAEMU) in 1997 and signed several unilateral and multilateral agreements, including its accession to the World Trade Organization, World Bank and the International Monetary Fund in 1995 (CATEIA ET AL., 2018).

Since then the political measures both in the economic as well as in the social area have been taken in partnerships with these institutions. But despite major advances in several sectors, socioeconomic indicators suggest that Guinea-Bissau is one of the poorest countries in the world, because of the relatively low performance of its economy that reflects the backwardness of its low-growth productive sectors.

Several factors could explain these results, but analysts converge on the argument that the lack of reform in the public sector has hampered the implementation of development programs, since the modern assessment criteria, such as accountability, are often loose (Cateia et al., 2018). However, such reforms have never been easy to implement. For instance, after initiating state reforms including the establishment of the multi-party system in 1994, the country faced an 11-month civil war that began on June 7, 1998, which wiped out more than 1/3 of its economy. And, before even recovering from war episodes, political instability occurred, culminating in a coup d'état that disbanded the President of the Republic in 2003. The national reconciliation start following the attempt by international organism and sub-regional partners to promote dialogue between the parties, and it enabled the holding of the second presidential election in 2005 (see GUINÉ-BISSAU, 2010).

In 2001, the first National Poverty Reduction Paper (I NPRSP) was established, which was only implemented in 2004. An IMF report at the time (IMF Country Report, 2007, p.5), however, notes that the country's high level of instability did not permit it to focus government initiatives on the search for ways and means to tackle the challenges of the country's development, which resulted in the failure of this plan. That failure is officially pegged to the cashew nuts price fall in 30 percent in 2009.

The country has experienced moments of political stability that have benefited economic activities practice. The challenges it has faced have been to carry out reforms of the public administration, to restructure the productive system and to formulate economic policies consistent with its comparative advantages. The actions taken by governments along with their international partners are also intended to combat mainly rural poverty, because most extremely poor people live in rural areas and the basis of their livelihood comes from the agricultural sector (BOUBACAR-SID ET AL., 2007). Thus, in 2011, the II NPRSP was designed to promote inclusive growth and reduction of social inequalities, although their operating mechanism was less tied to the performance of a sector (CATEIA ET AL., 2018).

In short, the Guinean economy can be characterized as follows: first, it is an economy that depends crucially on the performance of cashew nut production, which represents 98% of export earnings and about 17% of government revenues (GUINEA-BISSAU, 2010). More than 85% of the population is directly involved in cashew nut production process whose planting occupies approximately 6% of the national territory. That is, an area of almost 210,000 hectares, and on average each Guinean produces more than 53 kg of cashew nut a year, that is, an average of more than 90,100 tons produced annually in the country (CATEIA ET AL., 2018). Second, it is an economy with infrastructure base that suffers with the chronic degradation problem since, according to Guinea-Bissau (2010, p.01), both roads and port facilities have received little maintenance or improvement since 1975 and continue to suffer from the effects of the civil war that took place in 1998/99.

The DDA is a reform program to prevent and correct distortions in the world agricultural markets and it was expected to contribute to current socioeconomic indicator and boost Guinea-Bissau trade. The distortions stem from excessive agricultural subsidies by developed country governments, which have spent billions of dollars each year to support their agricultural sectors (World Trade Organization Documents - WTO, 2001).

The subsidies to the agriculture products impact developing country because there is a competition effect associated to the fact that they allow the production from developed countries to be offered at prices below the production cost. Farmers in developing country may lost their market share and invest less to improve the production chain. At the macro level, the poor countries like Guinea-Bissau may remain as food importers. Conversely, tariffs applied by poor nations also distort agricultural products markets, so it is recommended that they should be reduced.

However, although important trade new guidelines were established in 2001, there was no agreement on bandwidth and exact threshold for subsidies, not even for the level of tariff cuts. The broad acceptance of reducing such burdens was achieved in the General Council Decision 579, known as July 2004 Package, where it was proposed higher cuts in higher subsidies and tariffs from answerable countries. For Guinea-Bissau, whose performance of the aggregate macroeconomics depends on the agricultural sector, the agreement was signed with some enthusiasm.

3. RELATED LITERATURE

The conventional economic theory argues that fewer trade restrictions can accelerate the development of poor countries (Bhagwati 1965). This is because trade liberalization can reduce trade cost (Portugal-Perez and Wilson 2012) and increase exports (Iwanow and Kirkpatrick 2007; Coşar and Fajgelbaum 2016). The resources obtained through positive trade balance can be used for various development purposes, such as to fight against poverty (Ju, Wu, and Li 2010). Policymakers are then advised to adopt trade facilitating measures. They seem to be doing that, since the expansion of world trade by 146 per cent between 1960 and 2017 would have been their response in using such available facilitating mechanisms, thus a clear example of why open economies is preferable (WTO 2015).

Trade liberalization can also affect the development of a country because it impacts national comparative advantages (Bernard *et al.*, 1999; Bernard and Wagner, 2001). For instance, in the Melitz (see Melitz, 2003) trade-type model, trade shock, which induces competition among firms for scarce labor, causes real wages to be increased by relatively more productive firms. Such firms can enter export markets and thus be able to expand production. Therefore, promoting productivity growth is one way of increasing the export opportunity while trade liberalization can increase the firms' growth productivity. Therefore, trade and productivity affect each other, and both can be affected by the same factors (Melitz *et al.*, 2008; Helpman *et al.*, 2008).

The present study fits into the context of economic literature that assesses socioeconomic impacts of trade liberalization (Dutt *et al.* 2009; Amiti and Cameron 2012), essentially those for developing economies using CGE approach, such as Chitinga and Mabugu (2008) study for South Africa. The experiment of this literature consists of designing various economic opening policies scenarios and verifying which one contributes to the improvement of the households welfare, in terms of income and consumption gains, or in terms of income inequality reduction, using the usual inequality measures, such as the Gini Index.

The theory seeks to capture the short, medium or long-term outcomes of these scenarios by establishing a series of causal relationships provided by the open framework of a consistent CGE model. Although its short and medium-term effects depend on the context, in the long run, trade liberalization is expected to contribute to economic growth and the reduction of income inequality. Possible negative short-term impacts are related to the delay in contracts renegotiation and, more generally, to relative price readjustments. In such a situation, economic theory predicts that cuts in a country's tariffs, for example, tend to trigger relative price changes unfavorable to its economy (WTO 2001).

This is the result explained by the inverse relationship between demand and price. The domestic demand for imports, for example, is a function of the price of the imported good in the domestic market and this price is the sum of the international price and the tariff that acts as an addition to the cost of transportation. Thus, the reduction in the tariff will lead to a decrease in the domestic price of the imported goods (see Rutherford and Paltsev, 1999), which increases the demand for imports. For countries that export only a small proportion of their production, demanding more imports can generate negative external savings and an increase in foreign indebtedness.

By analyzing the effect of the openness because of the increase in the number of foreign competitors caused by the reduction of tariffs arising from trade agreements, Bittencourt *et al.* (2008), find that, for Brazil, unilateral liberalization generated a real trade-off between aggregate welfare gains and losses for low-income households in urban areas. Therefore, according to Kis-Katos and Sparrow (2015), short and medium-term implications of trade liberalization in labor market are context-specific. They depend on several factors such as the previous protection structure to regional market access as well as the degree of market flexibility (see also BITTENCOURT 2004; GOLDBERG and PAVCNİK 2005; AMITI and KONINGS 2007; CHIQUIAR 2008, LEE and WIE 2015).

However, as domestic production is carried out by combining inputs from different sources, basically national and imported, the decrease in import prices means that economic activities are using more imported goods as intermediate inputs in the production process. If taxes, endowments and offer prices remain unchanged, the firm's production will increase, as well as its profit. The firm will hire workers and, consequently, income and household consumption will rise. The increase in demand for total production will increase the offer price and the firm will also win. Industries should increase their production if the weight of the foreign commodity in the composite good is greater than the weight of the domestic one. If this is case, the sector should demand more workers and capital.

The increased demand for primary factors is expected to increase its price, assuming that each factor is remunerated according to its marginal productivity. But what types of workers can benefit most from trade liberalization is an issue under investigation. What is expected is that the increase in household income and the decrease in prices of imported goods will increase household consumption. Therefore, for developing countries, trade liberalization might be a feasible way that leads to the redistribution of wealth and increases aggregate welfare in long-term.

There is growing body of empirical literature analyzing the effect of trade liberalization through negative import tariff shocks. For instance, in their study for Ethiopia, Kebede, Aredo and Fekadu (2012) noted that liberalization resulted in a decline in economy output as well as in poverty in the short term, but it has benefited more farming agriculture sector. They also observed an increase in import volume while exports slightly decrease. In the same direction, Chitinga *et al.* (2005) for Zimbabwe find also strong evidence of general decreasing in poverty and inequality due to trade liberalization. Several studies, however, find ambiguous results of trade reform including Decaluwé *et al.* (2008) and Aka (2006) for Benin and Ivory Coast, respectively. In particular, Nwafor *et al.* (2007) for Nigeria show a weak short term but a strong long-term increase in poverty resulting from trade liberalization. This contrasts the Annabi *et al.* (2005) findings. Using a dynamic CGE model for Senegal, they show that, in the long-term, trade liberalization increases capital accumulation, leading to significant increases in welfare and decreases in poverty, although the effects are greatest for urban and non-

poor households. Durongkaveroj (2014) applies the same methodology to simulate free trade policy effects on the Thailand economy, and they showed that removing tariffs increases the national prosperity.

Meanwhile, export taxes work as an important source of government revenue in many developing countries, particularly those with agricultural-based economies like Guinea-Bissau¹⁵². In fact, many countries incorporate export taxes as an important element of their trade policy and use them as a strategic industrial policy strategy, as well as to overcome domestic economic crises (Ruta and Venables, 2012). According to Solleder (2013), the rise of export taxes relative to other trade policy measures may be explained by a lack of discipline on export taxes in the WTO law. GATT in its article XI stipulates only that export should not be subject to quantitative restrictions, but does not determine any obligation on the maximum level of export taxes defined, which makes countries take advantage of this loophole by using these taxes as restrictions on exports of raw materials.

Ruta and Venables (2012) argue that mutual gains from trade are possible upon coordinated policy reforms. Several studies provide empirical evidence of these gains, including Grossman (1980) and Staiger and Alan (2010), who show that both negative shocks in import tariffs and export taxes bring long-term gains to households.

4. METHODOLOGY

We use PEP (*Partnership for Economic Policy*) recursive dynamic CGE model. This is a detailed model, making it impossible to provide here a full description of its theoretical structure. We refer interested reader to Decaluwé, Lemelin, Robichaud and Maisonnave (henceforward DLRM, 2012). The foundations of this model stems from neoclassical microeconomic assumptions in the tradition of Dervis, De Melo and Robinson (1982) that have used an analytical framework developed almost a century ago by Leon Walras (Devarajan and Rodrik, 1989; Davies and Torvik, 1994; Devarajan and Robinson, 2002).

We describe productive activities and agent's demand in an interconnected environment, that is, a national open economy to international trade. The model's agents are firms, households, government, and the rest-of-the-world, however, only firms and households optimize.

There is a representative firm operating in a perfectly competitive environment and each firm in an industry j maximizes profits ($XS_{j,i,t}$) - Eq.1,

$$XS_{j,i,t} = \frac{XST_{j,t}}{(B_j^{XT})^{1+\sigma_j^{XT}}} \left[\frac{P_{j,i,t}}{B_{j,i}^{XT} PT_{j,t}} \right]^{\sigma_j^{XT}} \quad (1)$$

subject to its production technology constraints (Eq.2),

$$XST_{j,t} = B_j^{XT} \left[\sum_i B_{j,i}^{XT} XT_{j,i,t} \rho_j^{XT} \right]^{\frac{1}{\rho_j^{XT}}} \quad (2)$$

taking the prices of factors, goods, and services as given. Where, at time t , $XST_{j,t}$ is the total aggregate output; $P_{j,i,t}$ is the basic price of industry j 's production of commodity i ; $PT_{j,t}$ is the basic price of industry j 's output; B_j^{XT} is the scale parameter; σ_j^{XT} is the elasticity of transformation, $0 < \sigma_j^{XT} < \infty$; and ρ_j^{XT} is the elasticity of substitution, $\rho_j^{XT} = \frac{1+\sigma_j^{XT}}{\sigma_j^{XT}}$, $1 < \rho_j^{XT} < \infty$.

As results, the production technology provides clear understanding of the firm optimizing production process. Firm combines intermediate inputs and value added in fixed shares to produce the sectoral output of each productive activity. There is strict complementary in inputs use that we model through the Leontief production function.

Each industry's value added consists of transformation of composite labor and composite capital. There are 12 types of worker, 6 skilled and 6 unskilled, and one type of capital, a land and capital add up, used as primary inputs, with the requirement that each factor receive the value of its marginal product. As both labor and capital can replace each other, and a constant elasticity of substitution (CES) specification is adopted to model this substitution.

The households maximizing the utility function by choosing between domestic and composite commodities is carried out in a combined system of CES/LES preferences. At the highest level, the utility generated by the consumption of these commodities is maximized using this function.

Consistently, there are 12 types of households, 6 urban and 6 rural, demanding local and imported commodities. It is assumed that they have Stone-Geary utility function from which derives the Linear Expenditure System (LES). A characteristic of this function is that there is a minimum level of consumption of each commodity (so-called subsistence consumption), which may be zero for some commodities. Demand equations are derived from each type household h maximizing utility function for each commodity i subject to the budget constraints, so that:

$$PC_{i,t} C_{i,h,t} = PC_{i,t} C_{i,h,t}^{MIN} + \gamma_{i,h}^{LES} (CTH_{h,t} - \sum_{ij} PC_{ij,t} C_{ij,h,t}^{MIN}) \quad (3)$$

where, at time t , $PC_{i,t}$ is the purchaser price of composite commodity i (including all taxes and margins); $C_{i,h,t}$ is the consumption of commodity i by type h households; $C_{i,h,t}^{MIN}$ is the minimum consumption of commodity i by type h households; $\gamma_{i,h}^{LES}$ is the marginal share of commodity i in type h household consumption budget; and $CTH_{h,t}$ is the consumption budget of type h households.

Investors are responsible for creating capital goods in each sector of the national economy. This representation resembles that of the production technology of firms, but with subtle difference. Here investment demand includes both

152 However, The Lerner Symmetry Theorem (Lerner, 1936) states that, under some conditions, import tariffs and export tax have the same effect on the economy. See Casas (1991) and Costinot and Werning (2017) for more qualification on this theorem.

gross fixed capital formation and changes in inventories. It is assumed that the quantity demanded of each commodity for investment purposes is the sum of the quantity demanded for private investment and for public investment, and that, for a given amount of investment expenditures, this demand is inversely related to its purchaser price.

Firms use transport, and retail and wholesale trade services to lead commodities to the final consumer. The commodities services are paid. Usually, the payment is made in terms of marginal rates that are applied to the value of domestic production and imports to determine the quantities of this margin services necessary to distribute goods to potential demanders, local or foreigners.

Although government does not maximize any function, its introduction into the model enriches further analysis, since it receives tax transfers, but also makes expenditures. The government demand in this model is identified from SAM values. As investment demand, for a given current expenditure budget, the quantity demanded by government of each commodity varies inversely with its price.

Next, we present producer supplies functions and international trade. The underlying assumption of Guinea-Bissau's economy is that it is a small open economy to foreign trade, implying that the world price of traded goods (imports and exports) is exogenous. Trade relations with the rest-of-the-world is set through specification of domestic consumer's behavior with respect to the different supply sources and domestic producers' supply behavior. The supply side comprises two things: first, the transformation of the composite product into the supply of final products, and second, the supply of each product to destination markets.

The first case has already been treated by Equations (1) and (2). The second ensures that every product of each industry is shared out among domestic or export markets. However, the production directed to consumer of Guinea-Bissau is somewhat different from that for exports. We use a CET (constant elasticity of transformation) aggregator function to represent this imperfect substitution, showing how readily the production of an industry can be redirected from Guinea-Bissau to export market and vice-versa.

Relative supply functions ($EX_{j,i,t}$) are derived from the first-order conditions of profit maximizing problem subject to the product of each industry, yielding Equation (4)

$$EX_{j,i,t} = \left[\frac{\beta_{j,i}^X PE_{i,t}}{\beta_{j,i}^X PL_{i,t}} \right]^{\sigma_{j,i}^X} DS_{j,i,t} \tag{4}$$

where, at time t , $PE_{i,t}$ is the price received for exported commodity i (excluding export taxes); $PL_{i,t}$ is the price of local commodity i (excluding all taxes on products); $DS_{j,i,t}$ is the supply of commodity i by industry j to the domestic market; $\beta_{j,i}^X$ and $\sigma_{j,i}^X$ are the scale parameter and elasticity of transformation (CET - exports and local sales), respectively, for each $0 < \sigma_{j,i}^X < \infty$ and $\rho_{j,i}^X = \frac{1+\sigma_{j,i}^X}{\sigma_{j,i}^X}$.

Buyer's behavior is derived symmetrically by assuming that local products are imperfect substitutes for imports, or that goods are differentiated with respect to their origin. Commodities demanded on the domestic market are composite goods, combinations of locally produced commodity demanded locally and imports. Then a CES aggregator function is used to represent the imperfect substitutability between the two with sector-specific scale parameter.

Our model is very rich in price information. It has at least 25 types of prices, including wages and other production costs. Prices and price indexes are defined according to the hypotheses and functional forms already declared. This means that, in aggregations, the price of an aggregate variable is a weighted sum of the prices of its components. For instance, the commodities purchased on the domestic market are composites. The price of the composite commodity is a weighted sum of the price paid for domestically produced and imported goods.

It is worth noting that, in the aggregations of Leontief-type function, the weights are invariant to relative price change. The model's price indexes include the GDP deflator and the consumer price index, the former being the Fisher index and the latter is the Laspeyres one.

With the agents, the supply and demand for production, as well as the price structure' blocks, we will now verify theoretical model micro-consistency, i.e., the market equilibrium condition. A market is in equilibrium when there is neither demand nor supply excess, i.e., demand must be equal to supply. For instance, market clearing for export market means that supply of Guinea-Bissau commodities to the external market should be exactly equal to the demand of the rest-of-the world for those exports. This notion of equilibrium is verified for all markets including factor and services markets.

This is usual structure of a static CGE model. We include the dynamic module in this structure. In this, we are free from the task of distinguishing between the short and long term. The immediate implication is that we let investment to adjust, rather than being fixed, and allow the model to recursive and dynamically incorporate investment and endogenous accumulation of capital, as well as the savings dynamics and the accumulation of wealth over time.

The evolution of capital stock is modeled through the investment demand functions, where the volume of new type capital allocated to business-sector industry is proportional to the existing stock of capital. The proportion varies according to the ratio of the rental rate to the user cost of that capital (Tobin's q) and the rate of depreciation (DLRM, 2012). The level of investment demand is used in capital accumulation rule equation (Eq.5):

$$KD_{k,j,t+1} = KD_{k,j,t}(1 - \delta_{k,j}) + IND_{k,j,t} \tag{5}$$

where, at time t , the stock of capital in industry i in period $t+1$ ($KD_{k,j,t+1}$) is equal to the stock of the preceding period ($KD_{k,j,t}$), minus depreciation of capital ($\delta_{k,j}$), plus the volume of new capital investment in the preceding period ($IND_{k,j,t}$).

4.1 Data and simulation scenarios

We use an updated 2014 Social Accounting Matrix (SAM) of Guinea-Bissau originally built by Cabral (2015) from International Food Policy Research Institute (IFPRI)¹⁵³. This matrix has 22 sectors, 2 production factors, and 6 accounts: factor, institutions, activity, domestically sold commodity, export commodity, and accumulation. Each account represents the agent’s relationships determining the dynamics of the economy in the period in question.

The calibration process requires additional data, such as trade and production elasticities, household consumption elasticities, interest rate, and population growth rate. While the latter two are from the World Bank, the production, trade, and substitution elasticities have not yet been estimated for Guinea-Bissau. We consider it possible to resort to the already estimated elasticities for Tanzania, which is an economy with the production technology very similar to Guinea-Bissau¹⁵⁴.

For the micro-simulation purpose, we use the 2014 official minimum wage to disaggregate households in six urban and six rural types (Table 2) and then emerge the resulting shares with every rows and columns in the SAM as to obtain a new level of consumption and income for every household, generating an updated SAM for the current minimum wage base year.

Table 2 – Household disaggregation by minimum wage

Household 1	H1	≤ 1 minimum wage	50,000*	0.018
Household 2	H2	≤ 2 minimal wages	100,000	0.036
Household 3	H3	≤ 4 minimal wages	200,000	0.072
Household 4	H4	≤ 6 minimal wages	600,000	0.218
Household 5	H5	≤ 8 minimal wages	800,000	0.290
Household 6	H6	≤ 10 minimal wages	1,000,000	0.363

Source: Authors elaboration. *:50,000 is the current official minimum wage.

The main general observation for households is that we respect the initial classification that there are two types of workers (skilled and unskilled) and two types of households (urban and rural). Therefore, in terms of the treatment of the labor market, all urban households offer skilled labor, while their rural counterparts offer unskilled labor. The reason for disaggregating workers in several types is that it allows to visualize which sector demands more the labor offered by poor households, for example. We could observe that, for a given total supply of factors, the agricultural sectors demand more unskilled labor from the rural environment, while the industrial and service sectors demand more skilled labor.

The trade liberalization policy is simulated based on two scenarios. The first scenario is a uniform 100% import tariffs reduction for importer sectors. The scenario 2 consists to perform the shock based on the export taxes cuts. It refers to mentioned government's response in 2019 to the exporters claims that the export tax charge is too high. The government reduced taxes for exported products by 2.5 percent in April 2019. Therefore, our shock size in this scenario is based on this value across all exporter sectors.

4.2 Model closure

For household, we assume that disposable income after savings and transfers to other agents is entirely dedicated to household consumption and that household savings are a linear function of disposable income. For the government side, we represent income taxes as a linear function of the total income of households and firms. This specification makes it possible to differentiate the marginal rate of taxation from the average rate when a nonzero intercept is determined, a specification as much as useful for fiscal policy modeling.

The model also specifies several constants and variables to grow at the same rate of population growth. The constants are the follows: households and firms’ income tax function intercepts, intercept of the household transfers to government function, transfers from government, and from the rest of the world. Exogenous variables are labor supply; government current expenditures; current account balance; minimum consumption of commodities in the LES demand equations; changes in inventories; and public investment by category and by public sector industry.

5. RESULTS AND DISCUSSIONS

We present simultaneously the results of scenarios 1 and 2, which represent unilateral decision to cut down imports tariff to product from abroad and exports taxes policy, respectively. It is worth emphasizing that these results represent percentage deviations from the BAU scenario.

5.1 Macroeconomic results

The effects of the trade liberalization on GDP depend on effective performed the shock. First, the uniform cuts in sector import tariffs has a negative impact on GDP, especially in the immediate period after the shock (Figure 1). We observe that this result was due to the increase in imports, which were incentives for the fall in the import goods price (Table 3).

153 The Social Accounting Matrix of Guinea-Bissau is obtained by request. Interested parties can access: <http://www.agrodep.org/dataset/2007-social-accounting-matrix-sam-guinea-bissau>.

154 We perform sensitivity analysis of most of the parameters used for our model. We realize that there was no change in the signals in the sensitivity test. The results have not changed so much when we change the values of the free parameters.

Figure 1 – GAP compared to BAU scenario for real GDP

Source: Author elaboration, Model's results.

In fact, a unilateral import tariff reduction generated deviation in relative prices that favored imported products relative to national exports, with a clear increase in export prices. In contrast, export taxes cut led to a drop in the export price, facilitating the placement of the national product on the world market. This policy circumvented the exogeneity of the world price by directly adjusting the exports price. Such adjustments had two implications. First, they led to an increase in aggregate exports and a consequent improvement in the trade balance. Second, the inflow of funds via improved external accounts favors the creation of investments in the country. We saw that reductions in export taxes would not have sustained a lasting growth in GDP if the demand for investments had not increased. It is the amount of aggregate investments made that sustain GDP over time, whose long-term stability is due to capital depreciation.

Table 3 - Aggregate macroeconomic variables at the end of simulation

Variable	Scenario 1	Scenario 2
Imports	5.100	-6.500
Exports	-5.270	0.515
Investment	-0.692	6.317
Government Consumption	-2.620	-3.427
Export price	0.570	-2.308
Import price	-5.200	3.631

Source: Author elaboration, Model's results.

A common feature of our result is that both policies to cut import tariffs and export taxes contributed to reduce government consumption at the end of the simulation. This result is not surprising, since the government's revenue depends on both imports and exports the burden. However, we must observe that reducing export taxes generates a greater drop in government consumption, possibly due to the weight of these taxes on government revenue, which is 17% percent, instead of 3% of the import tariffs.

5.2 Sectoral results and labor market

In this section, we discuss sectoral and labor market results from two policy scenarios. Sector-level results are in terms of the sector's aggregate output, while the labor market ones are represented in terms of employment by each type of worker, rural and urban (Table 4), and for type of skill set, skilled and unskilled (Table 5)

Two lessons can be drawn from Table 4. First, that imports tariff cuts negatively affect the service sectors is what industry output results reveal. Second, the production of cashew nuts has been negatively affected by import tariff reduction policy. This helps to explain the GDP result obtained, that is, it is the behavior of cashew nut production that justifies, for example, why the positive response in some agricultural sector production to the import tariff negative shock did not translate into an increase in aggregate real GDP.

Meanwhile, as the government reduces current exports taxes, the positive effects on the level of economic activity are underpinned by the growth in production of the majority economy's sectors. Thus, the impacts of export taxes reductions are more forceful in the sense that only three sectors (millet, construction, and other industries) responded negatively to the fall in export taxes, while the remaining 19 sectors of the economy benefited from this policy.

This result is associated with the performance of the export sector, whose effect of folding favored the production of the national sectors. In other words, the increase in world demand due to the lower FOB price generated growth in exports,

which translated into positive economic growth. Over time, this growth in aggregate product was sustained by an increase in investment demand, resulting in increased production in national sectors including those that do not export.

Table 4 - Scenario 2: GAP compared to BAU scenario for industry output

Sector	Scenario 1	Scenario 2
Millet	4.070	-0.062
Sorghum	0.180	0.037
Maize	0.170	0.037
Rice	0.366	0.026

Financial services	-0.025	0.002
Real state Serv.	-1.077	0.072
Public administration	-0.557	0.026

Source: Author elaboration, Model's results.

In addition, the results suggest the potential of current policy to promote diversification in the economy. In fact, we observe that in each period the amount of investment of the sectors grows in the same direction as the growth of capital accumulation and that sectors producing capital goods have also experienced growth in their production. This signals that the policy of reducing taxes on exports may be important for the government to start creating instruments that encourage investments in non-traditional sectors, which are those not directly linked to agriculture.

In term of its impact on labor market, trade liberalization by uniform import tariffs cuts increase the employment of both skilled and unskilled workers, but the skilled ones increased faster. This policy benefited more the poorest workers in both categories, with a cumulative percentage deviation ranging from 0.690 to 2.347 for the unskilled worker and from 1.129 to 1.322 for the skilled worker earning up to two minimal wages.

Table 5 - Unskilled and skilled employment at the end of simulation

Worker	USK1	USK2	USK3	USK4	USK5	USK6	SK1	SK2	SK3	SK4	SK5	SK6
Panel A: Unskilled and skilled employment at the end of simulation												
Worker	USK1	USK2	USK3	USK4	USK5	USK6	SK1	SK2	SK3	SK4	SK5	SK6
Scenario1	2.347	0.690	0.622	0.467	0.455	0.465	1.322	1.129	0.968	0.721	0.581	0.566
Scenario2	7.768	1.929	1.654	1.286	1.158	1.052	2.634	2.195	1.882	1.464	1.317	1.197

Source: Author elaboration, Model's results.

Although their benefits are different among workers by category and type, export taxes shocks affect positively aggregate employment. There is an increased in intra and inter-category employment. For instance, the difference in the percentage of employment between an unskilled worker earning up to one minimum wage (UKS1) and another same type of worker but earning up to 10 minimal wages (USK6) is 4.137 percent. For the same type of skilled workers, this difference is 0.336 percent in favor of one who receives up to one minimum wage.

In short, in response to the export tax shocks, employment of unskilled labor increases by up to 5 percent more than skilled labor one. Next, we examine whether this employment gain among less skilled workers can translate into more income and consumption opportunities, which potentially may suggest some distributive effect of this trade policy.

5.3 Results at household level

A general inspection of the results reported in Table 6 suggests that, ceteris paribus, import tariffs cut has positive impacts on rural and urban household incomes. Households with higher wages earn substantially higher incomes than those with lower minimal wages in both rural and urban environment. In other words, in the shock of import tariff cuts, households with the highest income that benefit most, both in rural and urban areas. However, with the same initial wage, negative shocks in import tariffs increase rural household incomes more than urban household ones. The incomes gap between rural and urban households earning up to one minimum wage is 0.019 percent, while the income gap between rural and urban household earning up to 10 minimal wages is 0.327, both in favor of rural household.

Table - Unskilled and skilled employment at the end of simulation.

Impacts of export tax reductions on household incomes are more direct. Like import tariff shocks, both uniform and sector level export tax cuts increased rural and urban households' incomes. Tax cuts in the cashew nut sector accounted for most of the gains, with a percentage deviation ranging from 0.445 to 0.623 percent for rural households receiving one and ten minimal wages, respectively. In general, export tax cuts policy increased more household incomes negative import tariffs shocks one. The export scenario benefits more households with lower income. This is due to the performance of the sectors after each shock, since in the export taxes scenario the agricultural sectors are most benefited and, as they employ many households in the lowest income categories, the increase in their production increased the demand for employment and consequently income of such households.

Table 6 - GAP compared to BAU scenario for household income and consumption

Panel A: Rural and urban household income at the end of simulation												
Household	HR1	HR2	HR3	HR4	HR5	HR6	HU1	HU2	HU3	HU4	HU5	HU6

Source: Author elaboration, Model's results.

Considering the dynamic structure of the present model, households whose income is growing faster after the shock will accumulate greater wealth along the growth trajectory. At the end of the simulation period, they will be in better situations than in their initial positions before the policies implementation. As a result, the export promotion policy instruments that are being used for the country's socioeconomic development or, more specifically, for poverty alleviation, should be deepened, since the result shows the improvement of the condition of the poorest households, mainly in rural areas, after the shock is delivered.

Uniform tariff reductions increase rural household consumption by 0.019 percent more than urban households receiving up to a minimum wage (HR1 and HU1). For households in the middle range of income distribution, that is, those who receive up to 4 minimum wages (HR3 and HU3), the consumption difference is 0.027 in favor of the rural household.

Rural household consumption increases more with uniform export tax cuts than consumption achieved with uniform import tariff reductions. For instance, uniform export tax shocks increase by 0.627 percent more the consumption of rural households receiving up to a minimum wage (HR1) than shocks in import tariffs. The difference in consumption of urban households verified after each shock is more pronounced. Uniform export tax cuts accounted for increasing urban household consumption receiving up to a minimum wage (HU1) by 1.290 percent, while imports tariff cuts did so with a percentage of 0.064 percent, that is, the former policy increase the poorest households consumption by 1.226 percent more than the latter one. However, as we move to the household receiving higher initial wages, we see that the difference of the two results regarding to consumption drops significantly.

This is consistent with the result previously analyzed. The consumption of the rural household in the lower tail of the distribution range is increasing more than the consumption of any household because their income has increased more than the income of any household after the shock of export taxes. This policy positively impacted household consumption more than the policy based on cutting import tariffs, because it had a more intense impact on the income than the results achieved by the last policy.

Meanwhile, the export tax reduction policy has benefited relatively less the sectors that employ higher-income workers. Household income in this range then grew less as did consumption. Thus, the smallest difference in the results obtained from consumption of households that receive higher wages obtained through the two policies also reflects the more intense sectoral impact achieved by these policies.

These trade policies scenarios corroborate the findings of Moreira and Correia (1998), Amiti and Cameron (2012), as it shows gains through economic liberalization. However, while these authors observed the short-term gains from trade policy due to increased factor reallocation, we found that the household wealth accumulation over time was responsible for increased consumption of rural and urban households in Guinea-Bissau due to tariff and tax reductions-, and, thus, was responsible for increasing their welfare. This study also collaborates with Brighth (2017) studies for Ghana, Ferreira and Rossi (2001) and Figini and Santarelli (2006) studies for Brazil and developing countries.

As it emphasizes capital accumulation as a key variable for long-term welfare gains, our study also is in accordance with recent growing body of literature analyzing the effect of trade reforms including Kebede, Aredo and Fekadu (2012), Annabi *et al* (2005), Chitinga *et al.* (2005), Decaluwé *et al* (2008), Aka (2006) and Nwafor *et al.* (2007), Durongkaveroj (2014), Porto (2008), and Menezes-Filho and Muendler (2007).

In their study for Brazil, Bittencourt, Larson, and Kraybill (2008) show through a CGE model that tariff reduction policy resulted in equivalent welfare gains of 0.7% for both low-income and middle income rural households, but resulted in a loss in the same proportion for the low-income urban household, and has no impact on the middle-income urban one. This study is important since it shows that there is no equivalence between distributive concerns, emphasized by the standard trade theory, and poverty concerns. This is the line that supports the rationale behind the comparison we make

of our results for all simulations, that is, to show whether there are gains in welfare and occurrence of inequality after the policies have been implemented.

We also observe that all current policies may mitigate income inequalities in the country, since the projected inequality percentages (0.58% in BAU) are above those obtained after each shock. As a result of negative import tariff and export taxes shocks, the Gini index reduced respectively for 0.57 and 0.53%, respectively, signaling the potential of trade reform to reduce long-term income inequality. In their studies for Colombia, Attanasio et al, (2004) found similar results, albeit in the short term.

6. CONCLUSIONS

This study analyzed the effects of Doha Round and recent government policy to incentive national exports on the Guinean economy. The purpose is to deepen the understanding of how the country's economy reacts to tariff shocks. By using a dynamic recursive computable general equilibrium model, we evaluate the impacts of such shocks on macroeconomic aggregate and household level outcomes.

The simulations were carried out through two policy scenarios, namely import tariffs and export taxes reduction. Trade reform through complete import tariff cuts negatively affected the overall economy product in the early years. We observe that CDP results had been influenced by relative price changes, that increase imports vis-à-vis the exports. In the absence of a macro compensatory variable that adjusts as to balance the initial negative impacts, we saw that not even the GDP values were negatives, but government revenue as well as its consumption also decreased.

Conversely, export taxes policy has immediate, positive, and persistent impacts on macro aggregate and sector output. The endogenous export price change favored exports increase, investment, and the diversification of national production. We observe that the way in which the government directs its trade policy as to promote the country's comparative advantages will be important in determining household welfare outcomes. Current trade scenarios provoke an increase in demand for poorest workers labor in both rural and urban settings, however, import tariff reductions increase more de employment of urban-skilled worker, while the export taxes reductions increase more employment of unskilled rural household. These results led the capital accumulation favoring the poorest households, as they increase more the income and consumption of those households receiving least initial minimal wage.

What is reported so far suggests the importance of trade liberalization as a feasible option the governments can fulfill to potentialize the country comparative advantage as well as to improve the households' living conditions, both in urban and rural areas. The potential gains observed lead us to suggest that diversification of the export basket and the robust insertion in the national economy can be achieved by relieving the current restrictions on trade. Staggering the reduction in tax rates and tariffs for sectors with comparative advantages would strengthen the development of these sectors, as they will be forced to compete with others producing similar products. Naturally, although this implies the exclusion of those sectors that will not be able to participate in competitive international markets, conscious free trade will bring gains even for the poorest household in rural areas. This is because the sectors that survive economic opening will produce more, invest more, and employ more workers of different levels of qualification.

We emphasize, however, that the promotion of trade liberalization may not achieve the desired results in a small economy like this one with a low level of productivity. Institutional reforms that eliminate internal restrictions on production will be desirable. The country will be able to exploit its condition of relative backwardness by investing in human capital, since economic openness naturally implies the existence of national and international firms demanding qualified workers. Thus, once the country's ability to exploit its comparative advantages is guaranteed, the human capital availability with different skills will enhance the diversification of the economy that our results suggest.

ABSTRACT

The Latin American (LATAM)-China trade relationship is based on the exchange of Latin American commodities for manufactured goods from China. This paper aims to analyze the impact of the composition of the LATAM-China trade basket on the economic growth of Latin American countries. Based on a Cobb-Douglas production function, productivity is expressed as a function of exports to China, imports from China, China's share of overall U.S. imports, and other control variables. Exports destined for China are disaggregated into: (1) commodities, (2) low-tech manufactures and, (3) medium and high-tech manufactures while imports from China were broken down into: (1) consumer goods, (2) intermediate goods and, (3) capital goods. Non-exporting GDP to China is used as the dependent variable to remove the effect of exports on the national accounts. Regression analysis techniques are applied with panel data on 23 Latin American countries for the period 2002 - 2017. Considering the structural differences between countries in the region, the exercises are applied in two separate panels, one corresponding to South American countries (SA) and the second to Mexico, Central American and Caribbean countries (MCC). The results indicate that: (1) exports destined to China and imports from China exert negative and positive effects, respectively, on LATAM economic growth. The negative effects of exports to China are attributed to the commodity sector and low-tech manufactures while the positive effects of imports correspond to the three types of imported goods. The effects according to the composition of the trade basket are heterogeneous between SA and MCC, (2) the competition effect with China generates negative effects on SA's economic growth. The Latin American region needs to concentrate efforts to increase the share of medium and high technology manufactures in its export basket, in order to face the changes in international trade patterns both as a trading partner and as a competitor.

KEYWORDS

China; composition of the trade basket; economic growth; Latin America

1. INTRODUCTION

The Latin America-China trade relationship has intensified since the formalization of China's entrance in the World Trade Organization (WTO) in November 2001. Between 2002 and 2017, Latin American exports destined for China increased from \$75.8 million USD to \$884.6 million USD while imports from China grew from \$142.9 million USD to \$1,552.8 million USD (constant prices, base year 2009) (UN COMTRADE, 2019).

The effects of exports and imports on economic growth via productivity are linked to the composition of the trade basket. Based on the ELG approach, the technological content of exported goods is a determining factor. According to Lall (2000), Dreger and Herzer (2013) and Arteaga, Cardozo and Diniz (2020), commodities and low-tech manufactures are basic and homogeneous goods, which offer a limited scope for the development and innovation of new products; consequently, these sectors are not effective in generating spillover effects. On the contrary, medium and high technology manufactures have greater potential to induce innovation processes and the capacity to promote spillover effects to the remaining of the industrial sectors (Hatzichronoglou 1997; Lall 2000).

Regarding the ILG hypothesis, the effects of imports on economic growth are captured according to the final usage of the imported goods. Kim, Lim and Park (2007) indicate that imports of consumer goods stimulate the competitiveness between local and foreign goods, inducing productivity improvements in local production. Keller (1997) explains that imports of intermediate goods and capital goods boost productivity through the transfer of foreign technology to local production units. However, Balassa (1978) and Priede (2012) warn that imports can generate a substitution effect of local production for imported goods.

On average, 79.4% of Latin American exports to China are made up of commodities, followed by medium and high technology manufactured goods (10.7%) and lastly low technology manufactured goods. In addition, on average, 41.2% of imports from China correspond to intermediate goods, 31.9% to consumer goods and the rest to capital goods. The current literature (Feal, 2015; Vianna, 2016; Murakami and Hernandez, 2018; Hou, 2019; Timini and Sanchez-Albornoz, 2019; Arteaga et al., 2020) analyzes the impact of trade with China on Latin America's economic growth considering aggregate exports and imports; an analysis considering the composition of the Latin America-China trade basket is needed.

On the other hand, Jenkins (2010), Jenkins and Barbosa (2012) and Ray and Gallagher (2015) explain that the supply of manufactured goods from China in the international market have generated market losses for Latin American goods. Arteaga et al. (2020) show that the substitution effect of Latin American imports for Chinese imports in the US inhibit the economic growth of South American countries.

The objective of this paper is to analyze the impact of the composition of the Latin America-China trade basket on economic growth via productivity of Latin American countries. In addition, it analyzes the effect of China's penetration of the US market on the economic growth of Latin American countries. In accordance with Feder (1983), Greenaway and Sapsford (1994), Feal (2015) and Arteaga et al. (2020), non-export-to-China GDP is used as the dependent variable in order to remove from GDP the contribution of exports destined for China to the national accounts. This analysis is performed for the period after China's entry to the WTO, 2002 - 2017. Regression analysis techniques are applied with panel data on 23 Latin American countries. In accordance with the differences in productive structures between Latin American sub-regions pointed out by Ocampo (2012), Rosales and Herreros (2013), Bernal (2015) and Arteaga et al. (2020), the present study applies the analysis for two subgroups of countries, the first corresponds to South American countries and the second to Mexico, Central American and Caribbean countries.

This paper is organized as follows: this section corresponds to the introduction; section 2 contains theoretical aspects about the composition of trade basket and economic growth. The next section shows the characteristics of the LATAM-China trade basket. The fourth section presents the methodology, while the fifth section shows the results. The last section concludes the paper.

2. COMPOSITION OF THE TRADE BASKET: THEORETICAL ASPECTS

According to Crespo-Cuaresma and Wörz (2005), Herzer, Nowak-Lehmann and Siliverstovs (2006) and Arteaga et al. (2020) the effects of exports on the productivity levels of an economy depend on the technological composition or degree of complexity of the exported goods. This paper considers the criteria of Lall (2000), under this classification exports are disaggregated into three major groups: primary products and natural resource-based manufactures (also called commodities), low-technology manufactures and medium and high-technology manufactures. Table 1 describes the main characteristics of these goods.

Table 1 – Classification by technological composition of goods traded according to Lall (2000)

Classification	Examples	Main characteristics	Main means of competitiveness in the international market
Primary products	Fresh fruit, meat, rice, cocoa, tea, coffee, wood, coal, crude petroleum, gas, etc.	Homogeneous products with low technological content and intensive in natural resources. Low-income elasticity. Products vulnerable to shocks in international commodity prices.	Abundance of natural resources.
Resource based manufactures	Prepared meat/fruit, beverages, wood products, vegetable oils, etc.		
Low technology manufactures	Textile fabrics, clothing, headgear, footwear, pottery, simple metal parts/structures, furniture, jewelry, toys, plastic products, etc.	Homogeneous products with low technological content and labor intensive. Low income elasticity.	Market prices.
Medium technology manufactures	Passenger vehicles and parts, commercial vehicles, synthetic fibers, chemicals and paints, fertilizers, engines, motors, industrial machinery, etc.	Products with high technological content. Their production requires specialized labor. Products linked to Research and Development (R&D)* activities. High income elasticity.	Product differentiation and value-added. Market prices.
High technology manufactures	Office/data processing/telecommunications equipment, TVs, pharmaceuticals, aerospace, optical/measuring instruments, etc.		

Note: * According to Lall (2000), in the medium and high-tech manufacturing sector, operations are also installed in labor-intensive production units located in low-wage countries. Source: Own elaboration based on Lall (2000).

On the other hand, the literature discusses the effects of imports on the economy according to their final use. A country imports goods to use them as consumer goods or as factors of production (intermediate goods and capital goods). Thus, the classification by Broad Economic Categories (BEC) (United Nations, 2002) is the most appropriate for studying the effects of imported goods on the economy. Table 2 describes the main characteristics of these goods.

Table 2 – Classification by Broad Economic Categories (BEC) of traded goods according to United Nations (2002)

Classification	Components	Examples	Final consumption	Main characteristics
Consumer goods	Food and beverages, transport equipment, durable goods, semi-durable goods and non-durable goods.	Milk, fruit, textiles, jewelry, motorcycles, bicycles, vehicles, etc.	Household consumption	These types of products can be commodities, low technology manufactures or medium and high technology. These goods may originate from countries specialized in

Classification	Components	Examples	Final consumption	Main characteristics
Intermediate godos	Food and beverages, industrial supplies, fuels and lubricants, parts and accessories of capital goods.	Wheat, grains and seeds, petroleum, valves and tubes, machine tools, resistors, transistors, etc.	Production factor	commodities or highly industrialized countries.
Capital godos	Equipment, machinery and transport equipment.	Steam boilers, tractors, electrical instruments and apparatus, freight vehicles, railroad systems, etc.	Production factor	They correspond to medium and high technology manufactures from highly industrialized countries with a high level of Research and Development (R&D) activities.

Source: United Nations (2002).

Kasahara and Rodrigue (2008) explain that the adoption and imitation of imported technologies improves the efficiency of production units. For their part, Lee (1994), and Halpern, Koren and Szeidl (2015) point out that increases in efficiency and productivity levels in local economies can materialize through the importation of cheaper intermediate and capital goods.

3. LATAM-CHINA TRADE BASKET

Between 2002 and 2017, South American countries were responsible for 92.3% of Latin American exports destined for China and 52.18% of Latin American imports from China. Mexico, Central America and Caribbean countries accounted for the rest of the volumes traded with China.

Figures 1 and 2 show details of the composition of the Latin America-China trade basket. The box plots in Figure 1 show the share distribution in total exports to China by type of good and by Latin American sub-region. In the South American countries, primary products and natural resource-based manufactures account for at least 70% of total exports, thus this subregion's export basket to China is specialized in commodities. Figure 1 also shows that Barbados and Costa Rica stand out for concentrating more than 75% of exports to China in low-technology manufactures and with medium and high-technology manufactures, respectively. However, considering the subregion made up of Mexico, Central America and the Caribbean, commodities account for an average of 67.2% of exports to China; therefore, the export basket destined for China in this subregion is also concentrated in commodities.

Figure 1 - Share distribution in total exports to China by type of good according to Lall (2000), and by Latin American sub-region, period 2002 - 2017

Source: Own elaboration based on Lall (2000) and UN COMTRADE (2019).

The box plots in Figure 2 show the share distribution in total imports from China by type of good according to United Nations (2002), and by Latin American sub-region. In South American countries, imports of intermediate goods account for 45.3% of imports from China, while in Mexico, Central America and the Caribbean this percentage is 40.8%. In the second sub-region, Mexico stands out for having the lowest share of consumer goods in its total imports from China (13.7%), while in Panama at least 70% of imports are made up of consumer goods.

Figure 2 – Share distribution in total imports from China by type of good according to United Nations (2002), and by Latin American sub-region, period 2002 - 2017.

Source: Own elaboration based on United Nations (2002) and UN COMTRADE (2019).

4. METHODOLOGY

We follow the theoretical model applied by Arteaga et al. (2020) and incorporate imports from China within the set of explanatory variables.¹⁵⁵ For each country *i* at time *t*, non-export-to-China GDP (NonEC_GDP) is explained by the following variables. Labor stock (*L*), net capital of imports of capital goods from China (NonIC_K),¹⁵⁶ terms of trade (TERMS), China's share of overall U.S. imports (SHAREUSA). Exports to China are segregated according to the Lall (2000) classification: primary products and natural resource-based manufactures (COMMODO), low-technology manufactures (LT) as well as medium and high-technology manufactures (MHT). Lastly, imports from China are grouped according to the United Nations (2002) classification: consumer goods (CONS), intermediate goods (INTER) and capital goods (CAPG). Via national accounting identity, exports destined for China are a component of GDP, therefore, based on Feder (1983), Greenaway and Sapsford (1994), Feal (2015) and Arteaga et al. (2020), the most appropriate proxy variable for economic growth is non-export-to-China GDP (NonEC_GDP).¹⁵⁷ On the other hand, the capital stock (*K*) includes imported capital goods (European Commission et al., 2009), therefore, it is more appropriate to exclude from capital the capital goods imported from China (BCAP), this operation results in the variable NonIC_K.

$$\ln(\text{NonEC_GDP}_{it}) = \lambda_1 \ln(L_{it}) + \lambda_2 \ln(\text{NonIC_K}_{it}) + \lambda_3 \ln(\text{TERMS}_{it}) + \lambda_4 \ln(\text{SHAREUSA}_t) + \lambda_5 \ln(\text{COMMODO}_{it}) + \lambda_6 \ln(\text{LT}_{it}) + \lambda_7 \ln(\text{MHT}_{it}) + \lambda_8 \ln(\text{CONS}_{it}) + \lambda_9 \ln(\text{INTER}_{it}) + \lambda_{10} \ln(\text{CAPG}_{it}) \quad (1)$$

i = 1, ..., *N*; *t* = 1, ..., *T*

Following Leybourne (1995), Banerjee and Russel (2005), Dreger and Herzer (2013), Feal (2015) and Arteaga et al. (2020) the labor effect can be treated as an individual effect conditional on time $\alpha_{1i}T_t$. On the other hand, the country fixed effect (λ_{0i}) and the idiosyncratic error (ϵ_{it}) are included. Equation 2 results in these adjustments:

$$\ln(\text{NonEC_GDP}_{it}) = \sum_{i=1}^N \lambda_{0i} D_i + \sum_{i=1}^N \alpha_{1i} D_i T_t + \lambda_2 \ln(\text{NonIC_K}_{it}) + \lambda_3 \ln(\text{TERMS}_{it}) + \lambda_4 \ln(\text{SHAREUSA}_t) + \lambda_5 \ln(\text{COMMODO}_{it}) + \lambda_6 \ln(\text{LT}_{it}) + \lambda_7 \ln(\text{MHT}_{it}) + \lambda_8 \ln(\text{CONS}_{it}) + \lambda_9 \ln(\text{INTER}_{it}) + \lambda_{10} \ln(\text{CAPG}_{it}) + \epsilon_{it} \quad (2)$$

i = 1, ..., *N*; *t* = 1, ..., *T*

¹⁵⁵ The work of Arteaga et al. (2020) presents details of the development of the model structure.

¹⁵⁶ NonIC_K = Capital (*K*) minus imports of capital goods from China (BCAP).

¹⁵⁷ NonEC_GDP = GDP minus exports to China

The data sources for the variables were CEPAL-STAT for GDP, World Bank for capital (K) and terms of trade (TERMS), and UN-COMTRADE for the variables related to exports to China, imports from China and U.S. imports from China and overall U.S. imports. The variable NonEC_GDP is GDP minus exports to China. NonIC_K is Capital (K) minus capital goods from China (CAPG). The ratio between U.S. imports from China and overall U.S. imports expresses the share of China in U.S. imports (SHAREUSA). All variables except TERMS and SHAREUSA are expressed in constant dollars (base year 2009). Annual information is available for 23 Latin American countries: Argentina, Barbados, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, El Salvador, Guatemala, Guyana, Honduras, Jamaica, Mexico, Nicaragua, Panama, Paraguay, Peru, Trinidad and Tobago, Uruguay and Venezuela for the period 2001 - 2017. The variables NonEC_GDP, TERMS and CONS have unit root in levels; however, all variables are integrated of order 1. To avoid spurious relationships, equation 3 results from applying first differences to equation 2.¹⁵⁸

$$\Delta \ln(\text{NonEC_GDP}_{it}) = \alpha_{1i} + \lambda_2 \Delta \ln(\text{NonIC_K}_{it}) + \lambda_3 \Delta \ln(\text{TERMS}_{it}) + \lambda_4 \Delta \ln(\text{SHAREUSA}_t) + \lambda_5 \Delta \ln(\text{COMMOD}_{it}) + \lambda_6 \Delta \ln(\text{LT}_{it}) + \lambda_7 \Delta \ln(\text{MHT}_{it}) + \lambda_8 \Delta \ln(\text{CONS}_{it}) + \lambda_9 \Delta \ln(\text{INTER}_{it}) + \lambda_{10} \Delta \ln(\text{CAPG}_{it}) + \varepsilon_{it} \quad (3)$$

$i = 1, \dots, 23; t = 1, \dots, 16$

In equation 3, the coefficients λ_{ki} explain the elasticity of non-export-to-China GDP with respect to the explanatory variables. The estimations are performed through regression analysis with panel data. The panel formed by 23 Latin American countries (LA panel) for the period 2002 - 2017 is divided into two subgroups of countries according to the differences in export structures pointed out by Gallagher and Porzecanski (2008), Jenkins (2010), Correa (2012), Ocampo (2012), Rosales and Herreros (2013), Bernal (2015), Anderson and Strutt (2016) and Arteaga et al. (2020). The first subgroup is made up of South American countries (panel SA) whose overall export basket tends to be primary exporter. The second is made up of Mexico, Central American and Caribbean countries (MCC panel), these countries have managed to position technological content manufactures in their export baskets. For the SA panel, corrections must be made for time dependence and heteroscedasticity, while for the MCC panel, corrections must be made for heteroscedasticity and serial correlation. The panel-corrected standard error estimator (PCSE) method is used to make these corrections.¹⁵⁹

5. RESULTS AND DISCUSSIONS

Table 3 shows the effects of the composition of the Latin America-China trade basket on the economic growth of Latin American countries. Column 1 indicates the effects for South American countries (SA Panel) and column 2 for Mexico, Central American and Caribbean countries (MCC Panel).

The results show that capital exerts positive effects in both subregions; however, the effect is greater in South American countries. On the other hand, the terms of trade generate positive effects in Mexico, Central American countries and the Caribbean. A possible explanation for the behavior of this last variable is obtained from Jenkins, Dussel and Mesquita (2007) and Rosales and Kuwayama (2012). These authors indicate that the increase in commodity prices and the decrease in manufacturing prices induced by China's entry into the WTO caused a deterioration in the terms of trade in Mexico, Central American and Caribbean countries, since their global exports have a significant volume of manufactured goods. These conditions generated negative effects on the balance of payments. Once non-export-to China GDP contains exports to other trading partners, the results of this paper show that a 1% improvement in the terms of trade in Mexico, Central American and Caribbean countries stimulates the growth of non-exporting GDP to China by approximately 0.20%, a value higher than the contribution given by capital.

Table 3 also indicates that China's share of global imports from the United States have no effect on the economic growth of Mexico, Central American and Caribbean countries and negative effects in South American countries; these results coincide with those found by Arteaga et al. (2020). Among the possible reasons is that the export portfolio of South American countries is concentrated in few products. In this condition, South American countries tend to be more vulnerable to changes in trade patterns, the negative effects of which can reach production destined for local consumption via a decrease in productivity.

Column 1 shows that, in South American countries, exports to China of low-technology manufactures generate negative effects on economic growth via productivity. With respect to imports from China, consumer and capital goods exert positive effects, however, the most notable impact corresponds to consumer goods. Also, column 1 shows evidence of negative effects produced by imports of intermediate goods from China. Column 2 shows that, in the group of countries comprising Mexico, Central America and the Caribbean, commodity exports have negative effects on economic growth via productivity, while imports of intermediate goods have positive effects.

158 Note: for all variables except SHAREUSA, the Harris-Tsavalis [HT] (1999) unit root test for panel data was used because it is the most appropriate for very small t-values. On the other hand, the variable SHAREUSA is a time series that does not vary between countries, therefore, for this variable the Augmented Dickey-Fuller (ADF) test was used.

159 The Generalized Least Squares method is also used in panels with non-spherical errors, however, according to Beck and Katz (1995), this method is suitable when the average contemporaneous correlation is greater than 0.75 and T is at least twice N. In the SA and MCC panels, the average values of contemporaneous correlation are less than 0.75.

Table 3. Effects of the composition of the LATAM - China trade basket on economic growth of Latin American countries

Dependent variable: non-export-to-China GDP (NonEC_GDP)				
Independent variables:		SA panel		MCC panel
		1		2

Number of countries		11		12
Period		16		16
Number of observations		176		192
R-squared		0.7092		0.3825

Note: All variables are expressed in first differences of logarithms. As a robustness test, regression was performed on the panel of 23 countries using a Dummy variable with a value equal to 1 for MCC countries and zero for the rest, the significance results coincide with those shown in Table 3. DC = contemporaneous dependence, HET = Heteroscedasticity, AUTOCOR = Autocorrelation. Superscripts ***, **, and * indicate 1%, 5%, and 10% significance level, respectively.

The empirical evidence found in this paper on the effects of commodity exports and low-tech manufactures on economic growth via productivity in Latin America is consistent with the arguments of Lall (2000), and Oreiro and Feijó (2010). These sectors are lacking in the generation of spillover effects due to the fact that they are basic products with low technological content. As shown in Figure 1, in Latin America, exports to China are concentrated in few products, generally homogeneous and of low value added, therefore, it is possible that the expansion of exports to China is diverting and capturing resources from sectors of production of goods with higher technological content as warned by Sachs and Warner (2001), Herzer et al. (2006) and Arteaga et al. (2020). In the case of Mexico, Central America and the Caribbean, the export basket destined for China is specialized in commodities; however, the overall export pattern of this sub-region is oriented towards manufacturing. It is possible that the expansion of commodity exports to China is inducing a reorientation of the export pattern of these countries, as noted by Oreiro and Feijó (2010), Devadason et al. (2017) and Arteaga et al. (2020).

Regarding the effects of imports, the positive effects found confirm the theoretical contributions of Keller (1997), Kim et al. (2007), and Kasahara and Rodrigue (2008). However, in South American countries there is evidence of negative effects of intermediate goods, as noted by Balassa (1978) and Priede (2012).

6. CONCLUSIONS

China's entry into the World Trade Organization (WTO) in 2001 deepened Latin America-China trade, based on the exchange of commodities for manufactured goods. Evidenced by Latin American sub-regions and by type of good traded with China shows heterogeneous effects of these transactions on Latin American economic growth.

In South American countries, exports of low-technology manufactures and imports of intermediate goods produce negative effects on economic growth via productivity, which seems to indicate that trade with China follows a process of deterioration of productivity levels in the rest of the sectors of the economy and substitution of local production by imported goods from China. On the other hand, in this same subregion, imports of consumer goods and capital goods produce positive effects, with the former having a greater effect than the latter. The large volumes of soybeans, copper, iron and oil exported by Latin America to China come from South American countries; this sub-region benefited from the commodities boom after 2001 and some countries had trade surpluses with China. It is possible that the income received from the expansion of commodity exports to China was channeled into the supply of consumer goods from China and that these goods generated at least one of the following two effects: first, these goods stimulated the competitiveness of local production. Second, the acquisition of cheaper imported goods induced the growth of demand for other locally

produced goods, redirecting resources to sectors where aggregate demand grew, i.e., the expansion of demand for consumer goods imported from China had a complementary effect with local goods.

In Mexico, Central America and the Caribbean, commodity exports to China have negative effects on economic growth via productivity. One possible explanation is that the expansion of aggregate demand for commodities is inhibiting the growth of higher value-added sectors, since the overall export basket of this sub-region has a significant manufacturing content. On the other hand, imports of intermediate goods from China generate positive effects either by acquiring cheaper goods or by transferring technical progress to production units.

The results indicate that exports to China are not generating positive externalities to the rest of the sectors of the economy, since they are of low technological complexity and concentrated in few products; in fact, the evidence of negative effects indicates that these exports generate stagnation in sectors that do not export to China. However, imports from China, characterized by being more diversified and with higher value added, catalyze economic growth in Latin America, with greater intensity in South American countries. The sources of the positive effects vary among sub-regions, in South American countries these effects are attributed to consumer and capital goods and in Mexico, Central American and Caribbean countries to intermediate goods. On the other hand, the competitive nature of China in the U.S. market generates losses in the economic growth of South American countries.

To mitigate the negative effect attributed to exports to China and China's participation in the U.S. market, it is necessary to stimulate the manufacture and export of products with greater technological complexity, especially medium and high technology manufactures that generate the diffusion of technical progress and innovation to the rest of the sectors of the economy, diversify the export portfolio and verify the multilateral agreements with China that inhibit exports of higher value-added goods.

COMPETITION FOR ILLICIT PAYMENTS ON ROAD NETWORKS OF WEST AFRICA 1988-2016

[Glenn Rogers](#)

Independent Advisor, France

ABSTRACT

At a regional scale across multiple countries in West Africa there is a spatial market for illicit payments (IP)s along roadways that is distinct from the market for any specific commodity traded. Efforts over five decades to promote intra-African trade from the Mano River Union in 1973 to the 2019 African Continental Free Trade Area have had slower success than anticipated. In part this is due to non-tariff barriers related to IPs demanded at roadblocks by soldiers, police, political party authorities, private collection agents and customs officials. The dynamics of this IP market play a crucial role in creating the spatial structure of economic activity, conflict, trafficking and migration pressure in West Africa.

In 1997 I pessimistically concluded in conference presentations and an unpublished working paper that given road infrastructure at the time and without increased competition in the IP market, even if legal taxes are eliminated, transport losses are reduced and producer efficiency is increased dramatically through rural development programs, IPs on a regional basis would increase to choke off expected development benefits. This paper re-examines this question using my 1990s framing and empirical results in combination with more recent findings of others on competition in this regional IP market.

This is the first time findings are compared from empirical analyses based on two micro-datasets of IPs for 1988-1997 and 2012-2016 developed with support from US Agency for International Development (USAID) country programs. Improvements in data collection and digital archiving that make IP time-series data publicly available has enabled more analyses and refinement of empirical hypothesis testing. The manifestations of competition in IP markets are examined using characteristics of three distinct scenarios: 1. independent monopolists, 2. joint monopolists and 3. competitive agents. Evidence of changes in these basic manifestations over time and space are used as an indication of shifts in competition in the IP market. Related institutional contextual understanding draws from decades of work of many analysts on the political economy of IPs, how they constrain regional integration, governance for broader anti-corruption efforts and costs IPs impose on commodity-specific crop and livestock trade.

Since the 1990s researchers and policy makers have continued to highlight the persistence of bribery in West Africa. Foltz & Li (2020) reiterated my 1997 call for corrupted officials to face increasingly competitive markets as a necessary condition to reduce the socio-economic costs of IPs. Over recent decades there has been an evolution in governance and an increase in the number of alternative transport routes. These changes have the potential to lower total IPs or reduce volatility in the economic welfare costs they impose. But we still know little about the actual impact of more competition for IPs, the topic of this paper and needed future research.

REGIONAL DEVELOPMENT IMPLICATIONS OF IMPROVED CENTRAL TO SOUTH ASIA TRANSPORT DEVELOPMENT: SUMMARY OF RECENT ANALYSIS BY THE WORLD BANK

[Nathan Hutson](#)

University of North Texas, USA

ABSTRACT

Background: Regional integration of the economies of Central and South Asia has long been stymied by the lack of transport connectivity. Path dependent development of the railroad infrastructure, in particular, has created a situation where the economies of the former Soviet Central Asian states have negligible trade flows with South Asia despite the formers' large resource supplies and the latter's massive consumer market. In addition, the decades-long instability of Afghanistan, which serves as the principle gateway linking Central and South Asia has inhibited infrastructure investment to improve connections. In the last few years, the planned construction of the Mazar-e-Sharif to Herat railway has served as the beginning of a larger project for regional connectivity. The government of Afghanistan has coordinated with the World Bank to engineer a series of rail connections to Pakistan, including the new container port of Gwadar and dry ports of Baramcha and Spin Boldak. Given the considerable investment risk, a team from the World Bank has evaluated existing and potential cargo flows with the goal of determining which of these linkages would be economically justifiable. In addition, this analysis illustrates which regions of Central and South Asia would be most impacted by a reorientation of existing supply chains. This paper illustrates the key results of this analysis, showing which gaps in the transport network continue to persist, which options exist for new routes, and the logistical and political challenges of pushing forward with infrastructure investment prior to the time when Afghanistan is fully stable. Methodology and Data: Base data is extracted from publicly available sources such as UN-Comtrade as well as from interviews with current shippers and potential future mineral producers. Additional insight on gaps in predicted versus actual trade are identified using a revealed comparative advantage (RCA) analysis using data from World Integrated Trade Solutions (WITS). RCA is used to compare Central Asian States' existing trade relationship with South Asia compared to their relations with Russia and China – two states with which trade relationships are already well developed. Preliminary Findings: Initial findings show that while existing Central Asia-South Asia flows are inadequate to recoup the substantial investment, a reduction in transport costs could allow a significant share of exports to South Asia that currently originate in China and Southeast Asia to relocate to Central Asia – thereby reorienting regional supply chains and enhancing regional integration. Mineral projects within Afghanistan also have the potential to bolster total tonnage and improve revenue adequacy over time. While investment risk persists, improved trade relationships can aid Afghanistan's incorporation into the global trade system. A major test is in ensuring that Afghanistan receives economic development beyond transit rents. Coupling inland port development with rail gauge change locations is seen as a critical element creating an environment for job creation and value-added services.

**INTEGRATING SPATIAL DEVELOPMENT WITH INFRASTRUCTURE
PROVISION: A CONCEPTUAL FRAMEWORK AND ITS APPLICATION TO
INDIA**

[Manisha Jain](#)¹, [Artem Korzhenevych](#)¹, [Jörg Knieling](#)²

¹Leibniz Institute of Ecological Urban and Regional Development, Germany. ²HafenCity University, Germany

ABSTRACT

In recent years, scholars of urban studies have advocated strategic spatial planning as a way to better integrate infrastructure provision with spatial development in the Global South, especially given escalation in large-scale development projects under neoliberalism. Although strategies to create transport corridor are prevalent in the global South, there is a lack of empirical research to evaluate these initiatives, in particular whether they have realized their general goal of reducing regional disparities. The current paper describes a multi-method approach involving spatial and non-spatial analysis to investigate spatial disparity along a proposed corridor and examine its integration within the existing settlement structure. The analytical framework is tested on India's Delhi-Mumbai Industrial Corridor. A rationale is developed to enable a critical view of corridor policies as strategies for development in the global South.

RURAL TO URBAN TRANSFORMATION IN INDIA AS CENSUS TOWNS: RURAL-URBAN DICHOTOMY REVISITED

[Manisha Jain](#)¹, [Artem Korzhenevych](#)¹, [Jörg Knieling](#)²

¹Leibniz Institute of Ecological Urban and Regional Development, Germany. ²HafenCity University, Germany

ABSTRACT

The urbanization process in the Global South is characterized by the blurring of the boundaries between urban and rural areas and the lack of institutional capacity, which have made the process highly unsustainable. In India, an example of such development is the rapid growth of “census towns”. These settlements are not acknowledged as urban by the state, but they play an important role in accommodating population growth.

The current discourse on urbanization calls for new approaches to capture the peculiarities of growth in the global South. This paper takes the National Capital Territory of Delhi as a case study and adopts a mix of methods (field survey, ordinary least squares regression and geographically weighted regression) to highlight the emerging gradient of urbanization within official rural areas.

The article first examines the population and municipal status dynamics, location and economic characteristics of census towns as well as their migratory and commuting patterns. The status and costs of providing basic amenities and social infrastructure are then analyzed. The paper emphasizes the contribution of contemporary theories that explain the growth of census towns and the role of secondary and primary data in capturing their characteristics. Taking advantage of the economic potential of India's urbanization as census towns will require the following: (i) the enforcement of reforms to empower Gram Panchayat for spatial planning and growth regulation; (ii) the discontinuation of subsidized infrastructure provision and charging development tax; and (iii) investment in decentralized infrastructure for more accountable and more efficient delivery of basic amenities.

INNOVATION-DISRUPTED SPATIAL EQUILIBRIUM: INSIGHTS FROM THE ISRAELI EXPERIENCE

Raphael Bar-El^{1,2}, Liran Maymoni^{1,2}

¹Ben-Gurion University, Israel. ²Sapir Academic College, Israel

ABSTRACT

The emergence of innovation as a major engine of development challenges regional economic balances due to the strong concentration of high-tech activities in central metropolitan regions. Besides the positive influence of innovation on national growth, there is a regional market failure, leading to a disruption of peripheral regions' efforts to integrate into the national and global economy. We hypothesize that labour supply in the periphery responds by adapting to new requirements, while labour demand (through high-tech activities or start-ups) responds to changes in labour supply but also tends to concentrate in central regions. We expect that public policy can create a new equilibrium in the labour market, reducing the periphery-centre socio-economic gap.

We use Israel as a case study, given that it is a major leader in innovation but concentrates these activities in the metropolitan centre. We propose and test a conceptual approach using secondary data on the changes in the labour market.

The analysis of the Israeli experience leads to several preliminary conclusions:

1. Labour supply in the periphery shows a tendency to adapt to the new conditions, with increases in quality and quantity, which contradicts arguments about periphery desertion.
2. Labour demand in the periphery reacts to innovation new opportunities and to public policy measures and leads to changes in the domestic economic structures.
3. Yet, labour demand does not fully accommodate changes in labour supply, apparently as a result of insufficient or inappropriate policy measures.
4. A consequence of the insufficient balance between labour supply and demand is the persistence of periphery-centre gaps in unemployment and income.
5. An intensive research effort is needed in order to identify the policy measures that would lead to a better labour market balance.

RESILIENCE, DEVELOPMENT REGIONS AND LOCAL REVENUE COLLECTION LEVELS IN ROMANIA

Octavian Moldovan, Bogdana Neamtu

Department of Public Administration and Management, Faculty of Political, Administrative and Communication Sciences, "Babeş-Bolyai University", Cluj-Napoca, Romania

ABSTRACT

This paper explores if location in a development region influences local revenue collection levels (public revenue mobilization conceptualized as the ratio between the amounts collected at the local budget during one year divided by the amounts that were supposed to be collected during that budgetary year) in the case of Romania. As such, the revenue collection levels of 3227 (almost all) Romanian territorial-administrative units are analyzed for the 2008 to 2011 budgetary years according to the eight development regions (NUTS 2 level) created and maintained since 1998 in order to facilitate regional development, progress towards European Union accession and manage post-accession funding. The data analysis consists of descriptive and exploratory techniques (such as Tukey Boxplots, central tendency analyses and One Way ANOVA with Post Hoc).

The research provides corroborated evidence that Romanian development regions have a statistically significant effect on the levels of revenue collection at the local level. The results show that local administrative institutions from the North-West (with collection levels between 85.54% and 90.61%), West (with collection levels between 81.69% and 87.55%) and Bucharest (with collection levels between 84.27% and 88.29%) development regions constantly attained higher levels of local revenue mobilization between 2008 and 2011, while the North-East (with collection levels between 74.43% and 82.25%), South (with collection levels between 73.88% and 83.43%) and South-East (with collection levels between 78.68% and 81.89%) regions under-performed in regard to local revenue collection/mobilization. No clear pattern seems to emerge in the case of the remaining two regions (Center and South West) as they constitute an intermediary level between the aforementioned two categories.

Policy implications, especially for sustainable development, are discussed both in for the current administrative framework and in view of a potential administrative re-organization.

THE RELEVANCE OF SMART CITIES IN ASSESSING URBAN LABOR MARKET RESILIENCE. A POST-TRANSITION ECONOMY SPECIFICITY

Dan Lupu, Liviu Geroge Maha, Daniela Elena Viorica

Alexandru Ioan Cuza University of Iasi, Romania

ABSTRACT

Resilience is a well-established concept that is used to assess whether a system has the capacity to respond to a variety of challenges. One of the dimensions of resilience is the labor market ability to overcome the perturbations imposed by internal and external shocks and improve its capacity to respond to it. The cities' characteristics in terms of infrastructure, demographics, socio-cultural, governance, mobility, standards of living in general, as characteristics that describe key features of a smart city, can significantly influence the resilience of the urban labor market. From this perspective, a focus on explaining spatial variations in labor market resilience by analyzing the performance of urban areas is relevant in a geographical context of economic growth and development policies. This paper aims to assess the urban labor market resilience, the urban labor market resilience capacity and the relationship between the two, for the European Union's metropolitan areas from Eastern Europe. Also, the paper will follow the idea that this relationship is less significant for the borderline metropolitan region than for the most central ones. In building the resilience capacity index, we explored the extent to which key features of smart cities contribute to the evaluation of the resilience capacity of the urban labor market. The urban labor market resilience will be evaluated by building an aggregate indicator, using variables that measure specific characteristics of a labor market for post-transition economies. A profiling of the metropolitan areas with different degree of labor market resilience will be identified, using key features that define a smart city, in order to understand the extent of spatial variation in terms of urban labor market resilience. A spatial analysis using a visualization tool, namely a self-organizing map, will be employed to assess the regional disparities between borderline and non-borderline metropolitan regions. Analyzing the urban labor market resilience for a post-transition economy is considering the specificities of its labor market: the ongoing restructuring of the economy; the unemployment, especially for youth and female employment; massive migration of the workforce towards the Western developed countries. This approach can help investigating the possibility if a city with the key characteristics of a smart city can better cope with labor market shocks in a young market economy.

Do we need new data, models and planning for the post-pandemic city?

Room: Dakhla

<https://us02web.zoom.us/j/88500705804>

Organizers: Peter Batey, Guney Celbis, Kingsley Haynes, Karima Kourtit, Peter Nijkamp and Neil Reid

The Regional Science Academy

Aim & Scope

The past decade saw the emergence of connected intelligent infrastructures used for facing growing urbanization challenges. These networks of integrated computerized systems began collecting and transmitting urban data in real time, leading to automated and/or supervised interventions aimed to facilitate the lives of the individuals in cities. As part of the general concept of a “Smart City,” real-time data management and analysis has been used to streamline the distribution of energy, waste management, management of traffic congestion, and environmental protection among many other examples. One major purpose of the fast and efficient collection and analysis of city data is to anticipate urban challenges and intervene preemptively.

As the world was just entering a new stage characterized by urban communication networks powered by the Internet of Things infrastructures, the Covid-19 pandemic broke out. Monitoring population density to assess transmission risks and the place-based management of health services based on spatial information on COVID-19 cases have emerged as essential policy-relevant measures. The collection and rapid analysis of data related to the spatial accessibility to health services became an essential task for organizing the effective allocation of healthcare resources. Retuning intelligent transportation systems and developing heat maps identifying hotspots of are already recognized as imperative. This being said, privacy concerns and accessibility to data are vibrant discussion topics alongside with the technical aspects of the collection and processing of information.

What will be the aspects of the new types of data that we need with regards to the new urban life characterized by the pandemic? How will the lasting effects of the pandemic on urban life be represented and tracked digitally? How will this new data be translated into planning the post-pandemic city? This TRSA session will initiate a scientific discussion on how urban data will shape our lives after the pandemic.

CLUSTERS OF CULTURAL AND CREATIVE INDUSTRIES: EMPIRICAL EVIDENCE FOR CATALONIA

[Lina Maddah](#)¹, [Josep-Maria Arauzo-Carod](#)¹, [Fernando LÓpez Hernandez](#)²

¹Universitat Rovira i Virgili, Spain. ²Universidad Politécnica de Cartagena, Spain

ABSTRACT

Creative clusters are increasingly being recognized as vital tools in the promotion of a city's competitiveness, innovation, urban development, and growth in developed countries. This paper studies the geography of Cultural and Creative Industries (CCIs) in Barcelona (Spain) for the years 2009 and 2017.

Although several studies have made contributions on CCIs clustering, there exists a need to understand how clusters change, grow or decline and what processes influence their geographical concentration and knowledge embeddedness, with a variety of theoretical efforts and empirical means. This is an initial attempt to identify CCIs clusters' evolution over a period of time, to understand their lifecycle and progression. Though the benefits of clusters have been asserted in preceding literature, this paper attempts to fill an existing gap in understanding those patterns for CCIs by exploiting Kulldorff's scan statistics methodology using SaTScan as an additional input to existing work on "third-generation methods" for identifying significant industrial agglomeration.

Our findings indicate that CCIs are not haphazardly located, as they tend to cluster in and around Barcelona's prime districts. The evolution of the clusters over nine years reveals distinct patterns of clustering among the twelve sub-sectors of CCIs. The mature clusters in Barcelona's core tend toward greater growth and have enhanced transformation capabilities. The clustering patterns reflect that the maturity of an existing cluster or the emergence of a new one is not a "coincidence" and can be rather explained by understanding the local environment and the related variety among CCIs at the subsector level. This reinforces existing arguments that locations with older but related industries have a higher likelihood of forming a cluster. With this being said, the findings confirm two major economic claims (1) Jacob's claim on the development of new work on the basis of old work as a 'branching' process that is fundamental to the way that economic growth happens in cities (2) Schumpeter's claim on how economies evolve through the process of new innovation and path interdependence, not only dependence (depending on the knowledge base of the CCI subsector). Furthermore, clusters' evolution findings reveal linkages to knowledge flows within and outside the cluster, suggesting that knowledge embeddedness can either widen the spatial boundary of a cluster or narrow it down. Also, the role of institutions and local policies is highlighted and is assumed to modulate the sustaining and emerging clusters in the core of FUAB. Our results can guide CCIs cluster policy, taking into account the specificity of each sub-sector. In addition, they can direct place-based development strategies and creative urban planning and restructuring within a polycentric context.

MAPPING AND ASSESSING WATER RESOURCES RELATED INTERACTIONS IN THE BEKAA, LEBANON

Rana El Hajj, Jasmine El Kareh, Nadim Farajalla, Abed Halim Hajj Chehadeh

Issam Fares Institute for Public Policy and International Affairs at the American University of Beirut, Lebanon

ABSTRACT

Water resources can serve as both a source of tension and conflict, or as a tool for cooperation and partnership. Successful interactions over shared water resources can help build confidence between involved parties, foster cooperation in managing other resources and could even be a path for dialogue and negotiation. In Lebanon, the increasing scarcity of water resources and the fragile state of water governance has worsened water-related interactions among stakeholders. The Bekaa, whose resident population has nearly doubled due to the Syrian refugee influx, is perceived to represent a microcosm of the challenges facing the water sector in Lebanon. By examining the nature of new and existing pressures on water-related interactions among stakeholders in the Bekaa, this study aimed to assist development organizations working in the water sector to identify priority areas prone to conflict. This is done to ensure that cumulative efforts effectively contribute towards abating existing pressures and improve governance of the sector in the Bekaa. In order to achieve this aim, the research sought to identify and map stakeholders involved in the water sector in the Bekaa; determine the state of water resource related interactions among the identified stakeholders; identify and analyze different factors that contribute to the negative interactions in the Bekaa; and identify hotspots or areas in the Bekaa that are predisposed to water-based conflict. Factors contributing to water-related conflict in the Bekaa were categorized into three main groups: socioeconomic and demographic; institutional; and physical and geographic. The most negatively and frequently mentioned factors were considered areas of concern that must be addressed and were found to be, in decreasing order of importance: refugee influx; water quality; untreated wastewater; water availability; and implementation of Law 221. Seventeen towns/villages in the Bekaa were identified as having the highest predisposition to conflict based on the previously mentioned factors. This was done while taking into account two demographic factors: the first included local population density alone, while the second added to the first refugee populations. The main recommendations drawn out from this study include improving communication with local communities on water and wastewater related issues in relation to informal settlements; easing tensions by enhancing wastewater treatment capacity through developing integrated solutions relying on the reuse of wastewater; and assist in capacity-building of municipalities, enabling them to take over some functions and responsibilities regarding the management of the water sector to help achieve better decentralization.

IMPACT OF CLIMATE CHANGE ON RURAL LIVELIHOODS IN LEBANON**Leya Zgheib, Nadim Farajalla, Mira Zaghbour, Karim Korban**

Issam Fares Institute for Public Policy and International Affairs, Lebanon

ABSTRACT

Lebanon has been enduring multiple crises for the past 18 months that have had economic, political, and social repercussions all over the country threatening the livelihood of many. The agricultural sector not only suffers from these economic threats but is also subject to the impacts of climate change and natural disasters. Farmers have been highly affected by climate variability as well as the current economic crisis and will need to implement adaptation measures to sustain their production and secure income generation year-round to ensure their food security. Building on the World Food Program's efforts to expand activities that promote food security and livelihoods for refugees and host communities in Lebanon, this study aimed to generate evidence on the impact of climate change and climate variability on food security and rural livelihoods. The WFP Consolidated Livelihoods Exercise for Analyzing Resilience (CLEAR) was used to identify, design, and implement pilot interventions to test new approaches and generate lessons learned to help upscale UN's World Food Programme's (WFP) agriculture and climate related activities in Lebanon. The study adapted and applied the WFP-developed CLEAR methodology relying on extensive desk-research and stakeholder consultations at the national and sub-national levels. CLEAR has three distinct analysis steps: (1) Mapping of livelihood zones; (2) Developing a resilience index based on poverty, food security, climate sensitivity of crops and livelihood diversity; and (3) Assessing the impact of future climate risks on livelihoods and food security. The livelihood zoning conducted for this study resulted in the division of Lebanon into 19 different livelihood zones focused on eight main agricultural sources of livelihoods. Those zones were divided into three main categories based on agricultural land density. Three out of four zones relying heavily on agriculture showed a low resilience index regarding impacts of climate change on livelihoods. Zones with low agricultural land density had mixed results with a high resilience index for the four highly urban zones. The other two zones in which scarce agriculture land comprises of deciduous fruit trees and field crops displayed a low to moderate resilience index. Five of the zones with moderate agricultural density displayed a low to moderate resilience index, while the remaining four zones had a moderate resilience index. The main recommendations for implementing effective adaptation to climate change revolve around a comprehensive and dynamic policy approach covering a range of issues, from helping farmers understand risk profiles to the establishment of efficient capacity-building programs and pilot projects that facilitate response strategies. More systemic changes in resource allocation need to be considered, such as targeted diversification of production systems and livelihoods and working towards increased climate change adaptation action.

CLIMATE CHANGE VULNERABILITY ASSESSMENTS: THE CASE OF BATROUN AND TYRE

Celine El Khoury, Rana El Hajj, Nadim Farajalla

Issam Fares Institute for Public Policy and International Affairs - American University of Beirut, Lebanon

ABSTRACT

According to the Intergovernmental Panel on Climate Change, low-lying coastal zones are at a particularly high risk of severe harm due to climatic hazards and various vulnerabilities. Climate change vulnerability assessment is a critical exercise for defining climate change risks and developing climate change adaptation options that are context specific, which could be accounted for in city development plans.

In Lebanon, vulnerability assessments to climate change have rarely addressed the city scale due to its complexity and lack of data at such a scale. The understanding of the vulnerabilities to climate change impacts and risks on local and city scale in Lebanon is still limited, obstructing the mainstreaming of climate change adaptation into city planning and governance.

This study adapts and applies an integrated approach, mixing both bottom-up and top-down methodologies initially developed by GIZ et al. (2017), in Lebanese coastal cities, Batroun and Tyre. First, vulnerable sectors were identified in a stakeholder consultation meeting. Next, an impact chain was developed for each sector to select potential impacts, and vulnerability components. The approach used a simplified formula which defines $Vulnerability = Exposure + Sensitivity - Adaptive\ capacity$. For each component, a set of indicators were identified to ultimately compute the vulnerability index of each sector. The developed impact chain and associated indicators were validated by experts in an expert consultation meeting. Data collected for each selected indicator was normalized into a 0 to 1 scheme, whereby 0 is optimal and 1 is critical.

Our research has shown that, in both Tyre and Batroun, the most vulnerable sectors were tourism, water resources, infrastructure and fisheries. The tourism sector scored 0.66 and 0.61; the water resources sector scored 0.54 and 0.52; the infrastructure sector 0.57 and 0.52; while the fisheries sector scored 0.53 and 0.47 for Batroun and Tyre, respectively. The score of the tourism sector for both cities is considered as 'rather negative' while the other sectors' are seen as 'neutral'. In all sectors, the adaptive capacity component, specifically governance, is the one that impacted the vulnerability of sectors the most. This highlights the need and role of local and national Lebanese governments in integrating sound adaptation actions while also enforcing existing policies. Key institutions and authorities should build their know-how and capacities to enforce and update environmental laws. Laws should tackle accountability and participation practices to guarantee sustainable management of natural, financial and social capacities.

DIGITAL ECONOMY AND REGIONAL INDUSTRIAL UPGRADE: EVIDENCE FROM THE YANGTZE RIVER DELTA

[Jie Huang](#)¹, [Jianjun Chen](#)¹, [Yinxin Shen](#)², [Ying Zhou](#)¹

¹School of Public Affairs, Zhejiang University, China. ²School of Economics, Zhejiang University, China

ABSTRACT

Developing the digital economy and forming the new impetus of regional industrial upgrade are the significant strategies of China. It is of great theoretical and practical importance to figure out the relationship between them, as well as quantitatively analyze the related process. This study takes the Yangtze River Delta, which is China's pioneer region of developing digital economy, as the research scenario. The main work and possible innovations of this study include: (1) From both the meso and micro levels, it reveals the mechanism that how to realize industrial upgrade with promoting digital economy. (2) The paper puts forward the theoretical hypothesis that there might be three paths, on which would help digital economy accelerate the industrial upgrading: technological upgrading, factor-input-structure upgrading and product market upgrading. In addition, we conducted an empirical test using a multi-step multiple mediator model, and the results support the three assumptions above. (3) Comparing to previous research, the paper takes the response mechanism of regional development as one of the variables, solving the endogeneity problem, which is high-efficiency enterprises more tend to use digital technology. The results show that the development of digital economy is an important driving force of industrial upgrading in Yangtze River Delta. Furthermore, the regional response mechanism and market response mechanism triggered by digital economy have an attention-worthy impact on regional industrial upgrade.

URBAN BUILT ENVIRONMENT QUALITY AND ECONOMIC DEVELOPMENT: AN EXAMINATION WITH BIG DATA ON 50 CHINESE CITIES

Lun Liu¹, Hui Wang²

1 School of Government, Peking University, China, liu.lun@pku.edu.cn; 2 School of Architecture, Tsinghua University, China, wh-sa@mail.tsinghua.edu.cn

ABSTRACT

The quality of urban life has been considered as an important factor in determining the attractiveness of cities and the flow of human capital and other resources. While Edward Glaeser argued for aesthetics and physical setting as a critical urban amenity (Glaeser et al., 2001), yet empirical examination of its role is still not enough. To fill in the gap, this study employs newly-available big data on urban built environment in 50 most-populated Chinese cities and produces fine-grained evaluation on their quality, which was hardly measurable with conventional urban data. More specifically, we utilize street view images provided by online mapping services to evaluate the quality and aesthetics of urban buildings and utilize building footprint data to evaluate the comfortableness of urban space. An R package is developed for this purpose, which will also be introduced. With such unprecedented information on urban built environment, we aim to examine its role on urban economic development and answer questions like whether high built environment quality drives urban economic development. The work is on-going and will be reported in the conference.

MANAGING MULTIPLE AIRPORT REGIONS VIA PERIMETER RULES: AN EMPIRICAL ANALYSIS

Hideki Fukui

Faculty of Law and Letters, Ehime University, 3 Bunkyo-cho, Matsuyama, Ehime 790-8577 Japan,
fukui.hideki.hz@ehime-u.ac.jp

ABSTRACT

We examine the effects of perimeter rules, which set limits on the distance of nonstop flights to and from a given airport, on the traffic performance of carriers operating at airports within Multiple Airport Regions (MARs). We use a difference-in-differences strategy with propensity score matching and weighting methods by taking advantage of the repeal of the Wright Amendment at Dallas Love Field in October 2014. The estimation results for the Dallas and Washington MARs suggest that (1) the perimeter rules do seem to have a negative impact of air traffic; but (2) the rules do not necessarily incur negative effects on airfare competition; and (3) the repeal of the rules does not necessarily lead to increases in economic welfare: negative side effects such as higher congestion should be anticipated.

KEYWORDS

Difference-in-Differences, Multiple Airport Regions, Perimeter rule, Propensity Score Analysis Methods

1. INTRODUCTION AND BACKGROUND

Perimeter rules set upper limits on the distances of nonstop flights at airports in Multiple Airport Regions (MARs), in which several closely located major airports are operated. This research empirically assesses the welfare effects of perimeter rules, which is based on the US experience, is the first to explicitly examine the effects of perimeter rules on airport congestion.

The operational interactions and allocation of air traffic between airports are major challenges for airport management, especially in MARs. To control congestion and optimize the use of airports in the given MARs, some airports have set limits on nonstop flights. In the US, LaGuardia Airport in New York, Reagan National Airport in Washington DC, and Dallas Love Field Airport in Dallas have been under the perimeter rules.

2. PREVIOUS STUDIES

Despite the well-intended motives, the perimeter rules have been criticized. Indeed, previous studies (Le, 2018; Pukar, 2019; TRB, 1999; US GAO, 2012) suggest that the perimeter rules lead to fewer flights, reduced competition, and higher fares.

Among these studies, Le (2018) and Pukar (2020) are valuable contributions to the literature because these provide quantitative evidence that supports the criticism of perimeter rules which has been based only on descriptive and qualitative analyses. However, both Le (2018) and Pukar (2020) have several limitations that should be improved. Especially, these studies do not assess whether the perimeter rules have contributed to controlling airport congestion.

3. DATA AND MODEL

To examine the effects of perimeter rules on air traffic, airfares, and airport congestion, this paper uses a difference-in-differences strategy with propensity score matching and weighting methods by taking advantage of the repeal of the Wright Amendment at Dallas Love Field in October 2014. The treatment group comprises routes from airports in the Dallas and Washington DC MARs where airports are owned and operated by the same authority and one of its airports has/had perimeter restrictions. The control group consists of routes from airports in the Chicago and Houston MARs because the airports in these MARs are owned and operated by the same authority and have never been under the restrictions of perimeter rule.

The data are carrier-route level quarterly unbalanced panel data that are constructed from the US DOT's T100D, On-Time Performance Data, and DB1B for the period from October 2010 to September 2018.

The basic estimation model is given by Eq. (1):

$$Y_{iodt} = \theta_t + \alpha POST_t + \sum_p \beta_p APT_p + \sum_p \gamma_p (POST_t * APT_p) + X_{iodt} \delta + C_{iod} + U_{iodt} \quad (1)$$

Where $p = 1 \dots 4$ (DAL, DFW, DCA, IAD)

The subscripts i , o , d , and t denote carrier, origin, destination, and quarter. The dependent variable, Y_{iodt} , is either the numbers of (a) flights (logged) or (b) passenger (logged) or (c) average departure delay (minutes) or (d) average airfare deflated by CPI (logged). The estimation model includes a dummy for the period after the Wright Amendment was repealed ($POST_t$), origin airport dummies (APT_p), an interaction term between these two dummies ($POST_t * APT_p$), and controls (X_{iodt}). To mitigate the endogeneity problem, propensity score matching/weighting methods, lagged endogenous variables, and IV method are used.

Table 1 Variable balance across the treatment and comparison groups: Standardized differences between two groups

Sample type	(1) Passenger dataset			(2) Airfare dataset			(3) Delay dataset		
	Original	Weighted	Matched	Original	Weighted	Matched	Original	Weighted	Matched
	Standardized differences			Standardized differences			Standardized differences		
Slot controlled airport dummy	0.862	0.034	0.047	0.731	-0.055	0	0.576	-0.075	0.041
Number of effective competitors per route (t-1)	-0.463	0.001	0.035	-	-	-	-0.477	0.009	-0.004
Southwest's presence dummy (t-1)	0.061	-0.009	0.036	0.232	0.068	-0.035	0.128	-0.002	0.049
Distance (miles) (log-transformed)	-0.200	-0.074	-0.126	0.019	-0.058	-0.022	0.048	-0.015	-0.029
Quarterly average population size of the two endpoint states of the given route (log-transformed)	-0.115	-0.147	0.015	0.085	-0.134	0.099	0.199	-0.115	0.045
Quarterly average per capita personal income of the two endpoint states of the given route (deflated by the CPI-U) (log-transformed)	0.116	-0.062	0.001	0.051	-0.062	0.007	0.013	-0.007	-0.007
Quarterly average kerosene price deflated by the CPI (log-transformed)	0.060	0.012	-0.001	-0.020	-0.006	-0.001	0.060	0.009	0.010
Quarterly total number of performed flights calculated on a carrier-route basis (log-transformed)	-	-	-	-	-	-	0.128	-0.086	0.043
Quarterly total number of performed flights calculated on a carrier-route basis (log-transformed) (t-1)	-	-	-	-	-	-	0.146	-0.077	0.050
Observations	54492	54492	34568	29693	29693	19770	31861	31861	19942

Table 1 shows the balance of each variable between the treatment and control groups in the original, weighted, and matched samples for the passenger, airfare, and delay datasets, respectively. Table 1 suggests that many variables in the original sample would likely be unacceptable for the difference-in-differences analysis without weighting or matching. However, the propensity score weighting and matching improve the covariate imbalance of most variables. Most variables appear to be adequately balanced, which suggests that the propensity score is properly specified.

Controls, $X_{iодt}$, include the following variables: (1) slot-controlled airport dummy, which is 1 if at least the origin or destination is slot-controlled airport and 0 otherwise; (2) number of effective competitors (i.e., the inverse of the Herfindahl-Hirschman index), calculated by using each carrier's number of flights on a route/quarter basis (Source: US DOT, T100D); (3) Southwest's presence dummy, which is 1 if Southwest Airlines is present at the origin or destination of the given route and 0 otherwise (Source: US DOT, T100D & DB1B); (4) log-transformed route distance (miles) (Source: US DOT, T100D & DB1B); (5) log-transformed quarterly average population size of the endpoint states of the given route (Source: US BEA, SQINC1); (6) log-transformed quarterly average per capita personal income at the endpoint states of the given route (adjusted by the CPI-U) (Source: US BEA, SQINC1; US DOL, Consumer Price Index - All Urban Consumers); (7) quarterly average of monthly kerosene price (adjusted by the CPI-U) (Source: US EIA, US Kerosene Wholesale/Resale Price by Refiners (Dollars per Gallon); US DOL, Consumer Price Index - All Urban Consumers).

4. ESTIMATION RESULTS

Table 2 presents descriptive statistics for our datasets. Tables 3 through 5 report the estimation results using each dataset.

The estimation results partially support the findings of previous studies: the perimeter rule at Dallas MAR has led to fewer flights, reduced competition, and higher fares. Indeed, the repeal of the perimeter rule at the Dallas MAR resulted in the increase of flights and passengers (more than 100 percent) and the decrease of airfares (about 6 to 7 percent) on routes from Dalla Love Field Airport. However, at the same time, the results suggest that the average departure delay minutes on routes from Dallas MAR's two airports became longer about 3.8 to 6.7 minutes compared with the control group.

Interestingly, the estimation results for the Washington DC MAR suggest not only negative but also positive effects of the perimeter rules. On the one hand, the results suggest that the perimeter rule at Reagan National did neither lead to the passenger shift from National to Dulles nor the increase of passengers using the airports. However, the results suggest that the perimeter rule has a positive effect on controlling airport congestion: although the average departure delay minutes on routes from the Washington DC MAR's two airports increased about 1.8 to 4.6 minutes, the estimated increase in the delay minutes is 31 to 56 percent shorter compared to the routes from the Dallas MAR. In addition, the results suggest that even under the perimeter rule, competition at the Washington DC MAR is effective in reducing airfares on routes from Dulles (about 10 to 11 percent) and potentially from Reagan National (about 5 percent).

5. CONCLUSION

Overall, our analysis suggests that the repeal of the perimeter rules does not necessarily lead to increases in economic welfare: negative side effects such as higher congestion should be anticipated. As previous studies suggest, the perimeter rule does seem to have a negative impact on air traffic. However, the results of our analysis suggest that the perimeter rules can serve as tools to manage airport congestion without incurring negative effects on airfare competition. Future

studies should explore improved designs of the perimeter rules, which minimize their negative effect on air traffic and competition, and maximize their potential as tools to manage airport congestion in MARS.

MEASURING TRANSIT-ORIENTED DEVELOPMENT DEGREE BASED ON THE RAILWAY TRANSIT NETWORK PERFORMANCE CONSIDERING POPULATION AND FACILITY DISTRIBUTION

[Lan Yang](#)¹, [Sunyong Eom](#)², [Tsutomu Suzuki](#)³

¹Department of Risk Engineering, Graduate School of Systems and Information Engineering, University of Tsukuba, Japan. ²Center for Spatial Information Science, the University of Tokyo, Japan. ³Division of Policy and Planning Sciences, Faculty of Engineering, Information and Systems, University of Tsukuba, Japan

ABSTRACT

To respond to urban challenges such as car dependence, air pollution, urban sprawl, and congestion, transit-oriented development (TOD) is increasingly recognized and interested. TOD can effectively reduce car dependence by attracting people to attend activities near public transport. While previous studies are rich in the neighborhood- and station-level TOD, very few studies focused on a universal measurement of the city- and regional-level TOD, which can be used to make efficient TOD planning in different cities regarding railway transit network performance in connecting population and facilities. Therefore, this research aims to measure the TOD degree of the city- and area-level in terms of the travel time reduction benefit from a railway network in 40 cities worldwide considering the linkage of population, facilities.

First, the TOD degree is defined using the linkage index of city- and area-level, which indicates the gap between the ideal and current condition in terms of travel time or the number of facilities. To calculate the linkage index, we define three speed settings by changing the speed of the network: (1) travel by using only the road network, (2) travel by current road and railway networks (current condition), and (3) travel by road and railway with railway speed (ideal condition). Calculating the linkage by comparing the current and ideal situation can help understand how far the current network performance is from the ideal condition. We assume two travel patterns for measuring the linkage index: population to population (long-distance travel) and population to facility (short-distance travel). Then, these linkage indexes of 40 cities are calculated using data collected from OpenStreetMap, including road data, railway data, and facility data. Finally, the relationship between linkage index and city characteristics such as population distribution, transit system, and facility distribution is investigated to determine the reasons for differences in TOD degree.

The major conclusions include the followings: On the city-level, (1) the railway systems of European cities have a high linkage index than some cities in developing countries, whether in long or short distance travel, due to relatively well-developed railway infrastructures; (2) railway and station density have a positive relationship with the linkage index, but differences in linkage index are observed between cities with the same infrastructure level; (3) this difference indicates the importance of efficient connections in railway systems between distributions of population and facilities. On the area-level, the spatial differences of the linkage index are clearly displayed. This research enhances the understanding of the TOD degree and provides benchmark points that contribute to decision-making processes regarding the TOD development.

MEASURING THE EVOLUTION OF REGIONAL VALUE CHAINS IN NORTHEAST ASIA USING A CROSS-BORDER INTERREGIONAL INPUT-OUTPUT MODEL

Min Jiang, Euijune Kim

Seoul National University, Korea, Republic of

ABSTRACT

The recent Regional Comprehensive Economic Partnership (RCEP) Agreement signed by 15 East Asian countries in 2020 marks the first time that China, Japan and South Korea (CJK) have gathered together under a single trade agreement. As the world's largest regional free trade agreement, RCEP is expected to accelerate the development of regional value chain of CJK as well as regional economic integration of Northeast Asia. International IO table has been considered a very useful source of data for analysis of production network or value chain (VC). VC trade is separated into regional value chain (RVC) trade – involving only regional production partners – and global value chain (GVC) trade – involving also extra-regional partner countries. This paper adopts input-output decomposition techniques to analyze the evolution of production networks in CJK over the period 2005-2015 from a RVC perspective. The main objective of this study is to find out what are the locational patterns of trade in value-added in Northeast Asia and how are these patterns changing over time. In this paper, the area is composed of 7 regions of China, 4 regions of South Korea, and 9 regions of Japan, while each region having ten industrial sectors. The primary data sources are the Transnational Interregional Input-Output Table for CJK, 2005, constructed by the Institute of Developing Economies, JETRO. Then, the updated cross-border interregional input-output table of 2015 is calculated based on the Eora Input-Output Database, China regional Input-Output Table and Korea regional Input-Output Table of 2015. Based on recent IO-based GVC indicators, this study tries to provide a more detailed image of a certain region's (not only a country's) positions and degrees of participation in international production networks and measure the comparative advantage at the regional level rather than the national level. This cross-border interregional IO model is expected to find out (a) the evolution of interdependencies in regional trade and production networks between 20 regions in CJK through a matrix of cross-border transfers of intermediate goods by origin and destination, (b) value-added distributions and their evolution across the sample region, and (c) how a region's value-added is induced by its partner region's final demand.

SCHOOL INTEGRATION AND EDUCATION OUTCOMES IN INDONESIA: GLOBAL INFORMATION SYSTEM, MICRO SIMULATION AND CGE ANALYSIS

Bondi Arifin, Anda Nugroho, Eko Wicaksono, Abdul Aziz, Tri Wibowo, Akhmad Yasin, Praptono Djuned

Ministry of Finance Republic of Indonesia, Indonesia

ABSTRACT

Indonesia estimated age population at the primary and secondary education levels are reaching 70 million, and spread over more than 500 districts / cities. In 2020/2021 the number of elementary school graduates decreased by 200 thousand students compared to 2016/2017. In the same period, the number of junior high school graduates fell by 40 thousand. We investigate possibility of school integration in Indonesia to improve access to education using Global Information System (GIS), Micro Simulation and Computable General Equilibrium (CGE). We utilize many different data sources, including school location; National Socioeconomic Survey (SUSENAS); and Village Potential (PODES) for the year 2011, 2014, and 2018. Schools Integration is unitin three levels of education into one environment, so that primary school (SD), Junior High School (SMP), and Senior High School (SMU) can be implemented in the same location. Although there is no junior high school and senior high school on a village, but it more likely has primary school. Our findings indicate the integration brings closer the distance to the school by these school age students. At least three school integration benefits are identified: the existence of integration can solve the problem of school supply, in this case the distance is too far to get to school. The second benefit of school integration is the efficiency of the cost of running the school. The next benefit is the ultimate goal of education policy, namely to reduce inequality in access to education and increase the average length of education through increasing school enrollment rates in disadvantaged and isolated areas. Papua Island and Kalimantan Island are the islands that benefit from the largest change in distance compared to other island averages. School integration can lead to a reduction in the distance to schools on the island of Kalimantan by up to 40 km with an average reduction of the distance to the nearest school by 20 km. This is bigger for Papua Island, which can save up to 64 km of mileage with an average mileage of 50 km. Micro simulation suggest school integration related to increase the level of education of children in Papua Province by 0.06 years, the largest compared to other regions, followed by Southeast Sulawesi, Bengkulu, Aceh, North Maluku and Maluku Provinces. The education of children in Central Java and South Sumatra Provinces will increase by 0.01 years if integrated schools are implemented. Furthermore, our early finding exhibits school integration could lead to total savings in school operational budgets is estimated at 2.42 trillion rupiahs per year compared to if three separate schools were formed. Savings on school integration options include no need to acquire new land for school land, savings in maintenance costs and service subscriptions. Finally, CGE simulates school integration could improve Indonesia economic growth in the long run through labor productivity improvement. However, school integration may not be effective for areas on scattered small islands due to limited transportation links between islands even though the distance is getting closer to school integration.

Regular Session: RS20 - Biodiversity, ecosystems and ecosystem services

ASSESSMENT AND VALUATION OF ECOSYSTEM SERVICES AT A WATERSHED LEVEL- THE CASE OF BEHT IN THE MIDDLE ATLAS OF MOROCCO

Ismaili Hassana¹, Abdellatif Khattabi²

¹Faculté De Science IBN Tofail-Kenitra, Morocco. ²Ecole Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

The upstream Oued Beht watershed covers an area of approximately 1,810 km² and it is home to the best natural ecosystems of the central Middle Atlas Mountains. It provides a large number of ecosystem goods services, namely: wood, aromatic and medicinal plants, fodder, and a large variety of other services such as: recreation, water and soil conservation, carbon storage, etc. However, these ecosystem goods and services are considered gifts of nature offered for free and therefore suffer from irrational exploitation by a large number of people with multiple and divergent interests. Associating monetary values to these goods and services will contribute to the sensitization of their importance to human wellbeing. Several valuation methods can be used to assess their values. This assessment will contribute to take into account the ecosystem services during decision-making processes and for consequence the preservation of the natural ecosystems. In this study, we try to assess various goods and services at the river basin level using revealed preferences or stated preferences evaluation methods. This evaluation aims at supporting and redirecting the objectives set for the watershed development to be in conformity with the requirements of sustainable management.

VALUING MARINE BIODIVERSITY AND ECOSYSTEM SERVICES: A CONTINGENT VALUATION STUDY IN ITALY

[Stefania Tonin](#)

Università Iuav di Venezia, Italy

ABSTRACT

Marine biodiversity provides valuable benefits to human beings, some of those easily recognized, such as the provision of food, some much less well known, such as climate regulation; yet people lack a direct experience of their economic values since no relevant market exists. This study reports the results of a contingent valuation study to estimate the public's willingness to pay (WTP) to improve biodiversity in some rare coralligenous habitats in the Venetian North Adriatic Sea, called Tegnùe.

Coralligenous habitat constitutes one of the most important 'hot spot' of species diversity in the Mediterranean, notoriously affected by a loss of biodiversity as a consequence of human activities such as over-fishing and pollution, sediment deposition, recreational fishing and trawling, diving. A major threat is the increasing frequency of Abandoned, Lost or otherwise Discarded Fishing Gears (ALDFG) at sea. We surveyed a sample of 4000 Italian people and we found that WTP for interventions aimed to improving biodiversity through removal and restoration operations in the area is distinctly higher than the WTP for the preservation and prevention of further biodiversity loss. Our findings suggest that respondents perceive prevention and control activities as disentangled from restoration, the benefit of which can be clearly recognizable in their time horizon, while the benefits of preservation and prevention are perceived as much more ambiguous and less controllable. This study is particularly important because it proves that the aggregate benefits related to the improvement of biodiversity as a result of restoration and conservation activities are significantly higher in comparison to the estimated costs of these activities. Following the real activities undertaken during the project, the investigation, restoration, and removal costs incurred in cleaning up 20 Km² were estimated to be approximately €191,000. Thus, if we suppose that there are similar environmental conditions in all of the sites of the Adriatic Sea, the total cleaning up cost will be around €500,000, while the total benefits can be estimated as €97 million, assuming a discount rate of 5%, a number of families equal to 2,057,227 and a duration of the benefits equal to three years.

PRACTICAL VALUATION OF ECOSYSTEM SERVICES FOR LOCAL STAKEHOLDERS: ECONOMIC VALUATION CONSIDERING LOCAL EXPLICIT DATA

Takashi Hayashi, Daisuke Kunii

ABSTRACT

For the achievement of 2030 SDGs agenda and conservation of ecosystem accordingly, it is important to assess the value of ecosystem and its services. In light of this, some initiatives such as Millennium Ecosystem Assessment (MA), The Economics of Ecosystem and Biodiversity (TEEB), Wealth Accounting and Value of Ecosystem Services (WAVES), Intergovernmental Panel on Biodiversity and Ecosystem Services (IPBES), and Ecosystem Services Partnership (ESP) are launched to develop measures for valuation of ecosystem services (ES), and researches are ongoing worldwide to evaluate ES. Although researchers expect that the results to be used in various decision-making related to business and policies, some studies have pointed out that the valuation results are not fully utilized for the decision-making. So-called “information gap” issue is pointed out and, some reasons for the gap are raised. Among this, some studies questioned that local specific factors are not fully captured in the valuation. This means that in most valuation cases, national statistics are mainly used for the valuations, and local on-site information such as geographical conditions and information/data on residents are not sufficiently reflected in them. This makes the use of the results difficult for local stakeholders. In addition, most of ES valuations assess potential value instead of actual value which beneficiaries currently and actually receive from ecosystem. Some studies consider beneficiaries of ES, but ES valuations and tools that identify the beneficiaries of a given ES in a spatially explicit way are still minor. The economic valuation is regarded as a prerequisite for better decision-making, and some valuation results are already incorporated in various decision-making processes. In order to enhance the usefulness of ES valuation the number of beneficiaries of ES that link with economic valuation is crucial particularly for ecosystem conservation policies and management practices in a specific area. Additionally, local-specific information such as the number of beneficiaries can close the gap between valuation studies and decision-making regarding ecosystem conservation practices.

The purpose of this study is to obtain the valuation that is practically useful for policy decision-makings particularly for local policymakers. More specifically, we chose water storage service of forest ecosystem as a valuation object, and assess the value of the ES in monetary term. The valuation is combined with information on beneficiaries. By spatial analysis with geographical information system (GIS), we estimate the number of households influenced by deforestation of upstream forest caused by the construction of solar power plants. We use a case of Satetsu-gawa River basin in Ichinoseki-City, Japan. In this study, we firstly estimate the area of forest deforested due to construction of six solar power plants in Satetu-gawa River basin. Then the areas and the number of households located downstream of the river are also estimated. The households in downstream area can be regarded as beneficiaries of the services in the river basin. Finally, the value of each type of ES in monetary term is assessed using information on beneficiaries.

KEYWORDS

Beneficiaries; Economic valuation; Forest ecosystem services; Spatial information; River basin;

1. INTRODUCTION

Conservation of ecosystem and its services is included in the SDGs targets: targets 14 and 15. For the achievement of 2030 SDGs agenda and the conservation of ecosystem, it is important to assess its value (Costanza et al., 1997; Su and Peng, 2018). In light of this, some initiatives such as Millennium Ecosystem Assessment (MA), Intergovernmental Panel on Biodiversity and Ecosystem Services (IPBES), The Economics of Ecosystem and Biodiversity (TEEB), Ecosystem Service Partnership (ESP), and Wealth Accounting and Value of Ecosystem Services (WAVES) are launched to assess ecosystem services (ES) and develop its measures. In the academic field, researches are ongoing worldwide to evaluate ES (Costanza et al., 2017), and they hope that the results to be used to influence on business and policy decision-making (Laurans et al., 2013). However, some studies have pointed out that the valuation results are not fully utilized for the decision-making (Laurans et al., 2013; Rieb et al., 2017; Ruckelshaus et al., 2015), and so-called “information gap” issue is raised (Keishish and Salles, 2021; Barton et al, 2018; Levrel et al., 2017). Many reasons for the gap are raised by previous studies; researchers are not interested in the use of the valuation (Olander et al., 2017; Laurans and Mermet, 2014; Spash and Vatn, 2006), a degree of accuracy does not meet users’ demand (Villa et al., 2017), the explanation of constraints in the valuation is not sufficient (Schaefer et al., 2015), the contribution of valuation studies for policy decision-making is limited (Palmer, 2012) and local information is not reflected in the valuation (Pandeya et al., 2016; Nelson et al., 2009).

Waite et al. (2015) identified enabling conditions for informing decision-making: a clear policy question, strategic choice of study area, strong stakeholder engagement, effective communications, access to decision makers, and transparency in reporting results. Olander et al., (2017) pointed out that the factors for the gap fall mainly into two primary groups; the failure to develop transparent and unambiguous linkages between ecosystem changes and outcomes, and the methods applied to the valuation do not answer relevant policy and management questions. In addition, they also raised the question regarding local specific factors, which are not fully captured in the valuation. This means that in most valuation cases, national/regional statistics are mainly used for the valuations, and local on-site information such as geographical conditions and information/data on residents are not fully reflected in them. This makes the use of results difficult for local stakeholders. Pandeya et al. (2016) also deals with local vs regional approaches and insisted that “most existing frameworks are focused at regional scales and there is limited focus at local scale valuation.” (Pandeya et al., 2016, p.254). Villa et al. (2017) pointed out that most of ES valuations assess potential value instead of actual value which beneficiaries currently and actually receive from ecosystem and they include the location of beneficiaries into the valuation. Some other studies consider beneficiaries of ES (Schirpke et al., 2014; Bagstad et al., 2014; Garcia-Nieto et al., 2013; Syrbe & Walz, 2012). However, ES valuations and tools that identify the beneficiaries of a given ES in a spatially explicit way are still minor (Rieb et al., 2017). All above studies except Schirpke et al. (2014) do not actually estimate the number of beneficiaries of services provided from specific ecosystems. Even Schirpke et al. (2014) simply estimate the number of beneficiaries and do not link with economic valuation. The economic valuation is regarded as a prerequisite for better decision-making (Laurans et al. 2013; Daily et al., 2009), and some valuation results are already incorporated in various decision-making processes (Gowan, 2006; Navrud, 2001). In order to further enhance the usefulness of ES economic valuation, the economic valuation that link with the number of beneficiaries of ES is crucial particularly for ecosystem conservation policy and management practices in a specific area. Additionally, the number of beneficiaries as local-specific information can close the gap between valuation studies and decision-making regarding ecosystem conservation practices.

The purpose of this study is to obtain the valuation that is practically useful for policy decision-makings particularly for local policymakers. More specifically, we chose water storage service of forest ecosystem as a valuation object, and assess the value of the ES in monetary term. In this study, we define practical valuation as valuation that can close the information gap, and we combine the valuation with information on beneficiaries so that it can be practical. Specifically, we use a case of Satetsu-gawa River basin in Ichinoseki City, Japan. By geographical analysis with geographical information system (GIS), we firstly estimate the number of households benefitted by upstream forest ecosystems, and estimate the area of forest deforested due to construction of six solar power plants in Satetu-gawa River basin. Then the areas and the number of households located downstream of the river are also estimated. The households in downstream area can be regarded as beneficiaries of the services in the river basin. Finally, the value of the ES in monetary term is estimated using information on beneficiaries.

2. METHODS

2.1 Overview of Study Site

Ichinoseki, which is our study site is a middle-class city in Iwate Prefecture and located 450 km away to north from Tokyo. It has about 121 thousand population and 43046 households (as of 2015) and its area accounts to 1256 km². Average temperature in Ichinoseki in 2020 was 12.4 degree C with maximum 37.8 and minimum -7.6 degree C. Average precipitation and snowfall were 1306 mm, and 17 cm respectively in 2020. Kitakami-gawa River which is one of the main rivers in Northern Japan flows into the city, and our study site, Satetsu-gawa River, is a tributary of Kitakami-gawa River (Figure 1). Satetsu-gawa River is located in south part of Iwate prefecture and flows into former Daito, Higashiyama and Kawasaki municipalities, which was merged with Ichinoseki. The length of the river is about 44.6 km. In Figure 1, black lines, gray areas and black points indicate river channel, forest area, and sites of solar power plants, respectively. In July 2002, a typhoon raged and brought great damage to the Satetsu-gawa River basin with 743 above-floor and 222 under-floor inundation, with 529 hectares of inundation area. Since then, flood is one of the major concerns in this area.

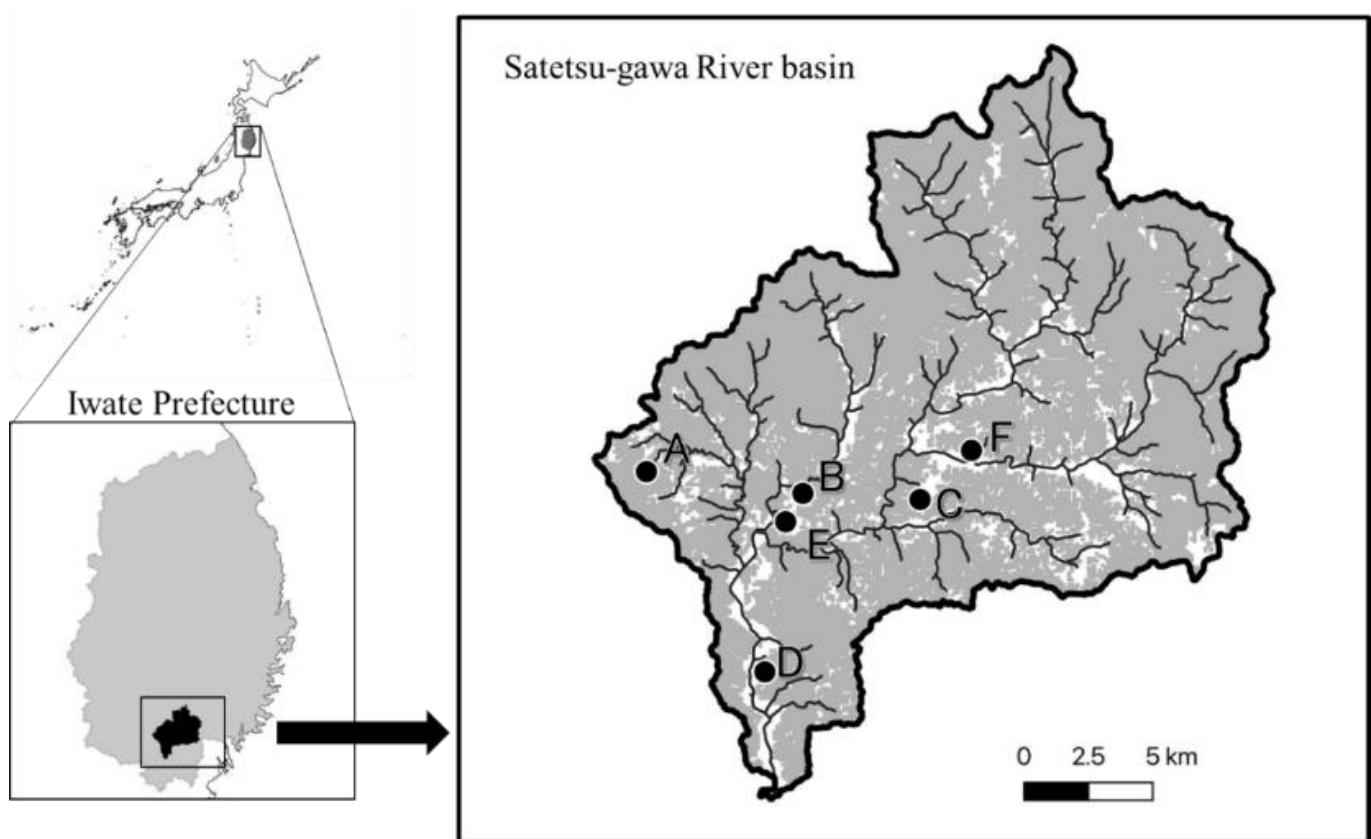

Figure 1: Location of Satetsu-gawa River basin and six solar power plants

In 2012, the Feed in Tariff scheme of renewable electric power is introduced in Japan, and the number of solar power plants has rapidly increased since then. A part of the plants was constructed by deforesting existing forest, and this holds on Satetsu-gawa River basin. In the river basin, additional flood prevention measures are requested, on the other hand, six solar power plants have been installed so far, all of them are constructed by deforesting. Therefore, we chose Satetsu-gawa River basin as study site. In addition, from analytical point of view, the reasons for selecting Satetsu-gawa River are; (1) there are multiple solar power plants and they are located remotely each other in the river basin, (2) the whole river basin is in Ichinoseki City, that makes the connection of statistical data and geographical data easy, (3) we already have forest registration data in Iwate Prefecture and have conducted analysis on forest in the Prefecture including Ichinoseki City.

2.2 Geographic analysis

In the analysis, we identify the area which is affected by reduction in water storage service of forest ecosystem caused by the construction of six solar power plants in Satetsu-gawa River basin, and hereafter we call the area affected area. To identify the affected area, we firstly assume that forests provide water storage service only to the area that is lower elevation than the forests in river basin and to the residents who live the area and can be seen as beneficiaries of forest water storage service. Under the assumption, we estimate the affected area and calculate the number of households as beneficiaries by each small river basin which is a sub-compartment of the whole river basin.

Since this study focuses on lost forest ecosystem services, specifically water storage service, due to the construction of solar power plants, it is important whether or not the power plants were constructed by deforestation. However, judging whether the deforestation was made for the purpose of constructing a power plant is controversial in terms of following two criteria (1) whether deforestation is made for the construction of a power plant, (2) when the forest was deforested. Regarding the former issue, there is no objective and rational criteria for determining whether deforestation is conducted for the purpose of constructing a solar power plant. Of course, if the forest was cleared just before the construction of the plant, it can be regarded as deforestation for the construction of the plant, but even in this case, how far should we go back to the past in order to judge deforestation for the plant construction? For instance, since our analysis applies 2012 forest registration data in the year of 2012, even forests that had been cleared land by 2012, it may have been for the purpose of installing a solar power plant which is related to the latter issue. The point is, it is quite difficult to set clear criteria for distinguishing deforestation for the purpose of solar power plant construction. Therefore, in this study, we assume that if there are forest registration data at the construction site, the site is deforested. Forest registration data is created only for the land that was previously managed as forest. Based on this, we think it is appropriate to regard the existence of the forest registration data on the site as a modification from the forest. As a result, all of the six power plants in Satetsu-gawa River basin meet the conditions that the construction sites have forest registration data. In this study, these six solar power plants, which are indicated A to F in Figure 1, are used as the cases.

Table 1: Data used for the analysis

Item	Type of data	Year	Source	Reference
Elevation level	10 m mesh	-	Website of Geospatial Information Agency	https://fgd.gsi.go.jp/download/menu.php
Number of households	250 m mesh	2015	Japanese population census	https://www.e-stat.go.jp/
Forest registration data	Polygon	2012	Provided by Forest Agency and Iwate Prefecture	
Location of solar power plants	Point	2020	Website of Electrical Japan INC.	http://agora.ex.nii.ac.jp/earthquake/201103-eastjapan/energy/electrical-japan/

As shown in Table 1, in this study, used data are Digital Elevation Model (DEM) as mesh elevation data, forest registration data, mesh data on land use, and zoned area for land use. We also use mesh data on the number of households which is originally from the Japanese Population Census to estimate the number of beneficiaries. Firstly, the area of Satetsu-gawa River basin is strictly estimated and polygons of the river basin is created from DEM by geographical information system (GIS). The polygons are subdivided by small river basin, and these sub-polygons are basic unit of our analysis. Under the above process, we also create water channel network data to identify river flow in the river basin. Affected area is defined as sub-polygons that overlap the flow path of the river and that are lower than the sub-polygon where a solar power plant is located. A point on the river which is the closest to a solar power plant and a sub-polygon that include the point (hereafter, plant sub-polygon) is identified by visual inspection. We calculate elevation level, and area by each sub-polygon. DEM is used to estimate elevation level of the sub-polygon, and sub-polygons that are lower than a plant sub-polygon are identified. These sub-polygons are regarded as affected area of the construction of a solar power plant. Finally, the sum of the area of these sub-polygons is estimated as total area of affected area, and the number of households is also calculated. These figures are seen as affected area and the number of people influenced by the deforestation caused by the construction of solar power plants. In other words, these people are regarded as former beneficiaries of lost forest ecosystem services. In the analysis, Arc GIS for Desktop 10.6 and Spatial Analyst are applied to river basin analysis, and QGIS 3.6 is applied for other analysis.

2.3 Economic valuation

Using results of geographical analysis, we also estimate the values of water storage service of forest ecosystem lost by the construction of solar power plants in Satetsu-gawa river basin. The unit value of water storage service is based on a previous study conducted by my colleagues (Fujii et al., 2017) which identified an equation to estimate a unit value of forest ES. In the study, they firstly assessed the total value of forest ecosystem using contingent valuation (CV) and estimated the unit value of forest water storage service. A questionnaire survey for CV was conducted in November 2015. On average, approximately 0.3% of the population of each prefecture is covered. After dropping non-responses or protest responses for the CVM questions and other insufficient answers, 192,704 observations from all 47 prefectures in Japan remained. From these observations, following regression equation for willingness to pay (WTP) is identified.

$$WTP = 2610.18 + 0.00015 * \text{income} - 354.57 * \text{woman rate} - 19.79 * \text{age} - 457.73 * \text{natural forest rate} + 788.72 * \text{broadleaf rate} - 5.75 * \text{forest age} + \epsilon \tag{1}$$

Age: age of respondent

Income: income of respondent

Woman rate: woman rate of the municipality where valued forest is located

Natural forest rate: natural forest rate of valued forest,

Broadleaf rate: broadleaf rate of valued forest

Forest age: average forest age of valued forest

Based on the equation, we insert variables for Ichinoseki-City where Satetsu-gawa River is located to estimate the unit value of forest ecosystem in the river basin. The result showed that the unit value of forest ecosystem in Ichinoseki was 2658 JPY per hectare per household. Secondly, as the above unit value includes all types of forest ecosystem service, the value of water storage service should be extracted. To do this, we also conducted choice experiment (CE) to estimate weights for each ES. The ES we chose for the estimation of weights are following six services: water storage, soil retention, habitat provision, timber production, recreation, and climate change mitigation. We conducted the CE survey along with CV one in 2015, and then estimated weights for each ES. The result showed that the weight for water storage service accounted to 0.201, which means 20.1% of total value of forest ecosystem is attributed to water storage service. Therefore, the weight is multiplied to the unit value and the value of water storage service account to 533 JPY per hectare per household. Using this unit value of water storage service, we estimate the lost value of water storage service due to the construction of solar power plants by multiplying the unit value to area deforested and the number of households in affected area which are estimated in geographical analysis.

3. RESULTS

The result of affected area is shown in Figure 2, and that of valuation is shown in Tables 2 and 3. Table 2 shows the results of geographic analysis in the whole Satetsu-gawa River basin, the total area of the basin accounts to 37952 hectare among which 25239 (66.5%) is dedicated to forest. Most of forest area is owned by private sectors and nationally-owned forest has minor share. The number of forest in the river basin accounts to 7244, as the total number of households in Ichinoseki is 43046, 16.8% of total household in Ichinoseki is in the river basin. In Figure 2, black stripe shows the affected area of all solar power plants. Light green and dark green show broad leaf forest and coniferous forest of the forest registration data, respectively. Overlapping the result with other data, we estimate the forest area and the number of households, in the affected area for each solar power plants. Table 3 shows the results of estimation of deforested area, affected area and the value of lost ES. First, deforested areas vary from 0.9 to 8.2 hectares, mainly depending on the scale of plants. The area deforested tends to be correlated with generation capacity of the plant, the indicator indirectly shows the scale of the plants. The total affected area ranges from 985 to 3672, the higher the location of a solar power plant is, the larger affected area is. Therefore, the plant F has the largest figure followed by the plants C, A and B. When looking at Figure 2, the relation with the location can clearly be seen. The values of lost forest ES: i.e. water storage service range from 0.3 to 3.3 million JPY. As the value considers both deforested area and the number of households in the affected area, the plants located lower in the river basin with less residents performs better.

Table 2. The area and the number of household in Satetsu-gawa River basin.

	Total area (ha)	Total no. of h.hold	Total forest area						
			Government			Private			
			Total	Conifer	Br. leaf	Total	Conifer	Br. leaf	
The whole river basin	37,952	7,244	25,239	559	437	122	24,680	14,761	9,919

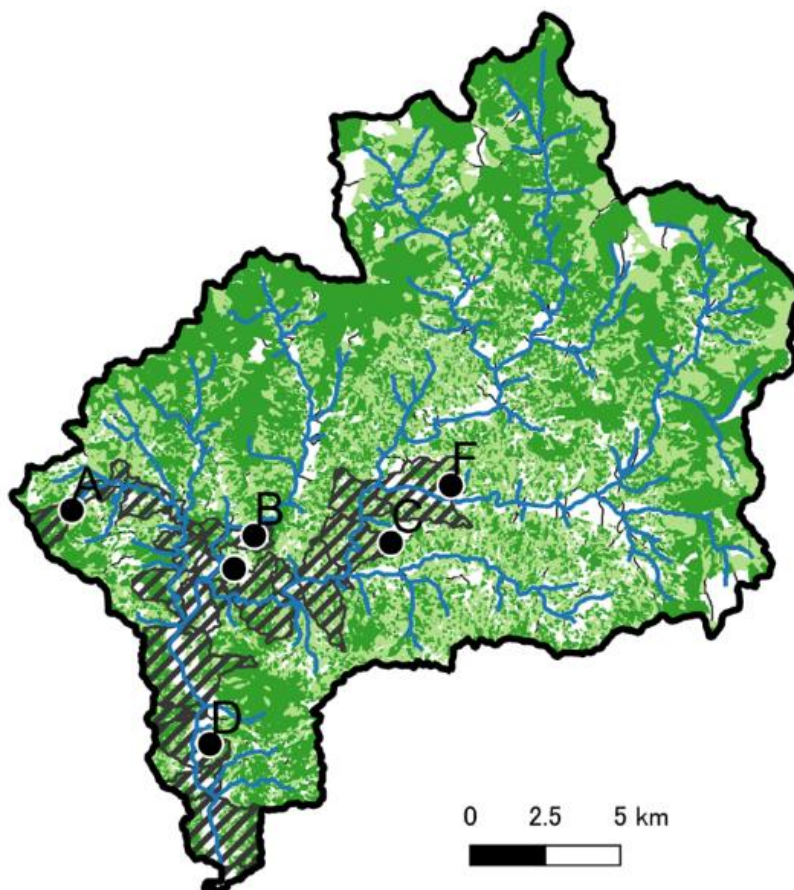

Figure 2. Result of affected area by solar power plants

Table 3: Area affected and value lost by the construction of solar power plants

Plant	Deforested area by the construction of solar power plants			Area affected by the construction of solar power plants			Value of water storage service lost by the construction of solar power plants		
	Deforested area (A) (ha)	Share in total forest area (=A/C)	Ratio (=B/A)	Total affected area		Number of h.hold in the affected area (D)	Unit price per ha per h.hold (E) (JPY/ha/h.hold)	Unit price per ha (JPY/ha) (F=D*E)	Total value (Mil. JPY) (=F*A)
				(B) (ha)	Forest area (C) (ha)				
Ind.no	Ind. 1	Ind. 3	Ind. 4	Ind. 2	----	Ind. 5	----	Ind. 6	Ind. 7
A	8.2	0.6%	309	2,528	1,433	767	533	409,038	3.3
B	2.7	0.2%	825	2,202	1,116	938	533	500,232	1.3
C	1.8	0.1%	1,661	3,007	1,593	1,130	533	602,625	1.1
D	1.5	0.3%	640	985	473	328	533	174,921	0.3
E	1.8	0.2%	1,106	1,990	980	824	533	439,436	0.8
F	0.9	0.05%	4,080	3,672	1,881	1,381	533	736,482	0.7

Note: The bold figures are the best results by each indicator among six solar power plants.

4. DISCUSSION

4.1 Indicators to assess the impact of solar power plants

Table 4 shows the seven indicators presented in the valuation. Indicator 1 is deforested area, which the simplest and the most popular indicators. It is obvious that the smaller area of deforestation is preferable, and the indicator has frequently been used by government agencies when approving development permits. Indicator 2 is the area of river basin located downstream of the solar power plant. This represents the area where water storage services decline due to the development of solar power plants and can be the area affected by the development of solar power plants. As this indicator includes the impact on land used for peoples' daily activities and business such as arable, residential, industrial, and commercial areas, it can evaluate the indirect impacts to people through impact to land they use. Of course, the smaller area affected by deforestation is desirable. Indicator 3 is the ratio of deforested area to total forest area in the affected area. Even if small area is deforested, it is not desirable to develop a large part of the forests in the affected area. Therefore, it is desirable that the indicator would be as small as possible. Indicator 4 is the ratio of the development area (Indicator 1) to the affected area (Indicator 2), and even if small are is deforested, it is not preferable if the affected area is large, thus the Indicator 4 should be small. Indicator 5 is the number of households in the affected area, and indicates how many people, in other words, how many households are actually affected by deforestation. The indicator can evaluate the magnitude of the direct impact on the residents, and obviously, the smaller number of affected households is desirable. Indicator 6 is unit price of water storage service per hectare of deforested area. The indicator is calculated by multiplying unit price of forest water storage service and its unit is JPY/ha/household. It can assess the unit value of lost forest water storage service and when based on the indicator, forest with smaller lost unit value should be developed. Finally, Indicator 7, shows the value of water storage services lost by the construction of solar power plants. The indicator is a composite indicator that integrate Indicators 1 and 5, and the indicator measured monetary value is effective when judging multiple different factors in a complex manner and the smaller value of the loss is preferable.

In this study, the above seven indicators were presented Table 4 also indicates the solar power plant selected as the best by each indicator (see also Table 3). The plant D is selected as the best by four indicators: Indicators 2, 5, 6 and 7. The plant D is selected as the best by more than half of all seven indicators. And the indicators mainly relate to the lost value and the number of households in affected area. This implies that the plant D has less influences on residents compared to other plants. The plant F is selected by two indicators: Indicators 1 and 3, and these indicators relates to deforested area, while the plants B, C and E are not nominated by all indicators, which leads to less preferable among others. When looking at the location of the plants, the plants located lower in river basin tend to perform better.

The next issue is, among these indicators, which one should be applied to evaluate the impact of solar power plants and be given the highest priority. It is determined by discussion and consensus building among various stakeholders. Nonetheless, presenting multiple indicators instead of a single indicator can provide more information to stakeholders, facilitating the use of assessments and making the valuation more practical.

Table 4: Indicators estimated in the valuation

Indicators	Title	Explanations	The best plant selected by the indicator
Indicator 1	Deforested area	This is the simplest and most popular indicator.	F
Indicator 2	Total affected area	The indicator is defined as area of water basin lower than solar power plants. It can assess impacts including indirect ones on land.	D
Indicator 3	Share of deforested area in total forest in affected area	The indicator is defined as a percentage of deforested area in total forest area in affected area. It can assess how much share in total forest in affected area is deforested.	F
Indicator 4	Affected-deforested area ratio	The indicator is defined as affected area divided by deforested area. The indicator can assess the affected area per unit of deforested area.	A
Indicator 5	Number of households in affected area	The indicator is simply the number of household in the affected area, and can assess how many persons are directly affected by deforestation.	D
Indicator 6	Unit price per hectare of deforested area	This indicator is defined by multiplying unit price of forest water storage service (JPY/ha/h.hold) and the number of household. The indicator can assess the unit value of lost forest water storage service. The forest with smaller lost unit value should be developed.	D
Indicator 7	Lost value of water storage service	The indicator is estimated by multiplying the number of household (Indicator 5) by unit value of water storage service of forest. The indicator can be regarded as a composite indicator integrating Indicators 1 and 5, and can assess the lost value of deforested. The smaller lost value is preferable.	D

4.2 Practical valuation for closing the information gap

In this study, we have strictly identified the range of beneficiaries, and estimated the number of them using GIS, and we also conducted an economic evaluation that reflected the number of beneficiaries. As explained in the Section 1, Olander et al. (2017) mentioned one of the factors that give rise to the information gap that local specific factors are not fully captured in the valuation. The range of beneficiary heavily depends on local specific conditions such as geographical, societal and biological factors, and it can be seen as local-specific factors. By considering the beneficiary into the valuation, we believe we can narrow the information gap.

Information gap refers to the absence of the ground in concrete operational decision-making contexts (Levrel et al., 2017). There are mainly three reasons why our economic evaluation which considers the number of beneficiaries can close the information gap. First, by clarifying the beneficiaries of ES, it contributes to the visualization of it, which is also advocated by TEEB and ESP. Most of previous studies have not linked valuations with beneficiaries, and it was unclear who would be affected by the loss of ecosystems and their services. By performing the evaluation that links with the beneficiary, it is possible to identify the person affected by the modification of ES. As a result, the beneficiaries can recognize that they are affected by the alteration of the ecosystem, and can use the valuation in order to make people’s behavior change toward the conservation of the ecosystem. Second, by identifying the beneficiaries, the beneficiary pays principle can be applied in a practical way. As mentioned above, if the people can recognize themselves as those concerned, it will be easier to obtain the understanding when requesting paying the cost for ecosystem conservation. Therefore, the evaluation can be used as a basis for the payment for ES (PES). More broadly, by presenting such grounds to the beneficiaries, it is possible to request paying for the cost with more objective evidences, which also contributes to evidence-based policy making (EBPM). Third, a more rigorous cost-benefit analysis is possible by conducting an economic evaluation that identifies the beneficiaries. Some of the previous studies have been roughly evaluated, for instance, by assuming that the range of beneficiaries is the entire city, which can lead to an overestimation of the benefits. In this evaluation, by conducting a rigorous evaluation that considers the beneficiaries, it is possible to perform a more

realistic cost-benefit analysis, and whether or not the ecosystem modification such as the installation of solar power plants is appropriate considering social costs and benefits for a region and a community. Specifically, our valuation can be used (1) as basis for explanation impact of constructing solar power plants; (2) to make a decision whether the construction is appropriate for the region and community, and to give a permission for constructing the solar power plants. According to Laurans et al. (2013), the purposes for the use of ES valuation can be grouped into three: informative, decisive and technical. Based on this, the former: (1) is categorized in informative purpose, and the latter: (2) are in decisive purposes.

5. CONCLUSIONS

This study proposed the valuation that is practically useful for policy decision-makings particularly for local policymakers. Olander et al., (2017) raised the question that local specific factors are not fully captured in valuations. In this study, using cases of deforestation due to construction of solar power plants in Japan, we considered the number of beneficiaries and identified area affected by deforestation as local factors so that the valuation can be practical. The advantages of our valuation are summarized as follows.

First, our valuation can identify area that are affected by the decline of ES as a result of deforestation. Such kind of local specific information is useful for local policy makers because the valuation can be used for explanation to residents who will be influenced by deforestation, and residents can determine whether they accept the deforestation or not. Thus, the valuation with much practical and real information can make residents recognize themselves those who concerned. Second, the valuation can provide multiple indicators for policy makers and residents and can lead to provision of evidences for decision-making in much broader way. The indicators that is applied to decision-making should be determined by discussions and deliberations among various stakeholders. Although our valuation does not provide a methodology to determine the indicators to be applied, we think this is future caveat of this study. Olander et al., (2017) pointed out that one of the factors for the information gap is the failure to develop transparent and unambiguous linkages between ecosystem changes and outcomes. Our valuation can indicate linkage between deforestation and possible influence on residents through geographic analysis, and can contribute to narrow the gap. In addition, Due to recent climate change, we have serious natural disasters more frequently, and from the view point of disaster prevention, more attention is paid for forest ES particularly for regulating services. However, the situation is more pessimistic. In Japan, area of planted forest dominates 40% of total forest area. Under current severe budget and declining timber prices, planted forests are less maintained and in some cases, they are abandoned. This causes lower capacity to supply ES and sometimes people are affected by this as results of disasters like landslides and floods. These are one of the main concerns for local municipalities in Japan. Therefore, in order to implement forest maintenance policies more effectively, policy makers should distinguish existing plantation forest which should be managed and which should be returned to natural. By the analysis in this study, we could identify hotspots of forest ecosystem in terms of supplying the ES, and we believe the results can be practical information for local policymakers.

ACKNOWLEDGEMENTS

This work was accomplished under the research project "Developing ecosystem accounting for national and local policies" led by Prof. Masayuki Sato, Kobe University, and implemented under the consignment study "Research on environmental economics and policy studies" of the Ministry of the Environment. We would like to thank the Ministry of the Environment for their financial support.

RAINFOREST CONSERVATION POLICY ASSESSMENT: THE CASE OF THE ATLANTIC FOREST IN BRAZIL

[Keyi Ussami, Ariaster Chimeli](#)

University of Sao Paulo, Brazil

ABSTRACT

The Atlantic Rainforest in Brazil, which used to be one of the greatest tropical forests in the Americas, is now reduced to 28% of its original area as a result of five centuries of strong human occupation. After a long negotiation process, the 2006 Federal Law n° 11.428 also known as the Atlantic Forest Protection Law (AFPL), established the formal framework to specifically protect the remaining Atlantic forests, including both primary and secondary forests.

In this article, we assess the effectiveness of AFPL focusing on the state of Sao Paulo, where AFPL has divided the territory into three main parts: the southeast and the northwest regions are protected by the law, whereas the remaining area in the middle is not.

We use a difference-in-differences approach to compare the natural forest cover and the frequency of environmental infraction notices in municipalities from treated and untreated areas. We restrict our analysis to municipalities whose territory is either 100% within the treated area or 100% within the untreated area, removing all municipalities whose territory was split in two parts (treated and untreated). We use a municipality panel data from 2001 to 2019 (treatment starts at year 2006) with natural forest cover as a percentage of municipality's total area from MapBiomas collection 5 data (Brazilian Annual Land Use and Land Cover Mapping Project). The starting date of 2001 was defined through an event study and it is consistent with the Environmental Crimes Law (Law #9605, from 1998), which specified ecological crimes in an effort to promote the legal certainty of previous laws and to make their enforcement credible.

Our results indicate that AFPL had a positive and significant effect on the natural forest cover in treated municipalities. Interestingly, the frequency of environmental infraction notices in treated municipalities is estimated to be lower relative to the untreated ones. The latter result might be a consequence of a legal framework that increased the severity of credible punishment for illegal deforestation.

Using event study, we can see that the effect on the natural forest cover appears after 2013, which is consistent to the fact it may take years for a forest to recover (and for such recovery to appear in satellite data). The coefficients for infraction notices suggest an overall decrease in the treated area relative to the untreated area, but are no longer significant for the most part of the years after 2006.

We are currently extending the analysis to include covariates and robustness checks considering subgroups or alternative treatment starting dates. We are also interested in impact of the law in other Brazilian states.

ASSESSING DISASTER RISK BY INTEGRATING NATURAL AND SOCIO-ECONOMIC DIMENSIONS: A DECISION-SUPPORT TOOL

[Marco Modica](#)¹, [Giovanni Marin](#)², [Susanna Paleari](#)³, [Roberto Zoboli](#)⁴

¹GSSI, Italy. ²University of Urbino, Italy. ³IRCrES - CNR, Italy. ⁴Catholic University of Milan, Italy

ABSTRACT

The paper provides a conceptual framework for a multi-dimensional assessment of risk associated to natural disasters. The different components of risk (hazard, exposure, vulnerability and resilience) are seen in a combined natural and socio-economic perspective and are integrated into a Disaster Risk Assessment Tool (DRAT). The tool can be used in supporting disaster management strategies as well as risk mitigation and adaptation strategies at very disaggregated geographical or administrative scales. In this paper, the feature and the applicability of DRAT are demonstrated by mapping multidimensional risk for 7,556 Italian municipalities. DRAT can be particularly useful to identify hot spots that are characterized by high hazard, exposure and vulnerability and by low resilience. In order to identify hotspots, we perform cluster analysis of the municipalities in terms of their risks ranking within DRAT. We also suggest how the tool could be exploited within the processes of disaster risk policy in Italy.

**AN ECONOMIC ASSESSMENT OF RESILIENCE AFTER A LARGE-SCALE
TSUNAMI IN JAPAN**

Hiroyuki Shibusawa, Daiichi Matsushima

Toyohashi University of Technology, Japan

ABSTRACT

This study aims to investigate how the production activities in 1886 municipalities of Japan recover when these activities stop due to a tsunami caused by Nankai megathrust earthquakes. As a disaster area, we focus the flooded zones in the hazard map published by Ministry of Land, Infrastructure, Transport and Tourism and prefectures. Furthermore, we assume three damage scenarios and different recovery speeds in each production sector. The dynamic recovery processes are simulated by using an inter-regional input-output model with 1886 municipalities of Japan. We show the recovery processes in the municipalities and analyze the resilience of the regional economy.

SPATIAL DISTANCING, SPATIAL INTERACTION AND REGIONAL ECONOMIC DAMAGES

[Euijune Kim](#), [Hojune Lee](#), [Min Jiang](#), [Seulki Kim](#), [Dongyeong Jin](#)

Seoul National University, Korea, Republic of

ABSTRACT

We develop a spatial computable general equilibrium model of South Korea to assess effects of spatial distancing (SD) intervention on regional economies. This paper focuses on calibration of economic losses from the outbreaks in 2020. It examines how each element involved in SD (self-isolation, school closures, public events banned, and complete lockdown) affects the travel behavior of consumers and producers. The overall contribution of SD measures is assessed on national and regional economies in terms of efficiency and welfare. The model measures economic losses from COVID-19, including human health costs in cities and counties based on profit maximization of regional producers on the supply side and utility maximization of regional households on the demand side. We find that if the spatial interaction is regulated such that the travel time (cost) increases by 10%, the national gross domestic product (GDP) drops by between 0.815% and 0.864%. This outcome can be decomposed into -0.729% in agglomeration-loss, -0.080% to -0.130% in social costs associated with medical treatment and premature mortality, and -0.005% in reaction effects. The results of models and simulations shed light on the epidemiological effects of social distancing interventions. This ex-ante evaluation of the effectiveness of social distancing provides guidance for national, urban, and rural policy decisions with respect to changes in regional economic outcomes and spatial distribution of infected and confirmed cases of COVID-19.

MYANMAR'S MANUFACTURING EXPORTS AFTER THE LIFTING OF ECONOMICS SANCTIONS

Hiroyuki Taguchi, Soe Thet Mon

Saitama University, Japan

ABSTRACT

This paper aims to evaluate the Myanmar's exports of manufacturing products by using a gravity trade model for ASEAN economies. During the previous military-ruled regime before 2011, Myanmar had received the economic sanctions from western countries such as the United States, Canada and the European Union due to the suppression of human rights under this regime. Since March 2011, however, Myanmar has entered into a new regime of market-based economy with open-door policies under the civilian government led by President Thein Sein and the subsequent government headed by State Counsellor Aung San Suu Kyi. In accordance with the regime transformation, the economic sanctions have been lifted by the western countries since 2012. The critical question then arises whether the Myanmar's manufacturing exports have recovered towards the gravity-trade- standard of the other ASEAN countries for the post-sanction period of 2013-2018. It would be a relevant issue and timing to assess the current Myanmar manufacturing exports under the new open-door regime, in the sense that there have been a very limited number of quantitative studies on Myanmar trade under the new regime, and also that five or six years for the post-sanction period are rather enough to be analyzed at a minimum level. The main findings from the gravity trade model estimation are summarized as follows. First, the Myanmar's manufacturing exports for the post-sanction period have been still significantly below the level of the gravity-trade-standard of the other ASEAN countries. Second, the lack in the institutional quality (in terms of government effectiveness) and the high natural resources rents (implying the existence of the Dutch Disease) in Myanmar are identified to be the significant contributors to prevent Myanmar's manufacturing exports from recovering towards the gravity-trade- standard.

VIETNAM'S CHALLENGE TO BOOSTING LABOUR PRODUCTIVITY

Hidekatsu Asada

Saitama University, Japan

ABSTRACT

Vietnam has maintained a remarkable record of economic growth since the 1990s whose average real growth rate over 1990 to 2018 was 6.8%. A growth accounting exercise shows that growth has been largely driven by non-ICT capital investment. Contribution of total factor productivity rebounded to the positive territory in 2010-17 from negative growth in the decade earlier. Contribution of labour input was almost zero in the same period, partly reflecting the labour participation ratio that is high already. The shift-share analysis of labour productivity reveals that the impact of labour reallocation declined toward the period of 2010-17. This implies the slowdown of labour reallocation from low-productivity sectors such as the agricultural sector to higher productivity sectors. The sustained growth of overall labour productivity over the medium to long-term is crucial for escaping the "Middle-income trap". In Vietnam, workers in the agricultural sector still account for a large share of the total number of workers. This implies the potential to materialise productivity gains by facilitating the labour reallocation to the manufacturing and services industries. Human capital development is key to promoting the labour reallocation, making the most of Vietnam's high performance of basic education.

LOCAL GOVERNMENT EXPENDITURE AND SOCIO-ECONOMIC DEVELOPMENT: A CASE STUDY OF THE PROVINCES IN THE PHILIPPINES

[Arianne Dumayas](#)

Faculty of Global Management-Chuo University, Japan

ABSTRACT

The analysis of the link between public finance and development is an important topic for policymakers in countries which have experienced decentralization process, particularly on how public funds can be allocated efficiently to induce or accelerate local development. Many countries have pursued decentralization under the assumption that due to proximity and familiarity, local government officials should know what is best for their constituencies. In the case of the Philippines, local governments were given fiscal autonomy alongside with the responsibility of delivering basic social services such as agriculture, health services, social welfare services, infrastructure, and tourism development. This study aims to explore the link between local government spending, specifically, social services expenditure and socio-economic development using the case of the provinces in the Philippines. This study also aims to examine the differences among provinces in terms of socio-economic development and social services expenditure. This paper devises a socio-economic index to analyze the socio-economic condition of the provinces. Socio-economic index is computed using various indicators that falls into four categories: economic, education, health, and infrastructure. This study utilizes OLS regression to estimate the relationship between socio-economic development index and social services expenditure. The result of the study shows that there is a huge disparity among provinces in terms of socio-economic development and social services spending. Provinces located adjacent to the capital have favorable socio-economic conditions and higher spending on social services. While provinces located mostly in Mindanao, particularly Autonomous Region of Muslim Mindanao (ARMM) have both inferior socio-economic state and lower spending on social services. The findings of the study also demonstrate that social services expenditure have positive and significant effect to the devised socio-economic index. To corroborate the findings of study, this study also analyzes the relationship between social services expenditure and human development index (HDI). The link between social service expenditure and HDI also shows similar findings with this study: social services expenditure is positively correlated with HDI. This study also identifies four different types of provinces based on the relationship between socio-economic index and social services expenditure: Type 1 (provinces with high socio-economic index and high social services expenditure); Type 2 (provinces with high socio-economic index but low social services expenditure); Type 3 (provinces with low socio-economic index but high social services expenditure); and Type 4 (provinces with low socio-economic index and low social services expenditure). This study also outlines challenges and policy recommendations for the different categories of provinces.

SPACE, FACE, AND NETNOGRAPHY: THE VISIBILITY OF EVERYDAY VIOLENCE IN URBAN SPACES FACED BY THE PAN-NORTHEASTERN COMMUNITY IN BANGALORE

[Anisha Debbarman](#)

Tata Institute of Social Sciences, India

ABSTRACT

This research is grounded on understanding the concept of shared space and fragmented identity in Bangalore city. For pan northeastern communities residing here, life is far from ideal. Facing discrimination and forms of everyday violence has become a part of urban space. It hampered with the progress of placemaking, and influenced the community's access to resources (in state, private, and local bodies). As of today there are several online communities representing both singular and commonly shared goals. But does this online space eventually impact the overall safety and future sustainability of the pan northeastern populace towards making a "home" in Bangalore city?

This study adopts a qualitative and ethnographic framework, as a tool to map spaces of safety and uncertainty, through the lens of northeastern migrants. In-depth interviews and netnography are utilised to examine patterns of social interaction and networking among the online northeastern community- especially to cite how the strength of weak ties (Granovetter 1973) can push this community forward.

Significant elements to this analysis are: (1) The engagement of state-led regulatory mechanisms to tackle discrimination with the northeastern community, (2) Local law forums and citizen groups to create accessible networks between state mechanisms and the northeastern community. While there are several state-led mechanisms which are initiated to help reduce discrimination in urban spaces, they are not easily accessible, available, and understood. For example, while several police stations have private online "WhatsApp" groups for northeastern communities, assistance is required at ground level, where migrants face problems in language (conveying), cultural differences, and internalised biases held by state bodies towards the community. This is a dealt by local law forums and northeastern community groups, who intervene to provide agency.

One of the expected outcomes of this paper was to map how people navigate through the city as a geo-political space. The need to find trustworthy connections was important to the pan northeastern community and it was enabled by networking and online social capital. Enabling and engaging with social media networks is definitely a boon for vocalising their needs, however does it have the capacity to introduce a sense of security and allay concerns held by the people?

The need to understand this shared identity stems from abject failure of the state to incorporate tertiary systems into consideration: in terms of shared cultural heritage, artefacts, and a common history. A few subjects this study touches upon deals with shared cultural identity and fragmented ethnic identities. A topic which heavily influences certain northeastern communities is the role of Christian theology it's influencing agendas and goals. Lastly, the gendered nature of discrimination between men and women in urban spaces is also an essential factor to be discussed in future research. By ethnographically mapping urban minority representation this paper attempted to ascertain the patterns of recurring insecurities among pan-northeastern migrants living in Bangalore. Their importance today foreshadows the current political debates around racism, discrimination, and the failures of state mechanisms globally, thereby perpetuating everyday violence as a normative aspect of urban spaces

URBAN POVERTY AND VULNERABILITY IN GLOBAL SOUTH: ISSUES OF UNDERESTIMATION, CONCENTRATION AND TARGETING

Anita Rath

Tata Institute of Social Sciences, India

ABSTRACT

The mainstream conceptualization of poverty and vulnerability has inadequacies in dealing with urban problems, in general, and that of the global south, in particular. The dynamics of urban poverty and vulnerability plays out differently in the Global South which is host to more than three-fourths of the world urban population with ever increasing proportion living in mega-urbanized settings. The inordinate impact of the COVID-19 pandemic on the poor and marginalized urban dwellers and migrants in this region has led to a shift in the locus in the contemporary discourse on poverty and vulnerability towards urban centres, which hitherto had a rural bias in the Global South. The existing literature in this field insinuate at the problem large-scale underestimation of urban poverty, the problem of poverty concentration and rising and persistent inequality. However, there are limited empirical work in this field with a focus on global south.

It is in this backdrop, the current paper focuses on the following objectives: (a) to develop an alternative multidimensional poverty index (MPI), on the basis of a normative analysis of urban poverty with specific refence to the challenges posed by COVID-19 in urban centers in Global South; (b) to test the stability of the alternative index; (c) to review the mainstream approaches for measuring urban poverty and assess the scale of the bias, if any, with reference to the benchmark; (d) to analyse the problem of poverty concentration in the urban areas; (e) to review the poverty targeting practices in the urban centres in Global South. The Alkire-Foster Multidimensional Poverty Index identification and aggregation procedure is adopted in the study as the broad approach. For developing the alternative MPI, recent DHS (The Demographic and Health Survey) dataset for India is considered suitable for this analysis. The focus on India for an in-depth exploration assumes significance due to the following reasons. First, the poverty headcount ratio in urban India as per the official and mainstream sources is around 10 per cent barring exceptions. However, literature in the field indicate problems of underestimation. Second, the unidimensional and multidimensional approaches use the same dimension(s) and indicator(s) for rural and urban areas. Third, the poverty targeting for major central and state government schemes in rural India is now on the basis of Socio-Economic and Caste Census (SECC), 2011 data. However, SECC has not been the basis for indicator-based poverty targeting in urban India so far and disparate practices are being followed in different regions. Finally, the course of growing mega-urbanization in India insinuate at the deepening of these problems and the COVID-19 pandemic has revealed it in gory details. Based on the empirical analysis for India and review and case studies for countries in Global South, the paper reflects on the emerging situation of poverty and vulnerability in the region. It highlights the larger issue of urban and regional planning and best practices in poverty targeting in the region.

JAIPUR: AN EMERGING ENTREPRENEURIAL METROPOLITAN REGION OF THE GLOBAL SOUTH

Philippe Cadene¹, Abdul Shaban²

¹University of Paris – UMR CESSMA, France. ²Tata Institute of Social Sciences, Mumbai, India

ABSTRACT

Jaipur metropolitan region, in northern India, is famous for the splendour of its palaces, the beauty of its architecture and the skills of its craftsmen producing semiprecious stones, colourful textiles, carved furniture, painted miniature. From this prestigious past, the city and its region have been able to integrate into globalization with an impressive concentration of prestigious heritage hotels welcoming international tourists, large number of gems, jewels, cloths and handicrafts industries exporting all around the world, not forgetting dynamic computer companies in which successful engineers works in day to day with technopoles in the US and elsewhere.

The region demonstrates significant churning out around learning and human skills and is fast becoming integrated through leisure and knowledge-based economy, technology, and entrepreneurship. Where the historical evolution and inter-generational transfer of knowledge of entrepreneurship adds to the regional advantage, in recent years with globalization and adaptation of digital technologies, there has been constant adaptation to the new trends in production, business, and trade.

The proposed paper aims to analyse the process of learning, adaptation, and innovation in this rising Indian city and in its surrounding, foregrounding the links between a thriving regional culture and a set of strong business communities. Going beyond the debate on the genesis of global productive networks, the research within the framework of learning region (Hirsch et al. 2001) and regional innovation system (Asheim, Smith and Oughton 2011), attempts to explore the case of Jaipur within the framework of entrepreneurial and innovative metropolitan region as an area of established business groups, specific resources, and effective knowledge with global economic networks and processes. Such entrepreneurial metropolitan regions are rising in the global South and have now started to compete at the world level. There are three key questions around which the paper is structured. What are cultural capitals of the region which enhance its advantage in entrepreneurship? This question seems unclear to me. Do you mean cultural factors? What are the nodes around which human interaction get organized for mutual learning and adaptations to the new business environment? How external knowledge (proposition) to the regions are inserted and adapted to make the regional innovation dynamic and entrepreneurship competitive?

The paper as such also implicates not only the human interaction but how also the role of new technologies and the networks of globalised market system.

The data for the paper are drawn from both the government and non-government statistics on enterprises, innovations, businesses, trade and networks, and indepth structured and semi-structured interviews with senior business group officials and entrepreneurs. For the regional history, the paper learns from other relevant literature.

The paper draws methods from previous studies related to the network analysis of business firms (Godesiabois 2015) and frameworks of 'learning region' and 'regional innovation systems'.

URBANIZATION, PLANNING AND SCOPE OF COLLABORATIVE GOVERNANCE: A CASE STUDY OF DELHI METROPOLITAN REGION

Ujjwal Dadhich

Tata Institute of Social Sciences, India

ABSTRACT

Global South is now characterized by mega urbanization – a process resulting into rapid expansion of cities and increasing contradictions. One of the major outcome of this mega-urbanization is the shift from government to governance. That is, government cannot be the only single actor in planning and tackling urban challenges. Tackling the city problems now require new collaboration between different stakeholders and implementing agencies. This paper seeks to better understand this scope of collaborative governance and its promises for achieving urban sustainability and resilience in case of Delhi metropolitan region. While Delhi is India's capital region, its urban planning and quality of life is ranked globally at the bottom. Poor planning and complex administrative structure are both a cause of Delhi's compounding problems. Despite this, there have been innovative approaches adopted recently for better urban governance in the capital region. This paper giving an extensive planning history of Delhi, discusses collaborative approaches at six governance aspects – public transport, air pollution, urban greenery, energy supply, housing and climate change. Collaborative measures in each of these fronts exhibit innovation and creativity that has evolved with an active participation and contestation among stakeholders. The paper discusses this evolution and utility of few collaborative approaches in present. However, there are also concerns related to replicability, effectiveness and sustainability of these collaborative approaches. The paper discusses these aspects, presents evidences of success and poses critical questions for a better urban management in global Sout

DOES FOREIGN INVESTMENT GENERATE REGIONAL ECONOMIC GROWTH IN EMERGING COUNTRIES AND THEIR REGIONS? CASE OF CENTRAL & EASTERN EUROPE AND HUNGARY

Zoltan Gál^{1,2}, András Gyimesi²

¹Centre for Economic & Regional Studies, Hungary. ²University of Pécs, Hungary

ABSTRACT

The effect of foreign direct investment (FDI) on the host economy has attracted much research. Despite the literature is inconclusive it seems to agree that any positive effect of FDI on growth is largest in developed countries. However, in spite of this FDI is considered a panacea for the fundamental problems of economic growth in emerging transition countries including Central and Eastern Europe (CEE) where FDI became main source of investments from the 1990s. Post-socialist transformation is characterized by high dependency on FDI channeled by foreign MNCs into Central and Eastern Europe. In CEE economic restructuring was primarily driven by foreign direct investment (FDI) in the postsocialist period, which in the short term contributed to the increased productivity and competitiveness. The paper examines the effects of FDI on GDP growth and GFCF, and tests the causal relationship between these variables in the Hungarian regions. Based on the econometric analysis, the study argues that it is not FDI that causes GDP growth, but more FDI flowing into the already more developed, higher-growth regions. The inclusion of Gross Fixed Capital Formation (GFCF) into the model also eliminates the significant positive effect of FDI. Government and EU-funds-generated investments play a much greater role in GDP growth than FDI. Our study demonstrates that the attractiveness of target regions for FDI can be explained by their initial higher level of development and geographical proximity to Western European markets. However, this paper also hints that FDI-driven assembly platform economy, in the absence of spillovers and additional factors of endogenous growth, are not sufficient to ensure the the long-term prosperity of regions.

URBAN STRATEGIC PLANNING FROM THE PERSPECTIVE OF WELL-BEING: EVALUATION OF THE HUNGARIAN PRACTICE

Zoltán Bajmócy, Judit Gébert, György Málóvics, Boglárka Méreiné Berki, Judit Juhász

University of Szeged, Hungary

ABSTRACT

The present paper evaluates Hungarian strategic urban planning from the perspective of well-being. It conceptualises well-being in line with Amartya Sen's capability approach (CA).

An important theoretical and practical consequence of the revival of the strategic approach since the 1990s is the increased complexity of evaluation. This resulted in the quest for concepts and principles (substantive normative criteria), which evaluation could be based on; and revived discussions around the concepts of "common good" or "public interest. We argue that the CA provides a meaningful concept of common good or public interest for evaluation. The open-ended nature of CA allows to embrace the complexity of strategic planning, but it is definite enough to provide a clear normative framework for evaluation.

The CA suggests three main issues for evaluation: (1) how the objectives of the strategies fit to the set of capabilities deemed to be valuable in a community; (2) how can citizens actually make use of the means of well-being in order to further their ends; and (3) to what extent do citizens have the freedom to act as agents during the moulding and the realization of the objectives?

The paper evaluates the Hungarian practice of strategic urban planning. We base our results on 49 semi-structured interviews with various local actors in three second-tier cities. We carried out qualitative content analysis on the word-by-word transcripts of the interviews. We used deductive coding: we restructured the texts into categories derived from the capability approach, both in terms of the freedom for well-being and the freedom for agency.

Our results were rather critical towards the practice of strategic urban planning in Hungary. The CA-based evaluation showed that the actual objectives of strategic urban planning in Hungary are actually just means (and not ends) of well-being, which cannot necessarily be utilized by the actors. The diversity of actors and their values are largely overlooked. The direct concomitant is the loss of a huge set of relevant information for planning. The opportunities for agency are gravely restricted for numerous actors. The main barriers of agency are related to actors' inability to define and shape the spaces of participation.

In terms of theory, we conclude that the CA-based evaluation is able to supplement the dominantly used conformance- or performance-based evaluation approaches. We also found that instead of depicting an unachievable ideal, the CA is able to provide guidance for feasible steps to further well-being.

SMART COMMUNITIES IN THE COUNTRYSIDE: WHAT COMES AFTER PROOF OF CONCEPT?

Viktória Józsa¹, Pál Szabó², Ákos Jakobi²

¹Nord Consult Kft., Hungary. ²Eötvös Loránd University, Department of Regional Studies, Hungary

ABSTRACT

The objective of our research is to present a new conceptual approach towards the 'Smart City' concept and a pilot application focusing on smart rural communities in a peripheral cross-border environment (Nógrád county, Banská Bystricky & Kosický kraj). The scientific approach is based on the basic concepts of 'smartness' but introduces a new conceptual avenue in connection to small rural communities. Research generally focuses on mid-size and large cities and discover several aspects of smartness that are connected to size, number of inhabitants, functions and large-scale infrastructure as prerequisites.

To the contrary, our research objective was to support the basic hypothesis that smartness can be interpreted to less-developed rural small settlements also. Certainly, a different approach and methodology should be applied.

The main objective of becoming 'smart' is efficiency and technology-related. Our basic concept is that 'smartness' is not the privilege of cities and even rural areas and small settlements can break out from their lock-in situation through activities based on endogenous development, instead of placing and connecting ICT systems and infrastructures or promoting intensive industry settlement. We focus on the development of the local 'soft' elements and aim to generate 'smart citizens' instead of 'smart infrastructures and systems'.

In our previous research, we conducted an empirical research in a peripheral cross-border region in the Hungarian-Slovak border and based on the results, we identified several specific local needs for further development. We proved that smartness is not the privilege of cities, connected infrastructures and ICT are not the only means of the 'smartening' process.

As a follow-up applied research project, our basic concept is that welfare could be also achieved in the countryside with the application of the newest technologies. The main question now, after the proof of concept is: how? For this reason, we developed a new methodology to 'smarten up' small settlements in the countryside, that includes two main directions, such as Smart Village cross-border services and Smart Village know-how transfer. Our main objective is to support the 'smartening' process of rural settlements through the development of direct cross-border services, and thus, to operationalize the 'Smart Village' concept. This is facilitated by the Smart Village Roadmap, the Good Practice Catalogue, the Smart Database and Helpdesk service, the Smart Village Pilot Courses & the Smart Academies, the Mobile ICT Centre trainings, the Local Bloom Movement and the Local Development Hackathon.

As a final step, in order to measure & compare the development of the villages, we plan to elaborate & introduce a new, motivating service in the form of a Smart Village Award, that is based on a Smart Village Indicator System to be programmed together by the Slovak & Hungarian partners.

The objective of the current research is to operationalize the Smart Village concept and develop a conceptual model and an indicator system for Smart Villages. In the current era of planning the next EU programming period between 2021-2027, including the Horizon Europe Programme, the topic and its possible policy implications are outstandingly actual and important.

IMMUNIZING WORKERS IN THE PANDEMIC? LESSONS FROM SUPPLY CHAINS, TELEWORK AND COMMUTING

Sándor Juhász¹, Eszter Bokányi¹, Zoltán Elekes^{2,3}, László Czaller^{2,4}, Gergő Tóth^{5,2}, András Borsos^{6,7}, Tünde Szabó⁸, Márton Karsai^{7,9}, Balázs Lengyel^{2,1}

ABSTRACT

Vaccination may be the solution to the epidemic-induced health crisis, but the allocation of vaccines is a complex task in which both economic and social considerations can play a role. A central problem is how the limited number of vaccines can be most effectively used in a country to reduce the risk of infection and mitigate economic uncertainty as well. In this paper, we argue that besides the high risk population, vaccination plans should include workers and rank them according to their infection risk and economic importance. To establish this argument, we explore the empirical relationship between important work-related factors in the local spread of the SARS-COV-2 virus, like telework potential and neighborhood characteristics of workers and their commuting to work, and the structural characteristics of supply-chain networks of Hungarian industries and firms. Our study consists of two related parts. First, we construct industry-region level input-output networks from company reports on value-added tax and demonstrate the significance of telework potential in this network. Next, we explore the residence and commuting patterns of employees in manufacturing companies from mobile cell data, which we compare with the companies' position in the supplier network. Our results suggest early vaccination for workers in urban industries where telework potential is low. These are typically large industries that are central to the input-output network. By immunizing blue-collar workers in densely populated areas, vaccination can not only fight infection risks but can also mitigate production uncertainties of firms that are involved in many and difficult-to-replace value chains.

HEAVY METAL AND BACTERIA REMOVAL FROM RIVER NILE, EGYPT BY CARBON NANOTUBE FILTERS THAT ENHANCING THE MARINE CONDITIONS FOR FRESH WATER BIVALVES

Emad M. Elsehly^{1,*} and Aml Z. Ghonim²

¹ Faculty of Science, Physics department, Damanhour University, 22516, Damanhour, Egypt; e-mail: elsehlyfigo@yahoo.com; ² Faculty of Science, Zoology department, Damanhour University, 22516, Damanhour, Egypt

ABSTRACT

The contamination of water resources with a wide range of pollutants has become a source of concern in recent decades. Due to their unique properties such as chemical stability, thermal stability, and high surface area, chemically functionalized MWNTs (F-MWNTs) have a lot of potential as a new effective filter. The aim of this study is to see whether F-MWNTs can be used as an efficient filter to improve the aquatic conditions for *Mutela singularis* (*M. singularis*), a freshwater bivalve that is used as a bio-indicator of heavy metal contamination. The histological and biochemical composition of *M. singularis* was studied before and after the use of F-MWNT filters. The bivalves and water samples used in this analysis were obtained in Abu Hummus, Egypt, on the Nile River. At high pH, the metals Co, Cu, Fe, Pb, and Zn had high removal efficiency, while Cd, Cr, and Ni had higher removal efficiency at low pH. Copper was removed 99.8% efficiently by F-MWNTs-based filters at pH=10 for a 5 µg/L concentration. The mechanisms underlying F-MWNT filtration as a feature of pH were discussed. *M. singularis* samples filtered with MWNTs filters had a high standard of structure, as well as a large increase in carbohydrate, lipid, and protein content. The protein increased by 45% due to enhancing the aquatic conditions of *M. singularis*. Our research contributes significantly for water treatment applications, and to the potential feeding fields.

Aquatic conditions enhancement; Bivalves bio-indicators; Carbon nanotube filters; Heavy metal removal; *M. singularis*

SPATIAL VARIABILITY OF LAND USE TYPES IN RELATION TO SOIL MOISTURE AND CLIMATIC VARIABLES OVER EGYPT

Megahed Hassan

Zagazig University, Egypt

ABSTRACT

Soil moisture, as a fundamental factor in the hydrological process, it directly influence land use type capabilities in response to rainfall, humidity, temperature and topography characteristics. Many studies have documented land-atmosphere interactions, however, studies that investigate the impact of land-use/land-cover changes in the context of the processes involved in soil moisture-precipitation coupling have been lacking. This would be covered by understanding the spatial variability of land use type and soil moisture induced by different climatic elements.

Spatial modeling in land use types can influenced by slope gradient, followed by soil moisture and elevation and slope position, nonetheless climatic factors can be the reason for changing both soil moisture and Land use types. The coupling metrics exhibit a strong positive soil moisture-precipitation relationship within the water cycle, soil moisture and evapotranspiration (ET) influence each other. Therefore precipitation, humidity and temperature are the main climatic factors to be consider for the land use type and soil moisture changes.

The study provides an insight into policy making of land resource management and can be used in the modeling and integrates field inventory data with the satellite images. Analysis involves four major steps, namely, (i) landuse/cover types, (ii) soil moisture dataset (iii) important climatic factors (iv) change monitoring between land use types and the relationship with other variables.

**GOVERNMENT SPENDING AND REGIONAL POVERTY ALLEVIATION:
EVIDENCE FROM EGYPT.**

Dina Elshahawany, Ramy Elazhary

Faculty of Commerce, Zagazig University, Egypt

ABSTRACT

Poverty is one of the fundamental socio-economic problems facing most developing countries. In Egypt 32.5 percent of citizens are living below the poverty line. At the regional level especially in Upper Egypt the problem is more evident. Understanding the relationship between government spending and regional poverty reduction will help policymakers to design and implement programs that reduce regional poverty incidence and income inequality effectively. This study aims to analyze the impact of public spending in various sectors in alleviating regional poverty in Egypt by using panel data from 27 governorates during 2011-2017 period.

EGYPT'S NATIONAL ROAD PROJECT: ASSESSING THE ECONOMIC IMPACTS OF UPGRADED TRANSPORTATION NETWORK

[Dina Elshahawany](#)¹, [Eduardo Haddad](#)², [Michael Lahr](#)³

¹Faculty of Commerce, Zagazig University, Egypt. ²University of Sao Paulo, Brazil. ³Rutgers, the State University of New Jersey, USA

ABSTRACT

In 2014, Egypt has started a large infrastructure project (the National Road Project). This project is one of the greatest achievements realized in the history of the Egyptian roads. It aims to connect governorates, enhance accessibility and mobility of goods by expanding the transportation network from 23,500km to around 30,500km with a total cost about US\$9.79 billion. The ministry of transport has recently revealed that 4,500 out of the total 7,000 kilometers of National Roads Project have been implemented so far since the program's inception in 2014; another 1,300 kilometers are under construction, whereas an additional 1,200 kilometers are planned for the near future. The main goal of this research is to explore how the developing road network and increasing accessibility that enhanced by the National Road Project in the last 6 years, has affected the country economic variables at both national and regional levels. For this purpose, we tend to apply an interregional computable general equilibrium (ICGE) model for Egypt that has the ability to estimate the economic impacts of road projects.

APPROXIMATING THE IMPACT OF THE CONGESTION EFFECT ON USERS' ATTITUDE TOWARD THE PUBLIC BUS TRANSPORT SYSTEM: THE CASE OF BARCELONA

Miquel-Àngel Garcia-López^{1,2}, Rosella Nicolini¹, José Luis Roig Sabaté¹

¹UAB, Spain. ²IEB -UB, Spain

ABSTRACT

This study proposes to identify the basic features that shape citizens' decision towards the regular use of the bus public transportation. Despite the results of the current literature, income turns out not to be a statistically significant decision factor, whereas education and occupation are. Instead, it turns out that the congestion effect is the key determinants in making the decision to become a frequent bus user. Predictions about the impact of the reduction of congestion on the probability of becoming frequent user of the bus transport system emphasize that bus users with a high level of education and regular commuter in the urban territory are more reactive to the reduction of the congestion effect. These findings open an important discussion about the implementation of effective public policies to support the adoption of the public urban transportation system. Educated persons are very sensitive to the reliability of the public bus service, but to our understanding for other reasons. We previously discussed the potential pollution concerns of this group of people and it is worth noting that the bus fleet in Barcelona is mostly green in terms of source of energy, but the congestion effect may make this service not so reliable as expected. Finally, since income does not have a clear statistical significant impact on the probability to become a bus user, there is an interesting insight to discuss in terms of potential pricing policy for the service. Could a policy tailoring prices to the true trip distance be effective, rather than using a pre-established price criterion based on zoning?

IS THERE A LIGHT AT THE END OF THE EUROTUNNEL? IF NOT FOR THE INVESTORS THAN FOR THE REGIONS?

Johannes Lohwasser, Axel Schaffer, Andreas Schüler

Bundeswehr University Munich, Germany

ABSTRACT

Shortly after its opening in 1994, the American Society of Civil Engineers elected the Eurotunnel one of the “Seven Wonders of the Modern World”. The tunnel is 50-kilometer-long and links the region South-East in the United Kingdom with the region Nord-Pas-de Calais in France. It is one of the largest infrastructure projects in Europe financed by private funds only. However, exploding construction costs, which were financed mostly by debt, smaller than expected revenues (due to the delayed opening of the tunnel, fierce competition with ferry operators and overly optimistic passenger and freight numbers) led to substantial financial losses, and brought the operating company to the brink of bankruptcy several times. These losses, often considered transfers to the users, indicate a poor return on investment for the private equity and debt investors.

Against this background, the paper first offers an indepth analysis of the financial development of the operating company since it was founded in 1986. We will quantify the losses covered by private equity and debt investors, analyze the reasons for these losses, and discuss the rationale for investors to agree to several financial restructurings.

Aside from the financial implications for the investors, infrastructure projects of this size always have long-lasting regional impacts. However, many cost-benefit studies of the project reveal only small positive effects and therefore conclude that overall the French and British economy “would have been better off had the tunnel never been constructed” (Anguera 2006, p. 291).

In this context, we seek to analyze regional effects of the tunnel by constructing a counterfactual scenario, enabling us to analytically compare the actual regional development given the construction of the Eurotunnel with the hypothetical development without its construction. In contrast to traditional cost-benefit analysis this procedure allows for a better separation of the effects triggered by the construction of the tunnel from other overarching developments (e.g. EU enlargement).

Following this idea, the paper uses the synthetic control method for assessing the economic impacts of the tunnel on different regions. The method tries to construct a synthetic control group for the treated region(s) by a weighted combination of regions not affected by the Eurotunnel. These regions are chosen to mimic the region(s) affected by the Eurotunnel for a set of predictors of the outcome variable (e.g. per-capita-income). The predictors contain variables that are typically associated with growth potential (e.g. investments, population density or sectoral shares) and refer to regional data from the UK and France covering the years 1975-2015. Preliminary results indicate positive effects of the Eurotunnel on the direct affected regions for the first five years (i.e. 1995-1999). Afterwards, results turn negative.

Finally, for an overall assessment of the Eurotunnel, findings at the financial and regional level are jointly analyzed in a third step, for example in order to try to answer the question, whether regional benefits could have justified public funding of part of the construction costs. As this is work in progress, results are not robust so far, but will be presented at the conference.

LINKING SUSTAINABLE URBAN MOBILITY AND SEDENTARY LIFESTYLES IN THE DIGITAL AGE

Aritz Balerdi Blanco, Patxi Ojanguren Asolo, Eguzkiñe Elorduy Cortina

University of the Basque Country UPV/EHU, Spain

ABSTRACT

Unrelenting population growth and urbanization are hampering efforts to manage urban mobility in an optimal way. Currently, 55% of the world's population lives in cities, rising to 75% in Europe. This figure is expected to continue to rise, asserting the problems arising from urban mobility as detailed in the UN-Habitat report; cities produce more than 60% of the greenhouse gas emissions that affect the health of citizens as a consequence.

This problem in cities poses a challenge in determining the most appropriate actions to achieve urban development with the least possible impact on the environment and citizens' lifestyles.

Based on the objectives of sustainable development, the concept of sustainable urban mobility was born. In view of the impact of the use of "passive" means of transport, it is necessary to implement models that reduce the negative effects of urban development by making certain practices such as walking, cycling, and public transport accessible.

Sedentary lifestyles understood as lifestyles with little physical activity and as one of the key factors in human mortality, have been the subject of much research. According to the World Health Organization, 60% of the world's population does not get the physical activity needed for health benefits, and this is an even greater problem in large, fast-growing cities. This has recently been exacerbated by the impact of covid-19 and the restrictions put in place to address it.

In the new digital era, using information and communication technologies (ICT), tools are emerging that can monitor physical activity and provide feedback to the user. Although several studies have shown that the characteristics of the urban area have an influence on the amount of physical activity that is carried out and can favor or discourage it, the relationship between the promotion of sustainable urban mobility and the rate of sedentary lifestyles has not yet been studied in detail.

Therefore, this proposal aims to analyze whether there is an inversely proportional relationship between the implementation of sustainable urban mobility policies and the rate of sedentary lifestyles. To this end, certain indicators will be shown on the basis of certain technological monitoring tools and the linkage of certain indicators proposed in documents from European institutions will be studied.

SPATIAL JUSTICE (INEQUALITY AND INEQUITY) IN THE PROVISION OF PRIMARY SCHOOLS – THE CASE OF PORTUGAL

João Lourenço Marques, Jan Wolf, Fillipe Feitosa

University of Aveiro, Portugal

ABSTRACT

Spatial equity can be understood as the central principle of spatial planning which is, ultimately, concerned with guaranteeing that the attribution of property rights and the distribution of public funding counters spatial inequality (Kunzmann, 1998). But the way we judge spatial inequality is not self-evident and, necessarily, implies some overarching principle of justice. Probably the most frequently cited author when discussing matters of justice is John Rawls. Rawls' principles of justice, being broadly defined and including aspects such as power and self-esteem, besides economic resources, is also focused on the actual conditions of exercising different types of freedom (Rawls, 1971, 1981). Thus, even if assuming that inequality will always exist at some level, it is the responsibility of democratic institutions to redistribute resources and promote social justice in order to provide the maximum degree of freedom to different social groups and, in particular, to the least well-off (Resosudarmo, Kuncoro, & Hewings, 2019). In other words, spatial planning and public policy must assume the responsibility to ensure social justice principles in their actions, trying to find the right balance between: i) maximizing effectiveness and efficiency; and ii) minimizing inequalities (uneven distribution of opportunities and resources) and inequities (differences arising from poor governance).

The aim of this paper is to study and analyse territorial inequalities in the access to education. More specifically, it presents: i) an exploratory approach to assess spatial justice for different types of territories at different spatial scales, analysed by the relationship between the location of primary schools and the spatial distribution of different socioeconomic groups; and ii) a spatial econometric model to explain spatial equity, measured by an aggregated and single indicator of accessibility, regressed against a set of socioeconomic and territorial indicators. This study is developed in the context of Portugal, using the statistical subsections of the BGRI as the smallest spatial units. Three types of data are used: school locations, provided by the Portugal Directorate-General for Science and Education Statistics; a street network, available from OpenStreetMaps; and socioeconomic data, available from the National Statistical Institute. A database with approximately 240,000 subsection allows to assess how close different socioeconomic groups are to schools. This data can then be aggregated at different scales (e.g. parishes or municipalities), for which it is possible to calculate different measures, such as the minimum, maximum or average distances or the ratio of school by inhabitants.

The conclusions allow to identify two main dimensions of accessibility: i) distances to primary school and ii) coverage level of schools. A significant negative and non-linear relationship between the socioeconomic conditions of people and the level of accessibility, which is independent of the type of territories (clustered by the different kind of accessibility). For the number of schools by inhabitant, no relation was found with the IQ. This means that the inequalities in the provision of primary schools is restricted to distance and does not necessarily hold a relation to the per capita investment in territories.

NATURAL SPATIAL PATTERN–WHEN MUTUAL SOCIO-GEO DISTANCES BETWEEN CITIES FOLLOW BENFORD'S LAW

[Katarzyna Kopczewska](#), [Tomasz Kopczewski](#)

University of Warsaw, Poland

ABSTRACT

According to Benford's law, the first one or more digits of numbers in any natural dataset appear with defined frequencies. For the first time, we use Benford distribution for spatial analysis to the geo-location of cities. The long-term history of urban locations is usually explained by social and economic factors. However, the spatial pattern of the geo-location of cities and their populations is unknown. We claim that the geo-location of cities and inhabitants around the world followed the evolutionary process, which results in natural spatial distribution. Our study proves that mutual 3D socio-geo distances between cities and populations in the majority of countries conform to Benford's law, and thus the urban geo-locations have natural distribution. In a search for factors driving Benford's conformity, we discover that a mixture of three pure point-patterns: clustered, ordered, and random in proportions 15:3:2 makes the 2D spatial distribution Benford-like. We also find that the 1D distance between population modeled with the composition of gamma distributions follows Benford. In the simulation, we prove that for complex 3D Benford-like pattern, the conformity in 1D or 2D distributions is sufficient, although the spatial factor is more important. For spatial statistics, this study develops new spatial distribution to simulate natural locations and shows that n-dimensional space can be reduced to a one-dimensional variable of distances. For urban studies, it shows that evolutionary settlement patterns resulted in the natural location of cities, and historical distortions in urbanization, even if persistent till now, are being evolutionary corrected.

EQUAL OPPORTUNITIES TO ACCESS THE UNIVERSITY IN CHILE? AN APPLICATION WITH A SPATIAL HECKMAN PROBIT MODEL

[Juan Luis Quiroz](#)¹, [Ludo Peeters](#)², [Coro Chasco](#)¹

¹Facultad de Ciencias Económicas y Empresariales, Universidad Autónoma de Madrid, Spain. ²Hasselt University, Belgium

ABSTRACT

The aim of this study is to contribute to the debate of the accessibility of higher education in Chile, focusing on both socio-economic and geo-spatial dimensions of access to university education. The central question we address in this paper is the following: Does geography (physical distance, neighborhood effects) play a significant role in determining accessibility of higher education in Chile? We use Heckman-type (Heckprobit) models to adjust for selection in the process of completing the trajectory towards higher education – that is, pre-selection, application for university place, and, ultimately, admission (or refusal) of participation in higher education.

The results shows that the geo-spatial have a significant effect on the postulation and accessibility of the student on Chilean universities.

RELATED VARIETY: A META-ANALYSIS

Jeroen Content¹, [Martijn Smit²](#)

¹Netherlands Environmental Assessment Agency (PBL), Netherlands. ²Utrecht University, Netherlands

ABSTRACT

The concept of related variety allowed a more precise understanding of Jacobs effects, allowing the analysis of positive externalities from unrelated and related sectors. It took off with Frenken, van Oort & Verburg (2005) but was quickly followed by dozens of other papers. This literature finds many contradictory effects, depending on the place and time analyzed, the setup of the related variety variables, and other study characteristics. We employ meta-analysis to trace these contradictions back to the sources of variation.

NEW EMERGING POPULATION AND SETTLEMENT PATTERNS: THE CASE OF SLOVAKIA

Martin Maris

Slovak University of Agriculture, Tr. A. Hlinku 94976, Nitra, Slovakia, martin.maris@uniag.sk

ABSTRACT

The paper's main objective concerns population and settlement changes in the spatial-temporal dimension in the 1996 – 2019 time span. As a main methods of the research concentration quantities and local indicators of spatial autocorrelation were used. Achieved results point to the emerging outer city migration circle and inner – rural migration circle in most Slovakia regions on district LAU 1 level. Some of these clustering patterns also became statistically significant. Furthermore, the results show an apparent difference in population redistribution in municipalities between the Bratislava region and the rest of Slovakia; and significant imbalances between municipalities classified by size. Lower and medium-size municipalities (1,000 to 10,000 citizens) become decisive stabilization elements in settlement network formation. However, the current prevailing settlement form is unsustainable, especially in the Eastern part of Slovakia. Conclusively, in current terms, Slovakia is missing decisive territorial-urban policy. The urgency of the large scale communal reform in Slovakia is inevitable.

KEYWORDS

Municipalities, population redistribution, urban-rural dynamics, urban-territorial policy

1. INTRODUCTION

1.1 The general context of the settlement system formation

The world continues to urbanize. The long-term prospects continue to predict that the world will further urbanize over the next decade, from 56.2 percent today to 60.4 percent by 2030. Every region is expected to become more urbanized in the next ten years, although highly urbanized areas are expected to slow their rate of urban growth; UN-Habitat (2020). The increase in urban population has not been evenly spread throughout the world. By far, Asia has the highest number of people living in urban areas, followed by Europe, Africa, and Latin America; UN-Habitat (2016).

There are considerable differences in regional demographic patterns across the European Union (EU) from overcrowded, dynamic metropolises that may have relatively youthful populations to more remote, rural regions with declining population numbers and poor access to a range of services; Eurostat (2017). The share of the urban population in the EU continues to rise. Although almost three-quarters (72.5%) of EU-28 inhabitants lived in cities, towns and suburbs in 2014, there are considerable differences in the size and spatial distribution of urban developments between EU Member States. Overall, the increase in populations and the limited space available for urban developments has resulted in the divide between urban and rural areas becoming increasingly blurred. In many cities, people have tended to move out of inner cities to suburban and peri-urban areas on the outskirts of existing metropolitan regions; Eurostat (2016).

The EU's rural areas are diverse in nature, characterized by their specific natural environments and endowments. Just over one quarter (28%) of the EU-28 population lived in a rural area in 2015, with a somewhat higher share living in towns and suburbs (31.6%), while the biggest share of the EU-28 population lived in cities (40.4%). During the five years from 2010 to 2015, there was a gradual increase in the number of people living in rural areas across the EU-28, their relative share of the total number of inhabitants rising by 1.7 percentage points; the increase in the share of the population living in towns and suburbs was even greater (rising by 4.7%), while the share of people living in cities declined at a relatively rapid pace; these patterns possibly reflect Europeans leaving inner-city areas in search of more (affordable) space, in suburbia, towns, or the countryside; Eurostat (2017).

Urbanization developed independently in different regions, more or less in the wake of the agricultural transition's local completion. Explanations of these first transitions to city-based economies have emphasized several factors. The local concentration of population, stressed by Boserup (1981) or the emergence of cities as a function of trade, interpreted by Jacobs (1969) is one of the possible explanations; Knox, Agnew and McCarthy (2008). Zhao, Guo, Li and Smith (2017), as another factor, introduce the city's political power, which drives the government to allocate more resources toward the prime city, attracting migrants, resulting in a multiplier effect on income and population growth.

Stutz and Warf (2012) associate the Industrial Revolution with the cities' growth. In this period, the transformation of agriculture freed millions from rural toil lives and allowed for large, dense urban settlements. Almost everywhere, industrialization and urbanization have been virtually simultaneous.

It isn't very likely if there is some theoretical consensus about causative factors that resulted in urban forms of living. However, a more realistic interpretation is generated if the concept of an 'urban revolution' is replaced by the idea of an urban transformation involving a host of factors operating over a long period. As „ Redman (1978: 229) explained: urbanization was not a linear arrangement in which one factor caused a change in a second factor, which then caused a

change in a third and so on. Instead, the rise of civilization should be conceptualized as a series of interacting incremental processes that were triggered by favorable ecological and cultural conditions and that continued to develop through mutually reinforcing interactions “; Pacione (2009).

Cities could persist – as they have for thousands of years – only if their advantages offset the disadvantages. In economic terms, the advantages are labeled increasing returns to scale or economies of scale, just two sides of the same coin. Related to cities, we might speak about agglomeration economies. O’ Flaherty (2005) explains that an agglomeration economy exists when production is cheaper because more activity is going nearby. Agglomeration economies that arise from having many people located together, no matter what industry they work in, are called urbanization economies.

Furthermore, urbanization economies are the primary reason why cities are productive. Economic gains – higher output per worker, higher wages, higher profits, higher incomes – that come with firms and people’s geographic concentration. The reasons why agglomeration raises productivity – and thus incomes have been the subject of intensive research performed by Glaeser (2000), Henderson (2003), Duranton and Puga (2002). In all nations for which such data are available, cities, especially larger ones, generate a disproportionate share of wealth; Polese (2009).

Different types of agglomeration economies became focus of study, taken by Lichtenberg (1960), and Vernon (1960) and Chinitz (1961). The traditional analytical framework of agglomeration phenomena undertaken by authors had emerged as a fusion of Marshall’s (1890) insights and Hoover (1948). Marshall (1890) focused on the role of local knowledge spillovers, and the existence of non-traded local inputs and a local specialist labour pool, while Hoover (1948), Ohlin (1933) and Isard (1956) allocated the sources of agglomeration advantages into internal economies of scale and external economies of scale in the form on localization and urbanization economies, McCann and van Ort IN Capello and Nijkamp (2009).

Geltner, Miller, Clayton and Eichholtz (2014) speak rather about cities, which serve a functioning economy and geographic region. This suggests two points:

- Centralizing city causation (centripetal) forces are counterbalanced by opposing decentralizing (centrifugal) forces
- The relative strength of the centralizing and decentralizing forces differs for different functions and activities

The centralizing forces cause cities to form in the first place and to tend to agglomerate into fewer and larger cities over time. The decentralizing forces tend to limit city size growth and tend to make more small cities dispersed throughout the territory.

These empirical observations and economic intuition have been developed into a body of geographic theory known broadly as Central place theory, including extension known as the theory of urban hierarchy. Perhaps the most famous names associated with CPT development are the German geographers Walter Christaller (1933) and August Lösch (1944). In its nutshell, this theory explains the arrangement of the spatial distribution of sites known as service centers; Čadil (2010) and Ivanička (1983). Despite many simplifications, the main tribute of CPT is its ambition for explaining of geographical organization of society as a whole, including the definition of various features of the system of cities; Blažek & Uhlíř (2011).

The urban expansion process is the key driver of urban transformation. Urban expansion takes place in substantially different forms. In any given city, new expansion can take place with the same densities (person per square kilometer) as those prevailing in existing built-up areas, with increased densities, or with reduced densities. It can occur through the redevelopment of built-up areas at higher densities, through infill of the remaining open spaces in already built-up areas, or new ‘greenfield’ development in areas previously in non-urban use; Angel, Sheppard, Civco et al. (2005). However, the new greenfield development can either be contiguous with existing built-up areas or ‘leapfrog’ away from them and incursing to the rural areas located in the city’s hinterland. This phenomenon, commonly known as urban sprawl or peri-urbanization, may become the dominant 21st century challenge for regional and city planning and design. Increasing economic welfare and living standards, together with smaller household sizes but increasing household numbers, are important drivers behind this development; Nilsson et al. (2014).

So far, we haven’t mentioned the rural areas and related rural-urban interactions yet. There is broad consensus about no exact definition of the term ‘rural’, either conceptually or empirically; Wiggins and Proctor (2001), Hoggart et al. (1995) and Halcafree (1993). Wiggins and Proctor (2001); Ashley and Maxwell (2001) put forward three features that mark rural areas. The first and most evident is the relative abundance of land (and other natural resources). The second is that significant distances lie between rural settlements and cities. Moving goods between rural areas and either other parts of the countryside or the cities are costly. The third fact is the poverty of so many of the inhabitants. Average incomes are lower in rural areas than in towns and cities.

The number of authors highlights relatively abundant rural-urban relations and their role in developing the region (Satterthwaite and Tacoli, 2003; Tacoli, 1998; Akkoyunlu 2015; Berdegué et al., 2015 and Von Braun, 2014). When exploring rural-urban linkages, Satterthwaite and Tacoli, (2003) suggest that small and intermediate urban centers where most rural people and rural enterprises interact. There are a number of activities that such centers play in supporting social and economic development within rural areas – providing rural populations with access to schools, and health care centers, being a location for agricultural extension services, irrigation offices, and agro-industries linked to local products. Tacoli (1998) and Tacoli (2003); and Akkoyunlu (2015) point on rural-urban linkages, which include the flows of backward and forward linkages between agriculture, manufacturing and service sector. Also, many households in both urban and rural areas rely on the combination of agricultural and non-agricultural income sources for their livelihoods. Bellet and Llop (2000) in Berdegué et al. (2015) identify four services that urban centers offer to their rural surroundings:

- Specialized goods and services
- Greater social, economic and cultural interaction
- Links to infrastructure networks that connect local communities with regional, national and international communities
- Public and government administration services through which local demands and needs can be channeled

Von Braun (2014) conceptually distinguishes two dimensions: flow and linkage facilitators when speaking about urban and rural relations. The first includes infrastructures and government and other public and private actors; the second contains flows of people, goods, money, knowledge, information, and waste. Water, biomass products, and nutrients are relevant from biophysical perspectives, land and soil utilization.

Finally, we might speak about the processes which are driving rural-urban dynamics. Primary, we can speak about the time dimension and migration. 'Rural' vs. 'urban' is more than a simple dichotomy. There is a strong interdependence that produces a continuum from dense urban places to remote rural places. Before the Industrial Revolution, high transport costs and the relatively low productivity of farmers limited population densities and urbanization. In the nineteenth century, labor-saving technologies in agriculture and scale economies in manufacturing fueled large-scale rural-to-urban migration and the emergence of many large and medium-sized industrial cities. In the twentieth century, distinctions between rural and urban began to blur. After World War II the pattern changed dramatically: Urbanization slowed and population and production decentralized, leading to urban 'sprawl' and exurban development; Irwin et al. (2016).

2. SETTLEMENT OVERVIEW OF SLOVAKIA

According to the data provided by Joint Research Centre EU, urban centers in Slovakia in 2015 comprised approximately 14.98% of the total population, followed by urban clusters with 36.92% share, and the rest belonged to rural areas. Moreover, urban centers comprised only 9.81% in terms of built-up area, followed by urban clusters with 32.32% share and rest belonged to rural areas JRC (2020). According to a new common methodology for delineating cities, urban and rural areas (EU, FAO, ILO, OECD, UN-Habitat, WB, 2020); it suggests that the Slovak population predominantly settles rural areas and intermediate-density areas. Even taking the built-up area into account, there is another shift towards the rural area. The settlement system of Slovakia is politically and geographically tied with the polycentric settlement system of the EU. Urban development, including settlement development on the EU level, is coordinated through the ESPON program. The settlements are a major topic of interest in strategic goals and priorities in the strategy of Europe 2020; ESPON Atlas (2013).

The Slovak settlement system structure is defined in the Urban Development Conception of Slovakia and Slovak Spatial Development Perspective.

According to these two documents, settlement system is formed by a (i) network of settlement core areas, (ii) development axes, (iii) settlement centers, and other (iv) regional and local networks of small urban and rural settlements (the Urban Development Conception of Slovakia, 2001).

The system's foundations represent settlement centers developed on a five-tier hierarchy. Settlement centers fill the role of tertiary and even quaternary service centers. In their respective hinterland, settlement core areas are being formed, which are belts of the settlement groups. The Slovak Republic's development axes are created within a hub-belt settlement system, the core of settlement centers, and a transportation-communication system connecting individual centers.

The settlement centers with their respective core areas became focal nodes for commuting to work and services from their subordinated towns and countryside, short-term and long-term frequency, and even exchanging the labor between these centers. Moreover, these areas support labor mobility and migration on an interregional and even national basis (Slovak Spatial Development Perspective, 2012).

However, it does also exist other definitions of Slovak settlement structure. The most important classification in the so-called Functional urban areas concept (FUA) based on spatial interactions between the city and its hinterlands; Bezak, (2000). The system comprised fifty-one functional urban areas (the so-called system FMR 91-A) identified on interurban short-term migration from population census realized in 1991; Bezák (2008). In 2009 social typology of Slovak settlements was developed. The typology comprised nine classes based on sixteen identified variables. It showed a diversity of settlements based on its inhabitants' characteristics like predominant job occupations, social stratification, and settlements' functional structure; Gajdos and Moravanska (2009). One of the newest documents outlining settlement development strategy is The Conception of Urban Development of Slovakia. The crucial topics of the conceptions are (i) affordable housing, (ii) sustainable transportation, (iii) healthy environment, and (iv) cultural diversity of urban settlements; The Conception of Urban Development of Slovakia until 2030 (2018).

2.1 Urban-rural processes in Slovakia

Klobucnik and Slavik (2013) distinguish four main phases in the settlement development of Slovakia. They considered the second phase through the 13th and 14th centuries as the most important in terms of settlement system establishment in Slovakia. Mostly flatlands and basins were settled. In the third phase, foothill and mountain areas became occupied, and in the fourth phase, in the 18th and 19th century the settlement structure had stabilized. With a low industrialization rate and urbanization, Slovakia's country was predominantly rural until 1918. The communism period became an important phase of the development of the regional structure of Slovakia. This period's main feature was strong, balanced

industrialization and the collectivization of agriculture; Korec (2003). This period's urbanization process was managed according to the central settlement system's principles. Based on this principle, small and medium-size towns (20 to 50 thd.) of inhabitants were intentionally formed; Andrasko, Ira (2010); Fal'tan (2010), Ministry of Transportation (2001). Slavík et al. (2011) speak about the period of quantitative urbanization. The number of inhabitants living in the cities increased from 857 thd. to almost 2.9 mil. to 1989. Thus, the growth index reached the value of 351%. The degree of urbanization increased from 24.9% in 1950 up to 56.7% in 1989.

Danielova (2014) divides these processes into three groups: elementary transformation processes – which affect the only single structure (morphological, functional, demographical). Typical processes are intensification, revitalization, functional fragmentation, deindustrialization, or reindustrialization. Secondly, we might speak about partial transformation processes, which typically affect two or more structures like residential districts' humanization, commercialization or gentrification. Finally, complex transformation processes simultaneously affect morphological, functional, and demographical structures. Here belongs suburbanization or re-urbanization.

Fal'tan and Pašiak (2004) evaluate the major developing trends of the Slovakia settlement system during the transformation period: (i) the development leads to the deepening of divisions between the rural and urban environments. We might speak about social-economic differences contributing to regional gap growth, shaping core and peripheral regions; (ii) there are ongoing trends of suburbanization and decentralization. The growth or decrease of the cities or rural areas has significant, selective character. (iii) there is an ongoing depopulation and aging process of rural areas, especially tiny ones. These areas lack attractiveness, which is related to the shortage of job opportunities and low population density.

The rural settlement structure in Slovakia is now well differentiated. Up to 41.4% of municipalities in 2011 haven't had at least 500 inhabitants, and 69.6% of municipalities had less than 1000 inhabitants. In 2011 only 10% of municipalities had more than 2000 inhabitants. Concerning the spatial distribution of bigger municipalities, we may speak about the high concentration in Western Slovakia, predominantly located in the Bratislava region, followed by the Trnava region and Nitra region. In the middle part of Slovakia, the number of big municipalities is severely diminished, just 8.3% share, and the lowest share is in Eastern Slovakia, only just 5,6% Bleha et al. (2014), Drinka and Majo (2016). Fal'tan (2010) highlights the two-way development of urban-rural relations in the current period. Suburban pressure and its local demonstration mostly reveal on the municipalities located in suburban corridors (just copying carrier transport corridors) and in the hinterland of bigger cities. It is also a case of small municipalities' if they have good access to higher urban units. These municipalities record positive demographic increases. In a relatively worse situation, rural areas are located in lagging regions, with poor infrastructure, a weak labor market, and bad transport access. These marginalized factors initiate the mechanism of one-side spatial mobility outwardly from the region, which further worsens the situation.

The rural decline is an inevitable process associated with the agricultural transformation to the urban-industrial economy and, further on, to the knowledge economy. However, the rural decline is not pre-destined. It is by the interactions between rural areas and the external environment that rural communities either grow, decline or even vanish. In this process, rural communities of different geographic conditions, natural resource endowments and social relationships, and people's values, attitudes, and institutions will make different responses, which finally lead to different evolution patterns and outcomes; Li, Westlund, and Liu (2019). Several authors Allison and Hobs (2004); Gleeson (2008); call for better rural policies leading to revitalization, rural renewal, or rebirth. Birkmann (2016) points on the over congestion of resource environmental bearing-capacity of cities, especially small and medium-sized, due to the emigration outflow from the rural areas in developing countries.

3. MATERIAL AND METHODS

The paper's main objective is to search Slovak population and settlement dynamics in 1996 – 2019 on regional level NUTS 2 and local (district) level LAU 1. Firstly, we focus on imbalances in the spatial distribution of population among the settlements and regions. For this purpose, we used the concentration quantities for measuring the concentration ratio of Slovak sites, varying by size in each region on the NUTS 2 level. All used data come from the national statistical office of Slovakia. Formally, we observe m regions ($i = 1, 2, \dots, m$), with n_i municipality (settlement) frequencies $i = 1, 2, \dots, m$ units. Within each region there are c_k categories of municipalities by size $k = 1, 2, \dots, s$ units. In total we have $\sum_{i=1}^m n_i$ units. We distinguish ten sites categories by size in interval scale from 0 – 199 as smallest to > 100,000 as the biggest. The intervals are not equal.

The concentration measures might be expressed as the coefficient of concentration (also Gini coefficient) or the concentration ratio. In the regional analysis, both concentration statistics evaluate the distribution of some statistical phenomena in the area. In this relation, we might speak about the diversification (unequal) or equal distribution, Minařík, Borůvková and Vystrčil (2013); and Chajdiak (2009). The concentration coefficient may be written as

$$K = 1 - \sum_{i=1}^m p_i (X_{i-1} + X_i) \quad (1.0)$$

And the concentration ratio as

$$P = \frac{\sum_{i=1}^{m-1} (F_i - X_i)}{\sum_{i=1}^{m-1} F_i} \quad (1.1)$$

Where

p_i is relative value frequency in i - class

F_i is cummulative relative value frequency up to i - class

X_i - cummulative relative frequency of variable X

Both statistics have helped us reveal the degree of population concentration within the municipalities in regions; however, we do not know which particular municipality category dominates within the regions yet. For solving this issue, we introduce HHI-score (Herfindahl-Hirschman Index) modified for our purposes for measuring the degree of concentration of municipalities in particular size category in regions. Formally we can write:

$$HHI - score = (\%S_1)^2 + (\%S_2)^2 + \dots + (\%S_n)^2 \tag{1.2}$$

Where S_i is relative share of municipalities in particular region

Finally, we have evaluated rural-urban dynamics as population switch between the urban settlements and rural areas on local level LAU 1. Nowadays, there are 140 municipalities on the list, with city status. Moreover, *Act no. 50/1976 Coll. on territorial planning and building order (Building act)*, set the mandatory conditions when the settlement can achieve the city's status – exceeding the population over the 5 000 permanent residents in the municipality cadaster. For the study, we picked up all municipalities designed as cities according to the Ministry of Interior and all municipalities exceeding 5 000 inhabitants in 2019.

It is necessary to note that urbanization changes within each district's settlement structure include the population's migration changes and natural changes. Whereas the natural changes of the population could have a more or less even pattern of distribution over the entire country (Slovakia), migration changes could behave unevenly in various regions. The research sample consists all administrative units of Slovakia on LAU 1 (district) level, thus $N = 79$. The growth in the rural-urban ratio g_{urr} , between period t and period $t + 1$ can be expressed as

$$g_{urr} = \ln \left(\frac{URR_{tj+1}}{URR_{tj}} \right) = \ln \left(\frac{\frac{PU_{tj+1}}{PR_{tj+1}}}{\frac{PU_{tj}}{PR_{tj}}} \right) \tag{1.3}$$

which simplifies to

$$g_{urr} = \ln \left(\frac{PU_{tj+1}}{PU_{tj}} \right) - \ln \left(\frac{PR_{tj+1}}{PR_{tj}} \right) = g_{pu} - g_{pr} \tag{1.4}$$

The growth in the urban-rural ratio over time is simply the difference in the urban and rural populations' growth rates, respectively Bloom et al. (2007). However, it is reasonable to suspect that the magnitude of urban-rural differences is not necessarily uniform over the regions but rather varies from one part to another. To capture this phenomenon's spatial variability, we must rely on another set of measures that can indicate possible spatial autocorrelation at the local scale. These types of measures are referred to as *local measures*. There several statistics for measuring the spatial autocorrelation (Moran's I, Geary's C and general G-statistics), but for our purpose, we use Local Indicators of Spatial Association (LISA), which commonly refers to the local version of Moran's I, Geary's C; Anselin, (1995) in Wong and Lee (2005). To indicate the level of spatial autocorrelation at the local scale, a spatial autocorrelation value must be derived for each areal unit. The local Moran statistics for areal unit is defined as

$$I_i = z_i \sum_j w_{ij} z_j \tag{1.5}$$

Where z_i and z_j are deviations from the mean for the corresponding x values, or

$$z_i = \frac{x_i - \bar{x}}{\delta} \tag{1.6}$$

Where δ is the standard deviation of the variable x . Therefore, z_i is basically z-score of x_i . Similar to the interpretation of Moran's I, a high value of the local Moran statistics means a clustering of similar values and low value of local Moran statistics indicates a clustering of dissimilar values. High or low local Moran statistic for each district may occur by chance. These values must be compared with their expected values and interpreted with their standardized scores. According to Anselin (1995) in Wong and Lee (2005), the expected value under randomization hypothesis is

$$E[I_i] = \frac{-w_i}{n-1} \tag{1.7}$$

And

$$Var [I_i] = w_{i.}^{(2)} \frac{\left(\frac{n - m_4}{m_2^2} \right)}{(n-1)} + 2w_{i(kh)} \frac{\left(\frac{2m_4 - n}{m_2^2} \right)}{(n-1)(n-2)} - \frac{w_{i.}^{(2)}}{(n-1)^2} \tag{1.8}$$

Where

$$w_{i.}^{(2)} = \left(\sum_j w_{ij} \right)^2; w_{i.}^{(2)} = \sum_j w_{ij}^2, i \neq j; m_2 = \frac{\sum_i z_i^2}{n}; m_4 = \frac{\sum_i z_i^4}{n}$$

And the term

$$2w_{i(kh)} = \sum_{k \neq i} \sum_{h \neq i} w_{ik} w_{ih} \tag{1.9}$$

The z-scores for each unit is obtained by

$$z[I_i] = \frac{I_i - E[I_i]}{\sqrt{Var[I_i]}} \tag{2.0}$$

4. RESULTS AND DISCUSSION

Figure 1: Concentration of population in Region of Bratislava, own calculations

Figure 2: Concentration of population in West Slovakia area, own calculations

Figure 3: Concentration of population in Central Slovakia, own calculations

Figure 4: Concentration of population in East Slovakia, own calculations

Figures (1.,2.,3, and 4.) on layout 1 show the degree of concentration on NUTS 2 level in Slovakia. The horizontal axis captures the cumulative frequency of population, and the vertical axis captures cumulative frequencies of municipalities (settlements).

All regions on the NUTS 2 level show a fairly increased concentration level, graphically depicted by the Lorenz curve. We might also observe slight variations in the degree of the concentration between the period 1996 and 2019. So, it might be concluded that population patterns have not changed very much.

Table 1: The concentration measures in Slovak region on NUTS 2 level in 2019

Region/ NUTS 2	Coefficient of concentration (K)	Concentration ratio (P)
Bratislava region of Slovakia	0.519	0.689
West Slovakia	0.426	0.626
Central Slovakia	0.454	0.697
East Slovakia	0.459	0.694

Source: Own calculations.

Table 1 shows concentration measures calculated on Slovak NUTS 2 level in 2019. Taking it more detail, we might observe differences between the Bratislava region and the rest of Slovakia. Bratislava region has shown an increased coefficient of concentration, which results from imbalances between the population shares, which live in relatively small municipalities in the Bratislava region. Interestingly, in 2019, municipalities with up to 5,000 citizens capture just 17.8% of the population's share in the Bratislava region. Other Slovak regions on the NUTS 2 level show somewhat lower concentration levels. On average, they exceed 50% of the population share, currently living in municipalities with up to 5,000 citizens. In the term of the concentration ratio, West Slovakia and Bratislava region have shown lower figures, because of fairly representation of the medium and bigger sized municipalities (1,000 to 5,000 citizens) with 45% share on average, which can capture a significant portion of citizens up to 30% on average. Conversely, the Central and East Slovakia regions have shown up slightly higher concentration ratios, which results from a relatively high share of municipalities with up to 5,000 citizens (95% on average for both regions) on a total number of municipalities. In the Bratislava region, the relative share of municipalities with up to 5,000 citizens represents 75%.

So far, results point to relative significant imbalances between the population concentration observed in the Bratislava region; and the concentration of small municipalities in Central and East of Slovakia. However, it is still unclear what category of municipality dominates in each region based on its population share.

Figure 5: HH-score municipalities vs. citizens in Bratislava region

Figure 6: HH-score municipalities vs. citizens in West Slovakia

Figure 7: HH-score municipalities vs. citizens in Central Slovakia

Figure 8: HH-score municipalities vs. citizens in East Slovakia

Figures (5,6,7, and 8.) on layout 2 show scatterplots of calculated HH-scores of municipalities vs. citizens by size on NUTS 2 level in 2019. For the scatterplot diagram, we have used nine (in the case of Bratislava ten) size groups of municipalities. In each region, the distribution of size categories shows an uneven pattern. HH-score varies between 0 and 10,000. In general, values close to 0 show more proportional shares in represented sample units, whereas higher values indicate disproportional shares in the sample.

Bratislava region and West Slovakia show some similar features. Bigger size groups of municipalities (>10,000 citizens) have shown only small HH-score weight in the settlement system, and they are located in the lower-left corner of the scatterplot diagram. However, lower and medium-sized groups (1,000 to 10,000 citizens) have caught significant weight in both displayed variables and become a stabilizing element of the settlement system.

Central and East Slovakia have shown patterns with uneven HH-score weights distributed between the municipalities and citizens. Big-sized municipality groups (>20,000 citizens) located leftward have shown high citizen HH-score but only scant municipality HH-score. Conversely, tiny municipalities (<1,000 citizens) have caught the highest municipality HH-score and considerably lower citizen HH-score. Exception represents only lower and medium-sized municipalities (1,000 to 5,000 citizens), which have caught comparable proportions of the HH-score in both variables.

Finally, we switch our attention to evaluating spatial patterns by observing urban-rural growth rates on the LAU 1 level in 1996 – 2019. For measuring the dynamics, growth of the rural-urban ratio as a difference of the growth rates between the urban areas (municipalities >5,000 citizens) and rural areas (municipalities <5,000 citizens) has been used. The

statistics show a long-term pattern of spatial population distribution between the urban areas and the countryside. For evaluating broader spatial relations, local Moran's spatial autocorrelation statistics have been used.

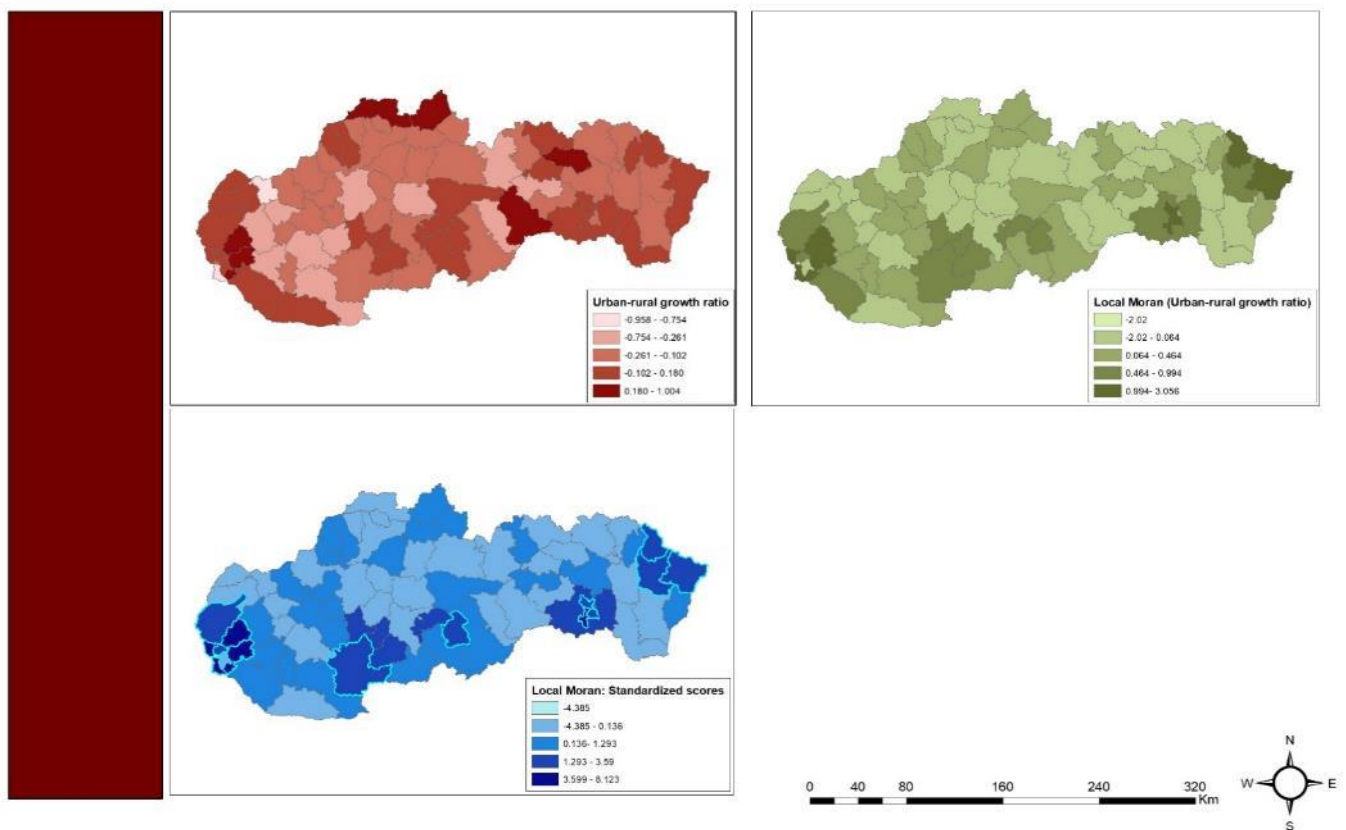

Figure 9: Spatial changes in population redistribution between the Urban and Rural areas on LAU 1 in Slovakia, 1996 – 2019 time span

The upper leftward figure shows the urban-rural growth ratio, according to equation 1.4, on LAU 1 level, calculated over the 1996 – 2019 time span. Subsequently, local Moran statistics about spatial autocorrelation were computed (upper right figure). The lower leftward figure shows computed standardized - score for each district on a significance level. The maps were arranged into the classes based on the *Natural breaks (Jenks optimization)* method realized in the ArcMap application. We might observe relatively distinct spatial patterns. In the western part of Slovakia, the ratio mostly has shown negative values, which does mean that cities (>5,000 citizens) lose population and rural areas gain population. So it is in line with current ongoing suburbanization trends observed also elsewhere. However, it is not the case in the Bratislava region, which despite witnessing one of the most vital suburbanization trends in the 90-years, most of the districts showed urban population gain. It might be explained that the population primarily prefers bigger municipalities (over 5,000 citizens), or either as a result of intensive suburbanization over the years, previously smaller municipalities (<5,000 citizens) have gained enough population and switched to city category, or simply urban areas have outpaced the rural ones in the rate of immigration.

Central Slovakia has shown mixed results, mostly prevailing ruralization patterns, except few areas located in the south and north. The same picture provides East Slovakia, where interestingly, several peripheral and border areas have shown urbanization patterns. Their spatial remoteness, poor transport infrastructure, or lack of services make those people generally prefer moving into cities.

Local Moran statistics have shown mixed patterns across all regions of Slovakia. It shows a higher level of similarity between the neighboring district in the Bratislava region, which also became statistically significant. Similar clustering values also show the Central-south, South-east, and North-east districts of Slovakia. Finally, a few cluster pockets reveal in the North of Slovakia; however, they did not become statistically significant. Conversely, the Central and Eastern part of Slovakia mostly shows clustering of negative values, indicating dissimilar values; however, any of them (except Bratislava II district in the far West) did not become statistically significant.

5. CONCLUSION

The paper's main objective has been to search for population and settlement changes in the spatial-temporal dimension in the 1996 – 2019 time span. In terms of the settlement changes, the population concentration measures in municipalities on the NUTS 2 level were observed. The results have shown relatively great imbalances between the population shares currently living in cities (more than 5,000 residents) and other municipalities (below 5,000 residents) located mostly in the countryside. There are also significant differences in shares of small municipalities (below 1,000 residents) represented in regions. Central and East of Slovakia have the lion's share of these municipalities; however, in

the West, there is much more balanced between the small (below 1,000 residents); and medium-sized or bigger municipalities (1,000 to 5,000 residents). Slovak settlement disintegration; Šprocha et al. (2015), Drinka and Majo (2016), Hrdina et al. (2019), Bucher (2011), Černenko, Harvan and Kubala (2017), Ištók and Lovacká (2005) as a major development barrier was also highlighted in a number of studies; Gajdoš (2009), Ira et al. (2010).

In terms of measuring of HH-score of the municipalities vs. citizens, on the municipality level, in respect to size, results also point to significant regional disparities. Central and East of Slovakia show an uneven distribution of HH-score weights between small municipalities (<1,000 citizens) and its citizens. However, in the Bratislava region and West of Slovakia, lower and medium-sized municipalities (1,000 to 10,000 citizens) show more balanced distribution HH-score weights, thus becoming a stabilization element of the settlement system creation. Nowadays, living in small communes and in the hinterland of big and medium-sized cities is becoming more attractive; Mladek and Čupelová (2010).

Finally, results point to selective population redistribution between the urban areas and the countryside; Fal'tan and Pašiak (2004). Significant population immigration to urban areas was observed mostly in the border and peripheral regions or economically disadvantaged regions, located mostly on the country's South and East. Poor infrastructure and lack of services might be the reason for this pattern; Fal'tan (2010). Michniak (2014) stresses the multi-dimensional nature of problems of the most marginalized regions. These regions are specific for diffusion or accumulation of several adverse characters and phenomena. They could be related to the physical-geographical constraints, historical legacy, demographical and social-economical aspects.

Districts located in the 'inner' part of the country mostly show rural immigration patterns. Broader spatial relationships in the case of several districts could not be ruled out. Several clusters of districts located in the Bratislava region and South and East of Slovakia show statistically significant similarity in local Moran standardized scores.

We might conclude that Slovakia, in general, is missing a more decisive territorial-urban policy. Over the years, more adverse settlement shaping patterns have developed, which do not contribute to the overall sustainability of living in Slovak settlements. Slovakia has too many very small municipalities located mainly in the East, lacking the infrastructure and services, and conversely congested Bratislava metropolis with its urban hinterland. More proactive policy measures toward municipality merging and using alternative transport moods are being demanded. Long-term urgency of this issue also stressed Sloboda (2005), Nižňanský (2005) and Nižňanský (2009); and Brix (2019).

PROXYING ECONOMIC ACTIVITY WITH DAYTIME SATELLITE IMAGERY: FILLING DATA GAPS ACROSS TIME AND SPACE

Patrick Lehnert, Michael Niederberger, Uschi Backes-Gellner

University of Zurich, Switzerland

ABSTRACT

Satellite data has gained increasing popularity among economists. The most commonly used type of satellite data is night lights data, which constitutes a valuable proxy for economic activity (i.e., GDP) at the national and subnational levels. However, evidence-based policy analyses may require measures of economic activity beyond the spatial and temporal scope of night lights data. When government policies affect economic activity in small regional units (e.g., urban districts), investigations of such policies need regional measures of economic activity. Moreover, studies on the economic consequences of historical events demand measures of economic activity with a long time series (e.g., analyzing economic activity in the former German Democratic Republic). Night lights or other data might not yield the necessary regional and temporal scope in these contexts.

We develop a novel approach to proxying regional economic activity. We use daytime satellite imagery and apply machine-learning techniques to identify six different surface groups, that is, types of land cover such as built-up land or cropland. We demonstrate (a) how we compute these surface groups and (b) that the regional combination of these surface groups is a valid proxy for economic activity. The surface groups allow the measurement of regional economic activity both over a longer time series and at a more detailed regional level than other existing measures. While we demonstrate our approach for the example of one country (Germany), we have produced them also for other European countries and are currently producing them for the U.S. In principle, our procedure is generalizable to any region in the world, for which various types of economic policy analyses might require data on economic activity.

We obtain the surface groups from Landsat satellite data, which has three advantages over night lights data. First, Landsat data has a substantially higher resolution (30 meters) than night lights data (one kilometer), thus making possible analyses at more detailed regional levels. Second, the Landsat data we use starts in 1984 (whereas night lights data starts in 1992), therefore allowing for analyses over a longer time series. Third, Landsat data enables researchers to identify different types of surfaces, thereby providing a more nuanced measure of economic activity.

We compute the surface groups by applying a machine-learning algorithm in Google Earth Engine, thereby closely following the remote-sensing literature. To assess the value of the surface groups for economic research, we test their validity as a proxy for economic activity for Germany, using reliable and regionally detailed administrative data on GDP (available since the 2000s). Furthermore, data on household income (RWI-GEO-GRID) make possible an analysis at the level of very small grid cells (sized one square kilometer).

Our analyses show that the surface groups constitute a valid proxy for economic activity. At small regional levels, they predict economic activity even more accurately than night lights. Furthermore, the prediction error tends to be less spatially and temporally biased. The surface groups thus constitute a valuable measure for economic research, particularly for assessing policy changes affecting small regional units and for analyzing historical contexts.

IMPROVING VACCINATION RATE THROUGH COMMUNITY AWARENESS¹⁶⁰

Fiscal Policy Agency, Ministry of Finance, Indonesia

ABSTRACT

The novel coronavirus 2019 (Covid 19) outbreak has devastated public health in general and a significant economic threat worldwide, including in Indonesia. The existence of vaccines has become the possible source of the decline in Covid 19 additional cases per day in various countries. Indonesia has started the vaccination program on January 13, 2021, which costs are estimated to be around Rp. 73 Trillion or equal to 500 million US dollars. However, there's a widespread concern that the vaccination program may not rapidly implement. On average, there are only 66 thousand people vaccinated per day in Indonesia. Those numbers are small compared to other countries such as the United States, which can vaccinate up to 1 million people per day. This paper investigates whether the vaccination acceleration plan can improve Indonesia's vaccination implementation by employing machine learning tools. Using the dataset from SUSENAS 2018-2019 and the Ministry of Finance, we estimate the proportion of health workers, the elderly, and the community aged 18-59 years who have morbidity symptoms and receive outpatient and inpatient health services proxy to health access. This study comes up with five simulations to estimate the result of vaccination programs under five different scenarios. In the first simulation, people go to government health facilities to get vaccinated. In the second simulation, we add to the first simulation with the assumption that the vaccines are given for free. In the third simulation, we add to the second simulation by expanding health facilities such as private hospitals, clinics, doctor and midwife practitioners. Since Indonesia also has a community access problem to health facilities, we add free transportation in the fourth simulation. Finally, in the fifth simulation, we try to integrate community awareness into the vaccination program. Community awareness is when one head of the household persuades and escorts at least one person to the vaccination facility. In the first and second simulations, we obtain the vaccination rate, which is around 66 thousand people per day, similar to what occurs nowadays. At this rate, there will be only 27 million people in Indonesia get vaccinated in March 2022, far below 181 million people as targeted by the government. The vaccination rate reaches 175 thousand people/day under the third simulation and 177 thousand people/day under the fourth simulation. However, under the fifth simulation, the vaccination rate can reach a staggering 1 million people/day. These results show that besides the availability of health facilities, health practitioners, and transportation assistance, community awareness plays a prominent role.

THE ROLE OF SHARED WORKSPACES AS AN ANCHOR OF COMMUNITY RESILIENCE FOR LOW-INCOME URBAN POPULATIONS

Dalit Harel, Sigal Kaplan

The Hebrew University of Jerusalem, Israel

ABSTRACT

In the last decade shared workspaces are widely spread world-wide with thousands of public and private sectors shared work-spaces. This study investigates the role of shared workspaces as an anchor of community resilience for low-income urban populations. To date, studies explored the role of shared workspaces from the employee and regional innovation perspective, while the effect on the community empowerment remains unraveled.

This study focuses on a new municipality owned multi-functional shared workspace serving the variety of uses and is geared towards empowering the residents and promoting low-income young adults. Besides providing a workspace, the following activities are initiated by the management staff (all residents) in order to answer community needs: ii) lectures and community events, iii) university exam preparation courses, women empowerment, entrepreneurship events and networking opportunities; iv) a hub for learning support.

Interviews were conducted with the management staff (ten employees) and with a sample of thirty 18-21 years-old attending the workspace. We identified processes leading to behavioral change among the young adults attending the workspace. We looked at the change processes via the lens of the Trans-Theoretical model positing five stages of behavioral change: observation, preparation, change action, maintenance and assimilation, including successes and backsliding. Additionally, via the existence-relatedness-growth model we identified the layers of human need that this venue meets.

The changes undergone by attendees who spend time and engage in activities at the facility foster personal and community resilience in Jaffa. According to the management staff, 60% of the young adults assisted by the facility enroll to universities, compared to 20% enrollment rate in the surrounding neighborhood. The venue creates anchors for young people and is a major springboard in areas of crucial importance: education and employment. The facility activities are aimed at all the five stages of behavioral change. Need awareness is promoted through school visits and collaboration, through word-of-mouth by creating a neighborhood "buzz", and through community activities and lectures by community and industrial leaders. Preparation is facilitated by courses and information. Action change is supported with personal help in scholarship submissions, networking and internship programs. Maintenance and long term assimilation is supported by the staff involvement over time. The workspace contributes to the young adults in three main areas. Firstly, the facility alleviates functional barriers by providing university preparation courses, language and academic writing courses, and information about university, enrollment, scholarships, student aid programs. Obstacles are addressed by the helpful, attentive, and closely-involved staff, who create a sense of personal connection. Secondly, the facility promotes social inclusion by providing a meeting-place and giving its users a homelike, familial atmosphere and sense of belonging. Thirdly, the facility plays a substantial role in strengthening the confidence and self-image of young Jaffa residents by offering them an experience of success helping them leave their comfort zone. All of these things help the venue's young clients achieve success in self-management.

ON SMART INSTITUTIONS: TOWARDS NEW TERRITORIAL ACTORS TO SUPPORT ECOLOGICAL TRANSITION AND REGIONAL DIVERSIFICATION¹⁶¹

Alberto Brugnoli¹, Johann Spitzer²

¹Professore Ordinario, Dipartimento di Scienze Economiche, Università degli Studi di Bergamo, Via dei Caniana 2, 24127, stanza 102, Bergamo, Italy. Email: alberto.brugnoli@unibg.it; ²Cultore della materia, Dipartimento di Scienze Economiche, Università degli Studi di Bergamo, Via dei Caniana 2, 24127, stanza 102, Bergamo, Ital, Email: johann.spitzer@gmail.com

ABSTRACT

The paper addresses the need for a change in the institutional framework of smart regions to address three challenges: (i) sustainability (SDG), (ii) innovation-diversification (RIS3), and (iii) the ability to properly allocate structural funds (Green Deal and Next Generation EU). These three challenges are assessed taking into account the complexity of managing smart regions, considering the presence of first and second-generation territorial commons, that lead to innovate the configuration of new institutional forms. In this context, the paper analyzes the role of territorial actors and their impact on the territorial systems. Some guiding criteria are outlined to support the configuration of smart institutions as the basis to enable the emergence and consolidation of smart regions.

KEYWORDS

Smart Institutions, Territorial Actors, Smart Regions, Institutional Innovation, Sustainable Development

1. INTRODUCTION

During the last decade, significant efforts have been done to strengthen the configuration of Smart Regions where the main challenge was to support innovation-diversification and, at the same time take advantage of the different assets and capabilities already available in the territories and regions. However, problems to implement RIS3 have been observed, especially in the process of screening, selecting, prioritizing sector, and allocate the ERDF, where the idea of Smart Specialization is confronted with the difficulties that political operators face by managing innovation funds D'Adda et.al. (2021), remembering the problem of "picking winners".

Part of the problem is the complexity behind the idea of RIS3, and in our opinion, the lack of appropriate institutional settings to implement it. In contrast, the origin of the Smart Specialization policy, back to the work of the "Knowledge for Growth" Expert Group (see Forey et. al. 2009a), specified that Smart Specialization is an "entrepreneurial process of discovery"¹⁶² and is far from being a top-down industrial policy or any form of "grand plan", where territorial actors, especially enterprises, are those that *discover future areas of specialization-diversification*. However, it has been the case for its implementation?

Capello and Kroll (2016) already observed the challenges regarding RIS3 in translating theory to practice, pointing out mismatches between functional and political-administrative regions, lack of inclination to admit bottom-up participation, lack of capabilities to engage regional entrepreneurial discovery; hence calling for *new governance* and linking projects with a broader approach considering the "*territorial capital*" (Camagni, 2009) avoiding narrow industrial policy perspectives and introducing more territorial complexities within RIS3, considering different actors and different typologies of assets and ownership.

Balland et. al. (2019) also remarked on the limits of Smart Specialization policies, especially regarding the lack of analytical tools and frameworks capable of orient policymakers in the selection-investment processes, where the authors propose to consider the analytical framework of *relatedness and knowledge complexity* as a valid instrument to foresee areas of feasible innovation and diversification of regions:

"We need to think more deeply about how to tackle the inherent tension within smart specialization policy between prioritizing and selecting activities based on regional potentials (as in the proposed framework), on the one hand, and reliance on the entrepreneurial discovery process in which this selection process is completely decentralized, bottom-up and process-led [...] One potential way to solve this tension is, first, to identify diversification opportunities in each region based on their scores on relatedness and complexity, after which, within that range of opportunities, the entrepreneurial

¹⁶¹ The paper can not be cited without the permission of the authors

¹⁶² Additionally, the experts of "Knowledge for Growth" not only conceived that SS was a bottom-up process, and spontaneous dynamic that would require governmental support on this matters, but also considered the need to *use one simple tool*: the General Purpose Technologies (GPTs) that can be diffused among regions promoting chatching-up dynamics base on waves of digitalization, Industry 4.0 , new business models, etc.

discovery process will unfold, in which a range of local actors will decide which activities to target...” Balland et al. (2019:1264).

Certainly, we can mention several limits and challenges that RIS3 where deeper analysis has been carried out by Hassink and Gong (2019) that deserved a reach and detailed response from Foray (2019), acknowledged that the word “specialization” was regrettably misleading. highlighting that “ the main function of the concept is to introduce a bottom-up component in a process that also has a top-down component” Foray (2019a: 2074), what he called a combination of planning logic and entrepreneurial discovery logic. However, revising the policy after ten years he proposed a “more obvious process that regions will find easier to implement [...], the three steps needed for the design and implementation” Foray (2019: 2068): (i) identify priorities for the region, (ii) translate these priorities in transformational roadmaps, and (iii) implementing with an action plan.

So what we observe is that the Smart Regions approach, if embedded in RIS3, is strongly shaped by a policy-mechanical tool containing several planning-implementing aspects to manage financial resources to support regional development in the EU, that is expected to work, taking into consideration business bottom-up dynamics, where, is excepted that in some stage policymakers will prioritize, select and support (see OECD, 2013). However, we ask if this intervention approach can make a region smart?; nevertheless, before deepen our analysis, we consider it important to understand what Smart Region is.

For practical purposes, and although our intent in this contribution is not to explore a proper definition of Smart Regions, we need to specify what we understand by a Smart Region as a basis to deepen our analysis on “Smart Institutions”. For this aim, we will synthesize this concept taking the main elements that characterized them as referred by the EC Smart Specialization Platform¹⁶³, in part due to the lack of studies on this concept. Based on this review, we can define Smart Regions as those capable to take specific *actions* and mobilize *resources* to provide support to *bottom-up entrepreneurial dynamics* based on unique *territorial knowledge and innovation* capabilities, allowing the discovery and development of new sustainable regional growth paths, a process that takes place through a *polyarchy governance system*, avoiding top-down and governmental-driven industrial policy approaches.

In our understanding, Smart Regions are intrinsically characterized by collective actions that shape the regional development assuring its sustainability through innovation and new forms to preserve and expand its territorial capital. However, is for this type of region the main role of local and regional governments to screen, select, prioritize, and mobilized the main resources?

According to Rodriguez-Pose et. al. (2014) in the RIS3 approach are different territorial actors (firms, higher education institutes, public research centers, members of civil society, and other local actors) as those suited to discover the promising activities for regional innovation, where these different set of actors should be part of the formulation strategy, emphasizing that the role of the government institutions in more on the quality of the government system (efficient, transparent, inclusive) with effective control and incentives; so providing good conditions for the operation for the territorial actors that implement the innovation and transformation processes. On the other hand, Cortinovis et.al. (2016) highlight that the role of the regional government to foster diversification matters when “bridging social capital”, it means when government supports the emergence of a specific type of social capital that “bridge”, peoples and communities, enabling open networks of cooperation.

All these aspects indicate that the actions of regional authorities, to shape Smart Region, will be more related to exert a role for enhancing the institutional quality of the territorial. Such quality is achieved, with the presence of inclusive institutions, that encourage the participation of the great majorities in the economy using their talent and skills (see Acemoglu and Robinson, 2012:144). All these aspects pointed out that the configuration of Smart Regions depends on the role and participation of the regional stakeholders, configured by different territorial actors and under a polyarchic territorial institutional system.

Rodrik et. al. (2004), Acemoglu and Robinson (2008-2012) exposed how institutions precede development over trade and geography among deep fundamentals of growth, however, the latter two influence institution through its effects on integration patterns (distance, environmental condition, and linked diseases, ruggedness, natural resources, etc) and behavior of the actors. Nowadays, we are not facing malaria and colonization, however, our regions are facing a significant impact due to Covid-19, and climate change is putting under pressure on our eco-system; where urban development and land regulations have a key role regarding carbon dioxide emission, (see Glaeser and Kahn, 2010). Now, the EU has launched the largest financial package to deal with these exogenous variables, Covid-19 and Climate Change, where Next Generation EU and Green Deal will allocate in the following years an unprecedented quantity of economic resources. In this context, the question is, how these supra-national policies will shape the Smart Regions strategies? will this massive fund impact the institutional setting? Are the regions ready to allocate efficiently such resources?

2. SMART REGIONS: CHALLENGES FOR SUSTAINABLE DEVELOPMENT AND REGIONAL DIVERSIFICATION IN TIMES OF MASSIVE STRUCTURAL FUNDS

Smart Regions, as we defined above, face several challenges and opportunities in times where the EU is approaching to apply a significant amount of resources to change the energy matrix, achieve CO2 neutrality, support information technologies as GPT for a massive transformation of business models. In this historical momentum, we have identified five main challenges for Smart Regions as exposed below:

- (i) *Centralism in times of crisis and recovery*

163 See <https://s3platform.jrc.ec.europa.eu/home>

In times of crisis is known that subnational authorities are shadowed by the power of central authorities (Douglas, 2019), leading a process of centralization cascade (Raudla et. al. 2015). So we ask if the massive presence of EU funds for recovery and CO2 neutrality may lead toward more centralization and less participation of local actors in shaping sustainability? Previous experience of crisis management and fiscal stimulus have shown the possibility to observe that such kind of patterns. The challenge is relevant because if such a phenomenon takes place, regions and localities may lose bottom-up dynamics generating an effect on policymakers and local authorities to monopolize the use of the resources increasing the presence of bounding rationality in decision-making processes (see Nelson, 2012).

(ii) *Resource allocation model*

We acknowledge that *traditional government allocation models* in a time of crisis (pandemic and environmental) may face the main challenge different challenges: (a) *efficiency, fairness, and speediness* in resource allocation, (b) *precision*: allocate in the right territorial actors and projects, and (c) *effectiveness*: support the bottom-up entrepreneurship and innovation processes.

The first issue (efficiency, fairness and, speediness) is linked to the institutional quality in terms of administration quality, transparency, and processes; the second issue (precision) is a more complex task, and the decision-making in this context of potential increasing centralism and political pressure for resource allocation would face significant challenges to should screen, select and decide how, when and who will receive financial resources, where such concentration of power and resources may lead to institutional problems and even increasing corruption or collusion, with the possibility of leaving behind territorial actors that has not the political space and capabilities to access to benefits. The third issue (effectiveness in supporting bottom-up entrepreneurship) is even more challenging in a scheme where top-down priorities are leading the ecologic transformation and recovery. Consequently, is rational to expect that in a context of crisis and recovery the complex process of supporting discovery dynamics and bottom-up entrepreneurship, would become a marginal activity, finishing in standards project calls, classical schemes of incentives for SMEs among others that may not have the capacity to respond to the urgent challenge of fostering sustainable development, deeper economic diversification and increasing knowledge intensity in the local economies.

(iii) *From linear value chains to circular ones*

Another relevant challenge in regions that look for ecological transition are changes in the value chain configuration and management. For decades companies and local entities have been managing linear value chains; focusing on the required infrastructure to support input and output process under a linear value chain perspective. In this way, institutions were arranged to support the provision of energy, transport infrastructure, water facilities, as well as water management, and waste management. Nonetheless, the increasing pressure of waste disposals and raising environmental concerns increases the need to work with semi-circular value chain processes, with a massive introduction of recycling centers based basically on management materials that were easy to recovers. Even so, the ecological transition is demanding a circular economy defined as “a regenerative system in which resource input and waste, emission, and energy leakage are minimized by slowing, closing, and narrowing material and energy loops. This can be achieved through long-lasting design, maintenance, repair, reuse, remanufacturing, refurbishing, and recycling” (Geissdoerfer et. al. 2017:759). In this perspective, the traditional recycling system and waste and water management solutions, that currently, most territories have, may be insufficient to respond to the challenge of a broader circularity, even more, if the idea to create regions of a circular economy is targeted, the strategy would demand to rethink the institutional set-up to manage circular value-added systems.

(iv) *SDG as core goals among territorial system*

The SGD goals of the Agenda 2030 set clear and broader goals; showing that sustainability not only considers planetary boundaries but also social once as Raworth (2017) conceptualized. These goals to be implemented, necessarily go through the implementation of 17 SDG at the territorial level, showing that, is at this level where the problem can effectively tackle. Bramanti and Brugnoli (2019) proposed a synoptic framework of how structural transformations that include the green economy, digitalization, demography are interlinked with different models of territorial development systems, which are synthesized in three types (see Table 1), where in one pole are those with a high level of industrialization, in the other pole areas with high environmental value and the middle the urban systems.

Table 1. Synoptic framework: structural transformations, territorial models and sustainable development in 17 SDG¹⁶⁴

Model of territorial development	Area with widespread industrialization	Urban systems	Areas of high environmental value
Structural Transformation			
<i>green economy - decarbonization</i>	4-5-7-8-9-10-11-12-13-16-17	5-7-8-9-10-11-12-13-16-17	2-5-6-7-8-10-12-13-14-15-16-17
<i>digitalization</i> Smart city / smart land	4-5-7-8-9-10-11-16-17	1-2-3-5-6-7-8-9-10-11-13-16-17	2-5-6-7-8-9-10-11-16-17
<i>demography - active aging / immigration</i>	3-4-5-8-9-10-12-16-17	1-2-3-5-8-10-12-16-17	2-3-5-8-10-12-16-17
<i>SDGs with high relevance for territorial development model</i>	3-4-5-7-8-9-10-11-12-13-16-17	1-2-3-5-6-7-8-9-10-11-12-13-16-17	2-3-5-6-7-8-9-10-11-12-13-14-15-16-17

Source: Bramanti and Brugnoli (2019)

As the authors specified that SDG Goals SDGs 5, 8, 10, 16, 17 recur in all quadrants, indicating the unquestionable contribution that the territorial systems have, in particular bottom-up SMEs dynamics, can offer for the achievement of these goals.

Additionally, the achievement of ecological transition based on decarbonization, push up digitalization as GPT, and innovation to shape Smart Regions requiring the support of the overall territorial system, which is moved by its actors where large corporations play also a key role. Consequently, our main concerns and questions rely on the current *regional government and governance systems* have enough “smartness” to identify such level of complexity, where is required to capture micro-signals, foreseen potential opportunities, and can raise and allocate massive resources with *efficiency, fairness, speediness, precision, and effectiveness*; set of concepts that are closer to “smart actors” prone to entrepreneurial and innovation dynamic. Consequently, we believe that it is important to identify territorial systems and models that better can tackle SDG goals using the appropriate tools and policy frameworks relying on *smarter institutional settings* which in our opinion require to foster the emergence of smarter territorial actors.

3. SMART REGIONS AND THE ROLE OF TERRITORIAL ACTORS AND ACTIONS

Forey (2019b) argues that in the last thirty years the policies of innovation “have been characterized by a moderate degree of interventions and neutral logics of resource allocation [...] of innovation policies are insufficient in supporting more radical transformation, such as the modernization of an old industry or the acceleration of innovation to solve certain grand societal problems.” Forey (2019b:1379-1380), suggesting that to increase the level of transformation, it is required to shift the level of intervention advocating for non-neutral policy intervention. Consequently, following this approach, is rational to think that in a Green Deal scenario, would be expected to move in the direction of radical innovation and transformation with strong non-neutral intervention, privileging the role of public authorities. However, the main problem of “transformational approaches” is how interventions take place?

Critical questions are in non-neutral intervention who is expected to (a) identity, (b) priorities, (c) allocated resources,(d) innovate, and (e) transforms?. Hence, in our opinion, the debate is not only about grades of intervention (moderate or radical) and orientation (neutral or non-neutral), but especially regards “*who acts*” the process. In the SIR3 approach, issues (a) and (b) are mainly led by policymakers and public authorities, with less of more degree of protagonism; issue (c) is also usually managed by central authorities and regional governments but also is supported in several cases by a financial mechanism where local bank systems matter; issue (d) is usually a cooperative process between the private sector and knowledge institutions (public, private or mixed) and the transformation (e), usually not discussed, is under the role of industries. So “a, b and c”, are the main areas of discussion in term o innovation and growth policy in the SIR3 approach, however, is not the case if we consider other perspectives.

For instance, transformational and planning shaped approaches are usually far away from remarkable schools of thought that have significantly impacted the understanding of innovation and sustainability (key vectors for Smart Regions), as is the case of the Austrian School and the Bloomington School, both schools that converge in different aspects as Aligica et. al. (2017) analyze, concluding that innovation - the whole processes from “a” to “e”- is linked to collective actions, where disruptive innovation take place through “non-linear and polycentric process whose participants include a wide

164 1: No Poverty, 2: Zero Hunger, 3: Good Health and Well-being, 4: Quality Education, 5: Gender Equality, 6: Clean Water and Sanitation, 7: Affordable and Clean Energy, 8: Decent Work and Economic Growth, 9: Industry, Innovation and Infrastructure, 10: Reduced Inequality, 11: Sustainable Cities and Communities, 12: Responsible Consumption and Production, 13: Climate Action, 14: Life Below Water, 15: Life on Land, 16: Peace and Justice Strong Institutions, 17: Partnerships to achieve the Goal

variety of actors (including researchers, university administrators, entrepreneurs, venture capitalists, corporations, and public officials)” Aligica et.al. (2017:12).

This polycentric approach allowed to reduced the problem of bounded-narrow rationality and reduced the problem of selection, prioritization, and resource allocation. A varied set of collaborative territorial actors are more fitted to manage the risk and evolutions of the whole territorial system.

For example, in the experience of Silicon Valley widely studied (see Engel, 2015; Kenney, 2000, Adams, 2003-2005; Bugos, 2001), the smartness of the place was configured by a network of specific territorial actors with precise action. It is also the case of the innovative milieus; however, part of the limitation to understand these smart places is that this experience has been mostly studied by urban economists and less by historians, where the role of the actors and their actions has not been fully captured and studied. From a historical perspective, we can learn more about historical facts, actions of people, families, groups, associations, universities, etc; to better understand dynamics without leaving behind a fundamental part of the “telling story” of smart places; where concrete (smart) people, or group of them, or specific institutions are the explanatory variables of outstanding experience.

Brugnoli and Garrone (2018) identified the case of the “Systemic Actor”, understood as a territorial actor that is capable to mobilize in a certain way the territorial capital of a place, capable to interact with Multi-Actors, Multi-Sector, and in Multi-Scale (3M) perspective; identifying that these kinds of actors can be entrepreneurs, or a group of them, or universities, local governments, or foundations, among others; so the sector o activity to which they belong, may vary, however, their traits are similar although different experience analyzed.

In this perspective, we consider that possibly much attention has been given to the “neutral” and “non-neutral” policy approach or the strategic and analytical frameworks that policymakers should take into consideration to “better select” sectors and activities. Instead, we suggest providing more attention to the study of “actors-actions” and adopt policies and practices according to the territorial actor setting. We argue that also several other potential categories or actors can be identified, characterized by a set of specific actions, and impact the evolution of territories.

To better explain this aspect, we have considered the experience of a well-known smart place, the Silicon Valley, analyzing, briefly the group of people that were behind this outstanding experience (see Table 2), where be trace, briefly the role of Leland Stanford.

Table 2. Traits of a Systemic Actor in the experience of Silicon Valley

<i>(i) Engagement and empathy with the community and the territory:</i>	Leland Stanford, founder of Stanford University, before ist endeavor, and even before be nominated Senator of the Union, became the Governor of California; a sign of its interest and commitment with the place, building a broad view of the region.
<i>(ii) Capacity to mobilize and raise large economic resources:</i>	Standford was a railroad magnate, and entrepreneur, capable to understand the economic environment. He can mobilize its 8.180 acres (stock farm) in Palo Alto to configure the campus of Standford University (territorial anchor institution).
<i>(iii) Inclusive mindset and behavior:</i>	On of the co-founder of the university, D. Starr Jordan shared with the Stanford family and collaborators the idea to build an institution "nonsectarian, co-educational, affordable, to produce cultural and useful graduates, to teach traditional liberal arts and technology and engineering" (Standford Univestity). As matter of fact the US West Coast, was already a place with strong migration dynamics and the university bridge different cultures and backgrounds and create a vibrant community.
<i>(iv) Market-driven and practical approach</i>	Frederick Terman, a historical professor, was focused to teach their students not only to invent and create, but also tocommercialized, linking the invention with market dynamics, to better read needs and providing useful innovations.
<i>(v) Vision and purpose:</i>	Since its foundation, the university clearly states its purpose “to promote the public welfare by exercising an influence on behalf of humanity and civilization” (Standford Univestity). This statement goes beyond short-term and pecuniary approaches, rather was focus on transcendental goals for the community with a global purpose.
<i>(vi) System mobilizers</i>	The systemic actor has a particular capacity to shape territorial institutions and to mobilize collection actions and support territorial capital creations. Its core capacity is to protect, expand and co-create different types of "commons".

Source: Own elaboration based on Nicholas, and Lee (2014).

They built was a strong community in the territory, with the will to transform the place, adding a strong quote of collective actions. After this dynamic was very well established, attracted the attention of Federal Government funds, with directionality in some specific areas, allocating, producing more radical innovation, and reinforcing the human capital, and innovation capacity of the place, adding significant knowledge spillovers in the area.

We understand that similar processes were also carried out in milieux (see GREMI contribution 1991 and 2004) experience and industrial districts (Becattini, 1979); however, as mentioned, a historical review of the actors among Smart Regions would significantly contribute to understanding the role and specific actions of the place.

What we wish to emphasize is that the transformation towards Smart Region cannot be built without the presence of certain types of actors-action, given their capacity to generate changes in the territorial system structure and to mobilize the institutional system. Following the case of Silicon Valley, that due to the scope of this contribution we will not fully expose, we wish to extract also the presence of other specific typology of actors-actions, where we found the following profiles:

- *propulsive*, characterized by its R&D capabilities, able to ignite new development trajectories; configured by researchers institution, think tanks, R&D enterprises, etc.
- *enabler*, characterized by its capacity to mobilize capital (financial and human), hence configured by financial institutions and educational ones.
- *rooted*, characterized by actions and actors that are deeply engaged with the territorial dynamic, these are citizens, manufacturers, investors and usually are not under a free-rider scope and its activities are deeply rooted in the place.
- *systemic*, as mentioned, it can mobilize the whole territorial system and attract different actors. Systemic are from different nature (public, private, mix) and scope (profit, not-for-profit, or fourth sector).

It is important to mention that Territorial Actors are not separate from governmental institutions (from different levels), rather in several experiences systemic actors may coincided also with local government in certain characteristics and capabilities, but due to the heterogeneity or regions, this can vary on nature and scope.

Such preliminary typology of territorial actors-action shapes new institutional settings and fosters collective actions mobilizing and transforming the territory in growth or backward performance. Hence, what we are highlighting is that RIS3 policies and the problem of industries and resource targeting should take into consideration the actors perspective and do not rely only on one typology of actor – usually public one – as those that lead resource allocation, selection, and investment activities to look for a Smart Region configuration.

On the other hand, we think that is also important to model in some way the dynamics of the territorial action that shaped innovation-diversification and increase (when positive) the territorial capital of the place. In this analysis, we found that *Boschma (relatedness)* provides key elements for understanding the *flow* dimension and *Camagni (territorial capital)* provides also key elements for understanding the *stock* dimension, to the complex dynamics behind the territorial transformation. Consequently, we consider that RIS3 and the Smart Regions policies require to rethink their approach giving more attention to the actors-action point of view. Fig. 1 provides an intuitive model of the function of the territorial system, where relatedness interplay with the territorial capital supported by specific actor-actions.

Fig 1. Territorial System and growth trajectories based on action-actors

4. ON SMART INSTITUTIONS: THE CHALLENGE OF INSTITUTIONAL SETTINGS FOR SMART REGIONS

The main two challenges that we observe when Smart Regions are approached, are: how sustainability-transition and innovation-diversification can be shaped. Main issues rely on the *nature of the problem* which is deeply rooted in the problem of the *commons*. The territorial system, cities, and regions deeply rely on the quality of the commons and its institution for collection actions (see Foster, 2018). This aspect has been deeply by Rajan (2019) who emphasized the need to support local actors to provide balance to the territorial system, as an essential pillar to achieve sustainability. Moreover, Giraud (2013) remarks also the nature of the problem, considering novel forms of commons that demand the reconfiguration of local and global actors to achieve ecological transitions.

Here we approach essentially two types of commons, one of first-generation, part of the territorial Common-Pool Resources (CPR), from natural resource base, and one of the second-generation, the commons of knowledge (Hess and Ostrom, 2007).

Hess (2008) defines CPR as “resources shared by a group where the resource is vulnerable to enclosure, overuse, and social dilemmas. Unlike a public good, it requires management and protection to sustain it” Hess (2008:37), presenting a large number of second-generation commons, among these are traditional commons and global commons (agriculture, forest, land tenure, water and irrigation, wildlife, biodiversity, pollution, waste, etc) as well as knowledge commons (universities, civic education, internet infrastructure, access, libraries, open sciences, genetic commons, peer production as open-source software, etc). The complexity of the commons relies on the innovation-collaboration capacity to design and agree on institutions for collective actions. In this perspective; Ostrom (1990) approach the commons under three fundamental institutional models for its management:

- Leviathan as the “only” way: argue that the tragedy of the commons cannot be resolved by cooperation, hence to avoid the tragedy it is required a powerful central government to protect and rule the resource system.
- Privatization as the “only” way: argue that to avoid the tragedy it is required to end the common-property system and work only under private property rights.
- An alternative solution: Ostrom argues that due to the particular nature of the commons, and applying the game theory framework, is demonstrated that collaborative private-public solutions in different forms can maximize the benefits for the community, proposing an institutional system that promotes the development and balance exploitations of the commons, control monopolistic and purely extractive behaviors and proposing a polyarchy system where “institutional deals” are required. Such alternatives are varied and work on self-governance structures.

Such analysis is particularly in the case of natural resources is well known their different application in special institutions; however the common of knowledge reserve more detail. For Hess and Ostrom (2007) knowledge commons, which can also be referred to as information, commons are not pure “open access” information, rather a complex set of information and actors which parts are open and other managed under exclusive networks and are not free, protecting essential property rights and at the same time providing an open basis for knowledge capitalization. This is extremely important in the context of the negative ‘market stealing’ effect from non-interactive knowledge search as explored by (Roper et al 2016).

Additionally, knowledge commons are particularly important in the configuration of regional and territorial technological externalities where knowledge spillovers boost innovation (see Breschi and Lissoni, 2001). Such resources are essential to managing strategic knowledge of a place and, usually are not the proper institutional settings that protect and administrate such dynamics. In these conditions “knowledge leaks” take place, and actors, with not rooted in the place grasp knowledge to be copied and replicated in other regions, that later may directly compete with the territories that create them, threatening the competitiveness of regions.

However, what is also significant is knowledge commons where R&D externalities take place, are prone to create their institutional settings, a dynamic that may help to re-shape Smart Regions institutional settings. Weder and Grubel (1993), following Coase principles, found that R&D externalities will induce the creation of self-organized private institutions able to internalize these externalities, where a vibrant institutional setting may be established.

However, some may suggest that under EU innovation fund interventions, would be better to keep control and lead innovation processes. However, authors have explored the impact of regional governments on innovation, and the results are not encouraging. Cortinovis (2016) and Boshma (2017) found that the role of regional governments on diversification is only remarkable when these “bridging social capital”, so when support institutional relatedness, mobility, and interaction between territorial actors. These are indications that support polyarchy regional systems with varied institutions may significantly help to support innovation particularly under a bottom-up approach; where different institutions may be specialized in specific functions, as well as in practices for resource allocation, and to reach new market opportunities. This regional innovation system would prevail on pushing up selection, specialization, and prioritization, a process and may lead to significant errors and strong inefficiencies, and loss of resources.

On the other hand, Boshma and Gianelle (2013) argue that to face the tension regarding prioritizing, and selection of activities is feasible to identify opportunities based on scores of relatedness and complexity, so local actors based on this information may decide. We argue that this is a valid but very sophisticated strategy framework difficult to assess and promote at the territorial and regional level because few institutions are capable to understand and work on these parameters; therefore local leaders may relying on regional advisors to translate these interpretations and applications the risk to do not verify its feasibility with local actors. However, if these instruments are work by *propulsive actors* as

research centers, local think tanks, etc., and may cooperate with *systemic actors*, this kind of policy and a sophisticated instrument may find a feasible way to be implemented.

Additionally, a regional specialization on actors' functions, rather than in sector, may provide more efficiency to the territorial system. For instance, local financial institutions are essential for the adequate allocation of resources, having in good knowledge of clients and capacity to innovate with financial instruments. Such kind of *specialized institutions* exert an *enabling* action in the territorial system and are essential to be engaged in the strategic process of resource allocation, rather than rely mainly on public leaders that may divert resources due to political pressures as explored by Dellmuth and Stoffel (2012) regarding European fund allocation.

Moreover, from an accurate analysis of the Bloomington School, we can derive that "Green Deal" and "Next Generation EU" funds are configured as a precise type of commons, a fact that has a significant impact on the model in this regional institutions are configured. Such fund are a specific (second-generation) type of common, because of:

- Is a common-pool resource based on the large accumulation of collective action of EU members and financial institutions (tax collection, collaterals, assets, production).
- Impact the overall territorial system and his contributions are intended to provide a resilient and protective measure of essential commons or the regions.
- Resources are limited and face high pressure and competition among EU actors and may put the resources under significant stress, requiring special protection and administration procedures.
- The resource can be expanded and even replicated again, due to the particular circular nature, allocation, interest, returning of loans ore return through future taxes increasing the CPR system.

So, what we consider is that regions and Smart Regions, require special settings or institutions to be able to manage such complexity of commons, rather we can observe an increasing centralization and a "leviathan way" unable to foster bottom-up dynamics, and shape Smart Regions.

Our analysis leads us to rethink the institutional setting of regions, to be able to achieve the Smart approach, with a structure able to support resource and knowledge sustainability fitting its particular nature. For this aim, we suggest considering that the following policy criteria to rethink institutions of Smart Regions:

(i) *Identify regional territorial actors*

Heterogeneity is intrinsic to regions as well as their institutional quality. And although EU regional administration may have similarities and the allocation of EU funds follow guidelines and rules for all the EU, the effectiveness of the allocation and quality of the efforts to pursue sustainability-transition and innovation-diversification will rely on the territorial actors-action. Consequently, it is important to identify, regional actor's capacities, specialization, and roles within the territorial system and support a new institutional arrangement.

(ii) *Apply the "golden rule": strong governance systems to manage commons including funds*

Polyarchy is essential to boost innovation and shape Smart Regions. This kind of regional approach implies a change of paradigm, particularly in terms of resource allocation. Smart Regions are not fitted to depend on top-down decision-making regarding funds and other resources. Smart Regions should be able to innovate on new institutional settings to manage public resources.

(iii) *Support institutional specialization and diversification, rather than targeting economic specialization-diversification*

Smart Regions should provide and support specialization on actors' functions increasing its capabilities.

(iv) *Support institutional innovation:*

Relatedness dynamics are not only essential for the evolution of business and more complex products; however, such kind of system also requires more complex and innovative institutions, where different types of actors (private, public, third, and fourth sectors) should configure new institutional settings to respond in a better way to territorial needs. Fear to lose control lead to path-dependence and lock-in dynamics. As an example, several policymakers see Singapore as a leader in the radical innovation process; however, little attention has been given to its complex institutional setting that has been created to manage different investment processes, governance structures, *fund allocation systems* to accelerate investment in new technology and knowledge capture. Singapore's "smart city" transformation cannot be understood without an accurate understanding of its complexity and varied institutional setting with mixed forms of institutions, showing how Ostrom's "alternative way" can release unique territorial dynamics to shape sustainability and diversification through institution innovation processes.

(v) *Support the emergence of strong territorial actors:*

Smart Regions require to reshape their institutional structure and be able to be supported by strong territorial actors that may exert *systemic, propulsive, enablers, and rooted actions*. This support is expressed in creating the proper legal framework for delegate, empower and support new roles and resource mobilization capabilities.

(vi) *Identify, expand and protect territorial commons:* Smart Regions should be able to identify traditional and new commons as having the smartness to support institutional agreements to support and protect them.

Finally, Table 3 synthesizes a process of change in the institutional setting of regions to support the emergence of smart dynamics.

Table 3. Old and New Institutional Paradigms in Smart Regions

Old Paradigm	New Paradigm
Prioritization led by government	Prioritization led by territorial actors
Target Sectorial specialization - diversification	Target Institutional specialization-diversification
Government-driven resource allocation	Actor-driven resource allocation
Self-government control	Self-governance control
Innovation Agenda led by government and experts	Innovation Agenda led by territorial actors
Golden rule: government decision making	Golden rule: governance decision making
Institutional silos	Hibrid institutional structures
Fiscal packages and stimulus as public resources	Fiscal packages and stimulus as commons
Stakeholder participation	Stakeholder empowerment

Source: Own elaboration

5. CONCLUSIONS

The Smart Specialization Strategy approach that shapes Smart Regions presents significant limits, particularly in its institutional setting approach that may reduce the capacity of regions to achieve the expected development results. Major limits of RIS3 are in process of screening, selecting, prioritizing, usually led by public authorities that decide on discovery-driven processes that are not inherent to their social functions. Smart Regions work on pivotal resources that take the form of “commons” (first and second-generation), where natural and knowledge common-pool resources are by nature complex and demand a more complex institutional setting to shape collective actions to preserve and transform essential territorial commons.

In the current context, Smart Regions dynamics expect to be reinforced through new massive structural funds as Green Deal and Next Generation EU. However, such resources may increase top-down dynamics and centralization, reducing the capacity of regions to achieve the goals that Smart Regions pursue and its SDG. Nonetheless, EU public funds, analyzed under the Bloomington School framework, shown that are configured as a new generation of commons, consequently demand the emergence of a new institutional regional system for resource allocation; rather new forms of “tragedy of new and traditional commons” would take place. In this perspective, we observed that the Bloomington School and the Austrian School, present similarities showing that sustainability and innovation fitted with a strong polycentric institutional setting; a paradigm that is coherent with the Smart Region approach.

We also observed that the development paths of the territorial system require considering Boshma actors-knowledge relatedness (flow dimension), and Camangi territorial capital (stock dimension), elements that support the mobilization and transformation of the territorial system through a specific actors-actions framework. Based on our work and using case studies analysis as Silicon Valley, among others, we have identified four different types of territorial actors: systemic actors, propulsive, enablers, and rooted. We recognize that such typologies require further analysis. Finally, we consider that to better understand the development of the smart regions from the actor point of view, it would be required to encourage its analysis using the historical method that can provide a wider understanding of the actors and its action in specific historical spaces.

DIGITAL REGIONS: A DIFFERENT EUROPEAN REGIONAL SPACE STRUCTURE

[Patricia Ikouta Mazza](#), [Maria Mavri](#)

Quantitative Methods Laboratory, Department of Business Administration, University of the Aegean 8 Michalon Street, P.S. 82100 Chios, Greece. pmazza@ba.aegean.gr; m.mavri@ba.aegean.gr

ABSTRACT

The Europe 2030 Agenda for Sustainable Development gives emphasis to people and to sustainable way of life. Sustainable development was identified as important aspect for European Strategy 2020, which is based on three pillars of growth: 1. *Smart growth*, focus on fostering education and innovation, 2. *Sustainable growth*, focus on low carbon emissions, tackling climate change and protecting the environment, 3. *Inclusive growth*, focus on establishing new jobs and reducing poverty.

In the last decade, there has been given a strong emphasis on Smart growth, which was mainly achieved through the transition of cities to the digital era and introducing the concept of Smart City. However according to our knowledge, the concept of Smart Region is slightly examined by literature.

Regions in contrast to a city, are associations of more areas or cities with different growth rates, with different spatial development and physical - technological infrastructure and with different needs of citizens. Moreover, the digitalization of our societies force regions to face new challenges such as e-economy, e-government, etc, issues that have already been examined in the context of Smart City”.

The goal of this study is to contribute to the literature and to the public discussion of smartness in our life, by introducing the concept of Digital Region.

The idea of Digital Region is the result of the rapid development of Information & Communication Technology (ICT) and their applications. Internet of Things, Artificial Intelligence, Cybersecurity, Big Data are some of applications that transform the both economy and society. The concept of region is redefined by this new digital environment. At the same time, the pandemic of the COVID-19 has highlighted the urgent need, to take actions in terms of digitalization at regional level. The introduction of the concept of Digital Region as a mental region that will consist of regions with common characteristics and common problems to face and which knows no borders but focuses only on creating the appropriate strategies to deal with a common emergency is the subject of this paper.

INFORMAL ENTREPRENEURISM IN THE GLOBAL SOUTH CITIES: CASE STUDY OF STREET VENDORS IN MUMBAI

[Ms. Meghamrita Chakraborty](#)

Doctoral student, Tata Institute of Social Sciences, Mumbai, India, India

ABSTRACT

The concept of urbanization and economic growth are mostly discussed together in the literature. Entrepreneurship is an important component for economic growth because it creates new business/job opportunities and fosters economic growth through increased productivity. Compared to the cities of the North, Global south cities like Mumbai in India, Dhaka in Bangladesh represent modern urban spaces with distinctive remnants of a traditional structure. The presence of informal workspaces like street vendors, daily wage or contractual laborers represent this duality; they are often considered the residuals of a traditional backward economy and society. The recent literature has started to give importance to entrepreneurship which does not have the ideal characteristics. This includes entrepreneurship in the informal sector. Street vending can be also considered as a form of 'street entrepreneurship', whereby vendors start-up a business venture/manage or own a business. This study, on street vendors, in three popular market places of Mumbai shows an interesting mix of vendors: some who are working on a subsistence basis and others who have turned their business into a profitable enterprise, willingly choose to work in an informal set-up and can be termed as commercial vendors.

What stands out is compared to the Global North, cities in India still do not recognize street vending as a legal occupation. Recently, the Street Vendors Act, 2014 was an attempt to legalize this occupation. However, it has added to the chaos and not resolved the question of effective rights, rents, and orderly and sustainable development of the city. In spite of the Street Vendors Act, 2014, the discrepancies and discrimination still continue. The social networks and relations of the vendors, thus, form an important part of their entrepreneurship and livelihood. Their daily negotiations with customers, local leaders and each other, influences their business environment. However, it is a fact that common spaces, especially the streets and pavements, in the city in the want to effective government policies are turning into tragedy of commons. They are facing increased occupation by the marginalised sections due to compulsive subsistence and survival questions. The lack of effective context-based urban planning to provide the spaces for hawkers, which form substantial share of population in the city, results into this tragedy of commons. The better-off vendors enjoy the free riding behind the poor and marginal vendors. The lack of effective rent even from the better off vendors results in lack of maintenance of the pavements which adds to the disorderliness of common spaces and walkways. The paper, thus, also engages with the question of this tragedy both through the policy analysis and vending politics through collective organization of vendors. The three street markets chosen, Colaba Causeway, Bandra Hill Road and Chembur station market, are popular destinations each with its distinctive feature. Chembur market caters more to the local population with essential household items while Colaba and Bandra are popular tourist hubs. The individual street vendors in Mumbai are the unit of analysis in the present study. Vendors who are static and have a particular spot from where they vend regularly were interviewed. Developing cases based on qualitative interviews and in-depth discussions with vendors, the paper attempts to show not all vendors are subsistent in nature, and how the nature and culture of entrepreneurship varies among the vendors which in turn gives rise to inequalities and a heterogeneity in the business environment of the vendors. In-depth interviews with government official, local leaders and NGOs were also conducted. These interviews and discussions have been essential since the study is exploratory in nature. Hence, while the interview schedule gives a more objective idea regarding the street vendors, the political economy of the vending business can be better analysed with the discussions where they shared their daily lived experiences.

SUSTAINING THE CREATIVITY AND INNOVATION: *CHIKANKARI* INDUSTRY OF LUCKNOW

[Rinku Prasad](#)

Doctoral Student, School of Development Studies Tata Institute of Social Sciences, Deonar, Mumbai, India.
rinku.tiss2017@gmail.com

ABSTRACT

In urban studies literature, the Global South towns have not found their due place with respect to the agency and creativity. They have been often considered as dormant, traditional, subordinate and less modern and innovative than the towns in the Global North. Robinson (2006) demonstrates that all the towns need to be understood in their context and also read through the lens of alternative modernity. From this latter perspective, many of the Global South towns can be considered possessing their own modernity and creativity. Lucknow is one such town which has been historically famous for its creative arts and in contemporary times hosts one of the leading creative embroidery sector, called Chikankari. Inspired by the Turkish embroidery, the Mughal empress *Noor Jahan* introduced Chikankari craft in India during late fifteen century AD, which flourished in Awadh region with local block printing techniques. During colonial rule Lucknow was a major centre for agriculture and art and craft industries like jewellery and embroidery clothes. Now, Lucknow and Chikankari is synonymous with national and global recognition by complementing each other as a brand. The creativity among the workers is produced from human interaction process. The first interaction is learning within the family and neighbourhood from elderly, that is inter-generation process of knowledge transfer. The second major source is external, that is, interaction with the contract providers, designers, buyers, and visit to the local hats and exhibitions. However, now-a-days the internet has become major source of receiving the design, videos how to produce the design, etc. A large share of Chikankari workers are women from Muslim community, and due to patriarchy and *Purdah (veil)* system they are immobile, which creates their dependency on external contractors. However, use of mobile phone and digital technologies are easing their interaction even from the four walls of the house.

This proposed paper will attempt to examine, (a) how for generations the creativity among the workers has been maintained in the city through the inter-generational transfer of knowledge, (b) what are the ways the external knowledge are constantly brought in to shape the products to maintain the relevance of the products to the market, and (c) what are the ways the workers benefits from this industry and whether the digital technologies (for communication, design, imitations, etc) and emerging globalization of the products have helped them to improve their wages and prospect of the industry.

As there are no public sources of data, we will try to estimate the total output by contacting Chikan producers' organization in the city. Further, we will take up case studies to 3 households to depict the process of how creativity is intergenerationally transferred, how the interaction to external agencies adds to the changes and sustenance of the craft and market relevance. The individual and community interactions in space will be depicted by drawings and descriptions. The paper also draws the data and method of investigation from the previous studies. Given the unorganised nature of the sector and lack of detailed data, the case studies method, structured and semi structured methods of interviews with workers, community leaders, entrepreneurs, executive, government officials is considered most appropriate. These methods will be used for the collection of the needed data. The samples of the cases, one each, will be from the family working for a reputed international company, that working for a national company and the family that it not connected with any of them but with local NGOs and market. The paper uses the framework of knowledge transfer developed by Argote and Ingram (2000).

The study may through light on how human interaction is essential for the creativity and sustaining the creative products in a globalised market system. It may also throw light on the causes of chronic deprivation among the workers of the Chikan industry, which if not resolved may undermine the creative city nomenclature of Lucknow.

There are hardly any studies which depict the knowledge transfer and method and sources of innovations in the Chikan industry in the city and this study will as such is original and adds to the knowledge about this sector.

The study will help us to understand the churning out taking place within the industry and impact of technology and globalised market system on the industry. This will also help us to understand the kind of policies needed to sustain the industry.

DEMOCRATIC PARTICIPATION IN NEGOTIATING URBAN PUBLIC SPACE IN INDIA: COEXISTENCE OF COLLECTIVISM AND INDIVIDUALISM AMONG STREET VENDORS

Debdulal Saha

Indian Institute of Science Education and Research (IISER), Mohali, India

ABSTRACT

This article explores how street vendors negotiate with different classes of people to sustain in urban space. Vendors' rights to use and appropriate public space have long been proven to be crucial to the emergence of intensive street life and productive urbanity in many cities of the global south (Bromley, 2000; Saha, 2017; Kamalipour and Peimani, 2019). Collectivism and individualism are discussed to understand workers' bargaining process within industrial relations framework (Olson 1965; Tilly 1978; Martinez Lucio and Stewart 1997; Kelly 1998; Beck and Beck-Gernsheim 2002; McGovern 2003; McBride and Martínez Lucio 2011; Taylor and Moore 2014). This study shows how street vendors as informal workers are practicing these interests as methods of negotiation to survive on the streets of urban India. Drawing case studies from New Delhi (North), Mumbai (West), Kolkata (East) and Guwahati (Northeast) during 2007-2021, the study examines the processes and natures of various forms of collective actions that vendors practice on the public space while vendors as a socio-economic group are discussed from researches conducted by the author during 2010-2019 using mixed methods research (MMR).

Vendors co-opt quasi-relationship with various stakeholders — civic authorities, service providers, fellow workers and customers— where class difference exists. Contrasting interests of individualism and collectivism are co-existed through self-devising strategies, participation, mobilization and organization. Unlike other cities in the nations of the Global South, labour market institutions (the Street Vendors Act 2014) legitimises re-construction of binaries—organised/unorganised, legal/illegal and licit/illicit— and power relations, thereby re-defining urban governance structure for street vendors in India. Male vendors are more engaged with large-scale operations, while females are engaged with small-scale operations selling perishable goods (Bromley, 1978; Agadjanian, 2002). As Saha (2017) argues, women's uses of public space are linked to the problems of vulnerability, intimidation, and insecurity posed by authorities, their male counterparts, passers-by, and customers.

A vendor exercises two kinds of bargaining – economic and social – across gender and class. Individualism and rationality are practised during economic bargaining for interest rates and bribes mainly among male vendors who sell products which has higher value. Collectivism are exercised by female vendors and those vendors selling lower valued products. Social bargaining is performed during collectivism to build social relations with different actors such as customers, other vendors and moneylenders. Thus, vendors exercise economic, political and social bargaining to form collective solidarity in acquiring controls over resources, accessing public spaces, and forming unions/other membership-based organisations to build relations and negotiate with various stakeholders, viz., vendors, shopkeepers and state. Vendors' collective interests are subdued in the class-based organisational structure. It can be protected through democratic process at the local level, thereby making collective and inclusive city.

BLUE-ING CHILDREN'S SPACE: THE PROMISE OF BLUE URBANISM TO MAKING CHILD-FRIENDLY CITIES IN THE SOUTHEAST ASIA

[Aireen Grace Andal](#)

Ural Federal University, Lenina Prospekt 51, Yekaterinburg, Russian Federation, aandal@urfu.ru

ABSTRACT

This paper proposes a framework for child-friendly coastal cities at risk (CCaR) in Southeast Asia (SEA) toward an inclusive blue urban agenda in the Global South. Southeast Asian coastal cities encompass two-fold projections: (1) the impact of climate change and (2) increase in children population. The low-lying Southeast Asian coastal cities are disproportionately vulnerable to environmental hazards such as floods, storm surges, and coastal erosion. Simultaneously, SEA cities expect a surge of young population by 2050. Focusing on children in SEA cities offers an understanding of the topographical and demographical uniqueness of Global South urban settings. Such context suggests South-South dialogue among Southeast Asian (SEA) coastal cities as they share vulnerable futures arising from coastal city risks. In line with the UN's Sustainable Development Goals (SDGs) and New Urban Agenda (NUA), this study examines five Southeast Asian "Global Future Cities" identified by Global Future Cities Programme (GFCP) under the UK Foreign and Commonwealth's Prosperity Fund (UK FCO): Surabaya (Indonesia), Iskandar (Malaysia), Melaka (Malaysia), Cebu (Philippines) and Ho Chi Minh (Viet Nam). Through a secondary data analysis, this study reviews City Context Reports from these five SEA cities and identifies opportunities and challenges to urban child-friendliness based on the UNICEF-recognised Child Friendly City. Drawing lessons from a comparative analysis, this paper discusses urban issues in coastal cities that impact children, as well as underlying barriers and enablers for a child-friendly blue urbanism observed across the five cities of interest. Three main observations transpire from such examinations. *First*, diversity of materials (manuals/maps) on child-friendly disaster guidelines is lacking, which calls for producing materials based on children's diverse backgrounds (differences in language, religion, gender, disability and/or ethnicity). *Second*, despite the existing efforts to educate children on resilience against coastal-related disasters, there is a need to draw attention to raising awareness and communicate climate change risks to marginalised children (urban poor and street children). *Third*, child participation in urban planning is limited, implying the need to include children as key informants to contribute toward climate change adaptation measures. With the wisdom from such observations, this work proposes a Child-friendly Blue Urban Framework customised for the SEA context and child-friendly city framework. This work hopes to encourage South-South dialogues among SEA coastal cities toward integrated coastal zone management that are both resilient and child-friendly.

KEYWORDS

Blue urbanism, child-friendly cities, coastal cities, Southeast Asia

1. INTRODUCTION

Many of the world's largest cities are located along the coast (Creel, 2003; Barragán and de Andrés, 2015). Coastal cities in Southeast Asia (SEA) are of particular interest because they face a double burden—climate vulnerability and crowding urban space. Most Southeast Asian coastal cities are low-lying coastal zones, which are disproportionately vulnerable to urban disasters and environmental hotspots compared to other water-based cities (Keogh and Törnqvist, 2019). Several recent extreme meteorological events in SEA have caused catastrophic human and economic losses in coastal areas, with adverse consequences including increased flooding, salinization, erosion, and wetland and biodiversity loss (Kelman, 2019; Kulp and Strauss, 2019). At the same time, the growing population of young people in Southeast Asia has gained traction in international policy-making to promote livability and sustainability in coastal cities (Asian Development Bank, 2016). Southeast Asian cities are predicted to increase in population by 520 million in 2050, with children comprising a significant portion of the population (Asian Development Bank, 2011). As such, the surge of urbanisation in SEA cities calls for attention as it amplifies risks to children. The young population of coastal cities face climate-related consequences and vulnerabilities arising from exposure to climate hazards, such as floods, storm surges, and coastal erosion coupled by a persistent spread of human settlements in high-risk urban areas (Neumann et al., 2015). In disaster-prone areas, children depend on other people for special care and supplies at times of crises and developmental, physical and psychological support in post-disaster contexts (Save the Children, 2015). The double burden of increasing population density and disaster risks put the children in SEA cities into a vulnerable position as urban dwellers. As such, coastal cities fall on a duty to accommodate the unique needs of children as most vulnerable citizens during disasters and in the long run, children will inherit such coastal urban spaces. Yet, while the ocean serves as an integral part of the urban experience of children in coastal cities, discussions on children's connection with blue spaces receive far less attention. This work aims to examine children's place in urban planning from selected Southeast Asian coastal cities and propose a framework for coastal cities toward a more child-oriented agenda, within their overall coastal city ideals. In doing so,

attention is given to the position of children as urban citizens, highlighting children's rights to the city. Through secondary content analysis complemented by relevant literature, this work provides a meta-analysis of the conditions by which children are included (or marginalised) in coastal cities of Southeast Asia. By drawing lessons from a comparative analysis, this article discusses urban trends in coastal cities issues that impact children, as well as underlying barriers and enablers for a child-friendly blue urbanism observed across the coastal cities in Southeast Asia. Finally, some pointers are provided that can serve as a basis for developing a child-friendly blue urban agenda.

2. LITERATURE REVIEW AND KEY CONCEPTS

2.1 Blue Urbanism in Southeast Asia

The notion of *blue urbanism* views the ocean as a non-human actor, which is "a common good that should be a shared aspiration of society" (Fletcher and Potts, 2007: 513). Non-human entities such as bodies of water, land and air enmesh with urban life through natural events such as disasters, crises and emergencies (Franklin, 2017). Blue urbanism places emphasis on both the environmental and social significance of the ocean in the process of urbanisation. It primarily fills the gap of urban frameworks that mainly foreground inland spaces and barely represent the nature of coastal cities. For instance, urban policymakers have typically employed the Brown and Green Agenda; the former represents pro-poor agenda for social justice issues in post-industrial areas, and the latter promotes sustainability in urban forest ecosystems (Du Plessis, 2015). Despite these achievements, the importance of oceans and marine environments in urbanity remain largely underrepresented. While there has been an effort to advance The Blue Urban Agenda to recognise the constant interplay between land and sea (Mycoo and Donovan, 2017), such literature mainly focuses on the Caribbean and Small Island Developing States (SIDS) in the Pacific while the Southeast Asian region remains at the margins.

Yet, the principles of blue urbanism resonate well with the history and development of Southeast Asian coastal cities. The ocean is part of a collective, environmental, transnational and transgenerational process of urbanisation in Southeast Asia, along with their distinct patterns of history and emergence of urban centers (Lieberman, 2003). For instance, maritime trading is a common trait of urban development in Southeast Asia (Suarez, 1999), which created urban centers or dominant metropolises (Kusno, 2000). Moreover, urbanity in SEA coastal cities share a built-in vulnerability arising from their exposure to physical hazards combined with a persistent spread of human settlements in flood-prone urban areas at risk. Disasters in developing countries, many of which are in Southeast Asia, will put more than 325 million people below the poverty threshold in large coastal cities by 2030 (Gitay et al., 2013). Thus, blue urbanism in Southeast Asia highlights that while urbanisation is a driver of economic growth, this also induces rapid concentrations of population in risk-prone areas and affects the natural wet/lowlands and drainage network. Such urban processes increase the vulnerability of children induced by urban coastal flooding (Zang et al., 2011; Wright et al., 2019). Further unregulated urbanisation leads to degradation and destruction of wetlands surrounding coastal urban agglomerations due to higher demand for land and subsequent territory grabbing (Seto et al., 2012), which in the past decades has already disrupted coastal ecosystem functions and programs for the urban and surrounding populations, in particular flood regulation (Hardoy et al., 2001; Costanza et al., 2008).

2.2 Blue Spaces for Children

When scaled to the lives of children, a key challenge is to build blue spaces that encourage children's involvement and participation towards blue urbanism. However, most literature on children's relationship with urbanisation and policies on urban safety for children mainly focus on land-based agenda. For instance, in the UN New Urban Agenda (2016), while there are child-specific action plans (e.g. Decade of Action for Road Safety), these plans do not cover the threats to children in coastal cities. Aside from disaster preparation, Southeast Asian coastal cities need stronger targeted search and rescue operations as response to modern-day piracy, from small scale sea-robber attacks to organised pirate gang hijackings (Mccauley, 2014). Moreover, although with the best intentions, most Child-friendly Cities initiatives (CFC) (UNICEF, 2004) mainly focus on streets and concrete in conducting placemaking activities for children. For example, non-government efforts (e.g. NACTO, 2019) developed a child-focused street guide to set a new global standard for urban streets designs focused on pedestrians, cyclists and transit riders. While these are all important developments in CFCs, coastal cities remain underrepresented. To be sure, there have been previous efforts in the scholarship on children's geographies to analyze the child-friendliness of cities in terms of policies, planning and design (e.g. Riggio 2002; Innocenti Research Center and Childwatch International, 2011; Carvalho and Koteng, 2014; Chan et al., 2016) The key areas that these instruments assess include criteria such as walkability and children's independent mobility in cities. The ability to compare different locations using CFC guidelines makes child-focused urban studies more commensurate in analysis due to its replicability and associated contextual descriptions about urban layout and form. However, there are limitations in terms of using the CFC guidelines since they are mostly inspired by Anglo-European settings. Using such standards may not be applicable to the complexity of the coastal cities across Southeast Asia. Children in Southeast Asia are more likely to suffer from economic, social and environmental disadvantages because the provision of basic needs such as water, housing, health and sanitation remain key challenges for urban policy-making. Whilst among the primary concerns of blue urbanism is intergenerational sharing of the ocean (Earle, 2010; Beatley, 2014), the literature that connects child-friendly cities and blue urbanism has received little attention, leaving discussions disjointed, along with weak connections between studies on child-friendly cities and coastal areas. What transpires from the urban approaches for children is that while the literature is rich in the interaction of children and the city environment, blue spaces remain at the periphery of discussions.

To address the literature gap, this paper draws together the principles of blue urbanism and child-friendly cities to map out the relationship between children and coastal cities. The relevance of creating a blue urban agenda inclusive of children is grounded in the two-fold anticipation of the effects of climate change and increase in children's population in urban areas. As such, to have child-friendly coastal urbanisation means to be future-oriented and far-sighted in terms of climate risks and sustainability. The connection between child-friendly cities and blue urbanism is critical because it addresses specific concerns on resilience of children in disaster-prone cities. Coastal communities are relevant because disasters disrupt the sense of routine and normalcy among children (Peek, 2008: 20), which emphasises the underlying child-ocean relationship constituted in the community. Although the issues raised about children's vulnerability can be considered universal issues of inequality, justice and fair distribution of resources, these concerns have unique implications for children in coastal environments such as the uncertainty of having permanent homes since coastal cities are sinking in Southeast Asia. In considering such issues, this work thus brings a child-focused geographical lens to coastal cities in order to reveal implicit tensions, and seeks to provide understanding and direction for further academic inquiry and key areas for research.

3. METHODOLOGY

For the purposes of this study, discussions mainly focus on Coastal Cities at Risk (CCaR), which refers to "contiguous area[s] along the coast that is less than 10 meters above sea level" (McGranahan et al. 2007: 17). This paper adopts a comparative approach to map out the shared contexts among selected Southeast Asian coastal cities and to flesh out cross-national contexts within which urban policy and planning practice take place. A comparative analysis is instructive to avoid repeating mistakes, missing out on lessons learned elsewhere in the region or inappropriately implementing foreign programs to local contexts (See Cropper, 1982; Masser, 1986). Each Southeast Asian country may assume similarities with existing urban frameworks abroad, as a matter of convenience or pragmatism, which overlooks the importance of regional distinctiveness. As such, this method provides some guidelines for research endeavors with respect to understanding where SEA cities resemble each other in relation to children's lives on the coasts, and where they are different. In view of blue urbanism and child-friendly cities framework, this paper examines the child-friendliness of Southeast Asian coastal cities through report analysis.

An important part of this comparative research work is the use of crosscutting and integrative themes that can show similarities (and differences) across Southeast Asian cities. The sample cities for this study is based on the identified "Global Future Cities" by the Global Future Cities Programme (GFCP) under the UK Foreign and Commonwealth's Prosperity Fund (UK FCO). In line with the United Nations Sustainable Development Goals (SDG) and New Urban Agenda (NUA), GFCP is an initiative that offers assistance to cities with high potential but face "considerable challenges such as rapid urbanisation, climate change and high and persistent inequality". Based on GFCP's assessment, five Southeast Asian cities were selected for this study because they have low-elevation coasts, increasing urban population and particularly interesting local contexts: Surabaya (Indonesia), Iskandar (Malaysia), Melaka/Malacca (Malaysia), Cebu (Philippines) and Ho Chi Minh (Viet Nam). Each city has published a City Context Report that reflects their own geographical vulnerabilities and policy approach that are instructive for understanding SEA cities. To provide the necessary comparative context, the reports from these five Global Future Cities were assessed by identifying which of their urban coastal practices are aligned with the principles of child-friendly cities based on UNICEF-recognised Child Friendly City vision and Framework for Action (2018). In this context, this paper analyses cross-national variations in city-level intervention plans and target impacts in terms of their potential implications on the young population:

- **Non-discrimination:** Every child and young person is valued, respected and treated fairly within their communities and by local authorities;
- **Participation:** Every child and young person has their voice, needs and priorities heard and taken into account in public laws (if applicable), policies, budgets, programmes and decisions that affect them;
- **Access:** Every child and young person has access to quality essential social services; a safe, secure and clean environment; and opportunities to enjoy family life, play and leisure

To increase the policy relevance of this research, it also takes relevant literature as a guide to the context of the five selected coastal cities to explore other potentially neglected discussions crucial to SEA coastal cities. The use of secondary sources is important for a substantive and context-based analysis and for fleshing out alternative perspectives in understanding urbanity at a regional level. There is no easy line to be drawn between opportunities and challenges in SEA coastal cities to be child-friendly. Nevertheless, this work contributes to discussions on Global South urbanism in terms of showing the shared aspects of SEA coastal cities and where they diverge in terms of urban contexts planning attached to the existing institutions, procedures and political actions.

4. RESULTS

4.1 Common Urban Contexts

Although there are many country-specific challenges in each Southeast Asian coastal city, there are two shared issues that transpired from the reviewed documents: demographic and topographic. Urbanisation in Southeast Asian coastal cities brings about various water-related vulnerabilities that directly or indirectly affect children. The common challenges among the selected coastal cities in this study include urban congestion near the coasts, leading to negative externalities such as flooding, water pollution, soil subsidence and urban runoffs.

Surabaya, Melaka and Ho Chi Minh are challenged by the interruption of socio-economic activities and damage to infrastructures due to flooding from the sea-level rise, especially in slums areas. This threat is amplified by a growing population and increasing human activities that cause such cities to sink faster than through only a geological process. Moreover, since coastal cities are unable to support the increasing urban population, the growth of slums persists in many flood-prone areas. Children are mainly affected in terms of their vulnerability to urban flooding (Vanos, 2015; Mavhura et al., 2017; Quintão et al., 2017). For instance, being the second biggest city in Indonesia, Surabaya hosts a dense population, whose activities lead to soil degradation (Imaduddinaa and Subagyo, 2013) that potentially jeopardises the environment where children live at present and in the long term (Rahmat et al., 2016). Meanwhile, there is a trend of a growing population accommodated in Ho Chi Minh’s highly flood-vulnerable areas as per its local government’s development strategy to attract more property investments into new districts (Duy et al., 2018). This results in an extension of water-protected areas in Ho Chi Minh, which increases the urban runoff (Vachaud et al., 2018). Speaking of attracting people, Melaka has reinforced its waterfront tourism industry as part of its image as a world heritage site (Erham and Hamzah, 2014). This tourism industry has attracted infrastructure development in flood-prone areas such as souvenirs and food shops near the fort (Syakir et al., 2017). Such an increase in population density in flood-prone zones makes children vulnerable because of human activities in an increasing urbanisation that results in soil subsidence. In cases of disaster, the social and psychological costs for children are high too, including being unable to play with friends, loss and damages in toys and personal possessions, and anxiety about uncertainties of the situation (Mort et al., 2016).

Cebu and Iskandar confront serious negative externalities of ocean pollution, together with an increased cost of traffic congestion, social and spatial segregation and environmental risks. Cebu’s exposure to hydrometeorological hazards such as flooding on top of challenges concerning “enormous amount of garbage that obstructs the flow of natural and [hu]man-made waterways” (ALMEC Corporation Oriental Consultants Global Co., 2015: 12). Such a condition exposes children, especially those living in slums, to “inadequate drainage infrastructure, sporadic and fragmented solid waste collection and the siloed approach to urban planning in producing and exacerbating flood risk” (Ramalho, 2019: 30). Meanwhile, Iskandar’s ecological challenges extend to Singapore’s borders. While Iskandar addresses pollution issues through government control over development and building plans and through facilitation of waste collection and water treatment, the city’s rapid industrialisation continues to pose a threat not only to its own urban space but also to Singapore’s coastal and marine environments (Cook and Hangzo, 2014). In the contexts of Cebu and Iskandar, children in informal settling conditions are particularly affected due to the hydro-hazards in the surface waters brought by the polluted ocean. Children living near the coasts are exposed to waterborne toxins and contaminants, hazardous sea waste, fecal infection and untreated stormwater which compromise their immune system (Soller et al. 2014; Jennings et al. 2018). This can be exacerbated by the urban poor settlements in the rapidly urbanising SEA cities, in which children live in crowded neighborhoods with sparse conditions (Dodman and Brown 2013; Purwar et al. 2020), which can easily transmit pathogen-laden water from septic tanks down to open channels and into street drains (Johannessen et al. 2014; Rothenheber and Jones 2018).

4.2 Beyond Water: Urbanisation Challenges in SEA Coastal Cities

Aside from water-related concerns, there is a clear variation among the urbanisation challenges faced by SEA coastal cities, which can distress children. Table 1 shows that different urbanisation issues exacerbate the already vulnerable conditions of SEA cities. For instance, Melaka and Ho Chi Minh share mobility and housing issues that affect young people in their daily lives. Cebu and Iskandar are faced with issues in land-use and distribution. Meanwhile, Surabaya has unique challenges, such as earthquakes and threats of volcanic eruption and typhoons altogether.

Table 1: Urban context of SEA coastal cities

Cities	Challenges	Intervention Plan	Target Impact
Surabaya	<ul style="list-style-type: none"> • Earthquake Risk • Moderate seismicity level 	<ul style="list-style-type: none"> • Setting-up a standard of urban transformation guidelines in neighborhoods • Earthquake Preparedness Strategy 	<ul style="list-style-type: none"> • Preparedness strategy for the poorest communities as they are most exposed to risks
Iskandar	<ul style="list-style-type: none"> • Rapid economic and population growth compromise sustainable urbanisation • Heavy real estate investments cause drastic levels of urban sprawl 	<ul style="list-style-type: none"> • Smart integrated mobility management system • Enabling data utilisation and data management for evidence-based urban and transport planning 	<ul style="list-style-type: none"> • Strengthened capacities of civil servants and increased citizens’ inclusion in planning and decision making processes
Melaka	<ul style="list-style-type: none"> • Exposure to environmental pollution induced by transport inefficiency • High levels of traffic congestion & burgeoning tourism industry 	<ul style="list-style-type: none"> • Green Transport Corridor Implementation Plan for sustainable travel • Heritage Area Integrated Mobility Plan to alleviate the heritage area from the many urban stresses 	<ul style="list-style-type: none"> • Better coordination and cooperation between government and its offices • Sustainable and resilient mobility options in favour of using public & non-motorised transport
Cebu	<ul style="list-style-type: none"> • Monocentric urban system concentrated in the center since neighboring cities’ topographies do 	<ul style="list-style-type: none"> • Cebu Data Hub to support the development of a data centre that enables data use across city 	<ul style="list-style-type: none"> • Sustainable urbanisation including land-use planning,

Cities	Challenges	Intervention Plan	Target Impact
	match the center’s urban development	departments and enhances evidence-based planning	transport planning and planning for climate change issues
Ho Chi Minh	<ul style="list-style-type: none"> Insufficient mobility: heavy reliance on motorbikes for transport and unaffordable fares Current database of drains and canals is not updated 	<ul style="list-style-type: none"> Smart ticketing system to optimise public transport Comprehensive GIS database for developing flooding models such as catchment, city and neighbourhood scale. 	<ul style="list-style-type: none"> Increased capacity, improved strategies and tools, especially for public transport and drainage system management

The quandaries faced by Southeast Asian coastal cities are also beyond climate-related concerns. On top of topographical vulnerability, the process of urbanisation itself complicates coastal cities in terms of congestion, mobility matters, issues on access to services and infrastructures and urban exclusions. When contextualised in children’s lives, such issues are entangled with children’s capacity to own their rights to the city due to the lack of safety, clean environment, fair access to urban amenities and efficient mobility. The problems in Surabaya, Iskandar, Melaka, Cebu and Ho Chi Minh are indicative that children are affected by issues of fairness in design or implementation of an inclusive urban planning concerning the distribution of spaces in coastal cities. This is especially relevant to children who reside in urban informal settlements in coastal cities, with crowded and deteriorated settings in which they live, play, and in some circumstances, work.

4.3 Urban Child-friendliness Comparison: Lessons and Challenges

The selected Southeast Asian coastal cities in this study have a mix of achievements and challenges in terms of an urbanism that is sensitive to children’s backgrounds and participation in urban design. Table 2 shows that some aspects of the Urban Transformation Plans in the five SEA cities recognise cross-cutting issues of children and youth with climate change, gender equality, human rights, and sustainable and inclusive economic growth. However, these cities also miss out on identifying specific needs of children and young people. The examination of the selected SEA cities unpacks the logic which fosters children’s relationship with their coastal city in terms of: 1) non-discrimination; 2) participation; and 3) access.

Table 2: Alignment with child-friendly cities principles

Cities	Non-discrimination	Participation	Access
Surabaya	Identification of child-oriented potential project partners (e.g. Save the Children)	Pilot projects and the community engagement with special attention to young people	Mainstreaming of environmental safeguards young people, gender equality, and Human Rights
Iskandar	Including young population in most integrated plans, frameworks and approaches to promote a more sustainable, resilient, and socially inclusive city	capacity building with data-related expertise to benefit young people citizen participation in developing municipal plans and decision making processes	Mobility designed “with special attention to the needs of those in vulnerable situations, women, children, persons with disabilities and older persons”
Melaka	Acknowledgement of public transportation issues among vulnerable citizens including children, the elderly, women, and low-income groups	Participatory planning to understand the different needs of diverse consumer groups including children and youth	Accessible and attractive non-motorised transport for all social groups, with attention to young people
Cebu	Interventions guided by mainstreaming of young people along with environmental safeguards, gender equality and human rights	Data hub with new protocols & data-gathering processes with disaggregated data to monitor improvements in equality of participation and access to opportunities for young people and women	Increased data availability for young people’s security
Ho Chi Minh	Transportation fares are assessed to ensure that the future ticketing system are inclusive of young people	Inclusion of young people in citizen participation toward developing municipal plans and decision making processes	Improvement of the public transport system for safer mobility, increasing young people’s accessibility to schools

First, the five SEA cities in this work have indicated non-discriminatory intervention plans for children but only Surabaya identified child-oriented organizations as partners. However, these cities do not show sensitivity to the heterogeneity and diversity of their young residents. For instance, children might have mobility needs that prevent them from engaging in resilience efforts. This potentially neglects marginalised children, excluding them from participation in the overall sustainable development efforts of the city. It is then crucial that urban policies produce frameworks that are sensitive to children’s diverse backgrounds in terms of religion, gender, disability and/or ethnicity.

Second, participation is stipulated in the intervention plans that include young people. Yet, there is a need to communicate marine and coastal science to children for an enhanced participatory planning in building resilience to the impacts of climate change and improving young people’s adaptive capacity through their own urban designs for climate change

adaptation measures. As aligned with the principles of child-friendly cities, participatory research with children is an explicit recognition of children’s special capacity to judge their experiences and express their own needs and of their peers. Aitken (2001: 8) notes that “children see things in environments that we may have forgotten to see, let alone understand”, making them capable of voicing out their views on urban disaster risk reduction (Dodman and Brown, 2013: 3).

Third, there are existing efforts to educate children to build resilience as preparations for disasters and for greater accessibility to urban facilities and spaces. However, there is a need to further strengthen raising awareness and communicate coastal-related climate change risks. While young people are included in the target population to benefit from intervention plans, no specific child-oriented guidelines were provided. For instance, the cities of Iskandar, Melaka, and Ho Chi Minh aim to improve transportation inclusive of vulnerable populations including children but there was stipulated plan for increasing the awareness of children about mobility issues.

However, due caution is to be applied in reading these urban contexts. The “Global Future Cities” reports do not take into account the distinction between the heterogeneity of potential impacts of interventions. For example, the reports did not take into consideration that mega-urbanisation plan and market-oriented development projects have fostered further gentrification by forwarding disaster and flood management plans that justify the displacement of slum dwellers in areas classified as “danger zones” (Ramalho, 2019). Property-led development of high-end residential real estate commodities creates a wider gap between classes (Chuangchai, 2019). Moreover, a given economic agenda can compromise the lives of children from boat-dwelling sea nomads, commonly known as Badjao in Southeast Asia. Urban industry presents territorialist policies that are intrusive of the Badjao culture of being “collectors of marine produce, guardians of sea lanes and knowledgeable pilots” (Andaya, 2019: 26). Children are especially affected as the economic agenda stigmatizes sea nomad children as “primitive, wild and uncivilised” (Hoogervorst, 2012: 250). Since these children are stateless, they are called “obstinate to the point of stupidity, dirty to the point of contagion and backward to the point of invalidity” in Southeast Asia (Hope, 2001: 140). This, nevertheless, highlights the relevance of further examining the diversity in SEA coastal cities with a focus on the lives of children who are socially marginalised and entirely lacking in resources and amenities in the metropolitan coastal zones.

5. DISCUSSION

5.1 Child-friendly Urban Agenda for Southeast Asian Coastal Cities

Despite their challenges, Southeast Asian coastal cities are not without potential for blue urbanism, such as being blessed with coastal resources and access to other rich natural amenities, making it easier for such cities to maximise these resources for children’s benefits. These cities also have substantial urban cores, with potential to prosper if sufficient urban size or density is sustained to provide spaces for various child-oriented urban features from educational public spaces to evacuation centers with children’s play spaces. Moreover, various non-government initiatives place emphasis on children’s participation in urban initiatives such as raising children’s environmental awareness through “children ecolife project” in Iskandar (Low Carbon Asia Center, 2013) or Surabaya’s “Child Friendly Village” with children and youth leading change in their communities (World Vision International, 2016). As such, this work proposes a **Child-friendly Blue Urban Agenda** for Southeast Asia, containing a child-focused adaptation plan for coastal urbanisation in SEA. Figure 1 shows a framework that integrates child-friendly city principles with the Ocean Cities Regional Policy Guide that is already being implemented in the Small Island Developing States (SIDS).

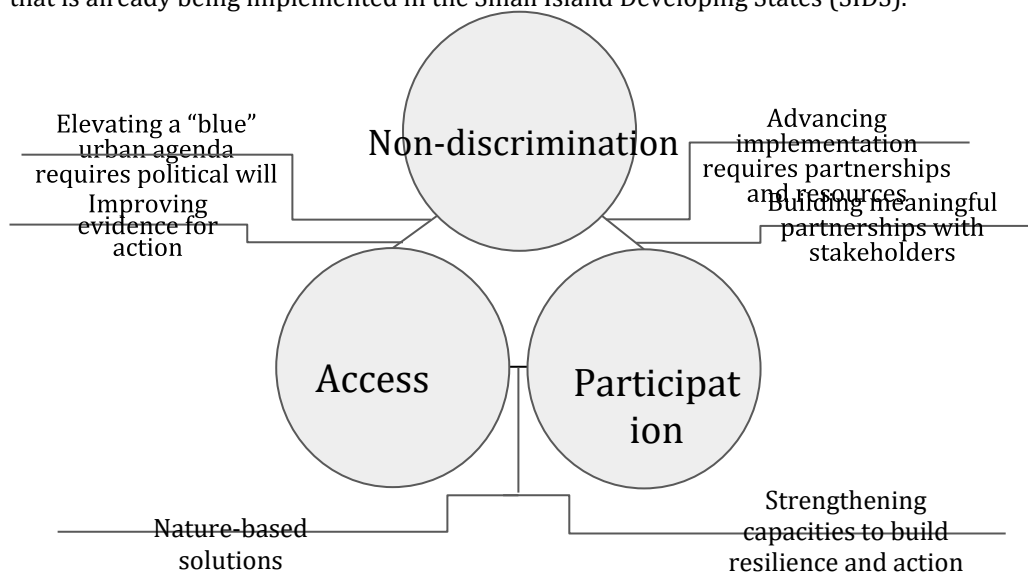

Figure 1. Child-friendly Blue Urbanism Framework

Child-friendly Blue Urbanism views children as solutions rather than problems in coastal cities. It is an invitation to put into dialogue the three main principles of child-friendly cities (in circles)—non-discrimination, access and

participation—and the principles of Ocean Cities Regional Policy (in branches), which are actions that bridge the overlapping aspects of two child-friendly cities principles. For instance, nature-based solutions (lower-left side) address the overlapping concerns of access and participation because of the wide accessibility of nature-based solutions, which also encourage the participation of more urban residents, including children. This results in an integrated urban approach for child-friendly and ocean-friendly urban development that is adapted to and sustainable in island systems, supporting regional and global frameworks for the overall aim toward sustainable development. Meanwhile, partnership with stakeholders (upper-right side) promotes a resilience strategy that is non-discriminatory and participatory at the same time, by taking children seriously as stakeholders, thus veering away from being a “city of elites” (Florida, 2017). This enables an urban policy that responds to the needs and demands of children for respect and dignity. All these point to a version of urbanity that views children as solutions rather than problems in coastal cities. It also opens the opportunity to craft an urbanity that is just & committed to children’s rights.

5.2 South-South Urban Dialogue

An urban agenda that places strong emphasis on children’s well-being in coastal cities is an opening for South-South urban dialogue among Southeast Asian coastal cities. The question that confronts Southeast Asian coastal cities, as well as all other archipelagic states, is how to balance ocean-related and urban development interests in a manner that protects the environmental capital for future generations and simultaneously facilitates development opportunities for children. In order to fulfill both environmental and human development principles, coastal cities in Southeast Asia need more coherent policy dialogue to address the increasing population of young people on urban coasts. The SEA cities presented in this study are at the frontier of both potential and vulnerabilities that could leverage a nuanced and unique strategy for a sustained and inclusive growth for urban residents. Moving forward, Southeast Asian cities are expecting new environmental challenges from the double burden of climate change and increasing children’s population in urban areas. A South-South dialogue among SEA cities is thus a promising agenda to foster exchanges of knowledge and experiences about (1) links between the role of children in the restoration of marine ecosystems; (2) the economic viability of child-friendly coastal and waterfront cultural heritage; and (3) the influence of age-related inequalities on the success of disaster response and overall coastal urbanity management. Ultimately, involving, training and nurturing the young members of coastal cities will further strengthen such South–South dialogue.

5.3 Key Areas for South-South Dialogue on Coastal Urban Policy and Research

In order for Southeast Asian coastal cities to make a real contribution to the future of Global South, it is important for urban planning and design to consider the issues unique to children for policy action and further studies:

First, it is crucial that policy research provides child-oriented frameworks that reinforce marine science communication with children, which emphasizes the role of children in the restoration of marine ecosystems. It is important for coastal cities to emphasise the value of coastal resilience through initiating science-based educational programs for children. For example, child-focused blue schools (Pittman et al., 2019) or ocean-related educational programs can enrich the child-ocean relationship (Mackintosh, 207; Puchol-Salort et al., 2021). Children are to be provided with a child-friendly system for enjoying the seascapes. Urban planning also needs to secure infrastructure systems that reinforce children to learn more about the marine ecosystems such as provision of child-appropriate materials for fishing. Equally important is the promotion of disaster response appropriate for children such as nature-based solutions, which offer alternatives over very technically demanding solutions that may not always fare well in coastal environments. This extends to disaster response strategies that work with, rather than against, coastlines’ physical properties (Olsen et al., 2005; Lambert and Oberhaensli, 2014).

Second, children need to be integrated in cultural and heritage-building endeavors of coastal cities. This entails actively seeking children’s views on building and preserving the culture of their waterfronts and seascapes. An important aspect of this is a continuous performance assessment of the Southeast Asian “Global Future Cities” from the stakeholders’ perspective, with special attention to children’s participation. For instance, child-oriented participatory appraisals in coastal cities would be valuable to how they perceive the heritage of coastal cities and examine the suitability of street signs, public maps, and disaster resilience instructions/materials toward this goal. With their ecological competence growing up, together with their unique spatial experience (Chawla and Helft, 2002; Karsten, 2005; Freeman et al., 2015), children are able urban citizens to participate in collaborative coastal community-led planning activities to demonstrate the importance of their unique cities.

Finally, future research is encouraged to focus on how children’s backgrounds and the inequalities they carry shape children’s urban needs. City policies, finance and programmes need to come together with proactive responses to disparities in children’s lives in order to ensure inclusivity of the city and to address “recognition gaps” or the deprivations felt about one’s own worth (Lamont, 2018). Data on the intersectional deprivations of children related to their diverse backgrounds in terms of gender, ethnicity, and/or disability among others should assist local city authorities, urban planners, development agencies, and various stakeholders altogether to put weight to the needs of underprivileged and vulnerable children not only in terms of protection against risks but also children’s overall empowerment.

6. CONCLUSION

Imagining the future of urbanity in the Global South is incomplete without taking into consideration marginalised populations in vulnerable areas such as children residing in coastal cities. As presented in this study, using a child-

oriented approach in the context of Southeast Asian coastal cities is instructive to understanding urbanism in the Global South and the struggles it seeks to lend weight to. The identified challenges and potentials in each SEA city shape an urban fabric characterised by the urban sprawl combined with their geographic vulnerabilities of coastal cities. This work has shown how the current dynamics between the premises of child-friendly cities and blue urbanism encompass and direct the make-up of children's relationship to the ocean. The child-friendliness of coastal cities in this study is uneven. Despite the existence of good practices, there are recurrent challenges and limitations in respect of child-friendly sites standards that undermine their effectiveness in practice. This paper has also presented a framework for understanding children's place in coastal cities, weaving together some of the most pressing issues surrounding child urban vulnerability identified in the literature. Salient issues such as flooding and ocean pollution in SEA coastal cities are yet to be addressed through policy and research. Overall, however, Southeast Asian coastal cities have a potential to accommodate the visions of child-friendly cities at different levels.

The challenges of urbanisation in Southeast Asian coastal cities are massive but so are the opportunities. As a way forward, this work encourages the need for dialogue among SEA coastal cities to learn from each other. Standalone efforts to address climate-related risks for children living in coastal cities are less optimal than integrated coastal zone management that are both future-oriented and child-friendly. The insights generated in this work suggest that the issues at stake for children can undermine the current potential of the emerging child-friendly blue urbanism agendas in improving outcomes for children in coastal cities. Applying the wisdom gleaned from examining Surabaya, Iskandar, Melaka Cebu and Ho Chi Minh, this work hopes that a child-friendly blue urbanism agenda not only provides valuable insights for further research endeavors but also will help inform local governments and international networks in Southeast Asia as well as urban citizens at large towards improving children's conditions unique in coastal cities. Analysis in this work hopes to propel coastal urbanity in order to be "exposed for investigation and scholarship as it is made and remade, or via contestations" (Pierce et al., 2011: 61). Otherwise, the urban future in the Global South will remain uneven and only favorable to those whose present conditions are secure.

**CREATING AND STRENGTHENING COMPARATIVE ADVANTAGE: THE
REGION OF THESSALY – UNIVERSITY OF THESSALY COOPERATION
NEXUS**

Maria Adamakou, Dimitris Kallioras, Spyros Niavis, George Petrakos

University of Thessaly, Greece

ABSTRACT

The literature on the role of universities on regional performance is broad and diverse, and some notable theoretical approaches have been developed over the years. The “entrepreneurial” university model attributes to universities the role of commercializing scientific knowledge. The “regional innovation system” university model perceives universities as carriers of innovation. The “mode 2” university model suggests that universities must be engaged in collaborative research with other organizations towards producing connecting-to-the-environment knowledge. The “engaged” university model understands that adaptation of university functions to regional needs. Looking at the other side of the theoretical spectrum, the literature on the role of regions on academic performance is scarce and no body of literature has been formed. Apparently, scientific knowledge, up to now, seems to perceive the linkage between regional performance and academic performance as a one-way – and not as a self-sustained - process.

The paper perceives the Region of Thessaly – University of Thessaly cooperation nexus as a means for creating and strengthening comparative advantage. Under this perspective, the paper scrutinizes the interplay between regional performance and academic performance. To this end, the paper conducts a pilot questionnaire survey on the basis of structured (on the 1-5 Likert scale) questions that cover both the topics already accentuated in the literature and some equally important topics that need to be analyzed. The survey is addressed to the actors that are (or need to be) engaged in the Region of Thessaly – University of Thessaly cooperation nexus. The findings of the paper provide valuable insight to both theory and policy-making.

**TRACING THE CHANGING PATTERN OF LOCATION AND
AGGLOMERATION OF MANUFACTURING ENTERPRISES IN GREECE: AN
APPLICATION OF POINT PATTERN ANALYSIS**

Yannis Psycharis, Anastasios Karaganis, Leonidas Doukissas

Panteion University, Regional Development Institute, Greece

ABSTRACT

The aim of this paper is to estimate the trends of location and agglomeration of manufacturing activity in Greece during the period 2002-2018. The location of manufacturing enterprises and the composition of manufacturing activity in the Greek regions has undergone important transformations during the last two decades. The introduction of euro in 2002 and the economic crisis in 2008 have signified important turning points that have affected/changed the evolution of manufacturing activity across time and over space. The analysis is based on a novel dataset that includes the point geolocations of manufacturing firms in Greece that have been classified into NACE-2 codes. The estimation of spatial agglomeration of industrial activity is measured by the spatial agglomeration index (SPAG) which is a recently introduced distance based technique which provides an exact and unbiased analysis of the spatial structure of the distribution of economic activity (Kopczeska et al, 2019). Results indicate the changing regional pattern of agglomeration of manufacturing enterprises and they are relevant to the location theory and the regional policy literature.

ECONOMIC CRISIS AND RESILIENCE AT LOCAL LEVEL IN GREECE

Panagiotis Artelaris¹, Dimitris Kallioras², Anastassis Katsinis³

¹Harokopio University of Athens, Greece. ²University of Thessaly, Greece. ³Joint Research Centre (JRC), Italy

ABSTRACT

A new strand of literature, known as regional resilience, has gained prominence in spatial economics in the recent years. Regional resilience has attracted academic attention in the current unfavourable economic environment mainly because of the generalised sense of uncertainty and insecurity, necessitating the search for formulas for adaptation and survival. The main aim of this study is twofold: firstly, to evaluate and map the impact of the 2008 economic crisis at the municipal level, comparing the income distribution pre and post crisis; secondly, to examine the main determinants of economic resilience among the Greek municipalities. As a result, a range of economic and other variables are included in a spatial econometric model built investigating several important hypotheses. The data used in this study were obtained from a relatively new database, including annual taxable household income at the micro-region level (zip codes). The results clearly point at very heterogeneous resilience for the Greek municipal level yielding critical policy implications.

EXPLORING POLARIZATION AND SOCIAL SEGREGATION TRENDS IN GREEK METROPOLITAN AREAS: THE CASE OF ATHENS

Yannis Psycharis, Anastasia Panori, Panayotis Pantazis

Panteion University, Regional Development Institute, Greece

ABSTRACT

Studies on polarization and social segregation are widespread in international literature, given that multi-developmental changes that are taking place within urban areas, influencing the evolution of income inequalities. This paper analyses the polarization and segregation trends in Athens during the period 2004-2015. The analysis is based on a novel database that utilises individual household data from the EU-SILC and declared income postcode data from national official sources. The paper applies spatial segregation indices in order to explore the evolution of segregation and polarization trends before and during the economic and fiscal crisis. Mapping declared income in the broader metropolitan area of Athens shows distinct patterns of high and low income concentrations. Our analysis shows a division between centre and periphery with local differentiations between north-south, particularly in the eastern part of Attica. More specifically, higher declared incomes are concentrated in the north-eastern part of the metropolitan agglomeration, in the centre of the Municipality of Athens, in the southern part and in an enclave that includes Psychiko and some zones of the Municipality of Filothei. Lower incomes cluster in the western part of the Municipality of Athens, a number of zones in the Municipality of Agios Ioannis Rendis and Tavros as well as parts of the north-western zone comprising. There is limited “mobility” of the spatial analysis units in the income hierarchy. Areas at the upper end of the distribution have a very high probability to stay there or move upward, while low-medium areas are likely to “move” either higher or lower. Economic crisis has intensified the segregation trends. Results are relevant to public policy and inclusive growth and development.

DISCONTENT IN THE “PERIPHERIES”: AN INVESTIGATION OF THE RISE OF POPULISM IN ITALY

Giulia Urso, Alessandra Faggian, Alessandro Palma

Gran Sasso Science Institute, Italy

ABSTRACT

The concept of periphery is not an absolute one. It goes beyond the mere interpretation in terms of geographical distance from a centre and of location on the fringes of a country or a region. It incorporates a “relational” character that is implicitly characterised by connotations of power and/or inequality. Therefore, peripheries can be actively created as an outcome of shifts in economic and political decision-making at various scales.

This study explores them from what we deemed to be a powerful lens nowadays, i.e. the growth of populism, and the discontent, as the perception of being too far away in relation to sources of power, it expresses. The recent populist wave has in fact brought to the fore the issue of peripheries as areas “left behind”, striking back in the ballot boxes.

In our paper, in order to investigate the role of different dimensions of peripherality and their changing geographies on populist voting patterns, we analyse the growth of discontent between the two last Italian general elections (in 2013 and 2018). To this aim, we first consider a spatial dimension of peripherality, i.e. the geography of access to services of general interest. Second, we explore some factors which might be associated with a condition of peripherality, meant as marginality. We find that geographical peripherality is a key factor in explaining the growth of recent Italian discontent with more remote municipalities driving populist voting. However, sources of resentment, very different in nature, are also present in another periphery, within cores, i.e. urban belts, where some conditions of social or material vulnerability, likely to be related to a condition of feeling “peripheral”, are strong predictors of the growth of populist parties.

THE RELEVANCE OF EUROPEAN FUNDING IN BUILDING REGIONAL ECONOMIC RESILIENCE

Liviu-George Maha, Elena-Daniela Viorica, Diana-Elena Abalasei, Lucia Ciubotaru

Alexandru Ioan Cuza University of Iasi, Romania

ABSTRACT

An important objective of the European funds is to enhance economic development and to increase competitiveness of the European markets so that the regional economic disparities between the Member States are likely to lessen. These economic disparities are more visible for the borderline regions, as they are more likely to suffer from less administrative, economical or technological progress. The objective of this paper is, firstly, to estimate the effects the European Funds granted from the European Union have on the regional economic resilience, and secondly, to evaluate if the regional disparities between the borderline regions and non-borderline regions are likely to reduce under the influence of these funds. Considering the time period 2007-2020, which covers the budgetary cycle 2007-2014 that was hit by an economic crisis, whose effects are still visible today, a panel regression model will be estimated in order to assess to which extent the European funds contributed as a support-factor in building regional economic resilience of the European Union (EU). A visualization tool to spatially analyze the regional disparities will be further employed to assess the dynamics of the borderline regions in terms of economic development generated by EU funding. The results will add additional information to a body of research with inconclusive results, which did not manage to decisively state that this EU project effectively ensures a long term and sustainable economic development.

CAN CITIES FROM PERIPHERAL REGIONS BECOME BOTH RESILIENT AND SUSTAINABLE?

Alexandru Banica^{1,2}, Karima Kourtit³, Peter Nijkamp³ Corodescu-Rosca¹

¹Alexandru Ioan Cuza University of Iasi, Romania. ²Romanian Academy, Iasi Branch, Romania. ³Open University, Heerlen, Netherlands

ABSTRACT

In a world in which more and more turbulences occur and risks are more present than ever, resulting in increasingly numerous natural and human-made disasters, cities and metropolitan areas find themselves in a difficult spot. The risks become higher if one refers to cities that are located in less developed or peripheral regions. They should make serious adjustments to simultaneously achieve a good resilience capacity (i.e. ability to resist and restore after destructive/damaging events), while also reducing vulnerabilities and ensuring present well-being for the population and long-term sustainability (i.e. maintain the main functions and resources to a degree that satisfies not only the present but also the future needs of society). Our approach intends to test, in an international context, whether disasters can become a "blessing in disguise" by looking at some extreme events that occurred in metropolitan areas and changed the approach of urban planners and institutions in peripheral regions. Within a selection of most damaging natural and technological disasters that occurred in some of the most remote or less developed regions in the world, we first correlate data on the losses with resilience indicators (preparedness capacity, coping capacity, and response capacity, Resilient city index), quality of life (Human Development Index) and sustainability (sustainable development index and environmental footprint of cities) – before and after the disaster. The statistical analysis using, classical methods but also machine learning techniques results in a typology that reflects the relation between disaster occurrence and the overall outcomes. Furthermore, taking into account one case study for each category, we try to look at the conflicts between the goals of the comprehensive sustainable development approaches and the more pragmatic purposes of resilience approaches. Examples of planning issues are taken into account and analyzed from a comparative perspective by using qualitative methods. An institutional and administrative approach taking into account the strategies and the overall approach on planning metropolitan areas leads us to insightful conclusions on good and bad practices that could conciliate short term purposes of resilience with long-term sustainable development goals in vulnerable urban areas from peripheral regions.

BUILDING RESILIENCE BEYOND THE EU'S EASTERN BORDERS. EU ACTORNESS AND SOCIETAL PERCEPTIONS IN UKRAINE AND REPUBLIC OF MOLDOVA

Gabriela Carmen Pascariu¹, Loredana Maria Simionov¹, Nadia Bureiko^{2,3}

¹Alxandru Ioan Cuza University of Iasi, Romania, Romania. ²Foreign Policy Council 'Ukrainian Prism', Ukraine.

³University of St Gallen, Switzerland

ABSTRACT

The resilience approach as EU's newfound paradigm places societies and communities at the heart of its interactions with external partners, and especially with its immediate neighbours. As such, in order to enhance its resilience and that of its neighbours, the EU has turned its attention from state to society, from a general top-down to a bottom-up approach. The success of this to a certain extent depends on the local trust in the EU's performance as a transformative actor. The present paper inquires how the EU actorness is perceived by citizens beyond its eastern borders, mainly in the border regions of Ukraine and Republic of Moldova and explores the implications for building a more resilient society in the Eastern neighbourhood. We argue that in spite of the EU's attempts to enhance its actorness in the region, to bring about reforms and promote European values, the positive citizens' perceptions and the overall awareness of the EU's impact are still modest, thus limiting EU's capacity to act towards building a 'stronger and more resilient society'.

SKETCHES VERSUS THE NEW TECHNOLOGY'S INNOVATION IN THE CREATIVE PROCESS

Ana Moreira da Silva

CIAUD, Lisbon School of Architecture, Universidade de Lisboa, Rua Sá Nogueira, 1349-069 Lisboa, Portugal.
anamoreiradasilva@gmail.com

ABSTRACT

The conceptual processes of most designers are based on the development of ideas through its expression in sketches. There is a deep relationship between sketches and creativity. As the designer has to conceive and develop solutions for specific problems which may be of different nature, sketches may present themselves as an operative support for creative reflection, problem solving and critical analyses within the several phases of the design process. Sketches arise from the human imagination and result from a constant iteration that culminates in creative approaches. Despite the innovation that new technologies introduced, sketches are universally used as a tool for thinking, planning, and exploring concepts. It is applied by a wide range of people including scientists, mathematicians, engineers, economists, publicists and teachers to help explain, provide instruction, or to register the evolution of ideas. One of the main questions we want to discuss and to find answers is if the nowadays wide use of new technologies doesn't invalidate the important role played by sketches, within several professional areas, as a stimulating instrument when sketching the first ideas and as a critical verification of the solution hypotheses.

KEYWORDS

Creative Process, Design, New Technologies, Sketches

1. INTRODUCTION

This paper stems from a current post-doc research project motivated for the need to produce more knowledge about the Drawing relevance in the conceptual process in Architecture and in Design.

The essential question of determining whether sketches will be the key of the design process, constitutes the starting point for this postdoctoral research project on the use of freehand drawing in design practice.

Through the study of several statements from various authors we intend to investigate not only the permanence of sketching important role since mid-last century to present, but also its possible use in the future. From this theoretical approach we also intend to verify the sketching relevance, despite the paradigm changes that emerge from time changes. We also want to discuss if sketching may serve as mind stimulus during the creative process phase and to verify its permanence and importance in different areas, although the use and the progress of the new technologies.

2. SKETCH DEFINITION

The word Sketch, deriving from the Italian *Schizzo*, has its origin from the Latin *Schedium*, which derives from the Greek *Skhedios*, both meaning 'done extempore': done without preparation, improvised. "Moreira da Silva (2010)"

According to the Oxford English Dictionary the word Sketch means: "a rough or unfinished version of any creative work", which directly implies creativity.

In the Cambridge English Dictionary: "a simple, quickly-made drawing that does not have many details", relate to its scarce rigor or definition.

So the word Sketch describes a quickly-made freehand drawing and its intention is to give a general overview or the guidelines of something, in relation to the intended final shape or figure, a rough drawing representing the chief features of an object or idea and often made as a project preliminary study.

Sketches are synthetic drawings, executed freehand, where we represent ideas that have not yet been fully defined. Sketches emerge from the need to fix those first ideas that occur in the project act and that are manifested through the first signs, coming from the thought, traced on a sheet of paper. A sketch can be like the 'thought of the hand', the hand as an extension of each thought fixed at the moment by the gesture that registers it. "Moreira da Silva (2017)"

3. SKETCHES IN THE CREATIVE PROCESS

A two-way link is established between the sketches and the mind, between thought and the action of representing it, and at the same time the character of the creative process is evidenced by allowing its self-exploration and self-evaluation. This last characteristic is important since it allows or encourages the method of qualitative approximation as it constitutes a vehicle for new modifications that optimize the original idea and open ways for obtaining new ideas.

The images are not created by the sketches, they only allow them to emerge from the ideas, creating the right environment for them to be recognizable and providing a means for their expression and for their realization.

Sketches arise from the human imagination and result from a constant iteration that culminates in the creative solution, the transposition and dissection of the mind's image generates abstract or concrete drawn forms. Reflection and experimentation through sketching, approximates the reality of things, recreating them. From sketches are born more sketches, from sketches are born things, in a cognitive iteration. Crucial reinterpretations for the advancement of the design process, especially when sketches are perceived and reconfigured for new interpretations. We can see that there are several types of sketches, according to its purposes: 'the thinking sketch', 'the talking sketch', 'the storing sketch'. "Van der Lugt (2001); Tversky (2009); Goldschmidt (2014)"

A sketch assumes a peculiar and determinant character in the conceptual/creative process, giving thought the possibility of transfiguring itself through graphics that reveal the ideas that give rise to it. It allows the anticipatory structure and the envisaged solution to be recognized.

Sketching, not only makes the author's idea become visible, which until then was purely mental, but also makes possible, through graphic signs, quick and decisive ones, which help him/her to better clarify the design subject, its transformation into a project.

Sketches allow concepts and ideas to come out. If they were impossible to be formalized through words, once fixed on a sketch, become analyzable, recognizable, evaluable, modifiable, that is, became capable of being explained verbally. The main objective of this type of drawing is to fix the idea, the design global image 'in thought', which the author gradually matures. The sketch works as a bridge between the abstract world of the imaginary and the concrete material explanation through graphic synthesis.

The act of sketching enables that reasoning and thoughts we have developed can be gradually translated and decoded throughout the drawn lines. Somehow we debate ourselves with our own ideas in this quickly-drawn lines. We scratch, we draw, we overwrite features, we configure, we represent, we visualize, giving physical form to our thoughts. There is a direct link between the thinking and the hand that performs the sketch. The hand as an extension of the brain, of the reasoning. "Moreira da Silva (2017)"

Embryonic ideas are quickly thrown onto the sheet of paper for primary analysis, before they disappear, relieving limited memory resources, leaving room for reflection and detailed observation of ideas, validating or discarding them, generating a constant flow of more ideas. "Barreira da Costa (2019)"

The moment when sketches are carried out is characterized by a propitiatory capacity for reflection, which allows and encourages the elaboration of new ideas.

We can conclude that it is important to recognize a creative system within the act of sketching that is part of the author's self-investigation process about his work.

4. SKETCHES TRANSDISCIPLINARITY AND THE NEW TECHNOLOGIES

Sketching has been traditionally used over the centuries, so it is often seen as an outdated method for design, as tradition can be thought as a strong and unalterable link to the past. In this sense sketching is often considered outdated, but nowadays its use has evolved and expanded, being widely used by various areas of knowledge and professional practice, surpassing the previous and restricted use only by areas linked to the project such as architecture, engineering and design.

Many creative professions use sketching as a tool in their design process, from UX designers to movie directors, great ideas start with simple sketches. One thing many share in common is the simplicity and usefulness of sketching.

Hayden Mills presents a few professionals, not only designers, which use sketching to help them brainstorm new ideas and better communicate with one another:

a) For civil engineer Peter Carrato, hand sketching is a means to clarify his thoughts. Ideas can be tested, relationships explored, and details developed. Without sketching, Carrato considers that a structural engineer may be at a loss to perform critical structural engineering thinking;

b) Designers at Disney Pixar Films say that Pixar's artists use traditional media to draw the initial design of the creation of characters or a new world for a movie. At Pixar, despite being a high technology company, an artist typically does hundreds, sometimes thousands, of sketches before they are satisfied with the design of their new character or a new movie environment. They also say that sketching out a storyboard is a way to write a story using pictures instead of words and that achieves the goal in a better and more practical way;

Figure 1: Pixar artist drawing a new world for a movie

(<https://medium.com/@haydmills/11-creative-professions-that-use-sketching-as-a-tool-in-their-design-process-and-why>)

- c) Industrial designer Adam Fairless, states that a sketch conveys the designer's ideas without being overly worked. Freehand drawings permit to get several good ideas down quickly and relay multiple thoughts and ideas at a glance;
- d) Nike footwear designer Tinker Hatfield, says he adopted sketching as a primary tool for moving through the early phases of a project. For him one sketch leads to another and he feels like having a conversation with himself;
- e) UX designer Jared Spool, says that words are powerful, but sometimes they do not clearly describe what we are imagining, but a sketched diagram usually does this and even more quickly;
- f) Mike, woodworker and carpenter, says that his sketchbook is where everything begins, where he works out designs and proportions, asks questions and solves problems;
- g) For graphic designer Aaron Draplin, sketching is meant to be fast, fun, and free, his hand is much freer than it would be with using Illustrator;
- h) Movie director Tim Burton, says that sketching helps him to hone in on his thought process, which tends to be all over the place; sometimes a doodle will remain, drawing it over and over until finding his own meaning.

Figure 2: Movie director Tim Burton's storyboard sketches

(<https://medium.com/@haydmills/11-creative-professions-that-use-sketching-as-a-tool-in-their-design-process-and-why>)

From these examples, presented by Hayden Mills, we can conclude that the use of 'traditional hand sketching' can be transdisciplinary and used in many new professional areas, even those more connected to new technologies, opening useful and innovative paths to the 'old drawing by hand'. "Mills (2017)"

The fact of using new technologies does not invalidate the vital role played by freehand drawing, both at the initial stage of recording the first ideas and during their subsequent development and in the critical analysis of the different hypotheses. "Moreira da Silva, (2017)"

To John Roome it is, in fact, the possibility of cross-fertilization between traditional and digital platforms that is interesting, beneficial and innovative. "Roome (2011)"

People have been sketching for a long time, but, with the advent of digital drawing tools, Hayden Mills tries to answer why some people still prefer to sketch with a pen, or a pencil on a paper. He concludes that, in the first place, sketching gives a place to start: many creative professionals begin with a pen and paper. The process of thinking through sketching

helps them getting their creativity flowing. Besides, it helps everyone to document the process. Early design process ideas come and go, sketching forces to shift the ideas into paper, helping to document those ideas in real-time as they arise in few seconds. Documenting the different iterations makes it easier to visualize, allows to see what was explored and, more importantly, what was not explored yet. “Mills (2017)”

Embryonic ideas are quickly thrown onto the sheet of paper for primary analysis, before they disappear, relieving limited memory resources, leaving room for reflection and detailed observation of ideas, validating or discarding them, generating a constant flow of more ideas “Barreira da Costa (2019)”

In summary, sketching is a very simple tool used by many professionals. A sketch helps to communicate visually what is in our head, a method to help moving from one idea to the next while keeping everyone on the team on the same page, it also can help professionals advance and inspire future innovations.

For Joshua Brewer, senior designer at Twitter and UX designer, the real value of sketching is that it allows you to explore and refine ideas in a quick, iterative and visual manner. Rapid ideation flow and interact, layout and hierarchy can be quickly established, rearranged or discarded, all of this without ever touching a computer. “Mills (2017)”

We all drew with crayons when we were children. Sketching is a universal language that helps us understand one another, explaining what words sometimes can't. Sketching breeds clarity. The only way to for others to clearly see what is in our mind is by showing them visually. Coming to a meeting with sketches, communicates to the rest of team that the idea is not finished. This promotes conversation and collaboration. It helps getting others involved in the design process.

In so many different professions, even not related to design like biologists or marketers, salesmen or teachers, no one can't share information and interact with any other way so easily than with sketches. People can draw on top of sketches and add information or new ideas or solutions to them. It can be a great way to garner feedback from others. With sketching, nobody have to learn any fancy design tools. It is enough to put a pen to paper or marker to whiteboard and let the ideas flow. It allows everyone in a team to work together regardless of title or position. This can be considered as an innovative approach to the traditional use of sketching.

Nowadays, with new agile technologies, it is fundamental to enhance the design process and make it leaner. And it is even more important that this process leads to a successful product.

Sketching can be a fundamental step in any design process. It pushes designers to step away from their desks and work with different tools. Furthermore, this can become a team's exercise where non-designers (developers, product owners, project managers, etc.) can contribute with their ideas and input from an early stage. “Carqueija (2016)” Once on paper, the ideas are ready to be tested with other teams, stakeholders or even potential users to feed into initial designs and help iterate.

Lean User Experience has been a much used design methodology in the last few years. Lean is about developing fast, through iterations, with multidisciplinary teams working together throughout the entire project. “Dourado (2014)” The focus of Lean UX is creating value for the customer while reducing waste, avoiding anything that deviates the focus from the design and the product being built. According to Andreia Carqueija it is imperative that the multidisciplinary team becomes more agile but they also need to be allowed to easily testing ideas. Even with a limited timeframe, the designer should be able to quickly put together some designs for early testing. And this is where sketching can be applied. “Carqueija (2016)”

So we can conclude that sketching can be useful in multidisciplinary team design even when applying recent innovative methods like Lean User Experience methodology.

According to José Silva et al. although drawing is being sometimes considered as an expressive tool far from the digital universe, it allows a holistic perception of information, connecting associations in a timeline map, presenting the various options along the project development. In addition to its representation possibilities, sketching gives access to a deeper learning, through the interactions and evolutions of a certain problem challenge. “Silva et al. (2017)”

Drawing holds, in itself, the making visible quality of the whole mental process underlying the conceiving stage, from the first sketches of a vague idea to the object to create final solution. Sketch's transcendent importance lies on the capacity it gives the designer to materialize abstract conceptualizations and to create the ideational basis for design creations. “Moreira da Silva (2017)”

Mike Rohde states that the real goal of sketching is about generating ideas, solving problems, and communicating ideas more effectively with others, particularly in an age dominated by digital media. For Rohde, sketches can work like a visual thinking tool as a primary language for capturing thoughts, exploring ideas, and then sharing those ideas. He gives an example where he used sketches for redesigning a Mac application. He says that sketches allowed him to visually capture and share his design ideas, making possible that he was able to show to the developer a variety of options for UI controls and structure before moving to the visual mockup and prototyping stage, saving time and efforts. “Rohde (2011)”

Figure 3: Pencil sketches with notes began Rohde’s process of redesigning the user interface of a Mac application.

(<http://alistapart.com/article/sketching-the-visual-thinking-power-tool>)

Sketching survival facing nowadays artificial intelligence growing importance is one of this research issues, as it can proves the innovative sketching ability to adapt to new paradigms. As we have already testify, even in the professions basically linked to artificial intelligence technologies, sketches continue to be successfully used during their creative process stages.

Frank Gehry is one of the contemporary architects who most uses new artificial intelligence technologies to achieve his final work, however, he always uses sketches to fully develop his creative ideas.

Bill Buxton, principal researcher at Microsoft, describes the process as a quick way to generate and share many ideas in such a way that this ideas can generate even more ideas. “Buxton (2007)”

The new information technologies offer new ways, allowing to save time and facilitating many of the daily practice tasks, even becoming indispensable in many work phases. However, they do not replace sketching, which continues to assume a ‘chameleon’ shape during the various historical periods, in a constant time adaptation, and, especially by incorporating a critical dimension in the creative process. “Moreira da Silva (2017)”

According to Peter Hamilton, the value of sketching is associated with the knowledge that hand-drawing is the essence of creativity and its measure would lie in the individual ability to continuously express and create, using self-exploration and creative thinking through the process of drawing, linking together interesting ideas and technical know-how, enhanced by assistance and interaction with new technologies. “Hamilton (2009)”

Pedro Domingos in his recent book, *The Master Algorithm*, talks about the extraordinary advances of Artificial Intelligence and its promising future, but as he mentioned throughout this book, Artificial Intelligence is developing in the direction of Automatic Learning, but not yet capable of creating something new which is the very essence of Creativity. Domingos is a fellow of the Association for the Advancement of Artificial Intelligence and Professor at the Washington University, being an expert in this subject. “Domingos (2017)”

Automatic Learning based on Artificial Intelligence can enlarge our data and integrate multiple learning components, and so, can be very useful for generating creativity through knowledge, but still, creativity is something more beyond knowing, it is a special ability that, for now, is an intrinsic part of the human being. Creativity is something that big data does not explain, but, however, machine learning can help us to build more accurate fundamentals and research findings for our creative works. “Moreira da Silva (2018)”

Figure 4: Napkin sketches about financial investment strategies by Carl Richards, financial planner and finance advisor

(<https://www.businessinsider.com/carl-richards-napkin-sketches>)

Countless great ideas, in many professional areas, have recently started out as napkin sketches. Facebook’s data center electrical system sketches by Jay Park where made on a paper napkin. The first ideas of the recent Louvre Abu Dhabi started with a simple sketch on a restaurant paper napkin, says the author, the French architect Jean Nouvel. “Moreira da Silva (2018)”

One of the advantages of sketching is that we can sketch everywhere, anytime with any medium in many different supports. We don’t need special conditions for sketching so we can sketch everywhere and we can do it using pencils, pens, markers or chalk, on any kind of paper, on sketchbooks, whiteboards, chalkboards and even new surfaces like tablets.

Mike Rohde says that he found the iPad an interesting tool for sketching, especially with the advancement of software like Sketchbook Pro. He usually uses a Griffin Stylus for iPad for sketching, sometimes he also uses his own fingers which he considers to work reasonably well for loose sketch work too. “Rhode (2011)”

Figure 5: Using tablet tool for sketching

(<https://www.google.com/search?=design+sketches+ipad&tbm=isch&source>)

Thanks to the new technologies we can easily use a tablet as support for our drawings. However, when sketching, in many different supports even the innovative ones, the hand is still working as an extension of our human brain.

The act of sketching allows that the reasoning and thoughts we have developed can be gradually translated and decoded throughout the drawn lines. Somehow we debate ourselves with our own ideas in this quickly drawn lines. We scratch, we draw, we overwrite features, we configure, we represent, we visualize, giving physical form to our thinking. There is a direct link between the thinking and the hand that performs the sketch. The hand as an extension of the brain, of the reasoning. “Moreira da Silva (2017)”

Sketching capacity to perform a link between the brain and the hand, since the first human drawings in remote times, is one of the reasons why sketching can perform actually a transdisciplinary and innovative role in many creative professions linked to project or communication besides the design area.

5. CONCLUSIONS

We can conclude that, in spite of the paradigm shift required by changing times, freehand drawing remains inseparable from many professional practices, assuming an essential operating support for developing creativity.

Although technological development has created several tools and new techniques for graphic representation, we can deduce about the importance of sketches permanence in many creative processes. Freehand drawing is used to facilitate the development of ideas and show them more quickly and efficiently, and is an essential tool for many professionals, regardless if the work is in informational, graphic, product, fashion or another design areas, engineering, architecture, marketing, advertising, cinematography, teaching and many others. Sketching seems to be present in almost all disciplines that identify with creativity and communication.

In creative teams, sketches represent a valuable tool, validating brainstorming, materializing concepts, externalizing the various ideas that float in different work groups. Sketching breeds collaboration and is a tool accessible to the whole team, like a common language that can bring clarity to ideas.

Sketching is fast and easy, it gives freedom to explore ideas as quickly as they arise, it helps problem solving faster. We can conclude that sketching's characteristics can be described as a fast and effective means of communication, universal in its reading and universal as a thinking tool used by a wide variety of people.

Sketches capacity to perform a useful link between the brain and the hand is one of the reasons why sketching can perform actually a transdisciplinary and innovative role in many professions linked to project or communication besides the design area.

No doubt new information technologies offer new ways, even becoming indispensable in many work phases. However, they do not replace sketches, which continue to assume a 'chameleon' shape during the various historical periods, in a constant time adaptation, and, especially by incorporating a critical dimension in creative processes.

“WITH NO SIBLINGS, BUT WITH HOME”: SINGLE PATENT-CLASS INVENTIONS (SPIS) AND REGIONAL TECHNOLOGICAL DIVERSIFICATION IN EUROPE

Claudio Cozza¹, Ilaria Gandin², Sandro Montresor³, Alessandro Palma³, Gianluca Tarasconi⁴

¹Department of Economic and Legal Studies – DISEG, University of Naples “Parthenope” (IT), Italy. ²University of Trieste, Italy. ³Gran Sasso Science Institute, L’Aquila (IT), Italy. ⁴ipQuants AG, Schaffhausen (CH), Switzerland

ABSTRACT

This paper aims to investigate the extent to which the incidence of single patent-class inventions (SPIs) on the regions’ knowledge base can affect their technological diversification. Drawing on the literature on technological relatedness, we argue that SPIs contribute to make regional knowledge bases more “siloeed” and reduce the opportunities of knowledge recombination on which technological diversification depends. We also maintain that SPIs contribute to attenuate the role of relatedness in regional technological diversification, as siloeed knowledge bases entail less dense local knowledge networks, with lower cognitive constraints for the entry of new technologies. Our empirical application, undertaken with respect to EU-28 NUTS2 regions over the 2008-2015 period, introduces different measures of regional SPIs and show that, as expected, they both negatively correlate with the regional propensity to technologically diversify and negatively moderate the effect of relatedness on the same capacity. Important implications are drawn with respect to the implementation of regional specialization strategies of research and innovation.

PRODUCTION EFFICIENCY OF ADVANCED TECHNOLOGY-GENERATING INDUSTRIES IN THE EU: STOCHASTIC FRONTIER ANALYSIS OF INDUSTRY-LEVEL PANEL DATA

[Giedre Dzemydaite](#)

Vilnius University, Lithuania

ABSTRACT

This research aims to analyze how the R&D spending contributed to the production efficiency of advanced technology-generating industries in the European Union. We applied the stochastic frontier analysis model for industry-level panel data from 1995 to 2017, based on a Cobb-Douglas production function. Results revealed that R&D spending had a statistically significant impact on the production efficiency for the whole sample. However, there was no statistically significant impact of this contribution to efficiency growth in most advanced technology generating industries in the EU. Physical capital (gross fixed capital formation) remained the key input for higher production efficiency. Therefore, advanced technology uptaking processes played an important role in the production efficiency growth in industries analyzed.

The comparison of levels of production efficiency in different EU countries revealed that some small countries and catching up economies like Lithuania and Estonia had comparatively high-efficiency scores of using available resources for an output generation. Therefore, this research contributed to the debate on previous findings that production efficiency is not necessarily lower in catching up economies. Higher investments in such countries' advanced technology-generating industries suppose to increase value-added considerably.

PREDICTIVE MODELLING OF GULLY EROSION IN ARID ENVIRONMENT: CASE OF THE RURAL COMMUNE OF EL FAID LOCATED IN THE SOUTH-MOROCCO

Ali Azedou, Abdellatif Khattabi, Said Lahssini, Mohamed Sabir

Ecole Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

Land degradation is major threat to food security and to the sustainable provision of ecosystems goods and services. In arid environment characterized by reduced vegetation cover, erosion process is the main threat to soil capital leading to its degradation. Gullies are one of the main expressions of soil erosion in such environment. Soil and water conservation interventions must then be implemented in order to curb soil erosion. However, there is need to precisely verify gullies location and distribution within remote and inaccessible lands. This study aims to develop model predicting the occurrence of gully in order to propose correction interventions that reduces erosion and flooding risks. The study concerned arid lands located in the rural commune of El Faïd located in south of Morocco which is an arid region. Gullies within the watershed have been identified using Google Earth and GIS. Eight hundred ninety-four (894) gullies have been mapped verified through field visits. Maps of predisposing factors have been digitized and include physical factors and anthropic factors (including Lithofacies, Land use, Slope, Slope Length, Aspect, Curvature, Topographic wetness Index, stream power index). The gullies database has been randomly split into two sets, training dataset (715) and testing dataset (179). Several predictive models have been trained including information values and machine learning based approaches (Artificial Neural Network and Random Forest) using R language. The model's quality was assessed using the area under the curve to choose the model with a best predictive capacity. Further, our results stressed out the main predisposing factors to gullies prediction. The fitted model has been used to predict, for all the watershed, even in inaccessible lands, the gullying susceptibility. Such maps are very important for managers in order to contribute to land degradation neutrality and to prevent flood events on the flat lands. Key words: Water erosion, gully, vulnerability, prediction models, Machine learning, El Faïd.

MACHINE LEARNING FOR FOREST STAND DELINEATION USING YEARLY LANDSAT TIME SERIES

[Anass Legdou](#)¹, [Aouatif Amine](#)¹, [Said Lahssini](#)², [Hassan Chafik](#)³, [Mohamed Berrada](#)³

¹National School of Applied Sciences IBN Tofail University of Kenitra, Morocco. ²Ecole Nationale Forestière d'Ingénieurs, Morocco. ³National High School of Arts and Crafts, Meknes, Morocco

ABSTRACT

Forests as natural capital provide goods and services contributing to human wellbeing. As their contributions to sustainable development goals are widely recognized, it has been globally agreed that forests need to be sustainably managed. Forest management rely on accurate information concerning forest resources, their dynamics and the social and market needs. Such information needs to be accurate and periodically updated. Forest stand maps remain a major tool for characterizing forest resources and for prescribing interventions to be undertaken within each stand and at the required timestamp. Nowadays, within Moroccan forestry context, forest stand maps are mainly produced using conventional approaches based on aerial photo-interpretation, and then ground truth verification using field mission. This process is time and resources consumptive. Within our study, we focus on the use of satellite imagery time series in addition to machine learning techniques in order to update forest stands map. The study focused on Cedar Forests located in the Middle Atlas region which has been recognized as national heritage. The used data consist on "Landsat" images time series, circular random plots randomly chosen from national forest inventory database, in addition to limited number of inventory plots measured within small scale forest management studies and at various timeframe. Data have been organized and preprocessed, then supervised classification of forest stands have been performed using either truth plots and the corresponding imagery or the whole imagery database while focusing on the sites on which the most important stands types changes have been undergone. Classification algorithms where based on various commonly used machine learning algorithms, whose effectiveness has been proven in several research studies. Supervised images classification, using different algorithms, gave satisfactory results with a high variability. Furthermore, temporal segmentation of the archive appears to be a feasible and seems promising.

MODELING FOREST TYPE TRANSITION OF MIDDLE ATLAS-MOROCCO ASSOCIATED TO HUMAN ACTIVITIES

[Anass Legdou](#)¹, [Aouatif Amine](#)¹, [Said Lahssini](#)², [Hassan Chafik](#)³, [Mohamed Berrada](#)³

¹National School of Applied Sciences IBN Tofail University of Kenitra, Morocco. ²Ecole Nationale Forestière d'Ingénieurs, Morocco. ³National High School of Arts and Crafts, Meknes, Morocco

ABSTRACT

Due to climate change scenarios projections, predicting higher probability of extreme/adverse climatic events, to the context of socio-economical changes of the population and the production systems, forest resources are ongoing/experiencing steady degradation process threatening the future of forest as natural capital. The higher anthropogenic pressure in addition to ecological fragilities leads to deep transformation of forest cover and then to the land use systems in mountainous area; such transformation is scale dependent. In order to sustainably manage forest resources, there is a need to understand the mechanisms underlying changes in forest cover either at the occurrence of the process or at the intensity of its manifestation. Then, the objective of our work is to develop models explaining the impact of various biotic and abiotic factors on cedar ecosystems and to predict the future state of such forest. The study was carried out on Ain Leuh Cedar Forest (Sidi M'Guild) located on the middle Atlas-Morocco. This forest is part of the UNESCO heritage Man and Biosphere Cedar Reserve. The used data consist on time series of "Landsat" satellite images covering a 14 years period from 1990 to 2004, maps of 19 bioclimatic factors, digital elevation model and socio-economic criteria including human settlement location, demographic data and human development criteria. The approach consisted on classification of the images then calculating transition probability using Markov chain for respective forest cover types and then modeling, the transition probabilities as function of the various bioclimatic, physical and socio-economic factors. On the other hand, ground truth data at different time laps was provided by forest management studies, national forest inventory and field visits. The most common transitions concern mainly species cover, species transformation remain very rare. In this work, factors that contribute to explain the transition between Cedar cover state and the other spaces in the same space of Ain Leuh Cedar Forest are six important parameters in which social parameters affect those transitions. The predicted forest cover map provide guidance to forest scientists, managers and decision-makers on the prospects for preserving and rehabilitating this natural capital.

CLOUD COMPUTING SOLUTION FOR MONITORING PROTECTED AREA IN MOROCCO

Said Lahssini¹, Said Moukrim², Hicham Alaoui³, Hicham Hajji⁴, Loubna El Mansouri⁵

¹Ecole Nationale Forestière d'Ingénieurs, Morocco. ²Mohammed V University, Morocco. ³Climatic and forest risk management center, Morocco. ⁴IAV, Morocco. ⁵IAV H2, Morocco

ABSTRACT

Morocco is qualified as a major contributor to the Mediterranean Basin biodiversity hotspots. Network of protected area has been established to protect its natural capital and to promote local population development. In spite of the protection efforts made by government, there is a need for an evidence-based approach to measure the conservation effectiveness, not only in management, governance and equity, but also in terms of ecosystem functioning and its ability to sustain the provision of ecosystems services. With the lack of data related to natural resources monitoring, the wide availability of open access earth observation data, acquired primarily by free access satellite such as Landsat, MODIS and Sentinel has triggered new development perspectives. Moreover, and in addition to this crowd sourced satellite data, the parallel cloud-based computational platforms such as Google Earth Engine (GEE) that becomes increasingly accessible, allowed to overcome data lack issues and to scale analysis across space and time. This work tries to assess the effectiveness of protection strategies on a Moroccan protected area case and aims to develop an automated solution for monitoring rehabilitation dynamics or degradation trends within a protected area located in arid region through harnessing the use of satellite data products with parallel cloud spatial big data processing. The study area concerned the Argane Biosphere Reserve which is recognized by Unesco MAB as natural Heritage since 1997. Data-driven modelling (DDM) based approach allowing the combination of Big Data, artificial intelligence algorithms were adopted. Ecosystem restoration trends was assessed through spectral indices analysis and continuous cover change detection based on temporal segmentation of satellite time series. The process was implemented using GEE API for java script. As results, a graphical user interface and an application prototype was released. It is exploitable using standard web browser and is accessible even to people without any background regarding programming languages or remote sensing skills. Such graphical user interface facilitates the process of analyzing temporal trajectories (time series) of different spectral indices derived from satellite images (Landsat or Sentinel) at the required spatial analysis scale. Further, the analysis of forest cover trends, using temporal segmentation, has been promising. It permitted to identify the occurrence and the intensity of abrupt forest cover changes underlying forest harvesting or land use changes through its rehabilitation.

PHYSIOLOGY OF MERLUCCIUS MERLUCCIUS IN THE NORTH ATLANTIC OF MOROCCO

Chaimae El Bouzidi¹, Mounir Hassani Zerrouk², Said Benchoucha³, Mohammed Bakkali¹

¹Faculté des Sciences et Techniques de Tanger, Morocco. ²Multidisciplinary faculty of Larache, Morocco. ³Centre régional de l'INRH, Tanger, Morocco

ABSTRACT

The common hake (*Merluccius merluccius*) is a unique specie. With various positive aspects such as a high Business value in term of monetary growth as well as representing a considerable part of the Moroccan fisheries. Even though bibliography about the specie is rich, yet few disparities persist. In particular on some of its biological, and ecological aspects. This lack of data has retrograding repercussion upon the quality and accuracy of the stock evaluation and falconry management. This study is targeting a more effective and rigorous bio specification that will assist us surveying and evaluating the local common hake stock as well as the administration of fisheries all along the north Atlantic Moroccan coasts. In this project, we chose the *Merluccius merluccius* hake, because it is the most important of the high-value demersal fish species exploited in Morocco from the point of view of landings; The maximum production of hake in Morocco according to the ONP (National Fisheries Office) was around 7000 tonnes in 2005 then dropped to 1538 tonnes in 2013. The *Merluccius merluccius* suffer from the lack of development plans which ensure a rational exploitation. This study then will contribute to improve the management of the common hake in the Moroccan fisheries, through a complete study of the biological aspects based on three axes: reproduction, growth, and diet of the *Merluccius merluccius*. The study of growth to determine body size as a function of age, this is why all stock assessment methods rely on age composition data, which form the basis of calculations growth rates and growth in the production of stocks (INRH 2013) Reproduction It is for the protection of the stock of hake which is constituted of 85% of juveniles at the level of the zone and the reconstitution of the areas of concentration of the common hake (INRH etat des stocks et des pêcheries au Maroc [Rapport]. - 2013). Sexual maturity and laying are always linked to a change in diet (Parz et al, 1993). Thus, the increase in energy requirements related to sexual maturity may be the critical factor explaining the change in eating habits of hake. Also, we will study the indicators of exploitation in order to show the economic value of this species and to show the current state of the stock of common hake in the North Atlantic of Morocco. This full review on all different biological facets of *Merluccis merluccius* (reproduction. growth conditions, nutritional restriction) could help to reduce the pressure of fishing on the common hake and to ensure sustainable production for the future generation.

CAN PHONE USAGE IMPROVE TECHNICAL EFFICIENCY OF RICE FARMING? EVIDENCE FROM INDONESIA

[Nugraheni Kusumaningsih](#)

Fiscal Policy Agency, Indonesia

ABSTRACT

Several studies have found that mobile phones are a promising tool to improve the livelihoods of smallholder farmers in developing countries, however whether the phone usage in rice farming can really improve the technical efficiency is mostly uninvestigated. There has been an increasing number on phone usage in rice farming in Indonesia for the past decade. In Indonesia, rice is the most important commodity because it is the staple food for around 270 million people. The agricultural sector still contributes greatly to job creation, about 30 percent of workers in Indonesia are in the agricultural sector. There has been a great concern within the country on the importance of food security and even going toward food self-sufficiency. Various challenges faced in rice farming, such as productivity that needs to be continuously increased, the lack of agricultural production factors, climate change, and the potential for supply disruption due to the Covid-19 pandemic, make this study necessary. This study aims to investigate whether the phone usage improve technical efficiency of rice farming as well as to determine the level of technical efficiency. The main data used in the study is household survey data from the 2014 Indonesian Family Life Survey (IFLS) managed by RAND (2015). The sampling carried out at IFLS used the stratified random sampling method by using the province and the regency / city category as the strata. Samples were randomly selected based on these strata. From these secondary data sources, we obtain 2120 rice household data. This study uses a production function which includes rice farming and capital as input. Stochastic frontier analysis with the Cobb Douglas production function which has been widely used to measure technical efficiency in various sectors including agriculture, especially rice farming is employed. Analysis using the stochastic frontier production function shows the technical efficiency of rice production in Indonesia is 0.6, where the area of rice and the use of new superior seeds has a significant effect on the output produced by rice farmers. In fact, labour does not have a significant effect on the estimated output because the number of workers in the agricultural sector is too large when compared to the availability of existing rice land. The estimation results of the stochastic frontier production function also show that there are inefficiencies in rice production in Indonesia. The inefficiency model shows that phone usage, farmers' education and irrigation improve technical efficiency. Phone usage in rice farming allows farmers to get information and coordinate better with other farmers. In addition, the use of cell phones, especially those connected to the internet, can provide opportunities for farmers to access more knowledge in rice production, thereby helping to use optimal inputs.

FAIR TRADE AND RURAL DEVELOPMENT: ASSESSMENT OF PREFERENCES AND POTENTIAL PARTICIPATION OF SMALL PRODUCERS IN NORTHERN MOROCCO

Eddahmouny Hicham, Elbroumi Soufiane

FSJES FES, Morocco

ABSTRACT

Since mid-1980, there has been a growing international awareness that « trade not aid » is one of the most effective tools to reduce poverty in developing countries. It is in this global context that the Fairtrade movement began more than 50 years ago. It starts from a simple observation: rather than providing financial assistance to poor small farmers, it is better to offer them the means and techniques to develop themselves. Indeed, numerous studies have examined the impact of fair trade on the well-being of small producers participating in programs and the willingness of consumers to pay for Fairtrade and other labelled products. However, few studies have examined farmers' preferences for participation in the movement. Our research is part of this framework and proposes the use of an experiment of choice, to examine the preferences of small farmers of olive trees in northern Morocco for Fairtrade standards. The results indicate that small producers prefer long-term contracts, individual and cash payments.

RETROSPECTIVE ANALYSIS OF RURAL DEVELOPMENT IN MOROCCO**Nora Hammouda¹, Hicham Alaoui²**¹Departement of agriculture, Morocco. ²Climatic and forest risk management center, Morocco**ABSTRACT**

In Morocco, rural areas are experiencing a revival of interest, in particular with ambitious public policies in terms of rural and agricultural development and natural resource management. In view of its importance, rural areas seem to be the driving force behind all efforts and political concern because of their demographic, social and economic importance. Several sectoral programs have been launched to reduce the gaps in rural areas in terms of infrastructure and access to basic services, such as the National Rural Roads Programme (PNRR and PNRR2), the National Education and Training Charter, the National Plan for the Promotion of Health in Rural Areas, the Programme for the Collective Supply of Drinking Water to Rural Populations (PAGER) and the Comprehensive Rural Electrification Programme (PERG), the National Rural Roads Programme (PNRR and PNRR2), the Green Morocco Plan (PMV). As a result of these interventions, considerable achievements have been made in the area of basic infrastructure. They have made it possible to achieve an accessibility rate of 78% in 2014, a rate of access to drinking water in rural areas of 94% in 2014 and an electrification rate that will rise from 18% in 1995 to 98.6% in 2014. Thus, the school enrolment rate for rural girls in the 12-14 age group was 61.5% in 2014 instead of 39.9% in 2007. Life expectancy at birth increased from 67.4 years in 2004 to 71.7 years in 2010. This paper presents a retrospective analysis of different facets of rural development in Morocco and raises questions about the effectiveness and efficiency of public policy governance, particularly the related axes, the convergence and coherence of plans and programs with the national strategic vision of rural development.

PLACE-BASED AND PARTICIPATIVE APPROACHES: REFLECTIONS FOR POLICY DESIGNS IN RURAL DEVELOPMENT

Kim Pollermann, Lynn-Livia Fynn

lynn.fynn@thuenen.de

ABSTRACT

Across the European Union the so-called “Community-Led Local Development” (CLLD) is a well-established policy design. It all started with LEADER in rural areas 25 years ago and now counts 2,600 Local Action Groups (LAGs). LEADER is a place-based and participatory approach where a Local Action Group (LAG) composed of stakeholders from local government, civil society and economy steers the implementation of its local development strategy. LAGs each have a budget at their disposal (approx. 3 million euro) to support project implementation within a funding period (time for implementation is around five years). A set of LEADER principles describes the characteristics of LEADER: territorial approach, bottom-up, public-private partnerships, integrated and multi-sectoral approach, innovation, cooperation with other regions and networking. The aim of this contribution is to discuss different options for the policy design of the LEADER implementation regarding different steering options of this place-based and participatory approach. To examine the performance of LEADER, we utilise results from the 2014-2020 funding period, especially structural data of 115 LAGs in Germany. Main material was collected by means of three surveys using written questionnaires (mainly executed as online surveys: LAG member survey n=1999, LAG management survey n=114, survey of beneficiaries: n=1079). The results are related to single variables of the LEADER implementation and their impact on LEADER performance. Due to complex relations of different aspects, we mainly elaborate findings on simplified output indicators. Regarding a suitable policy design, the results offer several insights: one being that a higher staff capacity in LAG managements in the different LEADER regions fosters a higher share of innovative projects. This supports a policy recommendation to predefine minimum targets for staff capacity as a prior condition for funding the LAGs as this shows to be an important factor for fostering innovation and participation of local actors. In the context of place delimitation, results show that a suitable region design/delimitation is not dependent on the population size of the various LEADER regions.

KEYWORDS

Community-Led Local Development (CLLD), LEADER, participation, place-based

1. INTRODUCTION

1.1 Place-based and participative approaches in rural development

The EU is characterised by enduring regional inequalities, partly as a product of successive enlargements, in which lower income countries acceded to membership, but also because of enduring structural problems in some regions in Western Europe (Tomaney 2010). Regarding rural development, there are different challenges in European regions. To deliver assistance for rural areas, different policies from the European Union as well as from national states try to support declining regions in particular. Sharing of power and participatory decision-making could facilitate more flexible, inclusive and effective solutions and planning (Castro-Arce & Vanclay 2020). Thereby, long-term strategies are required for adaptations to the present and future challenges. Thus, the commitment of the local actors is a crucial strategic success factor for planning processes (Pollermann 2014).

In recent decades, rural development policy made a substantial shift from a sectoral top-down approach to a territorial and integrated approach, which aims to include a variety of sectors relevant for rural development and a variety of government levels and stakeholders (Moseley 2003).

Such territorial or ‘Place-based’ development policies are partially a response to perceived failures of earlier regional policies, and focus instead on tackling underutilised economic potential and reducing social exclusion, through supply of integrated goods and services tailored to local contexts and triggering innovation, which is critical to economic growth (Tomaney 2010).

The participation of local stakeholders is another crucial element of such policies. Different experiences show that revitalisation succeeds when bottom-up initiatives of local stakeholders work in combination with assistance and support by government (Li et al. 2016, 511f). Thus the roles and co-working of different groups are important to develop a suitable design of structures for participation. In addition, the support and animation activities of some kind of local management (with its own staff) could foster suitable and effective participation.

Across the European Union, the so-called “Community-Led Local Development” (CLLD) is a well-established policy design. It all started with LEADER in rural areas 25 years ago and now counts 2,600 Local Action Groups (LAGs). The word LEADER is an acronym derived from the French language: “Liaisons Entre Actions de Développement de l’Economie Rurale” = Links between actions for the development of the rural economy.

1.2 Implementation in LEADER

To describe the characteristics of LEADER, there is a set of LEADER principles: territorial approach, bottom-up, public-private partnership, integrated and multi-sectoral approach, innovation, cooperation with other regions and networking (Thuesen & Nielsen 2014; Pollermann et al. 2020). A key element is a so-called Local Action Group (LAG) composed of stakeholders from local government, civil society and economy, formed to steer the implementation of a local development strategy. This contains a description of the regional demographic, economic and natural situation, an analysis of strengths and weaknesses, opportunities and threats as well as selected development objectives for the various LEADER regions¹⁶⁵ and different parameters regarding the organisation of the LAG, the selection of projects and the administration of funds, amongst others. The LAGs dispose their own budgets (approx. 3 million euro in examined regions) to support project implementation. Time for implementation is around five years.

The LEADER instrument requires tailoring to a specific area, so the delimitation of the LEADER region is a crucial explanatory variable. In Germany, LEADER regions are often designed beyond the traditional administrative borders and their size usually varies from 30,000 to 150,000 inhabitants.

Another crucial aspect of the LEADER approach is the establishment of an LAG management, which promotes participation of different stakeholders: usually one to three staff members per LAG work on coordination, consulting services and public relations.

A main result of LEADER is the implementation of projects (related to tourism, village development, basic services, mobility, education, culture, climate protection), whereby an innovative character of the project is not a precondition for funding the individual projects although it is an essential aim of LEADER to create innovative projects in the sense of new approaches to local development in the LEADER region (Dax et al. 2016, Navarro et al. 2018).

1.3 Research Questions

The research topic of this contribution is to discuss the influence of different variables of LEADER implementation on the performance of this place-based and participatory approach.

Thereby we will focus on two aspects:

- **Delimitation of the LEADER region:** What are differences in suitability for rural development related to the size of the region (= number of inhabitants)? Here, we use the opinions of LAG members as an indicator.
- **Staff capacity of the LAG management:** What are the effects of staff capacity (number of full-time equivalents/ hours per week capacity) on the outcome of the funded projects? In examining the implications of staff capacity, we use the share of innovative projects in different regions as an indicator.

Both aspects are important for the future policy design for LEADER since programme authorities may set guidelines and requirements with the aim of generating positive outcomes of local development in rural areas.

2. METHODS AND MATERIAL

To examine the performance of LEADER, we utilise results from the 2014-2020 funding period, especially structural data of 115 LAGs in four German federal states ("Bundesländer"). These constitute 24 LEADER regions in Hesse, 41 in Lower-Saxony, 28 in North Rhine-Westphalia, and 22 in Schleswig-Holstein. Main material was collected by three surveys using written questionnaires (mainly executed as online surveys):

- LAG member survey: members of the LAGs' decision-making bodies in all examined federal states in 2017/2018 (requested persons N=3308, answering persons n=1999, response rate: 60 %). Usually, a six point Likert scale was used to classify personal estimations of the LAG members.
- LAG management survey: one manager per LAG was surveyed in 2018 (N=115, n=114, response rate 99 %) with a mixture of general questions about the situation in the region, open questions to grasp more detailed assessments about specific problems, again using Likert scales and open questions.
- Survey of beneficiaries: questions regarding LEADER projects (for the implementation of local development strategies, sub-measure 19.2), (N=1267, n=1079, response rate: 85 %), the respondents were asked for estimations about project development, funding procedures and the results of their project, again using Likert scales and open questions.

To judge the performance of LEADER, several output indicators are compiled (in connection with the LEADER principles and the related expected benefits).

3. RESULTS

This paper contains only preliminary results; more detailed deliverables will follow in the session. The results are related to single variables of the LEADER implementation and their impact on LEADER performance.

3.1 Place delimitation

Regarding place delimitation, results show that a suitable region design is not dependent on the population size of the various LEADER regions when it comes to promoting regional development. The satisfaction of the LAG members surveyed is generally quite high with no significant differences based on population size, although a minor tendency of rating smaller regions more positively could be detected (see figure 1).

¹⁶⁵ Sometimes referred to only as „region(s)“ in this paper.

Figure 1: Size of region & opinions on size suitability (own illustration, n=115 regions)

NRW= North Rhine-Westphalia, SH = Schleswig-Holstein, HE = Hesse, NI = Lower Saxony

3.2 The role of LAG managements in promoting participation for innovative projects

Analyses of the structural and organisational data on the various LEADER regions show that working hours of LAG management teams in the four states vary on average between 40 and 60 hours per week. In some regions, weekly working hours fall below 36 or exceed 80 hours.

Regarding the incidence and kind of innovative projects the results are as follows: 56 % of the beneficiaries classified their own project as being innovative based on a definition of innovation provided in the questionnaire („ideas or approaches/strategies for action, that are new to your region“).

The nature of the innovation is also specified: 61 % of the respondents mentioned new products or services, 16 % new technological processes, 39 % the exploration of new markets/ customer groups and 42 % mentioned new forms of cooperation or organisation. A few examples of innovative ideas given by the respondents were the use of iPads in schools, organization of a poetry slam to engage the youth and an adventure trail for bike tourism.

In addition to that, in 33 % of the innovative projects the beneficiaries reported that interested persons contacted them to make enquiries about their projects.

Looking at the influence of personal capacity of LAG managements (number of weekly hours) there is a positive correlation between capacity and share of innovative projects (see figure 2). Thus preliminary results indicate that the existence of a well-equipped LAG management team contributes to innovative approaches in project development.

Figure 2: Staff capacity & share of innovative projects (own illustration, n=115 regions)

4. CONCLUSION

The establishment of a LAG management is a prerequisite for all regions funded through LEADER. However, a lack of predefined targets often results in understaffing. One of the insights our results offer is that a higher staff capacity of LAG

managements fosters a higher share of innovative projects. This supports a policy recommendation to predefine minimum targets for staff capacity as a prior condition for funding the LAGs. A suitable minimum could be 60 hours which brings with it the extra benefit of a minimum of two persons, thus enabling continuous functioning/availability of the LAG management and smooth transitions in the event of staff changes if this concerns only one of the LAG managers.

As mentioned before, the LEADER instrument requires tailoring to a specific area. Our results, however, indicate that place delimitation based on the regions' population is not the main requirement in this case. The recommendation is therefore, to give the LAGs a wide range of freedom in this decision. Suitable delimitation is more dependent on local specificities such as administrative or natural boundaries, or certain requirements in connection with the objectives of the local development strategies rather than the mere number of inhabitants.

DIGITAL TRANSFORMATION OF RURAL SOCIETIES: THE CASE OF KALININGRAD REGION

[Anna Mikhaylova](#)¹, [Andrey Mikhaylov](#)^{1,2}, [Dmitry Hvalej](#)¹

¹ Immanuel Kant Baltic Federal University, Kaliningrad, Russia; ² Institute of Geography of the Russian Academy of Sciences, Moscow, Russia, mikhailov.andrey@yahoo.com

ABSTRACT

Digitalization of rural territories is often proposed to be the effective development strategy that could overcome the peripherality – lack of public infrastructure and services, unemployment, economic backlog, and depopulation. Digital technologies are seen to foster social innovations in the countryside, as well as promote self-employment and freelance via the Internet. However, rural societies are highly heterogeneous. Different groups of the population live in the countryside – those employed in large agricultural production and farms, people involved in personal subsidiary plots, as well as the rural population working in the city and living in the countryside with an urban lifestyle. The aim of the study is to identify the differences in readiness for information and communication technologies across the different types of municipalities and population groups. The research design is based on the comparative assessment of rural areas of the Kaliningrad region by the Internet coverage, user density, the availability of various online services and e-government. The research sample includes rural settlements near the city and remote ones featuring different socio-economic structures, which are compared by infrastructure development and readiness of the population to implement digital routines. Results suggest that top-down initiatives will not be adopted by the local society if a population does not perceive the benefits of digitalization. A place-specific approach should be applied when drafting the digital transformation programs considering the established lifestyle, the needs of different types of residents, as well as the readiness of local societies for digitalization.

KEYWORDS

Information society, digital divide, digital service, internet coverage, digital sensibility, receptiveness to digitalization, digital routines

1. INTRODUCTION

Rural areas are experiencing depopulation worldwide, which is due to urban-rural inequality in the quality of life, including the state of public infrastructure, utilities, and services. Daily commute to more populated areas for the purpose of work, leisure, or personal needs, such as shopping, banking, professional consultations, etc. is inconvenient or impossible in many peripheral rural areas. Therefore, rural communities have to pay a 'rural penalty' (i.e. an extra amount of money) for using same or even inferior quality services because of greater distances from the service providers, low market capacity, and weak competition (Hindman, 2000; Onitsuka et al., 2018). Moreover, the sparsely populated rural locations, especially those distant from urban centers or key transport communications are looping in a vicious circle, where low returns on investment repel companies from opening a subsidiary or providing a full-flagged integration of rural areas into their current business processes (Malecki, 2003; Pěluča, 2019). One of the most prominent research topics with respect to territorial cohesion is, therefore, the issue of 'rural-urban digital divide' (Whitacre & Mills, 2007).

Nowadays rural areas can be labelled as 'digital periphery' both in terms of poor information and communication technologies (ICT) infrastructure and the actual internet usage statistics (Pěluča, 2019). Salemink et al. (2015, p. 360) note that "rural communities are most in need of improved digital connectivity to compensate for their remoteness, but they are least connected and included". Digitalization of rural territories is seen as an effective strategy to combat depopulation and its major reasons – lack of public infrastructure and services, unemployment, economic backlog, and social isolation (Komorowski & Stanny, 2020; Pěluča, 2019).

The internet and digitalization facilitate the transition of rural societies to non-agricultural sectors supporting diversification and economic resilience, providing a better integration with their surrounding regions and the world. Smart rural economic development and 'de-agrarianisation' are expected to bring the modern lifestyle to the countryside, along with an increased occupational plurality (along with declining share of labor in farming), improved spatial and social mobility, and intensified rural-urban interpenetration (Berdegué et al., 2014; Fahmi & Sari, 2020; Onitsuka et al., 2018). However, the effects from digital technologies in transformation of rural societies depends on numerous factors (digital inequality dimensions), such as usage purpose and the perception of benefits, the availability of ICT infrastructure and the quality of internet, the required digital skills, etc. (Barzilai-Nahon, 2006; DiMaggio & Hargittai, 2004; Onitsuka et al., 2018; Selwyn, 2004).

Bürgin and Mayer (2020) suggest that, on the one hand, penetration of digital technologies offers new economic opportunities to rural areas, but, on the other hand, puts pressure on local communities of becoming digital. Their study on mountainous countryside of Switzerland stresses on the difficulties of digital transformation. A study of Fahmi and

Sari (2020) further indicates that not all rural residents are taking the full advantage of digitalization – only those with the required skills. As mentioned by Meyn (2020), digitalization offers immense potential for rural societies, but it can only be realized given the appropriate skillset and the mindset required for using digital technologies. Studies suggest that the adoption of ICT and the issue of ‘digital connectivity’ are to be further analyzed for developing place-sensitive digitalization projects and policies (Komorowski & Stanny, 2020; Mikhaylov et al., 2019; Pěluha, 2019; Sept, 2020).

This study focuses on the problem of digital divide between municipalities within the region, with an emphasis on studying the effects of digital transformation in rural areas. Its purpose is to identify the differences between different types of municipalities in the willingness of the population to implement digital routines. We expect that in municipalities where the majority of the population lives in rural areas, the overall receptiveness to digitalization will be lower than in municipalities where the majority of the population lives in an urban lifestyle. However, we also believe that in some cases, agricultural municipalities can demonstrate higher rates of digitalization if this allows them to solve problems significant for the population in their everyday activities being difficult to solve without ICT.

The object for studying the problem of digital divide in the urban-rural inter-municipal space is the Kaliningrad region of Russia. This exclave region is a good example to explore for a number of reasons. Firstly, the region has an almost equal number of municipalities, which can be classified as “predominantly urban” with a share of urban population over 50% and “predominantly rural” with a share of rural population over 50%. This will allow avoiding data skewness in one direction or another when studying the phenomenon of digitalization in both urban and rural areas. Secondly, in the last few years, the Kaliningrad region has been actively pursuing a policy to reduce the digital divide between urban and rural areas, including via the development of ICT infrastructure in rural areas and the organization of free Wi-Fi hotspots. Thus, it is possible to assess the progress of the digital transformation of rural societies in relation to urban areas, highlighting the remaining problem areas. Thirdly, the issue of active digitalization of the village for the Kaliningrad region is of interest, since the region continues to have a trend towards a reduction in employment in agriculture and it is necessary to look for alternative ways to ensure employment and the quality of life in rural areas.

2. RESEARCH METHODOLOGY

The geography of the study covers 22 municipalities of the Kaliningrad region of Russia (Fig. 1). All of them are divided into 3 groups: the first group “urban municipalities”, which unites 11 municipalities of the region, whose share of the urban population is more than 50% - these are Pionersky, Sovietsky, Svetlogorsky, Ladushkinsky, Mamonovsky, Baltiysky, Yantarny, Chernyakhovsky, Svetlovsky, Gusevsky, Nemansky ; the second group of “rural municipalities” unites 10 municipalities of the region, in which the share of the rural population is more than 50% - Gvardeysky, Zelenogradsky, Polessky, Pravdinsky, Ozersky, Krasnoznamensky, Nesterovsky, Guryevsky, Slavsky, Bagrationovsky as well as the regional administrative center - the city district of Kaliningrad.

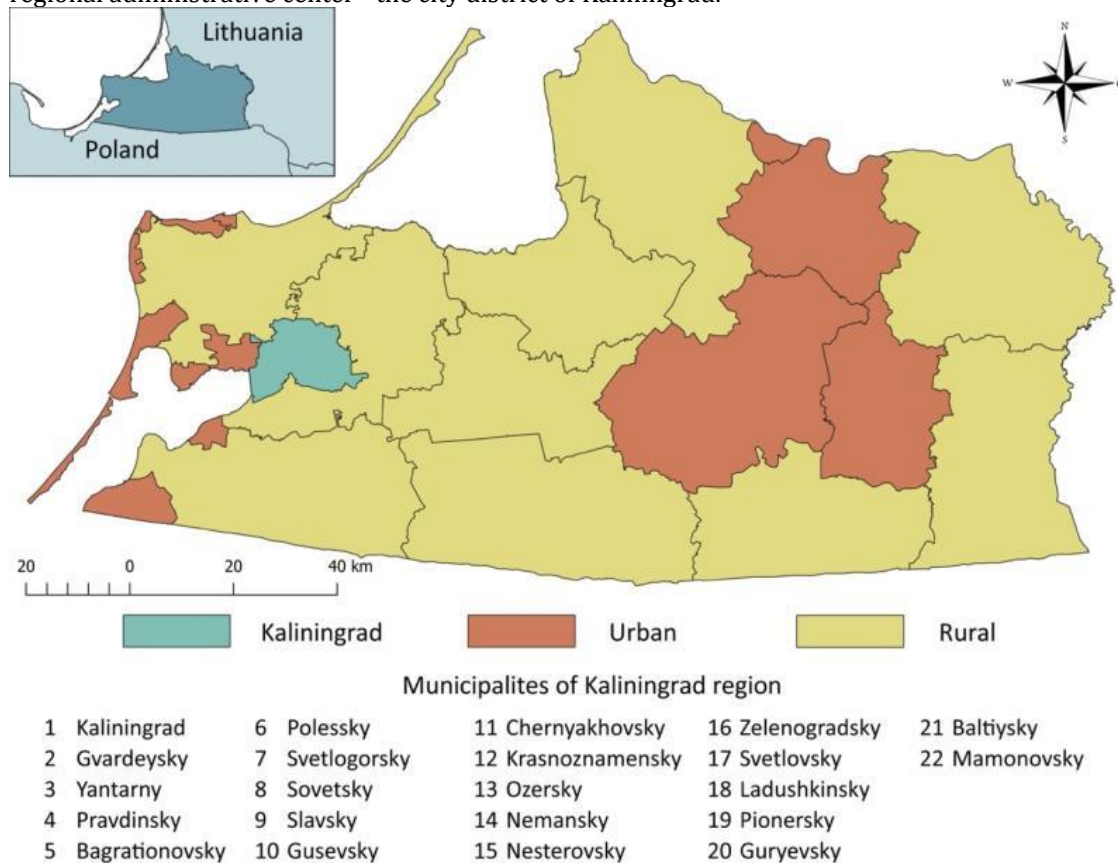

Figure 1: Municipalities of the Kaliningrad region of Russia

Source: developed by authors.

In total, 1.01 million people live in the Kaliningrad region as of January 1, 2021. Of these, the urban population is 792.1 thousand people, and the rural population is 226.6 thousand people. About half of the region’s population is concentrated in the administrative center – Kaliningrad, in which the highest population density is 2,179 people per sq.km (Fig. 2). In total, 82.6% of the region’s residents live within the boundaries of the Kaliningrad agglomeration, including 85.9% of the urban population and 70.9% of the rural population. The regional center is the main attractor of the population in the Kaliningrad region, forming a strong imbalance in the territorial development of the region. Also, a higher population density is characteristic of coastal municipalities, border municipalities with large checkpoints on the border with Poland and Lithuania, municipalities along the main transport route E28 (road of the European route network) – Fig. 2. On the contrary, most of the rural-dominated municipalities occupy a peripheral position in the eastern part of the region. Therefore, the problem of digitalization is really significant for them.

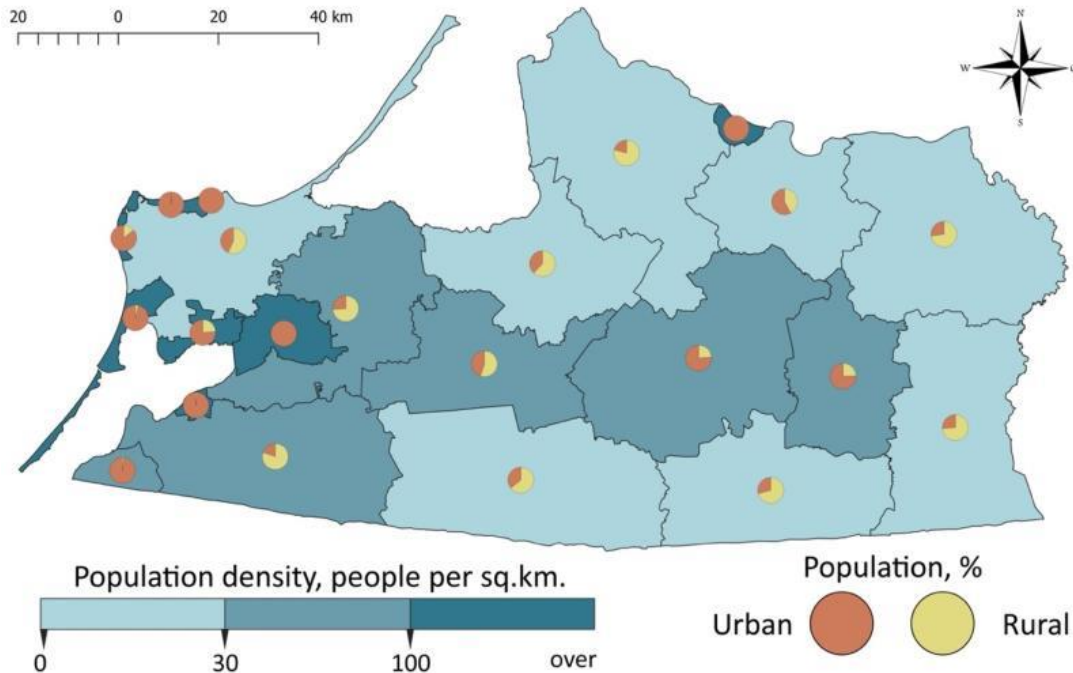

Figure 2: Population density of municipalities of the Kaliningrad region, 2020

Source: authors’ elaboration based on Kaliningradstat data.

The main data for assessing the digital susceptibility of the population of the Kaliningrad region were the results of a sociological survey in the format of an electronic questionnaire. A survey of citizens on the use of information and telecommunication technologies (ICT) was conducted in late 2020 – early 2021 by the Ministry of Digital Technologies and Communications of the Kaliningrad region on the portal https://cct.gov39.ru/press-center/opros/?SOURCE_LINK=CCT. In total, 2,727 respondents completed the questionnaire, while ensuring diversity and balance by age groups (14-25 years old, 26-35 years old, 36-45 years old, over 45 years old) and geography of residence in the context of all municipalities (Fig. 3, 4). Sociological data were analyzed in an impersonal and aggregated form in the context of three groups: Kaliningrad, urban municipalities, rural municipalities. This was done in order to identify differences in digitalization depending on the urban or rural lifestyle of the population.

Figure 3: Distribution of respondents who completed the questionnaire on the use of ICT, by age groups, %

Source: authors’ elaboration based on data from the Ministry of digital technology and communication of the Kaliningrad region.

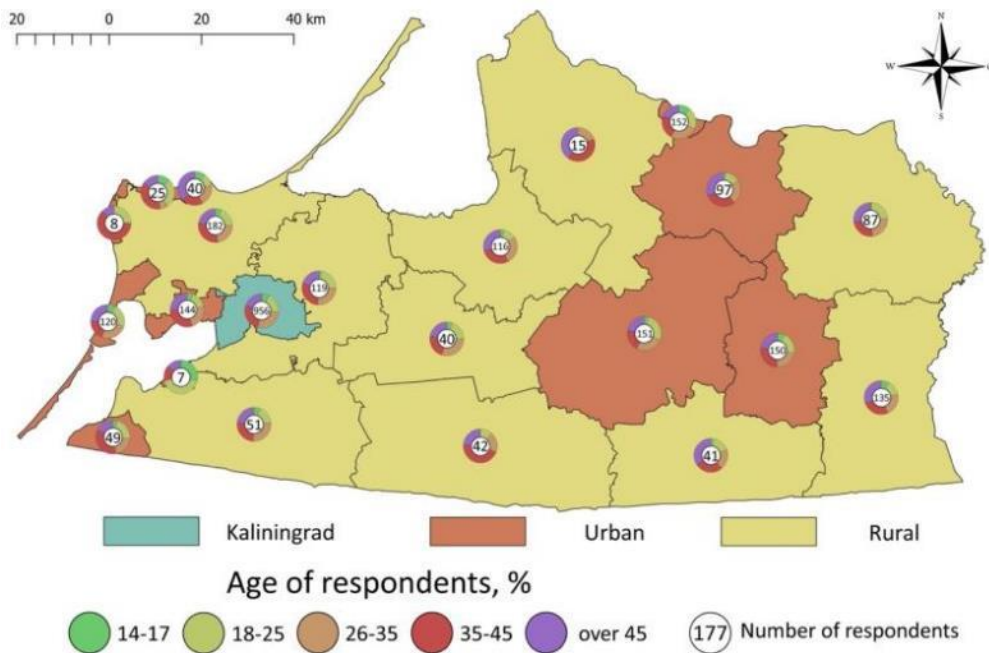

Figure 4: Geography of respondents who completed the questionnaire on the use of ICT

Source: authors' elaboration based on data from the Ministry of digital technology and communication of the Kaliningrad region.

The questionnaire consisted of 8 mandatory closed-ended questions with multiple answers: “How often do you use ICT?”; “I get access to ICT and services <choose a place>”; “I prefer to use <select devices> for working with ICT”; “Indicate what services you use”; “Assess your level of ICT proficiency”; “Using ICT during this year, your activity is <choose the nature of change>”; “Have you studied information technology?”; “Give an assessment of the benefits of using ICT”. Since this questionnaire was filled out online, the results of the questionnaire do not reveal the gap between those who use and who do not use ICT. When analyzing the data of this survey, we focused on assessing the territorial heterogeneity of the introduction of digital routines by the population of the region.

Data on the population's receptiveness to digital technologies were supplemented by an analysis of the infrastructural component of the digitalization process, primarily the density of Internet coverage and the location of free Wi-Fi hotspots in the rural area. The Internet coverage map is the total result of overlapping coverage by 3G and 4G networks of the main Internet providers in the region (MTS, Beeline, Tele-2, Megafon) as of 2020. Data on the location of free Wi-Fi hotspots in 127 rural settlements presented by Rostelecom within the framework of the federal project “Eliminating the Digital Divide”.

3. RESEARCH RESULTS

Most of the respondents who filled out the questionnaire use the Internet on a daily basis, while more than half have permanent access to it only in one place (usually at home or at work) – Fig. 5. Analysis by groups of urban and rural municipalities showed that there are differences between them both in terms of frequency of use and permanent access to the Internet.

Figure 5: Penetration of the Internet in the municipalities of the Kaliningrad region

Source: authors' elaboration based on data from the Ministry of digital technology and communication of the Kaliningrad region.

The most active users of ICT are residents of Kaliningrad, which, among other things, is explained by the better availability of digital technologies. 39% of respondents are residents of Kaliningrad, have constant access to the Internet in 2 or more places. Also, among the surveyed Kaliningraders, the lowest proportion of those who do not have constant access to the Internet is 6%. For a group of urban municipalities, as well as for Kaliningrad, a high rate of ICT use is characteristic (74% daily), but constant access to the Internet is provided mainly from one place, while 9% have no permanent access at all. Rural municipalities show the most modest indicators of population involvement in the use of ICT. About 17% of respondents indicated that they do not use the Internet or could not remember the frequency of its use, which is 1.5 times more than in urban municipalities, and 2.4 times more than in Kaliningrad. Also, rural municipalities are characterized by a lower availability of the Internet. In total, 29% of respondents have Internet access from 2 or more places, and 14% have no permanent place for Internet access at all.

Figure 6 shows the total Internet coverage by 3G and 4G standards across the territory of the Kaliningrad region. The territory of Kaliningrad is covered by 89.2% mainly by 4G standard. The average coverage density of the territory of urban municipalities is slightly lower – 87.2%. At the same time, this group includes both small municipalities, 100% of whose territory is covered by Internet communications (Pionersky, Sovietsky), and larger ones (such as Chernyakhovskiy, Gusevskiy, Nemansky), where the coverage level is lower (minimum – 72.2%) and in a number of localities of municipalities, only 3G network is presented. For rural municipalities, the average level of Internet coverage is the lowest at 69.8%. The 4G standard is usually presented around the administrative centers of municipalities, and for the Guryevsk urban district – around Kaliningrad.

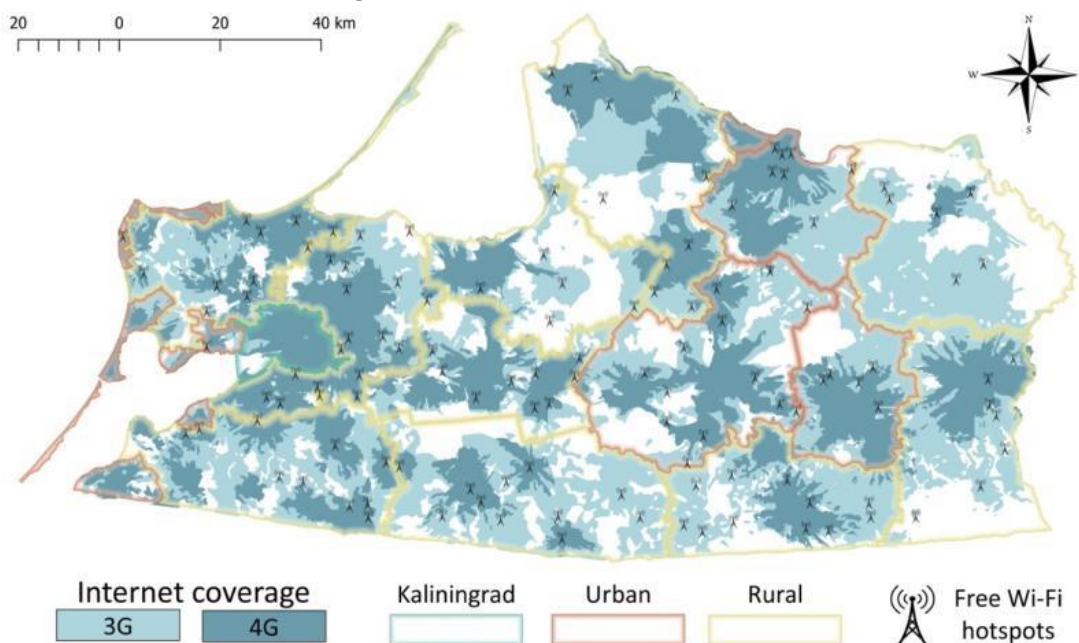

Figure 6: Density of Internet coverage of the Kaliningrad region, 2020

Source: developed by authors.

Part of the problem with access to the Internet in villages is being solved by installing free public WIFI access hotspots. In 2020, they are installed in 127 rural settlements with a population of 250 to 500 people and are usually used by residents to perform digital routines such as paying bills, communicating with relatives or sending letters. Also, residents note the emergence of such a phenomenon as “online walk” in the center of the village near the wi-fi access point (<https://vesti-kaliningrad.ru/v-kaliningradskoj-oblasti-organizovany-besplatnye-tochki-kollektivnogo-dostupa-v-internet>).

In general, the distribution of digital services by the level of their use by the population of Kaliningrad, urban and rural municipalities is shown in Fig. 7. The most popular are E-government services and Online shopping, followed by Working with e-banking & tax and Online payments (housing, communal services, etc.). There are noticeable differences between the types of municipalities in terms of the availability of various online services for the population and the willingness of the latter to use them. So, booking tickets for various types of transport, incl. taxi services are more widely used by Kaliningraders, while among the rest of the region’s residents, these services are much less in demand, least of all by residents of rural areas.

A similar trend is typical for Health service, Online shopping, Education. In many ways, the lower penetration of these services is due to their worse infrastructural accessibility for residents of rural municipalities in comparison with the group of urban municipalities and Kaliningrad (for example, taxi services are less developed, less provision of online shops with delivery desks, difficulties in using services for school education due to the instability of the Internet, etc.). The situation is somewhat better with digital services related to government services, electronic banking and payment

of utility bills – Fig. 7. The indicators for these digital services for rural municipalities are at the level of Kaliningrad, and the group of urban municipalities with the highest figures.

Figure 7: Distribution of digital services used by respondents – residents of the Kaliningrad region

Source: authors' elaboration based on data from the Ministry of digital technology and communication of the Kaliningrad region.

The receptiveness of the population to the introduction of digital routines is significantly influenced not only by the infrastructural factor, but also by the development of digital culture and skills in using digital technologies. Figure 8 demonstrates the difference between the types of municipalities in terms of participation of the population in the educational process in the field of ICT. While no significant differences were found between Kaliningrad, urban, and rural municipalities in terms of self-education, the residents of Kaliningrad have more opportunities in the field of vocational training and additional education. As a result, there is a significant gap between rural municipalities and Kaliningrad by 1.4 times in terms of the share of respondents who received ICT skills in an educational institution or in courses. In this regard, there is a significant lag of the population of rural municipalities in terms of ICT proficiency. If among the respondents – residents of Kaliningrad, 40% rated their ICT skills as high (professional and confident user), in rural municipalities only 26%, which is 1.5 times less.

Figure 8: Digital skills of respondents – residents of the Kaliningrad region

Source: authors' elaboration based on data from the Ministry of digital technology and communication of the Kaliningrad region.

The survey results also made it possible to assess the self-perception of the population on the impact of digitalization on their daily life – Fig. 9. More than half of the respondents of all types of municipalities positively assessed the benefits of using ICT and over 40% noted improvements in their activities in the last year from digitalization. However, among the surveyed residents of rural municipalities, the share of those who are dissatisfied with digitalization and have negative experience from using ICT is higher than that of urban municipalities and Kaliningrad.

Assessing the benefits of using ICT

With the use of ICTs during this year, your activities <...>?

Figure 9: Assessment of ICT implementation on the life of the population of the Kaliningrad region

Source: authors' elaboration based on data from the Ministry of digital technology and communication of the Kaliningrad region.

4. CONCLUSION

Assessing the susceptibility to digitalization of the population of various types of municipalities: the regional center, municipalities with a predominance of the urban population and the rural population, a significant digital divide between them was identified using the example of the Kaliningrad region. Differences have been identified both in infrastructure and technological provision, and in digital culture. Rural municipalities, despite the implemented state measures, still have a lower Internet penetration among the population. This is reflected both in the density of the Internet coverage and in the number of stable places with Internet access. The installation of free Wi-Fi hotspots has undoubtedly had a positive impact on the situation with Internet access in a number of villages. Residents have expanded opportunities to carry out such digital routines as communicating with relatives through instant messengers, paying bills or using a public service website, but the short range of the free Internet does not allow for longer actions, primarily remote work via the Internet. Therefore, this initiative has not yet brought a significant impact on the digital transformation of the rural environment.

Also, the rural population lags far behind in terms of the development of their educational skills in the use of digital technologies. This also does not allow us to draw a conclusion about the possibility of broad development of alternative digital employment in rural areas based on the existing potential. This is negatively impacted by the lower availability of specialized vocational training, courses and special education. As a result, the rural population turned out to be less prepared for the implementation of various digital services and has a higher proportion of those who perceive them negatively, including services implemented as response to the coronavirus pandemic, when digitalization has become more pervasive. It can be predicted that in conditions of high digital illiteracy aggravated by infrastructural insecurity, accelerated rigid digitalization in rural areas without duplication of traditional process options will lead to rejection and discontent rather than widespread adoption and receptiveness of ICT. A full-fledged digital transformation of a village is impossible without providing its residents with opportunities for Internet access, equal to those of townspeople, and implementing a broad program to improve digital literacy.

ACKNOWLEDGMENT

The study is funded by the RFBR, project 20-55-76003 "Social Innovation and Local Value Adding in Rural Regions of the Southern Baltics - SILVAR-Balt". AGGREGATE PRODUCTIVITY GROWTH FROM FIRM LEVEL DATA: THE CASE OF VIETNAM AND SOME METHODOLOGICAL ISSUES

Antonio Peyrache¹, Manh D. Pham¹, Hien Pham Thu²

¹University of Queensland, Australia. ²CSIRO, Australia

ABSTRACT

In this paper we use Vietnamese firm level data to provide a decomposition of the economy wide GDP per worker growth. The main components of the decomposition are: regional migration (labour movement across regions); TFP growth; Capital Deepening. In order to provide a figure for these components we propose to use production frontier methods to assess the performance of firms in each industry and in each region. After building the nonparametric production frontier we use it to quantify the magnitude of each component and aggregate it into economy wide effects.

We discuss the methodological issues associated with the use of firm level data and their aggregation into the economy wide components and provide some empirical evidence on the magnitude of these components in the Vietnamese economy. The underlying challenges in terms of estimating productivity growth are common to many other available datasets, including European firm level data.

A BALANCED POLICY APPROACH TO REGIONAL GROWTH: PRODUCTIVITY AND RESILIENCE

[Alexandra Tsvetkova](#), [Wessel Vermeulen](#)

OECD Spatial Productivity Lab, Italy

ABSTRACT

In the quest for efficiency, the considerations of resilience, which may or may not go hand in hand with productivity, are often disregarded until a shock hits. Large-scale shocks, such as the Great Recession and the ongoing COVID-19 pandemic, bring resilience forcefully to the forefront of policy agenda.

To understand how productivity and resilience are linked, it is useful to take a closer look at the concept of resilience. In the engineering literature, three dimensions define resilience of a system.^[1] These dimensions are robustness, resourcefulness and redundancy. Bruneau and co-authors (Bruneau et al., 2003^[1]) give the following definitions. Robustness is the ability to withstand a shock without the loss of a function; resourcefulness is the ability to deploy resources in order to resist a disruption or to recover from a shock and redundancy denotes the presence of elements that can be deployed instead of the affected ones in order to support uninterrupted functioning of a system.

Most generally, policies to promote productivity (growth) increase robustness and resourcefulness, thus buttressing resilience at the firm, industry or regional levels. The quest for productivity comes in obvious conflict with resilience in the redundancy element. Any redundancy is inefficient by definition. Firms and industries often strive to remove such redundancy by relying more on lean processes, just-in-time delivery and other practices. Narrowing the networks of suppliers to the “best” ones can also reduce redundancy and the associated costs of maintaining contacts with more partners. The downside is that a more concentrated supply networks can leave firms and regions vulnerable to shock affecting the suppliers (e.g. as a result of a natural disaster in the area of concentration or for other reasons).

Finally, the link between productivity and resilience also emerges from the system itself. Becoming a part of a system offers many opportunities to increase productivity, mostly through learning but also access to a wider range of suppliers and customers. In terms of resilience, the effect is not straightforward. On the one hand, embeddedness in a system can hedge against localised shocks where inputs can be procured from outside if local supplies are disrupted. At the same time, being a nod in a system makes an agent (a firm, an industry or a region) potentially susceptible to shocks in other nodes. The final effect depends on the configuration of the system and the nature of a shock.

This paper reviews productivity and resilience policies against different types of shocks and demonstrates where such policies go hand in hand, where they are independent and where they counteract each other. A discussion on how to better combine considerations of productivity and resilience in regional policy design is also offered.

^[1] The full list normally includes four elements, adding rapidity to robustness, resourcefulness and redundancy (Bruneau et al., 2003^[1]), although it is often reduced to the three most appropriate elements in specific applications (Fekete, 2019^[2]).

THE CHANGING ROLE OF LONG-RUN DRIVERS OF LABOR PRODUCTIVITY

[Yoki Okawa](#)¹, [Alistair Dieppe](#)², [Atsushi Kawamoto](#)³, [Cedric Okou](#)¹, [Jonathan Temple](#)⁴

¹World Bank, USA. ²European Central Bank, Germany. ³Ministry of Finance, Japan. ⁴, United Kingdom

ABSTRACT

This research explores the drivers of global long-term productivity growth and how their roles have varied over time, through extensive literature review, examination of the development of drivers, and empirical analysis using the Bayesian Model Averaging.

The following findings emerge. First, historically, labor productivity growth has been driven by innovation, better education, and investment in physical capital. Innovation and private sector investment require a growth-friendly environment, with supportive institutions and policies, including policies that promote macroeconomic stability and the rule of law. Productivity growth also seems to benefit from expertise in producing relatively complex and sophisticated exports, which is associated with international technology diffusion.

Second, the effects of different drivers on productivity growth have changed over time. Innovation and experience with economic complexity, related to participation in global value chains and cross-border technology transfer, seem to have increased in importance. So have demographic factors, notably changes in population age structures. In contrast, the importance of urbanization, related to the sectoral shift from agriculture to manufacturing and services, has weakened. Third, many productivity drivers in EMDEs fall short of advanced-economy conditions, despite remarkable improvements over the last 60 years in key human capital indicators such as the provision of primary education and infant mortality rates. This research documents these gaps in a systematic way. For some productivity drivers, including ones that are essential to innovative economies—tertiary education, financial development, and patents per capita—the gaps have widened. Improvements in other drivers, such as institutions and economic complexity, have stalled. In addition, many drivers of productivity growth have faltered, including those which had previously supported strong productivity growth. Working-age population growth has slowed, along with growth in average educational attainment. As the expansion of global value chains has lost momentum, so has the movement toward more diverse and complex forms of production.

Fourth, the COVID-19 pandemic has made the near-term outlook for productivity growth even more challenging. Weaker investment and trade, erosion of human capital, slower labor reallocation, heavier public and private debt burdens, and widening inequality could push down on productivity growth. Yet, the pandemic may also create productivity-enhancing opportunities such as lasting organizational and technological changes for business and education, diversifying global value chains, and changing social norms.

Fifth, the recent slowdown in productivity growth has multiple sources and, hence, action on a range of fronts will be needed. Governments seeking to raise productivity growth can increase public investment and stimulate private investment; improve human capital; foster firm productivity, partly through on-the-job training and upgraded management capabilities; increase the exposure of firms to international trade and foreign investment; enable the reallocation of resources toward more productive sectors; and, seek to diversify production. The benefits of many productivity-friendly policies could be enhanced by improving the macroeconomic and institutional environment.

ABSTRACT

The climate conditions may affect crops productivity and, as a consequence, as well as regional agriculture earnings. In this paper, we use a CGE model for Paraguay, which incorporates detailed information about the value chain of the agriculture sector in the country. According to the 2014 information input-output matrix, we calibrate climate shocks associated with the agriculture business in Paraguay. We model the climate shocks as a technical change in the agriculture-producing sector. Moreover, we calculated uncertainty systemics effects on crops productivity due to the climate change. Given the specific economic environment for the model and the proposed simulation; it is possible to observe the Paraguayan real GDP reduction around 2.55%. In terms of household consumption reductions, representing 4.15% of (2014) current per capita annual consumption.

1. INTRODUCTION

Effects of climate on agriculture and rural areas have been extensively studied, such as in Mendelsohn and Massetti (2017), Carter et al. (2018) and Nordhaus (2019). Agriculture is one of the most vulnerable economic sectors regarding climate change as it is directly affected by fluctuations, such as the temperature and rainfall. In general, the direct effects of climate change on agriculture are mainly related to lower crop yields, causing productivity loss. However, according to Stern (2006) the real economic impacts due to climate shocks are still uncertain. According to Nordhaus (2019) the damages are likely to be most heavily concentrated in natural systems as well as in low-income and tropical regions such as Latin America. In this context, Paraguay is not an exception, once the agricultural sector represents its economy and has regional disparities, so it is likely to have greater damage.

Therefore, there are not many studies that explored the systemic climate change impacts on the agriculture sector within a region. According to Haddad et al., (2014), given productivity shocks that a region may face, backward and forward linkages which will affect, to different extents, the local demand by the various economic agents sectoral and spatial sectoral linkages will also play an important role in the adjustment processes. The extent of the impact will depend on the degree of linkages with other regions. In an integrated interregional system, there is a need to address these issues in a general equilibrium framework. This regional view is essential to convey valuable insights to policy makers considering approaches to production value chains.

Thus, what are the economic costs of climate change? Which regions are chiefly affected and to what magnitude? How could the uncertainties of climate change affect the results in a qualitative way? Within this context, the aim of this study is to analyze climate change systemic impacts in Paraguay from business agriculture. We use a methodological framework in which physical and economic models are integrated for assessing the higher-order economic impacts of projected climate changes in Paraguay between 2010-2100 by the Economic Commission for Latin America and the Caribbean (2014).

The interregional computable general equilibrium (ICGE) models can take into account the associated productivity changes and generate the systemic impact of projected climate variables by considering the linkages of the agriculture sector with other sectors of the economy and the locational impacts that emerge to other regions. Thus, assessing the economic contribution of a part of a country or region economic sector requires some consideration of the likely paths

of interactions that are a consequence of the effects of climate on crop yields, consequently, on the economy (Haddad et al., 2014).

Accordingly, the process adopted here is to use estimates from ECLAC (2014) between climate variables and agriculture productivity, and then to feed the results into an inter-regional CGE model to capture the system-wide impacts of the projected climate Paraguayan scenario. In addition, we used the methodology proposed by Haddad and Garber (2012) in order to compare the uncertainties rising from the techniques employed, enabling the analysis of robustness and the consistency of the results throughout the Paraguay regions.

2. CLIMATE CHANGE AND ECONOMICS IMPACTS

The exercise of assessing the climate change impacts appears to be complex, since it contains an uncertainties set about the degree of future global warming and its effects on the whole economy, as well as how far the future technological capacity will evolve to counteract the negative effects. Nevertheless, it is possible to analyze these effects, having as reference the territorial space and the current data related to the present variables.

Recent studies presents developing economies tend to be more affected by climate shocks. According Wade and Jennings (2016) the countries of North America and Western Europe are less vulnerable to global warming. However, the countries vulnerable are distributed between the African and Asian continents. For example, Roson and van der Mensbrugge (2012) evaluated the impacts regional distribution due to climate change. The results presented that the impacts of climate change are substantial, especially for developing countries and, in the long term, it is necessary to take adaptation and mitigation measures to guarantee sustainable economic growth.

However, the countries vulnerable are distributed between the African and Asian continents. Nevertheless, even with the asymmetric on the spatial distribution of the effects of climate change, it is estimated that in the long run, the climate change effect on economic growth will be widespread and negative, taking into account the financial, political and economic integration of the world's economies. In this sense, global warming will mainly influence economic growth through the damage it will cause to infrastructure, productivity losses, migration and security threats (Wade and JENNINGS, 2016).

The global externalities due to climate change reaffirms that private markets do not allocate resources efficiently and that often the climate change economics involve a lot of uncertainty and risk. Thus, modeling it is a challenge, at the same time that it is an ally for the process of understanding the direction that human actions are taking the planet (Nordhaus, 2019). According to Guesnerie and Stern (2012), economists can evaluate the cost-benefit of decisions. In this sense, the study of climate change is part of its scope analysis because it involves understanding that actions taken will have long-term consequences, amid an uncertainty environment in which everyone can influence in some way.

In this context, Van Passel, Massetti and Mendelsohn (2017) estimated the climate change effect for European agriculture using a Ricardian model. The results report that the increase in temperature would increase the agricultural land prices in northern Europe and reduce prices in southern Europe. Increased rainfall would benefit all countries except Scandinavians. The sensitivity measure agricultural sector varies depending if the farm irrigates the plantations or not, in this second case it is more vulnerable to weather. According to Mendelsohn and Wang (2017), the intensive agriculture returns greater benefits due to the fertile soil and adequate climate, in the other words, applying intensive agriculture in non-fertile soils and with unfavorable climate, can bring losses. Therefore, if climate change reduces the productivity of agricultural activity, this will result in less revenue and farmers can reduce inputs demand. In view of the low supply, prices may rise and producers may increase inputs demand again.

The climate change effects can be intensified when other factors, such as public health, are affected. According Rasul (2021), climate change affects agriculture by changing the temperature, level of rainfall, floods and droughts. The South Asia already lives with the climate change negative effects on agriculture, these effects, together with others, for example a pandemic (COVID-19), reinforce the importance of the environment, climate and public health for the countries economies, especially for developing countries.

2.1. Business agriculture sector in Paraguay

Paraguay is a country located in the center of South America, and has Argentina, Bolivia and Brazil as bordering countries. It has a territorial extension of 406,752 square kilometers and an approximate population of 7,300,000 inhabitants by the end of 2020 (DGEEC, 2021). The country is divided into 17 States and the District Capital (Asunción). In turn, the Paraguay River separates the country into two main geographical regions: The Eastern Region or "Paraneña" and the Western Region or "Chaqueña" (REDIEX, 2021).

Considering the 2019 GDP, the 5 main sectors, with their corresponding shares are: Manufacturing (18.6%), Commerce (10.6%), Agricultural Production (9.8%), Government Services (9.6%) and Electricity and Water (8.2%). Therefore, with regard to exports (2019) equivalent to 7,962 million USD: Manufactures of Agricultural Origin corresponds to 33%, Primary Products (31%), Electric Energy (24%) and Manufactures of Industrial origin (12%). According to data from the REDIEX (2021), Paraguay is the first world producer of Stevia (*Stevia rebaudiana* Bertoni), the first net exporter of clean energy worldwide, the fourth world exporter of soy (*Glycine max*), the fifth world exporter of soybean oil, sixth world exporter of corn (*Zea mays*) and seventh world exporter of beef.

According to Borda and Caballero (2020) the Paraguay during the last 70 years faced three considerable economic cycles. The first growth cycle (1961-1983), of the accelerated type with expansion of the agricultural frontier and the construction of the Itaipú Hydroelectric Dam. The second cycle (1984-2002), slow, due to external shocks and financial crisis. The third economic cycle (2003-2018), a return to growth was observed, due to the good production of raw

materials, mainly related to agribusiness, and the macroeconomic stability reached by the country. Agribusiness, in recent years, has become one of the engines of economic growth in Paraguay. According to data from the Central Bank of Paraguay - CBP (2021), the production of commodities and bovines for meat, both as raw material and its derivatives, largely drove this growth.

Some consequences evidenced in Paraguay due to climate change presentation that in the period 1961-1990, the country registered 1.5 ° C above the average temperature of the period, therefore, an even greater difference with respect to the pre-industrial period 1850-1900. With reference to rainfall, an average annual increase of 3 millimeters was evidenced in the last 70 years and in the last decade 2010-2019 it was observed that rainfall exceeded the average of 1961-1990 by 11%. As for droughts, it is increasing and heat waves are three times more intense than in the last 40 years (Grassi, 2020). Therefore, we can see the importance of business agriculture sector for the Paraguayan economy and how much climate change can affect its performance. Therefore, understanding this process and estimating the possible costs becomes important for policy makers, since they can devise strategies to mitigate the possible consequences.

3. THE MODEL

We use the B-MARIA model that is an inter-regional CGE model in order to evaluate the wider and regionalize economic impacts of climate change on the business agriculture sector in Paraguay. The model structure represents a variant of the well-documented B-MARIA model (Haddad, 1999), calibrated for the Paraguayan economy. The B-MARIA model – and its variants – have been applied to many countries (Haddad et al. 2014). Following the Australian tradition, it qualifies as a Johansen-type model in that the solutions are obtained by solving linear equations system model. The result presentations the percentage change in the set of endogenous variables, after the policy is carried out, compared to their values in the absence of such policy, in a given environment. Johansen’s systemic solutions for such models are standard in the literature. Further detailed analysis can be found in Dixon and Parmenter (1996) and Haddad (1999).

The B-MARIA version Paraguayan model makes it possible to capture the effects of the entire economy and of all regions through an intricate plot of input-output relations for 18 regions and 33 sectors (Appendices A1 and A2). We calibrate climate shocks by defining a main transmission channel physical variable into economic inputs for CGE models (Figure1). As we do not econometrically estimate the direct links between the climate scenario and economic variables, we build narratives based on specialized literature to quantify the exogenous scenarios stylized to feed the CGE model.

Figure 1: Transition channel physical variable into economic inputs for CGE models

The quantity channel is the transmission channel deriving from a decrease in the agricultural productivity sector. We used the information carried out by the Government of Paraguay study together with The Economic Commission for Latin America and the Caribbean (ECLAC) (ECLAC, 2014), which estimated the agriculture business mean variation yield resulting from climate changes for the 2010-2100, as the increase in average temperature and the modification of precipitation patterns in the Paraguayan regions reduce the area and the quantity harvested. According to data from ECLAC (2014), the soybean production is expected to decrease by a mean point of -14.2%, wheat production should decrease by an average of -17.2% and maize should increase by 7.3%. It can be seen that soybean and wheat crops are most affected by climate change, on the other hand, maize benefits from these changes. Therefore, it is expected that the regions producing the soy and wheat be the most affected in relation to the regions producing maize. We model this channel climate shocks as a technical change in the agricultural production sector by region, decreasing the productivity of these crops in the agricultural sector.

According to the model analytical structure, the reduction in overall productivity is also associated with an increase in the inputs and primary factors requirements per unit of output in the business agriculture sector (technical change channel). This creates an upward pressure on input prices, wages and capital rentals, which are passed on in the form of higher prices.

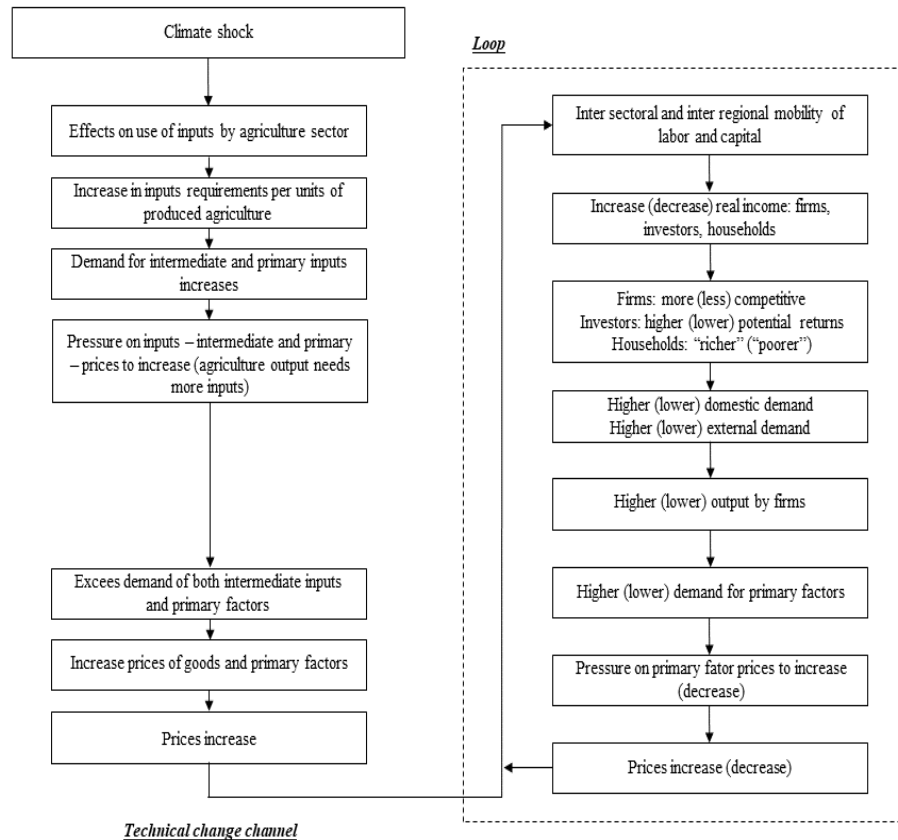

Figure 2: Causal relations underlying the simulation results

Figure 2 summarizes the transmission mechanisms associated with first-order and second-order effects in the adjustment process underlying the model's aggregate results in the context of the major channels through which the shocks operate. Second-order prices changes go in both directions – decrease and increase. The net effect is determined by the relative strength of the countervailing forces.

Lastly, the total economic impacts of climate change analysis, as well as accumulating all the aforementioned uncertainties, involve a plethora of hypotheses about the Paraguayan economic regional and sectoral productive structure, in addition to the assumptions coming from the EGC models analytical and functional structure.

The confluence of all these uncertainties breed a well-documented “snowball” effect in the science of the economic impacts of climate change (Stern et al. 2006). In order to try to deal with this effect, we will use the methodology that deals with this process in an explicit way based on the framework proposed by Garber and Haddad (2012). To implement this method, we explore the potential links of a physical model with the functional structure of the EGC model.

For such case, the idea is to conduct simulations that reproduce the behavior of a given set of endogenous variables from B-MARIA. Thus, it is enough to replicate the desired information within the exogenous set variables in the model, and similar shocks in order to achieve the best effects combination for its endogenous variables. In other words, we will use the real GDP variables and the regions consumption and place them as a “target” for the replica EGC model. Thus, the objective is to calibrate the exogenous productivity shocks on B-MARIA structure that will endogenously generate the aforementioned target results.

Therefore, given the intrinsic uncertainty in the magnitude of agricultural productivity shocks in the regions, the method can be applied in order to integrate the results with the structure of the B-MARIA model and, thus, deal with the uncertainty explicitly in the construction the productivity shocks for agricultural crops in the regions. Thus, for this study, 10,000 productivity shock simulations were carried out in order to assess the impacts on the state GDP and on household consumption. Each simulation was constructed from a randomly draw for the state productivity shock from a Gaussian distribution with mean and variance equal to the shock calculated based on ECLAC (2014) (Appendices A3).

4. RESULTS AND DISCUSSION

To measure the wider impacts of the prevailing climatic conditions that will affect agriculture business in Paraguay in 2014, we run the model under a long-term macro-adjustment closure. The adopted closure is chosen from the standard B-MARIA's long term closure (Haddad, 1999). In the long-term closure, capital and labor have intersectoral and interregional mobility, it is possible to assess the different impact if the policy takes over a permanent character. The main differences in relation to the short-run are in the labor market configuration and the capital accumulation process. In the first case, aggregate employment is determined by population growth, labor force participation and natural

unemployment rates. The spatial and sectoral workforce distributions are fully determined endogenously. The labor is attracted to the most competitive sectors and the favored geographical areas. Likewise, the capital is oriented towards the most attractive sectors. This movement keeps the return rates on capital at their initial levels. It should be noted that the base year of the B-MARIA model for Paraguay is 2014, so that the effects are conditioned to the economic structure for that period.

Table 2 presentation of the total impacts on economic aggregates arising from agricultural productivity shocks due to climate change. The combined effects of lower output agriculture would lead to a reduction of Paraguayan real GDP by -2.55%. Overall, a decrease in real investment (negative impact on GDP of -2.20%), followed by exports and imports (negative impact on GDP of -1.29% and 2.88%, respectively). Followed by a reduction in household consumption (-2.2%), reduction in national employment (-0.01%) and decrease in nominal wages (-5.36%) made the main contributions to the aggregate GDP result.

Table 2: The impacts on Paraguayan GDP

	<i>Total</i>
Nominal GDP from expenditure side	-3.75
Real GDP from expenditure side	-2.55
Aggregate real investment expenditure	-2.20
Export volume	-1.29
Import volume	-2.88
Real household consumption	-4.15
National Employment	-0.01
Nominal wages to workers	-5.36

In addition to the sector directly affected (agricultural business), the sectors (indirectly) most affected by climate change that affects crops yielding, which are those related to the agricultural business value chain, according to Figure 3. The mean change on the activity level in the sectors has been -1.94%. However, the government services sector (S33) and basic metals (S19) have been positively affected.

Figure 3: Impact on activity level, by sector

According Taconet, Méjean and Guivarch (2020) the climate damages will be shared unevenly among regions, because physical impacts may differ, and because the vulnerability to climate change vary widely across regions. Figure 4 presents the regional productivity changes impacts in agricultural business crops due to climate change on real GRP / GDP (% deviations from 2014 baseline). In terms of regional GDP, the states of Canindeyú (-5.27%), Caaguazú (-4.16%) and Itapúa (-4.37%) were the ones that obtained the highest results in the regional GDP. However, the regions of Boquerón (-1.52%), Alto Paraná (-1.59%) and Alto Paraguay (-1.65%) were the ones that obtained the lowest decrease in the regional GDP. In general, the most affected states are located in the eastern region of Paraguay, therefore, the least affected are located in the western region.

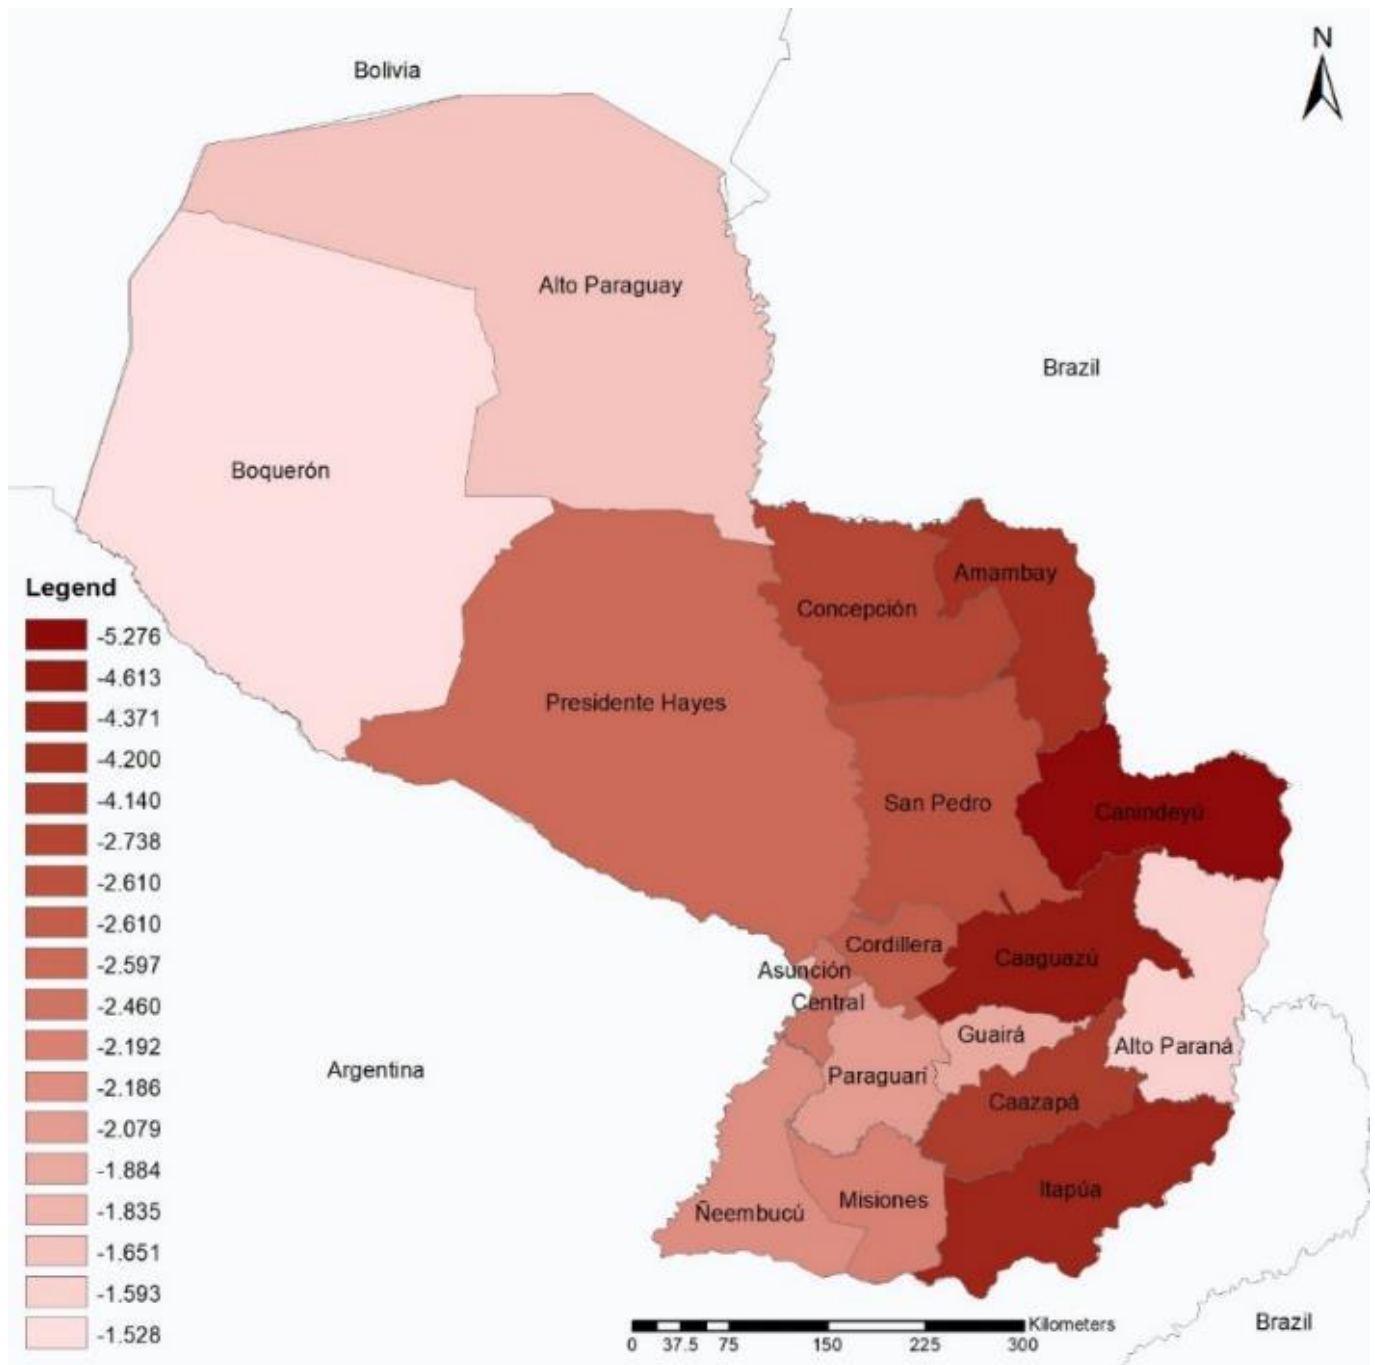

Figure 4. Regional impacts of productivity changes in business agriculture crops due to climate change on real GRP/GDP (% deviations from 2014 baseline)

The climate shocks have negatively effect on economy and, in particular, on agricultural productivity, affecting consumption and increasing economic inequality between households and individuals (Amare et al., 2021). Figure 5 presents the regional changes impacts in productivity in commercial agricultural crops due to climate changes in real consumption per capita (% of deviations from the 2014 baseline). The states of Cordillera (-5.30%), Presidente Hayes (-5.07%) and Paraguari (-4.91%) were the ones that obtained the highest levels of real consumption per capita. The regions Canindeyú (-1.10%), Alto Paraná (-2.23%) and San Pedro (-2.34%) were the ones that had the smallest decrease in real consumption per capita. In general, the most affected states are located in the western region of Paraguay and, consequently, the least affected are located eastern region.

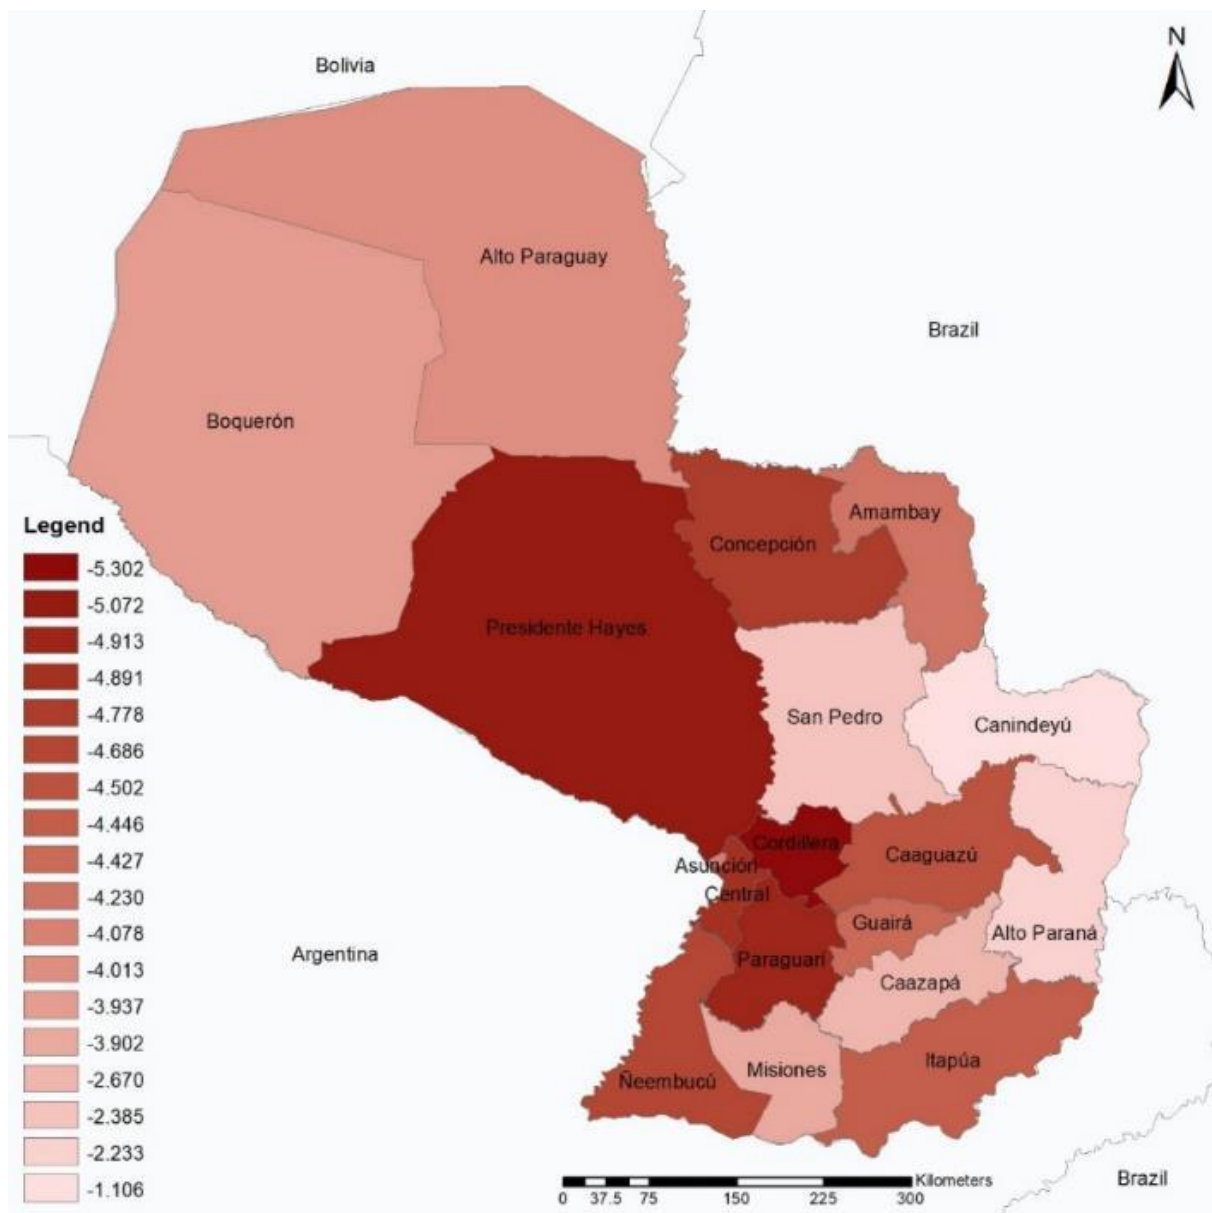

Figure 5: Regional impacts of productivity changes in business agriculture crops due to climate change on real per capita consumption (% deviations from 2014 baseline)

There are considerable regional disparities in the possible impact of climate change on crop productivity in Paraguay. The Figure 6 presents the distribution of the simulations for each Paraguayan state with the aim of mitigating a series of uncertainties about the possible impacts of climate change on agricultural production and, hence, on the economy as described by Stern et al. (2006). The analysis makes it possible to compare the magnitude and the difference in agricultural productivity shocks for each state. There is a great heterogeneity in the variation of agricultural business production between the states of Alto Paraná, Canindeyú, Presidente Hayes, Boquerón and Alto Paraguay. These states are located in the eastern region (bordering Brazil) and in the western region (bordering Argentina and Bolivia). In all regions, uncertainties with respect to the magnitude of the expected changes result in uncertainties of the impacts agricultural, such as in study Taconet, Méjean and Guivarch (2019).

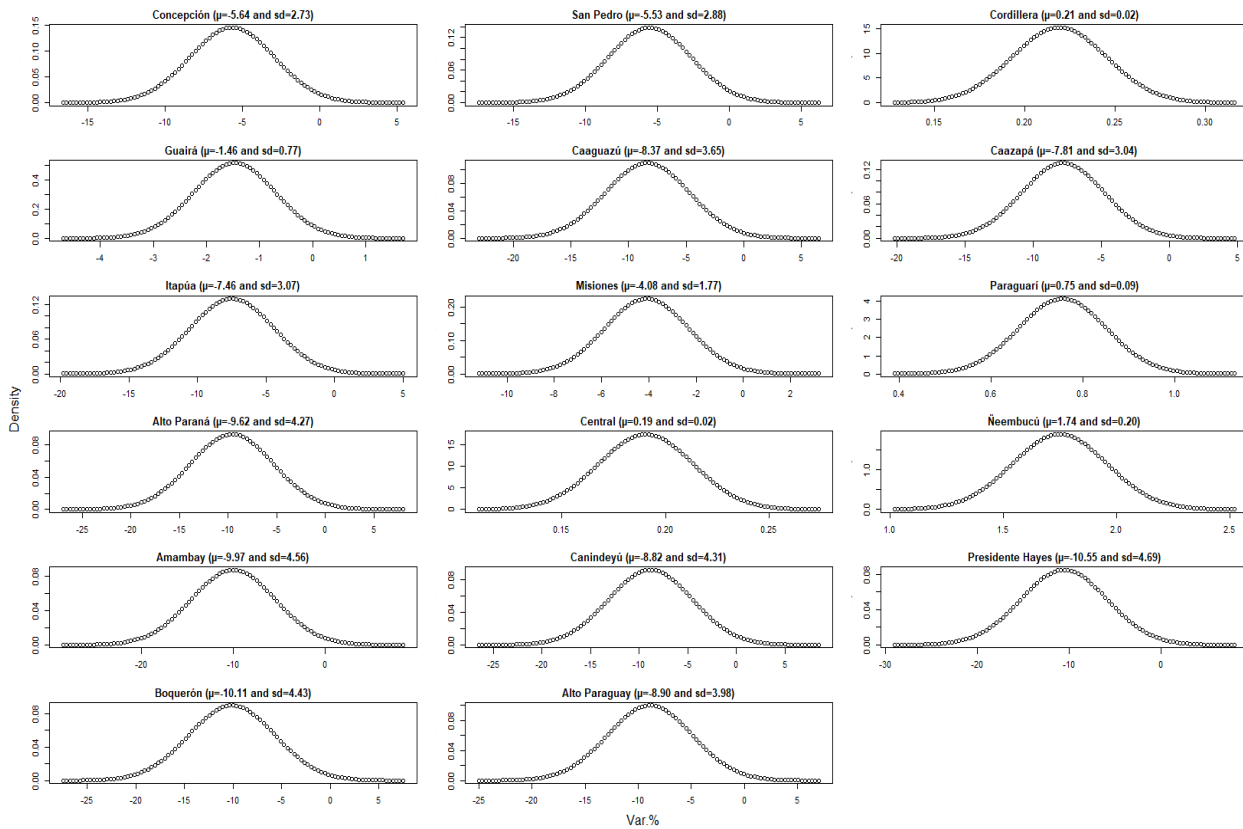

Figure 6: Simulated Distribution productivity shocks

Figure 7 presents the effects on the GDP real regions corresponding to each simulation the regional productivity impacts changes in agriculture business due to climate change compared with 2014 baseline. The distribution of effects must be interpreted as the possible response the regions production may have to uncertain agricultural productivity shocks. The possible responses to GDP rising from climate change in 10 regions are negative magnitudes, and the remaining ones can be positive. The states with the highest variances are Canindeyú, Caazapá, San Pedro and Caaguazú.

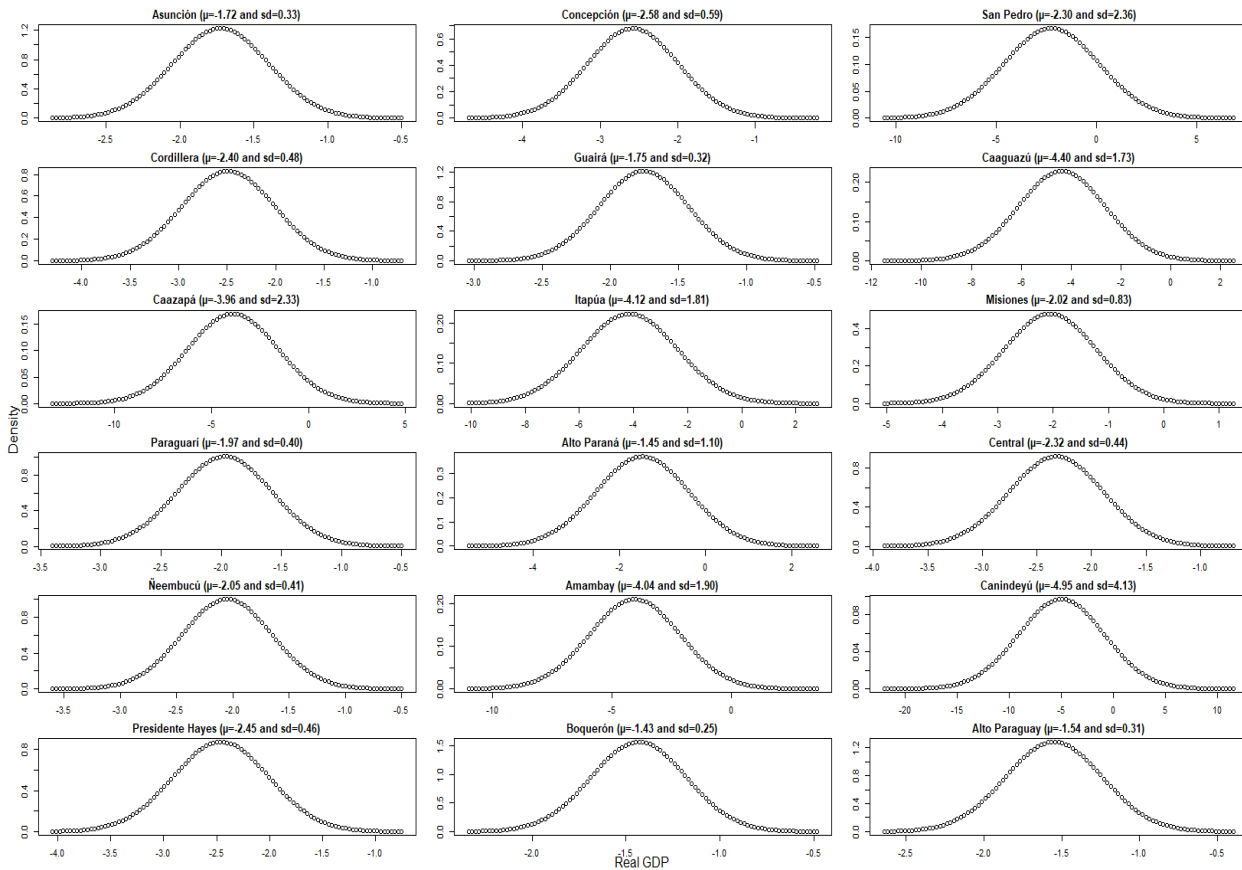

Figure 7: Distribution of simulated impacts for regional GDP (% deviations from 2014 baseline)

Figure 8 presents the effects on real per capita consumption for the regions corresponding to each simulation the regional impacts of productivity changes in agriculture business due to climate change compared with 2014 baseline. The distribution of effects must be interpreted as the possible response the consumption of the regions may have to uncertain agricultural productivity shocks. In most regions the results on consumption can be negative. The states of Cordillera, Paraguarí, Central and Presidente Hayes may experience a decrease in consumption up to -8% compared to the baseline.

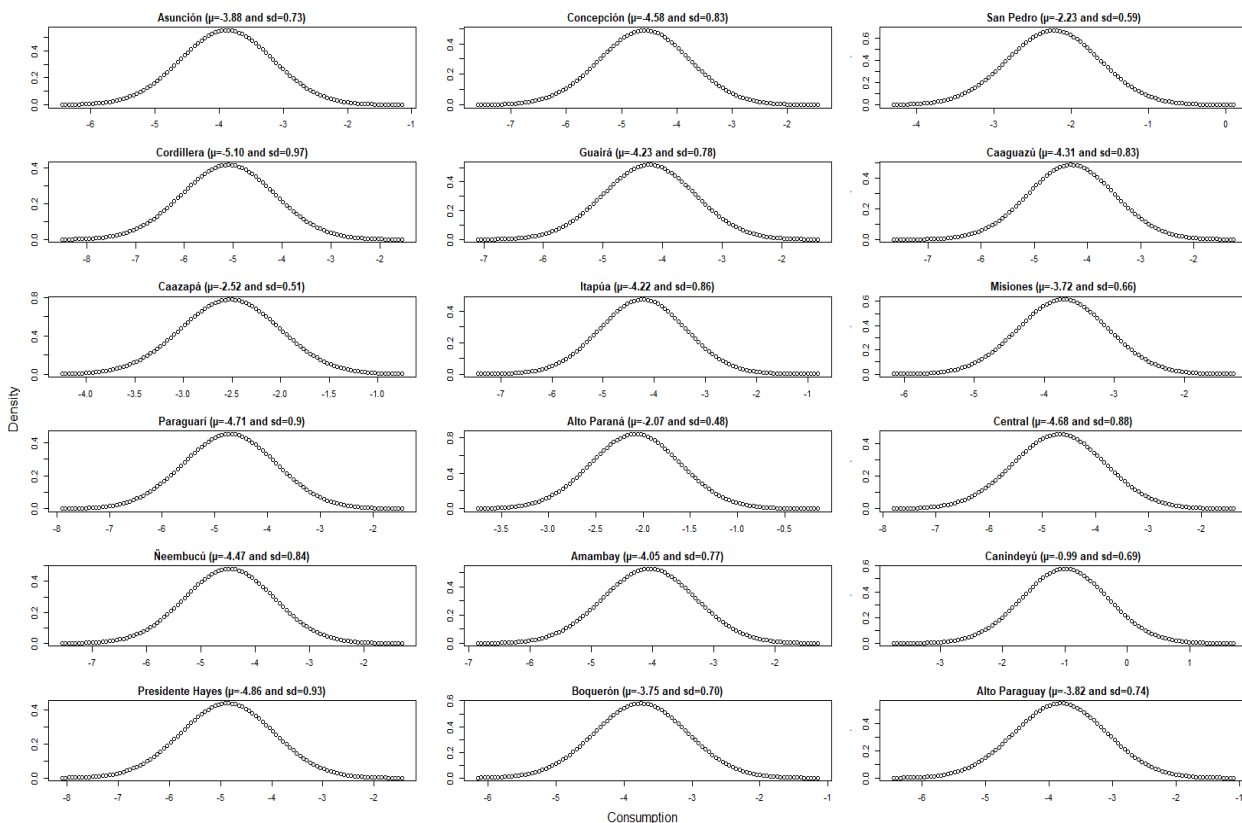

Figure 8: Distribution of simulated impacts for regional consumption (% deviations from 2014 baseline)

Climate change increases the unpredictability and inequality between regions regarding future economic outcomes, effects that may alter the valuation of climate damages beyond their expected cost (Hsing et al. 2017). The results understanding may be reached through the inequality index on each simulation. Thus, how important are the regional results on inequality, associated with climate change in Paraguay? To answer these questions, we calculated the Williamson index for each model simulation results (regional GDP and population). Figure 9 presents the results of the Williamson index and the real regional GDP in baseline percentage. The distribution of effects must be interpreted as the possible response inequality between the regions; it may have uncertain agricultural productivity shocks. Most of the simulated results are concentrated in the negative quadrant where there is a reduction in real regional GDP and an inequality index. However, there are results that presentation an increase in regional inequality. According to Hsiang (2017) climate change, in addition to increasing the unpredictability of its real impacts, it can increase the regional disagreement that it causes since there is a transfer of production factors from the most affected regions to the least affected ones.

Figure 9: Dispersion between the Williamson index and the regional real GDP (% deviations from 2014 baseline)

The analysis of the images presents some possible dimensions to be verified, such as the relationship between the variables at national and regional level and the dispersion of the simulated impacts. In summary, the imagens analysis presentation the possible conjectures are due to of climate change from different simulated scenarios and economic integration framework across regions.

6. CONCLUDING REMARKS

In this study we have computed estimates regions economic impacts, if climate change conditions (2010-2100) that prevailed in Paraguay in 2014. We have used an inter-regional CGE model calibrated for the Paraguayan economy using data for 2014. The general equilibrium approach adopted in this paper allowed a broader understanding of potential responses of agriculture business in Paraguay to a climate change scenario taking into account its whole value chain and, consequently, its uncertainties.

The results revealed the relevance of economic integration framework across regions and its heterogeneities to understand the systemic effects due to climate change. Revisiting the main results of the paper, if changes in productivity of agriculture business crops associated with climate change in Paraguay by 2100 prevailed today (2014), current GDP would be 2.55% lower, i.e. the annual cost in terms of GDP would reach close to USD 1 billion. In terms of welfare, the average Paraguayan citizen would have lost around PYG 719 thousand (USD 155) yearly, in terms of the projected reductions in household consumption, representing 4.15% of current (2014) per capita annual consumption.

The results are not without limitations. In our simulation-based approach, results depend heavily on the analytical, functional and numerical structures of the model. The other limitations refer to the model pre-selection and how climate change conditions may have affected other crops and regions sectors. Additional research is needed to help provide further evidence to evaluate these issues more completely. Our study of the economic impacts from climate change on crop yields in Paraguay, despite its limitations, shows that there are potential high costs and associated risks in more vulnerable country regions.

DIVERSIFICATION IN THE DESTINATIONS OF PARAGUAYAN EXPORTS: WHAT CAN THE TRADE COMPLEMENTARITY (TC) INDEX EXPLAIN ABOUT IT?

Plinio Esteban Ramirez Alvarez, Victor Ramón Enciso Cano

The National University of Asunción, Agricultural Science School, Paraguay. esteban.ramirez@agr.una.py, venciso@agr.una.py

ABSTRACT

The theory of international trade states that a free trade agreement enlarges the market for the subscribing parties and allows economies of scale. With an agreement, the trade between the parties grows as it happened with Paraguay's trade during the first years of the Southern Common Market (MERCOSUR in Spanish). Despite this, since the beginning of the millennium, it can be observed that regional market share in Paraguay's export is declining almost linearly. What is happening with Paraguayan exports? Is it diversifying, because the regional market is no longer attractive? Are Paraguayan exports a competition for the production of its commercial partners, which forces Paraguay to search for new markets? Perhaps, the Paraguayan exporters with the internationalization, due to the MERCOSUR, have improved the country trading as well as international negotiation capacity, resulting in the accession to new markets. Of these questions, and others, that may arise, this research focuses on the reduction of the regional market as a result of a lesser coincidence between the export supply of Paraguay and the import demand of MERCOSUR. Specifically, it aimed to: (i) calculate trade complementarity (TC) index between Paraguayan exports and MERCOSUR imports, using Brazil as a proxy for the regional market; (ii) identify which products are subject to change in their complementarity; (iii) identify those products that did not show any changes in their complementarity. It concluded that the participation of the regional (Brazilian) market has been reduced in the number of products, but there has been a strong increase in value, presenting a concentration of exports of products in which there is complementarity between the Paraguayan supply and Brazilian demand.

PRODUCTIVE STRUCTURE AND AGRICULTURAL SECTOR OF THE PARAGUAY: AN INPUT-OUTPUT APPROACH

Eduardo A. Haddad¹, Plinio Esteban Ramirez Alvarez², Gustavo H. L. Castro¹, Victor Ramón Enciso Cano²

¹The University of São Paulo Regional and Urban Economics Lab - NEREUS, Brazil. ehaddad@usp.br, gustavocastro@usp.br. ²The National University of Asunción, Agricultural Science School, Paraguay, esteban.ramirez@agr.una.py, venciso@agr.una.py

ABSTRACT

Researches report that Paraguay's agriculture sector has shown a high-performance last years, which put the sector in a key-sector status, in terms of economic growth. Actually, the agricultural and livestock sector is in evidenced, mainly in exports to the others countries; although it generates low incomes and jobs directly from the activity, it generates a high multiplier effect of these variables in the input supplier sectors to its production. The main goal of this paper is identifying the role of agricultural and livestock in Paraguay economy with an economy growth theories basis, which in a large viewpoint, consider the agriculture sector being essential to the growth of other productive sectors. For this purpose, it was used, the interregional input-output system for Paraguay, for the year 2014. The analyzed empiric data confirm the importance of agriculture sectors as a supplier of raw material to the other sectors, and as a buyer of manufactured products.

ABSTRACT

It is extremely important for the country's economy to analyze the behavior of soybean cultivation, because it is the main agricultural export product of the country and the one that generates the greatest amount of income, that is why this research had as its objective the main objective is to evaluate the convergence of soybean productivity in the producing departments of the eastern region during the period 2007-2018, to test the hypothesis of the existence of absolute convergence. For this, an exploratory data analysis was carried out, which were measured by the spatial econometric model where the initial level of crop productivity was associated with the increase in this same productivity over a certain time. The dependent and independent variables were used as study parameters, which were the growth rate of soybean production and the natural logarithm of soybean productivity, respectively. The parameters studied were significant at the 1% confidence level, this indicates that the dependent variable (y) is influenced by shocks from all departments, with the closest departments being the most influenced. Likewise, the spatial dependence through the residuals was detected, indicating the existence of non-modeled factors that may be influencing this process.

HOW TO MEASURE THE TERRITORIAL ECONOMIC IMPACT OF THE COVID-19 PANDEMIC IN CONTEXTS WITH SCARCE REGIONAL DATA? A METHODOLOGICAL PROPOSAL AND APPLICATION FOR ARGENTINA (APRIL-SEPTEMBER 2020)

Andrés Niembro¹, Carla Daniela Calá²

¹Universidad Nacional de Río Negro, Argentina. ²Universidad Nacional de Mar del Plata, Argentina

ABSTRACT

The trade-off between epidemiological prevention and economic activity is one of the most pressing issues that governments and societies are facing. Recent studies highlight that, unlike other crises such as that of 2008-2009, the impact of the pandemic has been regional rather than national. This is why the literature raises the need to adopt a regional perspective in the analysis of the economic impact of the COVID-19 pandemic.

However, the study of the regional economic impact often faces several limitations, in many cases due to the limited availability of updated information at the subnational level. The abundance of real-time epidemiological statistics for multiple geographical scales contrasts with the scarcity of economic statistics, which in developing countries are often non-existent or very outdated. Moreover, available estimates of the economic impact of COVID-19 are usually presented at an aggregate level, that is, by country or by sector.

In this paper, we wonder how we can measure the territorial economic impact of the COVID-19 pandemic in contexts with scarce or outdated regional data. To this end, we propose the calculation of an index that, with minimal adjustments or adaptations to each context, could be used to measure the regional economic impact of the pandemic and isolation measures, based on data or statistics that are usually available in most countries. Our index of territorial economic impact by COVID-19 (ITEI-COVID) takes into account: a) the sectoral production structure of the different regions, based on pre-pandemic data, b) the operational level of each sector, based on secondary post-pandemic information at the national level, c) the mobility of workers in each region, based on the easily accessible data from Google Mobility Reports, and d) the possibility of remote work across different activities or sectors, based on recent studies that have been carried out in many countries.

As an application, we show the results of the ITEI-COVID for the 24 provinces and the main 85 Labor Market Areas (LMAs) of Argentina, throughout the six months -or two quarters- of greatest economic contraction, from April to September 2020. In line with recent literature, the ITEI-COVID reveals large disparities between the 24 provinces and the main 85 LMAs of the country, as well as the heterogeneity within some provinces, which revalues the use of smaller geographical units. The results also showed that, although the economic impact of the pandemic has been decreasing over the months for the country as a whole, there is considerable stability in the relative position of the most and least affected regions. Besides, the economic impact in many regions has been dissociated from the health impact or the relative number of cases.

Finally, the comparison with sporadic official indicators of the regional economic impact of the pandemic emphasizes the validity of the proposed index, which also has a higher geographical and temporal coverage. Although we propose a relatively simple and descriptive exercise, the calculation of an index of territorial economic impact can be a relevant input for the design, implementation, and monitoring of targeted and place-based policies, which seek to mitigate the harmful economic impacts of the pandemic and isolation measures.

GREEN EXPORTS IN ARGENTINA: TRAJECTORIES AND OPPORTUNITIES FOR DIVERSIFICATION AT THE REGIONAL LEVEL

Andrea Estefanía Belmartino

GSSI, Italy

ABSTRACT

This project aims to analyze the trajectory and opportunities for export diversification in green products for the Argentinean provinces between 2003-2019. The development of products with environmental benefits (green products) is considered one step towards a sustainable transition, an issue of utmost relevance to any economy.

In particular, developing countries present conditions that could promote and limit a sustainable transition in these economies (Hansen et al., 2018; Köhler et al., 2019). On the one hand, Argentina has a wide range of resources that could be considered an opportunity to foster green development strategies. On the other hand, it faces structural problems that constrain regional development. In this context, ECLAC argues that it is possible to strengthen the productive capacity towards a green and more inclusive economy (ECLAC, 2019). Even though, a radical transformation could be perceived as not urgent or not possible in Latin America, we need to study niche options that can help avoid a lock-in process (Marin & Benavente, 2011). In this line, this research focuses on a group of products with environmental benefits, considered preferable in the world, with a growing demand that may represent an opportunity in terms of green development.

In order to distinguish these products, we follow the list provided by Mealy and Teytelboym (2020) that identify 543 traded green products (HS 6 digits). We analyze export data at provincial level (HS 6 digits) for Argentina between 2003-2019.

The empirical strategy draws on economic complexity and proximity concepts (Hidalgo et al., 2007; Hidalgo and Hausmann, 2009). We calculate indices that capture the present capacities of green production and identify potential diversification opportunities. The study presents an overview of the green economy in the Argentinean regions and concrete indications on future diversification opportunities. These results can be useful as a basis for regional policies that foster the green economy.

Preliminary results show that the green economy has a heterogeneous spatial distribution across the country. This pattern has also remained stable over time. In this line, the ranking is led by central provinces (Buenos Aires, Ciudad Autónoma de Buenos Aires, Santa Fe y Córdoba). Diversification opportunities are also seen to be greater for the above-mentioned regions, as well as for Neuquén, Chubut, Santa Cruz, and Mendoza.

ARGENTINA'S INTEGRATION INTO GLOBAL VALUE CHAINS: A SECTORAL AND PRODUCT ANALYSIS, AND AN ATTEMPT AT REGIONALIZATION

Pedro Esteban Moncarz^{1,2,3}, Nestor Clever Grion¹, Ileana Raquel Jalile¹

¹Universidad Nacional de Córdoba, Facultad de Ciencias Económicas, Argentina. ²Consejo Nacional de Investigaciones Científicas y Técnicas, Argentina. ³Centro de Investigaciones en Ciencias Económicas, CIECS (UNC-CONICET), Argentina

ABSTRACT

The aim is to identify sectors and products with potential for participation in value chains on a regional scale (South America) and in dynamic global markets. The type of integrations is that of importing goods as inputs and exporting them with a certain level of additional processing. In other words, an input is purchased from the region or the rest of the world and exported to the region or the rest of the world for final consumption or to continue the productive transformation process.

The identification of sectors with potential for participation in regional and global value chains was carried out using the information provided in the South American Input-Output Matrix (MIPS). Three types of indicators were constructed, each of which captures different ways of viewing the phenomenon under study: domestic intersectoral linkages, vertical integration with the international economy, and the degree of proximity to final demand. The selected sectors have high import contents, are generally far from the final demand, and have an important regional integration. Within the selected sectors, 90 products were identified. The main destination markets for these products depend on the type of good, although there is a clear presence of Brazil and other South American markets (although to a lesser extent) in all the selected sectors. For each of the selected products, the main inputs were analyzed using information from the temporary admission import regime, which allows linking inputs with products at an appropriate level of disaggregation. In general, the linkages refer to inputs that originate in countries outside the South American region, on which there is a high level of industrial transformation and which are then exported to countries in the region.

To complement the analysis, tariff and non-tariff barriers were considered to detect concrete possibilities and barriers to achieve productive linkages, especially in the case of trade with countries with which there are no trade agreements. For inputs where opportunities for regionalization were identified, Argentina already has a preferential tariff rate equal to zero for most of these products with its regional partners. In the case of inputs with low regional supply, most products have preferential rates equal to zero for partners in the region, but for extra-regional suppliers, there are no preferential agreements and the rate applied corresponds to that of Most Favored Nation.

With reference to the analysis from a regional perspective, using a provincial input-output model, we evaluated the regional impacts of an increase in exports in the eight selected sectors with the potential to join global value chains. These impacts differ according to the destination country considered (given the characteristics of the exported goods and existing trade links). The results show that for almost all the selected sectors, the region that benefits the most is the Pampean region, mostly through an increase in exports. In the second place, it appears CABA, which, in contrast to the Pampean region, benefits indirectly through an increase of sales to other regions inside Argentina.

A GAME-THEORETIC MODEL OF WATER THEFT DURING A DROUGHT

Amitrajeet A. Batabyal¹, Hamid Beladi²

¹Department of Economics, Rochester Institute of Technology, 92 Lomb Memorial Drive, Rochester, NY 14623-5604, USA. E-mail: aabgsh@rit.edu; ²Department of Economics, University of Texas at San Antonio, One UTSA Circle, San Antonio, TX 78249-0631, USA. E-mail: Hamid.Beladi@utsa.edu

ABSTRACT

We study water use by two geographically proximate farmers in a particular region during a drought. The two farmers each have an endowment of time that can be used either to produce water or to steal water. The price of water is exogenously given. The goal of the two farmers is to maximize their wealth from water production and water theft. In this setting, we perform three tasks. First, we determine the Nash equilibrium of the game-theoretic interaction between the two farmers. Second, we study how this equilibrium depends on the ease with which water can be stolen. Finally, we show how the preceding equilibrium is impacted when there is no water theft and then we determine the maximum amount that a farmer would be willing to pay to prevent theft.

1. INTRODUCTION

1.1. Preliminaries

There is no gainsaying the fact that water is a critical input for agricultural production and therefore it plays a key role in food security. Irrigated agriculture represents 20 percent of the total cultivated land and it contributes 40 percent of the total food produced worldwide.¹⁶⁶ Studies show that on average, irrigated agriculture is at least twice as productive per unit of land as rain-fed agriculture. Therefore, this kind of agriculture permits more production intensification and crop diversification.

A drought is normally defined as a natural hazard caused by a period of abnormally low precipitation.¹⁶⁷ As pointed out by Rey *et al.* (2017), agriculture is one of the sectors that suffers most from the consequences of droughts, which are responsible for the greatest loss of agricultural production in many countries. In fact, the effects of drought on agriculture are becoming an important abiotic stress in temperate and humid regions.

Within the agricultural sectors of many nations, droughts have given rise to abnormal behavior by farmers. In fact, in many nations, the acute scarcity of water during droughts has frequently resulted in farmers turning on each other and, in the process, stealing water. For instance, in 2008, in the drought stricken region of Bundelkhand in India, 2000 farmers were charged with stealing water.¹⁶⁸ Similarly, Pradhan and Pradhan (2000) and Meinzen-Dick (2014) discuss instances in the hills of Nepal where farmers have stolen water from each other. Khokha (2015) points out that in Madera County, California, in the United States, as wells have gone dry and water prices have soared, water theft from farmers has become commonplace. In Muzaffargarh, Pakistan, upstream farmers have been charged with stealing water from canals and thereby disadvantaging downstream farmers.¹⁶⁹ Finally, Viellaris (2019) shows that in Toowoomba, Australia, desperate farmers have turned on each other, stealing water from dams, tanks, and even household taps.

As the above examples and the work of Lowdermilk (1990) demonstrate, during a drought, the phenomenon of water theft by farmers and farmers turning on each other is now quite common. Even so, to the best of our knowledge, this issue has received virtually *no* empirical or theoretical attention in the literature. Focusing first on two empirical studies, Ray and Williams (1999) use a mathematical programming model to analyze water use by upstream and downstream farmers from canals in Maharashtra, India. They show that even though water theft increases the social cost of price policies, these same policies induce upstream farmers to steal water and hence leave downstream farmers with less water and lower incomes. In a later study of a canal in Maharashtra, India, Ray and Williams (2002) once again use a

mathematical programming model to analyze the extent to which farmers voting to cooperate can solve the problem of water theft. Their study shows that because the gains and the losses from cooperation are spatially distributed, voluntary bargaining will rarely achieve an efficient water allocation. Even though the phenomenon of farmers turning on each other and stealing water has a clear strategic aspect to it, there are *no* game-theoretic studies of this phenomenon.

1.2. Our objective

Given this lacuna in the extant literature, our objective in this paper is to provide what we believe is the *first* game-theoretic analysis of water use by two geographically proximate farmers in a particular region during a drought. The remainder of this paper is organized as follows. Section 2 describes the theoretical framework in which the two farmers under study each have an endowment of time that can be used to either produce water or to steal water. Section 3 determines the Nash equilibrium of the game-theoretic interaction between the two farmers. Section 4 analyzes how this equilibrium is impacted by a change in the ease with which water can be stolen by either of the two farmers. Section 5 shows how the section 3 equilibrium is affected when there is no water theft and then ascertains the maximum amount that a farmer would be willing to pay to prevent theft. Finally, section 6 concludes and then discusses two ways in which the research delineated in this paper might be extended.

2. THE THEORETICAL FRAMEWORK

Consider two geographically proximate farmers who grow the same crop in a particular region during a drought. Each of these two farmers has a total of $T > 0$ hours to allocate between water production and water theft. For the ultimate purpose of crop cultivation, the input water can be “produced” in a variety of ways. These include the construction of a tube well, the storage of water in tanks that are filled by tankers, and drawing water from one or more canals. Similarly, water can be stolen by illegally using the other farmer’s tube well to draw water, by directly removing water from a tank, and by illegally diverting water from one or more canals. Since these two farmers produce the same crop and they are located close to each other in space, we suppose that they are very similar in terms of their abilities to both produce and steal water. This means that in the ensuing formal analysis, it makes sense to analyze a *symmetric* Nash equilibrium.

The *production* process generates output of water (q_p) in accordance with the production function

$$q_p = \log(\tau_p), \tag{1}$$

where $\tau_p > 0$ denotes the amount of time spent producing water. If time $\tau_t > 0$ is the time devoted to *stealing* water by one farmer then a fraction $\zeta\tau_t/T$ of the other farmer’s output of water can be stolen. The parameter $\zeta > 0$ describes the ease with which water can be stolen by either of the two farmers. Each unit of water has an exogenously given price $p > 0$. The goal of both farmers in our model is to maximize their wealth from water production and theft. With this description of the theoretical framework out of the way, our next task is to ascertain the Nash equilibrium of the static game-theoretic¹⁷⁰ interaction between the two farmers.

3. THE NASH EQUILIBRIUM

We begin by mathematically delineating the value of the output of water produced by farmer 1. This value is given by

$$pq_p^1 = p \log(\tau_p^1), \tag{2}$$

where the superscript 1 refers to farmer 1. After farmer 2 has stolen water from farmer 1, the value of farmer 1’s output of water is reduced to

$$\left\{1 - \frac{\zeta\tau_t^2}{T}\right\} p \log(\tau_p^1), \tag{3}$$

where the superscript 2 refers to farmer 2. The value of the water stolen by farmer 1 from farmer 2 is

$$\left\{\frac{\zeta\tau_t^1}{T}\right\} p \log(\tau_p^2). \tag{4}$$

Putting the information in equations (2) through (4) together, farmer 1’s wealth (W^1) from water production and theft can be written as

$$W^1 = \left\{1 - \frac{\zeta\tau_t^2}{T}\right\} p \log(\tau_p^1) + \left\{\frac{\zeta\tau_t^1}{T}\right\} p \log(\tau_p^2). \tag{5}$$

A line of reasoning similar to that employed thus far in this section for farmer 1 tells us that farmer 2’s wealth from water production and theft is given by

$$W^2 = \left\{1 - \frac{\zeta\tau_t^1}{T}\right\} p \log(\tau_p^2) + \left\{\frac{\zeta\tau_t^2}{T}\right\} p \log(\tau_p^1). \tag{6}$$

The use of time by each of the two farmers is constrained by the fact that the total available time (T) is spent either producing or stealing water. In symbols, this gives us

$$T = \tau_p^k + \tau_t^k, k = 1, 2. \tag{7}$$

Let us now substitute the time spent stealing water or τ_t^k from equation (7) into the two objective functions given in equations (5) and (6). Doing this, the wealth maximization problems faced by farmers 1 and 2 can be expressed as

$$\max_{\{\tau_p^1\}} W^1 = \left\{1 - \frac{\zeta(T-\tau_p^1)}{T}\right\} p \log(\tau_p^1) + \left\{\frac{\zeta(T-\tau_p^1)}{T}\right\} p \log(\tau_p^2) \tag{8}$$

and

$$\max_{\{\tau_p^2\}} W^2 = \left\{1 - \frac{\zeta(T-\tau_p^2)}{T}\right\} p \log(\tau_p^2) + \left\{\frac{\zeta(T-\tau_p^2)}{T}\right\} p \log(\tau_p^1). \tag{9}$$

170 See Tadelis (2013, pp. 43-126) for a textbook exposition of static games.

When maximizing the objective functions in equations (8) and (9), each farmer takes the choice made by the other farmer as given.

Now, to find the Nash equilibrium of the game between farmers 1 and 2, we differentiate the maximands in equations (8) and (9) and set the resulting expressions equal to zero. The first-order necessary condition for an optimum for farmer 1, for instance, is

$$\left\{1 - \frac{\zeta(T - \tau_p^2)}{T}\right\} \frac{p}{\tau_p^1} - \left\{\frac{\zeta}{T}\right\} p \log(\tau_p^2) = 0. \quad (10)$$

As noted in section 2, the two farmers are very similar in terms of their abilities to both produce and steal water. Therefore, we look for a symmetric Nash equilibrium in which we have

$$\tau_p^1 = \tau_p^2 = \tau_n, \quad (11)$$

where τ_n is the Nash equilibrium amount of time spent producing water by each of the two farmers. Substituting the result in equation (11) into the first-order necessary condition in equation (10) gives us

$$(1 - \zeta)T + \zeta\tau_n\{1 - \log(\tau_n)\} = 0. \quad (12)$$

Equation (12) implicitly characterizes the Nash equilibrium amount of time spent producing water by the two farmers under study. We now proceed to discuss how this equilibrium is affected by a change in the ease with which water can be stolen by either of the two farmers.

4. IMPACT OF THE EASE OF THEFT ON THE NASH EQUILIBRIUM

Recall from section 2 that the ease with which water can be stolen by either farmer is described by the parameter ζ . So, in symbols, what we want to know is how τ_n changes when ζ increases by a small amount.

To answer this question, let us totally differentiate equation (12) with respect to τ_n and ζ . After differentiation and several steps of algebra, we obtain

$$\frac{d\tau_n}{d\zeta} = -\frac{T - \tau_n\{1 - \log(\tau_n)\}}{\zeta \log(\tau_n)}. \quad (13)$$

Let us now use equation (12) to substitute for $\{1 - \log(\tau_n)\}$ in equation (13). Doing this, the ratio on the right-hand-side (RHS) of equation (13) simplifies to

$$\frac{d\tau_n}{d\zeta} = -\frac{T}{\zeta^2 \log(\tau_n)}. \quad (14)$$

Inspecting equation (14), it should be clear to the reader that there are two cases to consider. To this end, suppose first that the optimal value of τ_n that emerges from solving equation (12) is such that $\tau_n > 1$. In this case, $\log(\tau_n) > 0$ and $d\tau_n/d\zeta < 0$. This is the intuitively meaningful case. In words, this result tells us that as it becomes easier to steal water ($\zeta \uparrow$), the amount of time allocated to producing water or τ_n declines ($\tau_n \downarrow$). However, this is not the only possibility. If, in contrast, the solution of equation (12) gives us $\tau_n < 1$ then $d\tau_n/d\zeta > 0$ is possible and counterintuitively, this result would tell us that for a certain region in the parameter space, even though stealing water becomes simpler, it still makes sense to allocate more time to producing and *not* stealing water.¹⁷¹ Our final task is to show how the section 3 Nash equilibrium is impacted when there is no water theft. We then compute the maximum amount that a farmer would be willing to pay to prevent theft.

5. WILLINGNESS TO PAY TO PRECLUDE THEFT

If there is no theft of water then both farmers will be allocating *all* their time to the production of water. This means that $\tau_n = T$. Now, let M be the maximum that either farmer is willing to pay to avoid water theft. Then, some thought tells us that this maximum is equal to the payoff without water theft (M^{wo}) less the payoff with water theft (M^w). In symbols, we have $M = M^{wo} - M^w$.

Inspecting equations (5) and (6) and keeping $\tau_n = T$ in mind, it is straightforward to verify that the payoff to either farmer without water theft or $M^{wo} = p \log(T)$. In contrast, the payoff with water theft is given by

$$M^w = \left\{1 - \frac{\zeta(T - \tau_n)}{T}\right\} p \log(\tau_n) + \left\{\frac{\zeta(T - \tau_n)}{T}\right\} p \log(\tau_n). \quad (15)$$

Therefore, combining the preceding two results, the maximum willingness to pay to avoid water theft is $M = M^{wo} - M^w$ or

$$M = p \log(T) - \left\{1 - \frac{\zeta(T - \tau_n)}{T}\right\} p \log(\tau_n) - \left\{\frac{\zeta(T - \tau_n)}{T}\right\} p \log(\tau_n). \quad (16)$$

The expression on the RHS of equation (16) can be simplified further. After a couple of algebraic steps, the simplified form we seek is

$$M = p \log\left(\frac{T}{\tau_n}\right). \quad (17)$$

Inspecting equation (17), we see that the maximum willingness to pay to avoid water theft is an increasing function of the exogenously given price of water (p) and a decreasing function of the equilibrium amount of time spent producing water (τ_n). These two results conform well with our intuition. Specifically, the first result tells us that as water becomes more valuable ($p \uparrow$), farmers are willing to pay *more* ($M \uparrow$) to avoid the theft of their water. The second result says that as the amount of time spent producing water by a farmer rises ($\tau_n \uparrow$), there is less time to steal water from the other farmer and hence water theft becomes a less salient issue. As such, farmers are now willing to pay *less* ($M \downarrow$) to avoid water theft. This completes our analysis of a game-theoretic model of water theft during a drought.

¹⁷¹ We disregard the $\tau_n = 1$ case for obvious reasons.

6. CONCLUSIONS

In this paper, we studied water use by two geographically proximate farmers in a particular region during a drought. The two farmers each had an endowment of time that could be used either to produce water or to steal water. The price of water was exogenously given. The goal of the two farmers was to maximize their wealth from water production and water theft. In this setting, we performed three tasks. First, we determined the Nash equilibrium of the game-theoretic interaction between the two farmers. Second, we analyzed how this equilibrium depended on the ease with which water could be stolen. Finally, we demonstrated how the preceding equilibrium was impacted when there was no water theft and then we determined the maximum amount that a farmer would be willing to pay to prevent theft.

The analysis in this paper can be extended in a number of different directions. Here are two suggestions for extending the research described here. First, the analysis we conducted in this paper assumed that the parameter values were such that a symmetric Nash equilibrium existed. Therefore, in a more exhaustive analysis, one could study the existence of corner solutions and asymmetric Nash equilibria. Second, it would be helpful to explicitly introduce law enforcement into the analysis and to then study how the enforcement of laws designed to preclude water theft influences the behavior of drought affected farmers. Studies that analyze these aspects of the underlying problem will increase our understanding of issues concerning water use by farmers during a time of scarcity brought about by a drought.

MODELLING AND EXPERIMENTATION OF OLIVE CAKE THIN-LAYER VACUUM DRYING PROCESS

Mohcine Ibn Maamar, Mohamed Mazouzi, Mohamed Lajdel

ENSEM, Morocco

ABSTRACT

The aim of this work is to study the effect of layer thickness (5, 10, 15mm), of pressure under the layer (-130, -200, 250 mbar) and of drying time (20, 60,100 mn) on the olive pomace vacuum drying kinetics, as well as the estimation of the moisture diffusivity coefficient and the activation energy of olive pomace during vacuum drying. Results clearly show the predominance of the depression under the olive pomace thin layer on the drying process with a contribution of 46% followed by the thickness of the thin layer (29%) and the drying time (26%). The results obtained show that the optimal combination minimizing the water content of the olive cake is a 5mm thick layer of pomace, a drying time of 100 min and a depression of -130 mbar, which identified as the most influential factor. The results of the numerical simulation show that the model can be used to improve the functioning of vacuum dryers. However, there is a slight disparity between experimental values and the results of the numerical simulation. This disparity is the consequence of the use of simplification hypotheses, and errors committed during the experiment.

PATTERNS OF MEDITERRANEAN AGRICULTURAL WATER IMPACTS IN THE CONTEXT OF THE SECOND GLOBALIZATION

[Ana Serrano](#)^{1,2}, [Rosa Duarte](#)^{1,2}, [Vicente Pinilla](#)^{1,2}

¹Universidad de Zaragoza, Spain. ²Instituto Agroalimentario de Aragón, Spain

ABSTRACT

During the twentieth century, the Mediterranean basin experienced an intense integration in global markets, becoming one of the largest agricultural and food suppliers in the world. This expansion was particularly intense during the second wave of globalization, and was possible thanks to the increasing consumption of water resources, hand-in-hand with irrigation development and modernization.

This study aims to evaluate the impacts that the Mediterranean agri-food trade specialization exerted on water resources between 1975 and 2015, focusing on the second globalization. Concretely, we would like to approach to the economic, technological, productive and commercial factors behind the growing pressures on Mediterranean water resources. Likewise, we would like to focus on the divergences between northern, eastern and southern Mediterranean countries, stablishing regional patterns in terms of the socioeconomic drivers of this process. To that aim, we will use bilateral trade time series with a high product disaggregation detail, which combined with decomposition analysis, make up the methodological setting of the study.

Some preliminary results show that most (over 85% of the total growth between 1975 and 2015) of the growth of Mediterranean water consumption associated with agricultural and food exports happened from the beginning of the twentieth century. This expansion was mostly driven by the great increase in extra Mediterranean exports, mainly from southern and eastern areas. These divergences also appear when evaluating the determinants of the flows. In northern European Mediterranean countries, the trade expansion, and a considerable structural change towards the production and trade of water-intensive agri-food products, were essential to explain the consumption of water resources. On the contrary, the pattern in southern and eastern regions was more erratic. We observe a clear scale effect, an increase in the water intensity of exports that would point to a decreasing efficiency in these trade flows, and also, to a strong origin effect, indicating that exports come from the most water-intensive countries in the region.

ECONOMIC VALUATION OF CULTURAL ECOSYSTEM SERVICES: THE CASE OF LANDSCAPE AESTHETICS IN THE AGRITOURISM MARKET

[Aliza Fleischer](#)^{1,1}, [Shachar Hatan](#)¹, [Anat Tchetchik](#)²

¹Hebrew University of Jerusalem, Israel. ²Bar Ilan University, Israel

ABSTRACT

Natural and agricultural landscapes provide a wide range of ecosystem services, aesthetic landscapes being among them. Since these services have no market value, land-use decisions often ignore them in favour of urban sprawl, resulting with sub-optimal resource allocation. Here we suggest a novel method to evaluate the aesthetic landscape services of natural and agricultural ecosystems using the case of the agritourism market in Israel. We model the agritourism market as an oligopolistic market and formulate an equilibrium model with structural, double nested-logit, demand and pricing equations. The structural equations are expressed as a function of the attributes of the agritourism firm and the ecosystems adjacent to the attractions. We use aggregated market data and Geographic-Information-System (GIS) maps to estimate the model. Counterfactual scenarios of urban sprawl were used to estimate the economic value of aesthetic landscape services. The loss of welfare in the different scenarios ranges between 15 thousand USD to 21 thousand USD per squared kilometre depending on the type of ecosystem and the scope of the urban sprawl. We contend that this welfare loss can be used as the economic value of aesthetic landscape services to the agritourism market. These findings illustrate the potential of this valuation method in guiding decision-making and place ecosystem services on a level playing field with market-priced goods, thereby, contribute to the sustainable use of the Earth's limited resources.

HUMAN CAPITAL AND SOCIAL CAPITAL AS ANTECEDENT OF THE GREEN DEAL. AN ANALYSIS ON WASTE SEPARATION ACROSS ITALIAN PROVINCES

[Alessandro Crociata](#)¹, [Chiara Burlina](#)¹, [Iacopo Odoardi](#)²

¹Gran Sasso Science Institute, Italy. ²University of Chieti-Pescara, Italy

ABSTRACT

Sustainable practices must entice and include a significant part of the population to achieve a significant impact. In this sense, pro-environmental practices start with waste management, which in turn presupposes a wide involvement of consumer households in waste separation. The behavior of individuals is influenced by the level of human capital (HC) and social capital (SC) which should indicate the degree of environmental awareness, knowledge of best practices and understanding of the moral and legal norms they should induce. We study the role of HC and SC in waste separation practices in the 103 Italian provinces controlling for other factors influencing the waste management. Policy implications are derived.

EFFECT OF URBAN RAILWAY NETWORK ACCESSIBILITY ON HOUSING PRICES

[Hojune Lee](#), [Euijune Kim](#)

Seoul National University, Korea, Republic of

ABSTRACT

Urban railway is one of key public transits to effectively improve economic and physical accessibility. Along with an expansion of urban territory, easy access to multiple sub-centers becomes important for selection of residential location in real estate market: housing prices accounts for degree of inter-regional accessibility by urban railways in the polycentric housing market. The purpose of this study is to identify the impact of accessibility based on multimodal transport including urban railway network on housing prices in the polycentric city. In this study, the housing price is defined as an average selling prices of apartment complex traded for sale in 2019 in Seoul. To measure the accessibility, Origin-Destination time matrix of railways in 2019 in Seoul and walking time to nearest railway station from the apartments and the employment center of town are calculated. Based on the time distances from the apartments to the employment centers, the accessibility using railways are measured with gravity-based accessibility reflecting the number of jobs by town. This paper reveals that the gravity-based accessibility index which take into account multiple work trips perform better than the physical and time distance from home to employment center. In addition, the accessibility to multiple employment centers has a positive effect on the housing price. This result provides public sectors and urban planners with new perspective to leads to stabilization of the housing price by improving accessibility of remote regions.

THE MORE INCLUSIVE, THE LESS BENEFICIAL TO THE NEIGHBORHOOD? A QUANTITATIVE ANALYSIS ON INCLUSIONARY ZONING IN SÃO PAULO, BRAZIL

[Eliane Teixeira dos Santos](#)¹, [Ciro Biderman](#)²

¹ PhD Student at Getulio Vargas Foundation (FGV), São Paulo, Brazil, eliane.santos@fgv.br; ² Professor at Getulio Vargas Foundation (FGV), São Paulo, Brazil, ciro.biderman@fgv.br

ABSTRACT

The regulation of land use to promote inclusive housing can take place through local policies that take advantage of economic gains from the appreciation of the real estate market to create low-cost housing. Thus, at market prices, the construction of new developments is linked to housing construction for low-income families. In the international literature, this type of program is known as inclusionary zoning. In its simplest form, it requires developers to sell a percentage of new residential units to low-income families if the construction is located in specific areas.

Already traditional in developed economies, such as in the USA, this policy began to expand in Brazil in 2001 with the creation of the urban policy instrument for the demarcation of ZEIS - Special Social Interest Zones. In São Paulo city, local regulation instituted the establishment of these zones in 2002. However, with the Master Plan of 2014, this policy took a qualitative leap, with the establishment of new ZEIS in well-located regions along the axes of public transport and the city center.

Due to the inclusiveness of development, this 2014 Master Plan, which established these zones of use, was recognized by the UN as an example for urban planning. But the construction of social housing in prosperous areas also faces a lot of resistance, especially from the residents of the region, who do not want to suffer from the effects of the devaluation of their properties. This work will contribute to this debate, evaluating through spatial statistical modeling if the construction of social housing in well-located areas of the city negatively affects the price of the surrounding properties and the magnitude of these effects.

Despite being a standard policy in developed economies, it has little empirical evidence. It also has very different characteristics between economies. In the USA, for example, it is generally established that a maximum of 25% of the housing units of a development is of social interest. In the ZEIS of São Paulo, this requirement reaches 60%. In addition to filling the gap in quantitative analysis of a policy with a different profile, this work will contribute with an additional view of assessing the impacts of social housing construction on the prices of properties in the immediate surroundings.

CLIMATE CHANGE, WATER RESOURCES AND ECONOMIC IMPACTS: AN ANALYSIS FOR THE BRAZILIAN HYDROGRAPHIC REGIONS

Ademir Rocha, Eduardo Haddad

¹University of São Paulo, São Paulo, Brazil, aamr.eco@gmail.com; ehaddad@usp.br

ABSTRACT

In the context of global climate change, one of the biggest challenges is in the field of water security. In Brazil, the prospect of water scarcity due to long-term climatic anomalies and the regional disparity between supply and demand for water resources point to limitations and risks to various economic and social activities. In view of this scenario, analyzes that integrate the themes of climate change, water availability and economic vulnerabilities are necessary. Considering the complexity of the problem, we built an Interregional Computable General Equilibrium (ICGE) model named Brazilian Multisectoral and Regional/Interregional Analysis Model with Water Extension (BMARIA-WATER), composed of 67 economic sectors and 12 Brazilian hydrographic regions, all this integrated with hydroclimatic modeling. The results show a drop in GDP-expenditure side in most of its components (reduced household consumption, government demand, export volume and increased imports). We conclude that the economic losses resulting from the effect of climate change on water availability are considerable and are equivalent to a reduction in GDP of R\$ 16 billion in the realistic scenario and R\$ 41 billion in the pessimistic scenario. Water-intensive sectors, such as “water and sewage”, “forestry production”, “agriculture” and “livestock” are the main impacted by climate change.

KEYWORDS

Brazilian hydrographic regions, climate change, ICGE model, water availability

1. INTRODUCTION

The global climate warming (from both anthropogenic and natural sources) is associated with changes in a series of components in the hydrological cycle. It is “very likely” that throughout the 21st century we will see a greater frequency of extreme water events characterized by intense and episodic rains with large amounts of runoff interspersed with long periods of drought and evaporation (IPCC 2007, 2014; Bates et al. 2008).

The irregular supply of water resulting from climate change brings limitations and risks to several economic and social activities (IPCC 2014). The cultivation of irrigated crops, forest production, fishing, hydroelectric power generation, industrial production, transport, tourism, water distribution and sewage treatment are examples of affected sectors (Gleick et al. 2009; Rosegrant 2014; Damania et al. 2017; Ritchie & Roser 2017). This reality becomes even more serious when considering the increase in global demand for water-intensive goods and services. (UN 2019).

In view of this scenario, studies capable of integrating the themes of climate change, water availability and economic impacts become necessary, presenting the vulnerabilities and possible mitigation and adaptation measures, thus seeking ways to guarantee the sustainable maintenance of the water supply and the social and environmental well-being (IPCC 2014).

When we argue about the regional management of water resources the concept of virtual water is central (Allan 1998; Hoekstra & Hung 2002, 2005; Chapagain & Hoekstra 2003; Zimmer & Renault 2003; Hoekstra et al. 2011; Hoekstra & Mekonnen 2012). The total volume of water required to produce a good or service includes its direct consumption used in the production process, as well as its indirect consumption, which is embedded in the production of the inputs. This implies that it is not enough to consider only the demand for water captured in the region, it is also necessary to consider the flow of water resources embedded in interregional trade. Thus, water use in a region can influence its use and availability in another location, through the sale of goods and services. This whole analysis of regional and sectoral interdependence around water can be enhanced by the different regional water restrictions imposed by climate change. It is in this context that we find the motivation to develop this work. Our objective is to examine the economic impacts of the change in water availability caused by climate change, focusing on the Brazilian reality. Considering the complexity of the problem, we built an Interregional Computable General Equilibrium (ICGE) model named Brazilian Multisectoral and Regional/Interregional Analysis Model with Water Extension (BMARIA-WATER), composed of 67 economic sectors and 12 Brazilian hydrographic regions, all this integrated with hydroclimatic modeling.

Based on the identification of sectoral and regional vulnerabilities, adaptation and mitigation actions can be taken with a view to meeting some of the Sustainable Development Goals (SDGs) in Brazil. Our work is directly related to SDG 6 “Ensure availability and sustainable management of water and sanitation for all” and SDG 13 “Take urgent action to combat climate change and its impacts”, and indirectly to SDG 2 “End hunger, achieve food security and improved nutrition and promote sustainable agriculture”, ODS 3 “Ensure healthy lives and promote well-being for all at all ages”, SDG 7 “Ensure access to affordable, reliable, sustainable and modern energy for all”, SDG 8 “Promote sustained, including

and sustainable economic growth, full and productive employment and decent work for all” and SDG 14 “Conserve and sustainably use the oceans, seas and marine resources for sustainable development”.

In order to reach our purpose and develop the discussion presented in this introduction, the work is organized as follows. The second section presents an overview of the availability and consumption of water resources in the Brazilian hydrographic regions. The third section presents the details of the ICGE BMARIA-WATER model, including its database, equations and mechanisms. The fourth section presents the main results. The fifth section concludes.

2. AVAILABILITY AND CONSUMPTION OF WATER RESOURCES

In a global scenario, Brazil is placed in a privileged condition in terms of availability of water resources, concentrating about 12% of all fresh water available on Earth (SNRH 2006a-l; ANA 2015). Table 1 presents water availability values per capita in different regions of the world for 2015. It is possible to observe that water availability per capita in Brazil is around 41,000 m³. This amount is above the average of most continents and is more than double the water availability of the world.

Amid the uneven distribution of water around the world, water-poor regions can compensate for their scarcity through the virtual water trade, that is, water contained in the manufacture of goods and services transacted with water-rich regions (Allan 1998; Hoekstra & Hung 2002; Chapagain & Hoekstra 2003; FAO 2003; Hoekstra et al. 2011; Hoekstra & Mekonnen 2012). Thus, rich and poor in water can mutually benefit from exchanging water-intensive goods, whether profiting from the comparative advantage or easing the pressure on their own water resources (Gil & Kamanda 2015). According to the Water Footprint Network the global volume of international virtual water flows in relation to trade in agricultural and industrial products averaged 2,320 billion m³ per year during the period 1996–2005 (Mekonnen & Hoekstra 2011). In turn, Brazil performs among the largest exporters of virtual water in the world with an average of 112 Gm³ per year during the period 1996-2005. The water contained in the production of cereals and animal protein for Asia, Europe and North America represents the highest recorded values (Mekonnen & Hoekstra 2011).

Table 1: Water resources per capita in selected regions, 2015

<i>Regions</i>	<i>Value (m³/people/year)</i>
Brazil	41,316
Africa	10,326
Americas (with Brazil)	34,732
Americas (without Brazil)	34,544
Asia	9,563
Europe	22,270
Oceania	46,093
World	18,560

The Brazilian Water Resources Council (CNRH), through Resolution No. 32/2003, defines a section of the Brazilian territory in 12 hydrographic regions. They are shown in Figure 1. They are named as: Amazon hydrographic region (AMZ), East Atlantic (ALT), West Northeast Atlantic (AOC), East Northeast Atlantic (AOR), Southeast Atlantic (ASD), South Atlantic (ASU), Paraguay (PRG), Paraná (PRN), Parnaíba (PNB), São Francisco (SFO), Tocantins/Araguaia (TOC) and Uruguay (URU). These regions are formed by contiguous river basins with similar natural, social and economic characteristics, and their objective is to guide the planning and management of water resources. (SNRH 2006).

Despite the apparent water comfort, there is an uneven spatial distribution of water supply and demand between the Brazilian hydrographic regions. Table 2 provides some data that reinforce this argument. In 2015, about 83.5% of the national water availability was concentrated in the Amazon hydrographic region. Despite this, it is possible to observe low values of water consumption, population and gross production value compared to the region's water potential. This puts this region in a comfortable situation in terms of water availability. On the other hand, the regions of Paraná and Southeast Atlantic, which have respectively 5.5% and 1.6% of the Brazilian water availability, it has rural areas with large agricultural production and urban-industrial areas with high population density, such as the metropolitan areas of São Paulo and Rio de Janeiro. As a result, water consumption in these regions accounts for almost half of the national total. This configuration leaves these areas under water stress conditions. Other examples of dissonance between water supply and demand, occur in the hydrographic regions of the Eastern Northeast Atlantic, East Atlantic and São Francisco. These regions are located in a semi-arid area whose climate of prolonged droughts generates an intense water scarcity. Water availability in these regions represents respectively, 0.2%, 0.3% and 1.1% of the national total. Despite this, there is a significant consumption of water in these regions to produce irrigated agricultural goods, hydroelectric power and manufactures.

The knowledge about the availability, abstractions and consumption of water is fundamental for directing planning, regulation, and management actions in hydrographic regions. This information can be obtained through of the Environmental-Economic Accounting for Water (IBGE 2020).

In 1992, the United Nations Conference on Environment and Economic Development (Rio 92) brought an agenda to encourage the monitoring and accounting of natural resources in member countries. Using the stock and flows idea present in the System of National Accounts (SNA), the international statistical community starts to develop the methodological set of the Environmental-Economic Accounts System (SEEA). In 2012, during the Rio+20 Conference, the United Nations Statistics Division (UNSD) recommended that Brazil start the process of building its SEEA. Since then, the country has instituted the Committee for Environmental-Economic Water Accounts (CEEWA) through Interministerial Ordinance No. 236/ 2012, with the objective of elaborating them, observing the recommendations and international practices. Following the methodology recommended by UNSD (UN 2020), the Brazilian Institute of Geography and Statistics (IBGE) provides the System of Environmental-Economic Water Accounts (SEEWA). They are composed of a set of tables with information on the stock and the flows of abstraction of water resources, return and consumption by economic activities. In this way, it is possible to observe the interaction between the environment and the economy, in terms of water.

Table 3: Brazilian Environmental-Economic Accounting for Water, 2015

<i>Description</i>	<i>Unit</i>	<i>Account</i>	<i>Value</i>
Precipitation	Million hm ³	a	13.498
Agriculture, livestock, forestry production, fisheries and aquaculture	Million hm ³	b	0.255
Extractive industry	Million hm ³	c	0.001
Manufacturing industry and construction	Million hm ³	d	0.003
Electricity and gas	Million hm ³	e	2.978
Water and sewage treatment	Million hm ³	f	0.033
Other economic activities	Million hm ³	g	0.000
Water returns from economic activities	Million hm ³	h=b+c+d+e+f+g	3.269
Other water inputs [†]	Million hm ³	i	11.272
Addition to water stock	Million hm ³	j=a+h+i	28.039
Evaporation and evapotranspiration	Million hm ³	k	9.090
Agriculture, livestock, forestry production, fisheries and aquaculture	Million hm ³	l	0.586
Extractive industry	Million hm ³	m	0.001
Manufacturing industry and construction	Million hm ³	n	0.006
Electricity and gas	Million hm ³	o	2.978
Water and sewage treatment	Million hm ³	p	0.019
Other economic activities	Million hm ³	q	0.000
Water abstraction from economic activities	Million hm ³	r=l+m+n+o+p+q	3.590
Other water outputs [‡]	Million hm ³	s	21.940
Reduction to water stock	Million hm ³	t=k+r+s	34.620
Total consumption of water resources	Million hm ³	u=aprox. r-h	0.341
Non-raw water	Million hm ³	v (share of u)	0.003
Raw water	Million hm ³	w (share of u)	0.337
Total water consumption/GDP	m ³ /BRL R\$	x=u/GDP	0.066

[†] Input of water resources in the Brazilian territory (e.g., water contained in the import of goods). [‡] Output of water resources in the Brazilian territory (e.g., water contained in the export of goods).

Table 3 presents a summary of the Brazilian SEEWA available by IBGE for the year 2015 (IBGE 2020). The accounts “a” to “j” represent water inputs in the system. The main water input occurs naturally and is represented by total precipitation (account “a”). Its value reaches 13.5 million hm³/year. Economic activities return part of the water collected (for productive use) to the environment. The account “h” (sum of “b” to “g”) shows the return value of 3.3 million hm³/year. In addition, there is the possibility of water resources entering Brazilian territory through the importation of goods and services. This is described in the Other water inputs (account “i”). Its value reaches 11.3 million hm³/year. The “h” and “i” accounts represent water inputs of economic source. Thus, the total added to the water stock (account “j”) is 28 million hm³/year. In turn, the “k” to “t” accounts represent water abstractions (or withdrawals) from the system. Most of the precipitation returns to the atmosphere through evaporation and evapotranspiration (account “k”). This represents 9.1 million hm³/year. This is the main natural cause of water loss. Economic activities collect water to use as an input in their production. This is described in account “r” (sum of “l” to “q”). Its value reaches 3.6 million hm³/year. A share of the water can leave Brazilian territory through exports of goods and services. This is described in the account “s” - Other water outputs, the value of which reaches 21.9 million hm³/year. The “r” and “s” accounts represent the economy’s abstraction of water resources. In the end, the reduction in the water stock (account “t”) reaches 34.6 million hm³/year. The water consumption of economic activities (account “u”) is the difference between the volume collected and the return. This value is 0.3 million hm³/year. The main water user sectors are agriculture, livestock and forestry production, fisheries and aquaculture. Together these sectors (considered very water-intensive) represent more than 95% of the total consumed by economic activities, totaling a volume of 334 hm³/year. Almost all of this value is raw water, that is, water that comes from environment (account “w”), most likely not charged. The rest is water consumed

from the water and sewage sector (i.e., treated water) (account “v”). In addition, the account “x” indicates that for each monetary unit of GDP (BRL R\$) it is necessary to consume 0.066 m³ of water.

3. MODEL DESCRIPTION

3.1. General aspects

The BMARIA-WATER model is an ICGE model with a water module capable of assessing the economic impacts of changes in water availability caused by climate change. The model files (databases and code) are available at <https://www.aderocha.com/> and can be implemented in the GEMPACK software (Harrison & Pearson 1996; Harrison et al. 1996). The structure of our model represents a variant of the ORANI-G model (Dixon et al. 1982; Dixon & Parmenter 1996; Dixon & Rimmer 2002; Horridge 2003) and BMARIA model (Haddad 1999, 2004), both well documented and widely used. Furthermore, it takes advantage of insights from the UPGEM model (Van Heerden et al. 2008). With a bottom-up structure (where national results are obtained from regional aggregations) the model recognizes the economy of the 12 Brazilian hydrographic regions. The model version identifies 67 economic sectors and goods/services located in these hydrographic regions - this implies that each sector produces only one good (see Table 4). Economic sectors can interact with domestic or foreign economic agents through the purchase of input and/or the sale of final goods. In production, the sectors can use two types of water: water from the “water and sewage sector” and raw water abstracted from environment. The sectors are divided into four categories of water use. “A” are large users of water and with low charges, where: “A1” agriculture sector, “A2” livestock sector and “A3” the forestry, fisheries and aquaculture sector; “B” indicates users of non-potable water with a relative volumetric charge; “C” are users of potable water with good volumetric change and “D” represents the public utility sectors that use water as an input, where: “D1” electricity, gas and other utilities and “D2” water, sewerage and drainage services. Labor and capital are also used as the primary factor of production (one type). In demand, five groups of users are considered - producers, investors, households, foreign demand and government. Furthermore, in this analysis we consider the payment of taxes and margins.

Table 4: BMARIA-WATER sectors

<i>Code</i>	<i>Type[†]</i>	<i>Industry</i>
I01	A1	Agriculture, including support
I02	A2	Livestock, including support

I64	C	Private health
I65	C	Creative and entertainment activities
I66	C	Other personal services
I67	C	Domestic services

† "A" are large raw water users with low charges ((1) agriculture, (2) livestock, (3) forestry and other); "B" are users of raw water with a relative volumetric charge; "C" are users of treated water with high volumetric charge; "D" represents the public utility sectors ((1) energy, (2) water and sewage) that use water as an input.

3.2. Climate change, water availability and economic impacts

In our model, we classify water in two ways: treated water from the “water, sewerage and drainage services” sector and raw water abstracted directly from the environment. Given this, water cost shocks, resulting from the greater/lesser difficulty in capturing water, will be imputed to the model in different ways. The first shock, related to the effects of climate change on the availability of treated water, will be introduced in basic water prices. This is described by (1):

$$p_j^r = \lambda_j^r + \varepsilon_j^r \tag{1}$$

where the basic prices (p_j^r) of the good j of the hydrographic region r are formed from a unit cost index (λ_j^r). An exogenous shock ε_j^r is added, which represents the change in the cost of water from climate change. The shock was attributed to the “water, sewerage and drainage services” ($j = 39$) located in the hydrographic regions ($r = 1, \dots, 12$). The economic effects resulting from this disturbance are referred to as “Channel 1”. The second shock, related to the effect of climate change on availability of raw water, will be introduced indirectly through capital expenditures to substitute or save water. This “trick” was used because most of the raw water used in Brazil is not linked to any economic mechanism (charging, taxation, etc.). Following Van Heerden et al. (2008) we used (2):

$$x(k)_j^r = \frac{1}{v(k)_j^r} \psi_j^r \varepsilon_j^r \tag{2}$$

where $x(k)_j^r$ indicates the amount of capital to substitute or save water adopted by sector j in the hydrographic region r , $V(k)_j^r$ is the current level of capital used, ψ_j^r is a price semi-elasticity of demand for water and ε_j^r represents the shock of water cost access from climate change. In this case, shocks were imputed to “agriculture, including support” ($j = 1$), “livestock, including support” ($j = 2$), “forestry, fisheries and aquiculture” ($j = 3$) and “beverage” ($j = 11$) present in the hydrographic regions ($r = 1, \dots, 12$). These goods/sectors correspond to more than 95% of the raw water consumed in the Brazilian economy. The economic effects of this disorder are named “Channel 2”.

The shock values used in the simulations is described in Table 5. Two steps were taken to calculate the water cost change values: (i) using a hydroclimatic model (precipitation minus evapotranspiration), we calculate the impact of climate change on the water availability of the Brazilian hydrographic regions; (ii) we calculate a coefficient that relates the cost per unit of water and outflow (a measure of water availability); and (iii) we multiply the values from the previous steps.

Table 5: Changes in the cost of water in the Brazilian hydrographic regions, using SSP4.5 and SSP8.5 (%)

Regions	SSP4.5	SSP8.5
AMZ	22.273	52.820
ALT	61.755	140.187

URU	-3.080	-2.724
Brazil	63.032	153.994

3.3. Model mechanisms (causal relation)

The water cost shocks from climate change will be transmitted to the economy through both channels. Figure 2 is a schematic representation of the causal relationships present in the modeling underlying each of these channels. Channel 1 describes the path of the shock in the basic price of water produced by the “water, sewerage and drainage services” sector. This will promote a shift in demand for water and sewage services. The size of this change will depend on the climate shock value and on how important the water factor is for each of the economic sectors located in each of the hydrographic regions, this will be quantified by the Armington substitution elasticity and the price elasticity for water demand parameters. Responding to changes in demand, water-producing sectors will alter their production. This will have consequences on the amount of primary factors (labor and capital) required by the industry and their respective market prices. Consequently, all prices of final goods in the economy are changed. This enters a loop in which the real income of economic agents is altered, which changes the firms' production plans, including their demand for factors of production, leading to another round of price adjustment. This dynamic is repeated until the economy reaches a new equilibrium. Channel 2 describes the path of the cost shock related to raw water access. The change in water availability can lead the sectors to use capital to substitution or save water (i.e., capital that can lead to greater efficiency, less waste or greater storage of water resources). In the long run, this could lead to changes in the quantity demanded by primary factors (labor and capital) and their respective prices. All of these disturbances have an impact on the final price of goods. This channel is also taken to a loop in which the agents' income is altered, the firms reevaluate their production plans including the amount of factors to be used. In the end there are changes in the prices of final goods. This is repeated until reach a new equilibrium.

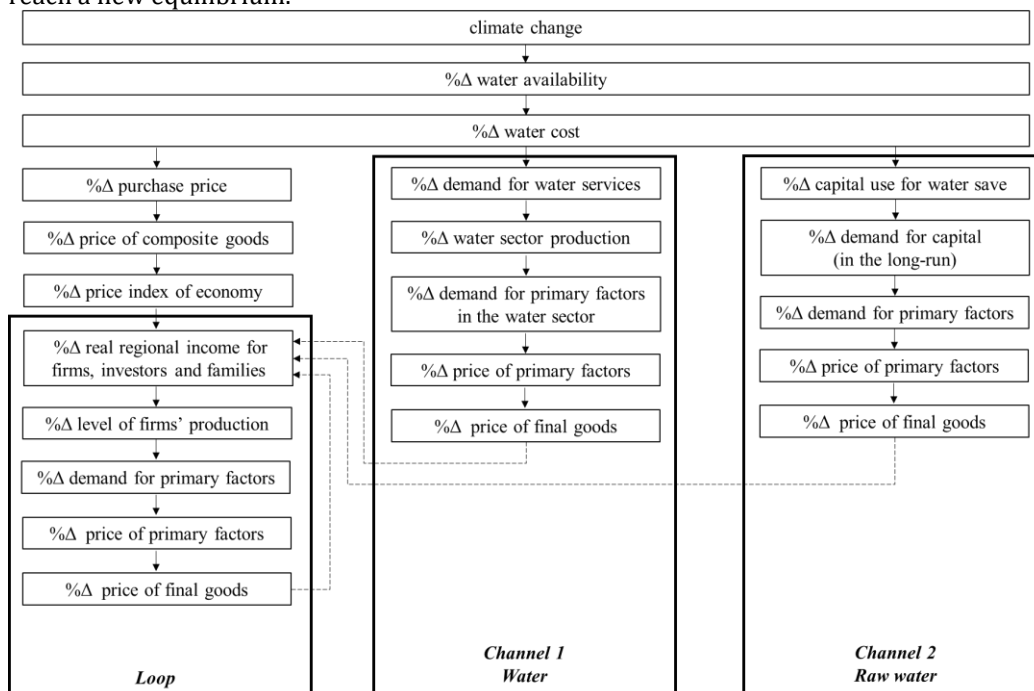

Figure 2: Causal relations underlying the simulation results

3.4. Model database

The BMARIA-WATER model uses a hybrid Interregional Input-Output matrix (hybrid IIOA) for the year 2015. The hybrid IIOA is composed of the dimensions: number of commodities (C = 67), number of industries (I = 67), regions of origin

and destination of goods and services ($S = 13$ and $R = 12$, respectively), trade margin ($M=1$) and water types ($W=2$). In addition, we use a wide range of parameters estimated or taken from the literature. Two parameters are considered key: (i) Armington elasticity which refers to the substitution between inputs from different regions (including between domestic and imported goods) and (ii) the price elasticities and semi-elasticities of demand for water that represent the sensitivity of the demand for water by different users/regions given changes in its price.

4. RESULTS

Table 6 presents the results of the simulations for the macroeconomic aggregates¹⁷². The total effects are decomposed into channel 1 (climate change shock on water prices in the “water and sewerage services” sector) and channel 2 (climate change shock on access to raw water that leads to capital demand to substitute or save water). Part “a” of the table shows the drop in real GDP-expenditure side and its components. In the SSP4.5 (realistic) scenario, the negative impact was -0.308%, while in the SSP8.5 (pessimistic) scenario, an impact of -0.785% is projected. In both cases, channel 1 has a greater contribution to these results. The low substitutability of water in most user sectors turns price increases into direct shocks to the economy. Among the GDP components there is a reduction in demand from regional and federal governments (-1.045% and -2.812%), in the export volume (-0.849% and -2.089%) and in household consumption (-0.198% and -0.522%). In this situation, the increase in the water price leads to an increase of the final price of domestic goods and the loss of real income of the economic agents. This explains the reduction in spending of households and governments and the shift in exports. With the increase in domestic prices, there is an increase in the imports volume (0.455% and 1.113%). It is possible to note that the shock related to channel 2 enabled a positive change in real investment (0.006% and 0.022%). In other words, the greater difficulty in accessing raw water in most regions can lead to investments by firms. Part “b” presents results related to the economy’s price indices. Overall, climate change and its effect on the price and availability of water leads to an increase in the GDP price index (0.211% and 0.534%). Decomposing this result, it is possible to notice that the export price index is the most affected (0.343% and 0.862%). We believe this is because the price of water directly affects sectors that produce agricultural goods and livestock, which are typically export-oriented. Part “c” presents results related to the use of primary factors. In both climatic scenarios, there is a reduction in the demand for labor (-0.571% and -1.455%) and an increase in the capital stock (0.002% and 0.007%). In this case, it is interesting to note the effect of each channel. In channel 1, firms receive the shock of water prices and reduce their level of production, consequently they will make less use of primary factors. In channel 2, firms will be able to buy capital to substitute or save water. Indirectly, labor will also be demanded. Part “d” presents information on the amount of water and raw water that will no longer be required. In the SSP4.5 scenario, there is a reduction in the demand for water and raw water by 23 hm³ and 21,392 hm³, respectively. In the SSP8.5 scenario, these values reach 55 hm³ and 51,828 hm³. In the case of treated water that is somewhere around 0.67% to 1% of total water currently demanded. For raw water, this represents somewhere between 6.34% to 15.36% of the total raw water currently demanded. These results show us that channel 2 has a greater potential to reduce water demand than channel 1. Finally, part “e” presents information related to social well-being. The level of national utility is reduced in both scenarios (-2.296% and -5.674%). This negative value comes from the increase in the price of water (channel 1). The acquisition of raw water-saving capital (channel 2) generated an increase in well-being; but its effect was not able to offset the effects of channel 1. We conclude that the economic losses resulting from the effect of climate change on water availability are considerable and are equivalent to a reduction in GDP of R\$ 16 billion in the realistic scenario and R\$ 41 billion in the pessimistic scenario (current values).

Table 7 shows the impacts of climate change on the level of sectoral activity. We categorize the sectors into water use classes. It is possible to note that type “A” sectors had a drop in the level of sectoral activity in both scenarios. This group is composed of large water users, especially raw water with low charges. In this case, the biggest impacts will be perceived in the forestry sector (-1.761% and -4.284%), followed by agriculture (-0.442% and -1.027%) and livestock (-0.126% and -0.261). In their productive structure, these sectors use more raw water than treated water from the water and sewerage sector. This explains the fact that channel 2 predominates over channel 1. Sectorial group “B” is composed of raw water users with relative charging. The mineral and crude oil extraction sectors and some industrial activities are present in this group. The simulations indicate a small positive impact on the level of sectoral activity (0.016% and 0.073%). Group “C” contains sectors that consume treated water with a high volumetric charge. The service sectors are present in this group. The reduction in the level of activity is -0.203% and -0.551%. In this case, given the greater relevance of treated water, the effects of channel 1 predominated over channel 2. Group “D” is composed of public utility sectors that use water as a key input. It contains energy sector (mainly hydroelectric energy) and water and sewerage sector. The energy sector has a projected impact of -0.215% and -0.534%, respectively for the realistic and pessimistic scenario. In turn, the water and sewerage sector has the biggest drop in the activity level among all sectors (-17.806% and -43.173%).

5. CONCLUSION

In this paper we have computed estimates of the economic impacts from climate change and water availability in the Brazilian hydrographic regions. We have used an interregional CGE model calibrated for the Brazilian economy. We evaluated two main channels of shock transmission, namely channel 1 linked to a change in the price of treated water and channel 2 related to the capital demand to replace or save raw water. The general equilibrium approach allows us to make systematic analyzes about the impacts of climate change on the economy.

The results show a drop in GDP-expenditure side in most of its components (reduced household consumption, government demand, export volume and increased imports). We conclude that the economic losses resulting from the effect of climate change on water availability are considerable and are equivalent to a reduction in GDP of R\$ 16 billion in the realistic scenario and R\$ 41 billion in the pessimistic scenario (current values).

This work focuses on the analysis of vulnerabilities. The next steps involve possible improvements in modeling, enabling discussions about adaptation measures such as water pricing and water markets.

IDENTIFYING THE ATMOSPHERIC AND ECONOMIC KEY DRIVERS OF GLOBAL AIR POLLUTION CHANGE: A COMBINED SDA APPROACH

[Sandy Dall'erba](#)¹, [Ran Xu](#)², [Nicole Riemer](#)¹, [Yilan Xu](#)¹, [Yao Yu](#)¹

¹UIUC, USA. ²Chinese Academy of Sciences, China

ABSTRACT

The transmission of pollution across countries has been studied through the lens of atmospheric chemical transport or through its content in international trade, but only a handful of studies consider both channels concurrently. Yet, the rare exceptions do not highlight the economic sector(s) at the origin of the problem and thus fail to identify effective abatement strategies. In this paper, we integrate environmentally extended input-output trade linkages with physical pathways of carbon monoxide atmospheric transport to uncover the key drivers of the changes in intercountry pollution transmission. Based on a five-region model, the results indicate that most of the CO experienced in a country comes from its own production which is primarily destined to the domestic market; yet, emissions due to upwind producers are not negligible. It is especially true for South Korea which received from China a flow of CO emissions above the level it produced itself. By providing new insights into the interconnected economic and geographic sources of air pollution, this paper suggests more nuanced global emission abatement policies than the consumer-focused or producer-focused approaches currently used.

THE REGIONAL ECONOMIC IMPACTS OF CLIMATE CHANGE ON FAMILY FARMING AND LARGE-SCALE AGRICULTURE IN BRAZIL: A COMPUTABLE GENERAL EQUILIBRIUM APPROACH

ABSTRACT

This paper analyzes the regional economic impacts of climate change on the agricultural productivity of crops linked to family farming and large-scale agriculture in Brazil. Variations in agricultural productivity estimated according to scenarios RCP 4.5 and RCP 8.5 (IPCC, 2014), between 2021 and 2050, were used as inputs in the Computable General Equilibrium Model (CGE) called Agriculture Regional Model - AGRO-BR. The model presents regional configuration composed of the 27 Federation Units and 42 agricultural sectors, disaggregated into family farming and large-scale agriculture sectors. The results, in terms of economic impacts, indicate that the North and Northeast regions would be negatively affected, Midwest and Southeast would suffer moderate impacts, while the South region would benefit mostly. São Paulo, Paraná, and Rio Grande do Sul would show economic growth, softening the negative impacts on national GDP, which would show a decline of 0,01% in both scenarios. The phenomenon could contribute to the increase of regional disparities and the deterioration of food security conditions in Brazil.

1. INTRODUCTION

Global Climate Change (CC) greatly affects life on Earth. Its impacts on ecological, economic and social systems, amplifies externalities and uncertainties along an extensive time horizon. The phenomenon is spatially heterogeneous and historically unprecedented in humanity, which elevates the complexity of its understanding. The immediate effects of climate change are verified by changes in average temperature and precipitation levels, key variables for determining agricultural productivity. Thus, changes in world agricultural production are expected (Mendelsohn and Schlesinger, 1999; Cline, 2007; Rosenzweig *et al.*, 2014). In Brazil, the scenarios projected by the Brazilian Panel on Climate Change, indicate changes in precipitation levels between +5% to -50%, temperature rise between 1°C to 5.5°C and increased occurrence of extreme events (PBMC, 2014). In this scenario, a new geography of agricultural production may be configured, with possible implications on food supply and consequently on food security (FAO, 2005; Assad; Pinto, 2008; Calzadilla *et al.*, 2013).

Brazil, a country of great territorial extension and whose agricultural sector plays an important economic role, may be severely affected by the phenomenon, with possible impacts on the supply, price, and stability of international food trade. The country stands out as one of the largest producers and exporters of soybeans, sugar, corn, orange juice, coffee, cotton, as well as poultry, pork, and beef (FAOSTAT, 2020). Internally, the sum of goods and services related to agribusiness corresponded to 21.4% of GDP in 2019, with 68% of this participation related to agriculture and 32% to livestock (CNS, 2020).

The literature related to the impacts of climate change on Brazilian agriculture indicates considerable losses, especially for commodities. Assad; Pinto (2008), assess that losses in 2020 would reach R\$7.4 billion, with a significant reduction in the production of corn, rice, soybeans, and beans. Feres *et al.*, (2009); Massetti *et al.*, (2013); Assunção; Chein (2016) and De Paula (2018) indicates that, on average, there would be a decrease in agricultural productivity in low latitudes, with negative impacts in the North, Northeast and Midwest regions, precisely the least developed regions of the country. Moraes (2010) and Margulis; Dubeux (2011) project GDP accumulated decline between 0.2% and 2.3% in 2070. Regarding the effects on international trade, Nazareth *et al.*, (2020) indicates an economic downturn in regions that demands Brazilian agricultural products, such as the rest of Mercosur, the rest of the Americas, and China.

Despite the relatively extensive literature, it focuses on commodity studies and makes no distinction between types of producers. It should be emphasized that the Brazilian agricultural production structure is heterogeneous. Producers are distinguished in the use of inputs, productive factors, types of crops and in the linkage to the domestic and foreign markets. Family farming is largely linked to food security and food production for the domestic market, while large-scale

agriculture stands out in commodity production and the foreign market. The analysis of the impacts of CM on agriculture and its potential economic effects should address the productive and regional specificities of farmers.

In this sense, the objective of this work is to analyze the regional economic impacts of climate change on agricultural production of family farmers and large-scale agriculture in Brazil, as well as to analyze its indirect economic effects, according to scenarios RCP 4.5 and RCP 8.5 (IPCC, 2014), between the years 2021 and 2050. The study seeks to answer: i) What are the economic, direct, and indirect impacts triggered by the effects of climate change on agriculture? ii) What are the effects on the production of family farmers and large-scale agriculture? iii) What are the regional effects of the phenomenon? Thus, the work seeks to indicate the direction and magnitude of the economic impacts arising from climate change on Brazilian agriculture, through explicit modeling of the family farming and large-scale agricultural sectors, considering its productive and regional specificities.

The study differs and, therefore, seeks to contribute to the literature on the impacts of climate change on agriculture by incorporating a disaggregated analysis, considering the impacts on the production of family farming and the production of large-scale agriculture. Adopts a General Computable Equilibrium model (CGE) called AGRO-BR (Tanure, 2020), the first CGE model in Brazil to address in a disaggregated way the producing sectors related to family farming and large-scale agriculture. It is an inter-regional CGE model with recursive dynamics mechanisms for 27 Federation Units (UF) and capable of analyzing regional and sectoral economic impacts resulting from the effects of climate change in Brazil over time. Its theoretical structure originates from the TERM model (Horridge; Madden; Wittwer, 2005).

The methodology used in this study has been more indicated for the analysis and economic projections of the impacts of climate change, because the dynamics of regional economic variables observed, in addition to being affected by climate change is also affected by conjuncture and structural factors, such as demographic, macroeconomic, and public policy aspects. Nevertheless, the effects of climate change on agricultural productivity and consequent economic effects are heterogeneous among the types of producers and regions. This chain of interrelations is captured by the CGE model. Thus, the results of the research could complement the information available on the theme, helping policymakers and producers, especially family farmers, to carry out a better planning to face the phenomenon, since the existing literature prioritizes studies involving commodities and the economic effects related to agribusiness.

The study is divided into 5 sections, including this introduction. Section 2 presents a brief literature review on the economic impacts of CC on Brazilian agriculture. Section 3 presents the methodology and data used. In section 4, the results of the simulations and discussions are presented, and finally, in section 5, the final considerations.

2. LITERATURE REVIEW

One of the first studies in Brazil to project the impacts of climate change on the economy through CGE modelling was developed by Domingues *et al.*, (2008; 2016). The study analyzed the impact of climate change on the economy of the Northeast region, based on estimates of areas suitable for agricultural cultivation, using the TERM-Cedeplar model. The estimates of land aptitude for rice, beans, corn, cotton, cassava, soybean, sugarcane, and sunflower crops, were used in the model, with the A2 and B2 climatic scenarios. Reductions in the land production factor, by Federation Units (FUs), were used as a shock in the agricultural sector of the model and represent a proxy for the effects of climate change on the region's economy between 2005 and 2050. The results indicate high economic losses, especially for the poorest states, with potential effects on migratory flows. The study projected a 13.1% decline in regional GDP and a decrease in employment levels by 5.95% in 2050.

The study by Moraes (2010) evaluated the economic effects of climate change scenarios A2 and B2 on Brazilian agriculture through the TERM-BR model. The policy scenarios implemented in the model were based on estimates of the aptitude of areas for the cultivation of beans, corn, soybeans, cotton, rice, sugar cane, cassava and coffee provided by Embrapa, considering two-time horizons: 2020 using scenario B2 and disregarding social and economic changes, and 2070 using scenario A2, with social and economic adaptations. The results of the simulation with scenario A2 indicate greater negative impacts in the states of the Northeast region, in addition to Mato Grosso and Mato Grosso do Sul, as a result of the reduction of the area suitable for soybean cultivation. The Southeast region would benefit from the increase of areas suitable for sugarcane cultivation. In scenario B2, the results indicate negative impacts for the Northeast and Midwest regions, and reduction of the positive impact in the Southeast region with the intensification of climate warming. The projections of impact on national GDP indicate a reduction in both scenarios, being 0.28% in 2020 in scenario A2, and 1.12% in 2070 in scenario B2.

Ferreira Filho and Horridge (2010) analyzed the impacts of climate change on agriculture and internal migration in Brazil using the TERM-MIG model. The simulations used changes in production and land availability for a group of crops, calculated according to scenarios A2 and B2 of the IPCC, for the years 2020 and 2070, respectively. The results showed that the economic downturn of the Northeast and Midwest regions could reverse the migratory flow, increasing the emigration of less qualified workers to the South and Southeast regions, resuming the migratory pattern observed before the 1980s in Brazil. The results indicate that the national GDP could retract by 0.8% in 2070, considering scenario B2.

In the study by Margulis; Dubeux (2011), the impacts of climate change verified through changes in river basin flows, sea level rise and changes in agricultural productivity have been quantified and analyzed. The study used the EFES (Economic Forecasting Equilibrium System) CGE model integrated with other impact projection models, adopting IPCC scenarios A2 and B2 as a reference. The results of the EFES were incorporated into the B-MARIA CGE model to carry out regional and sectoral macroeconomic projections. The results indicated reductions of 0.5% (Scenario A2) and 2.3% (Scenario B2) of national GDP in 2050, and large losses of areas of low risk of agricultural production for soybean crops (30% to 34%), corn (15%) and coffee (17%).

Farias (2012) developed an CGE model with detailed specification of land use in Brazil and evaluated the economic impacts of climate change in the country. The implemented shocks were calculated through the estimated sensitivity of land use changing, considering the climatic scenarios A2 and B2 of the IPCC, and the periods of 2010/2039, 2040/2069 and 2070/2100. In scenario A2, the results indicated an accumulated reduction in national real GDP by 0.02% in 2039, 0.05% in 2069 and 0.11% in 2099. For scenario B2, projections indicate a 0.02% decline in 2039, 0.04% in 2069 and 0.07% in 2099. In sectoral terms, the greatest losses would occur in agricultural activities, especially the retraction of the wheat and cereal producing sectors, Coffee in Grain and Soybean grain. The Sugarcane and Herbaceous Cotton sectors would benefit from the projections.

Miyajima (2018) evaluated the impacts of climate change on agricultural production in the regions of the Brazilian Legal Amazon, using the EGC model, REGIA. The shocks used as a proxy for the effects of CM were established through estimates of agricultural productivity calculated for 11 crops, with scenarios RCP 4.5 and RCP 8.5 as reference. The results indicated heterogeneous economic losses in both scenarios, with greater loss in the RCP 8.5 scenario. The regions with the highest agricultural participation in GDP were the most negatively impacted. For the GDP of the Legal Amazon region, projections indicate accumulated decline of 1.68% in the RCP 4.5 and 1.92% in the RCP 8.5 scenario in 2080.

Souza (2018) measured the economic impacts of climate change on Brazilian regions through changes in agricultural productivity of soybean, sugarcane, corn, beans, coffee, and orange crops and established a regional vulnerability indicator to climate change impacts. The climatic scenarios analyzed are RCP 2.6 and RCP 8.5, between 2020 and 2100. The results point to a variation in agricultural losses from 9.7% to 55.6% by 2100, with negative impacts on GDP in the order of 0.05% in the optimistic scenario and 0.26% in the pessimistic scenario. São Paulo, Paraná, and Minas Gerais would be the most affected states in terms of losses.

Nazareth *et al.*, (2020) analyze the economic effects of the reduction of agricultural productivity resulting from climate change on Brazilian regions and consequent impacts on international trade using the PAEGDyn model, derived from GTAP. They find that the economic effects are negative, especially in less developed regions, such as North, Northeast and Midwest of Brazil, whose GDP could be up to 4% lower in contrast to a scenario without climate change. The negative impacts also affect the rest of Mercosur, the rest of the Americas, the rest of the world and China, regions characterized by low income and dependence on agricultural products. The other regions would be negatively impacted via indirect economic effects. A positive impact on GDP would be observed only in southern Brazil, characterized by increases in agricultural productivity.

It is verified that use the CGE methodology to analyze climate change in Brazil began after the disclosure of the Fourth Assessment Report (IPCC, 2007), with more detailed climate projections, and which allowed the estimation of variables used as input in the CGE models. Those who analyzed direct impacts on agriculture basically used three approaches as a parameter for calculating the shocks used in the simulations: i) changes in areas suitable for agricultural cultivation; ii) land use changes; and iii) changes in agricultural productivity. Of these, the use of agricultural productivity is recent in the literature, being verified in Souza (2018), Miyajima (2018) and Nazareth *et al.* (2020). This approach is also used in the present study, however, we advanced in the regional and sectoral disaggregation, analyzing 21 agricultural crops for each type of producer, family farmers and large-scale agriculture, in the 27 Brazilian Federation Units.

3. METHODOLOGY AND DATA

AGRO-BR (Tanure, 2020) is an interregional CGE model with recursive dynamics mechanisms for 27 Federation Units (UF) in Brazil and large sectoral disaggregation for agricultural products, capable of analyzing regional and sectoral economic impacts resulting from the effects of climate change in Brazil over time. Its theoretical structure originates from the TERM model (Horridge; Madden; Wittwer, 2005). It is a bottom-up type model, whose national results come from aggregations of regional results. Moreover, it is the first model of CGE in Brazil, to adopt in a disaggregated way, sectors¹⁷³ related to family farming and large-scale agriculture. The i) agricultural; ii) livestock and other animal production, iii) forestry and iv) vegetal extraction sectors, are disaggregated into family farming and large-scale agriculture sectors, totaling 48 sectors. The AGRO-BR database is composed of the latest Input-Output table available by IBGE (2018), for the year 2015 and the latest Agricultural Census (IBGE, 2017).

3.1 Agricultural sector disaggregation

The process of disaggregation of agricultural sectors uses a set of data to differentiate family farming production from large-scale agriculture production, which is heterogeneous in terms of the use of inputs, productive factors, types of crops and linkage to the internal and external market. For example, following the IBGE Agricultural Census (2017), 23.2% of agricultural producers are large-scale, employ 33% of agricultural workers, occupy 77% of the area of the establishments and are the largest responsible for the production of Soybeans, Corn, Sugarcane and Cotton. Family farmers, represents 76.8% of the producers, employ 67% of the agricultural workers, occupy only 23% of the area and are the main producers of Cassava, Pineapple, Tobacco, Onion, Cashew nuts and Grapes, Coffee and Banana.

The definition of family farming, used to guide the configuration of the model sectors, is established by Law 11,326 of 2006, created to guide public policies aimed at the category in Brazil. Family farmers are considered to be individuals who simultaneously meet the following requirements: i) does not have an area greater than 4 fiscal modules¹⁷⁴; (ii)

¹⁷³ Table A1 in the Appendix section presents the sectors of the AGRO-BR model.

¹⁷⁴ The size of the fiscal module varies from 5 to 110 hectares among Brazilian municipalities.

predominantly use family labor; iii) obtain a minimum percentage of family income originated from economic activities of your establishment; iv) direct your establishment with your family (BRASIL, 2006).

Data from the Brazilian Agricultural Census (IBGE, 2006; 2017) were used to establish the sector shares related to land use, labor, machinery, and equipment (proxy for capital), internal consumption, exportation, and production value. Data from Agriannual (2018) and AnualPec (2018) were used to measure the participation of family farmers and large-scale producers in terms of the use of intermediate inputs: i) Fertilizers, ii) Pesticides; iii) Diesel; iv) Inorganic chemicals; (v) Electricity, Gas, and others; vi) Cargo Transport; and vii) Financial and Insurance Institutions, for representing together about 70% of the total inputs consumed by the agricultural sectors.

3.2 Structure of Production Technology

In the AGRO-BR model, the productive sectors operate in perfect competition, obtaining zero profit, and each sector produces only one product on a constant scale of production. Producers choose a combination of intermediate, domestic, or imported, and primary factors, capital, land, and labor, in order to minimize production costs, subject to production functions (Leontief and CES), as illustrated in Figure 1. The functional structures of optimization correspond to the figures in the form of trapezoid, the other structures refer to the products, factors, and inputs.

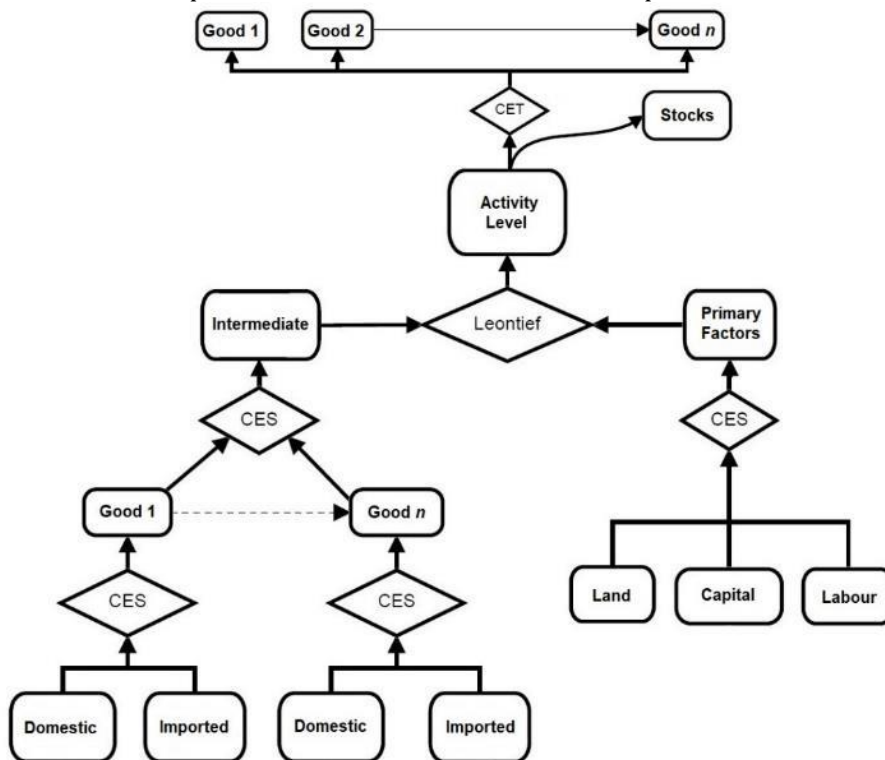

Figure 1: Production structure of the AGRO-BR model

Source: Adapted from Horridge (2011)

In the production process, the primary factors and intermediate inputs are demanded in fixed proportions, following a Leontief production function. That is, it is necessary to use the intermediate inputs and primary factors together, and it is not possible to replace them, as verified in the second level of Figure 1. At the level below, capital, land and labor factors are demanded through a CES-type production function. It is emphasized that the land factor is demanded only by the sectors producing agricultural products, cattle, other animals, forestry, vegetal extraction, and aquaculture. The demand for intermediate inputs is structured by a CES-type function, which allows replacement between different products. The source is also structured by a CES-type function, allowing the product to be replaced between the source regions.

3.3 Shocks and Scenarios

The policy scenarios, RCP 4.5, and RCP 8.5, used in the simulations of the AGRO-BR model, start from the projections of loss (or gain) of agricultural productivity estimated in Tanure (2020). The productivity changes, used as proxy to climate change in the model, were estimated with temperature and precipitation projections elaborated by INPE (Chou *et al.*, 2014) according to RCP 4.5 and RCP 8.5 scenarios (IPCC, 2014) and presented in Figure 2. The scenarios represent a plausible (RCP 4.5) and a pessimist (RCP 8.5) path in terms of GHG emissions.

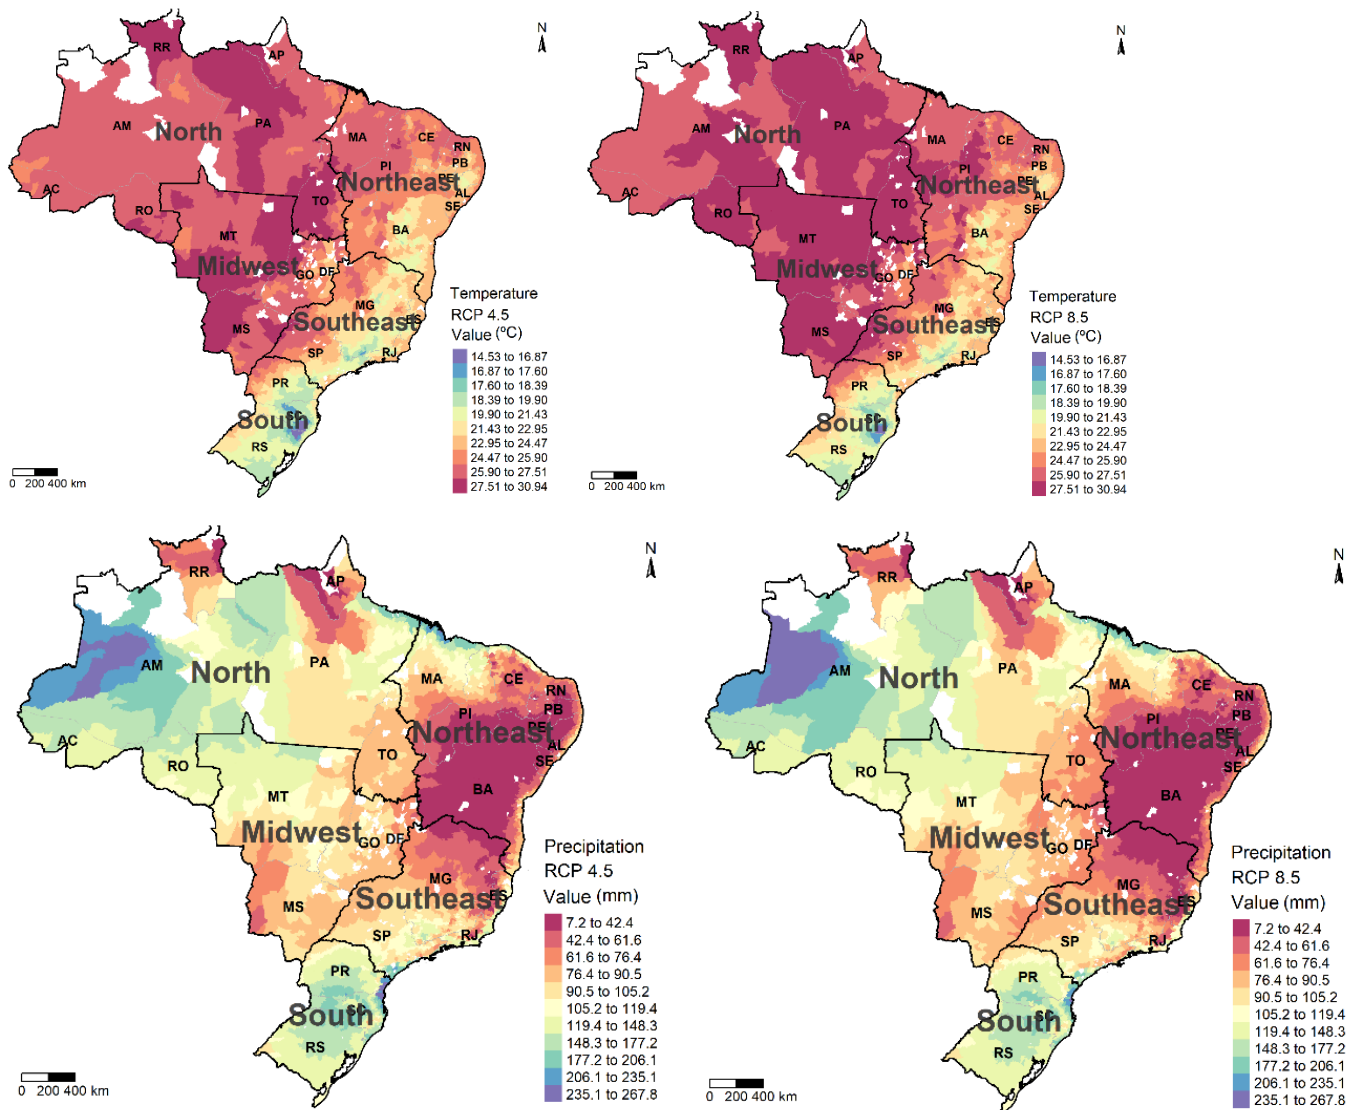

Figure 2: Average Temperature and Precipitation Projected by RCP 4.5 and RCP 8.5 (°C) (mm) (2050)

Source: Own development based on Chou *et al.*, (2014).

The North, Northeast, and Midwest regions, typical of high temperature, has the highest projected temperature elevations, while the Northeast, region characterized by low rainfall levels, has the highest projected rainfall reduction, compared to historic levels. Then, on average, an increase in agricultural productivity is projected on high latitudes, comprising the states in southern regions, while a decrease is projected in northern and northeast regions according to Tanure (2020).

The RCP 4.5 and RCP 8.5 policy scenarios are distinguished by the land productivity shocks applied to agricultural sectors. In RCP 8.5 policy scenario, the average land productivity variation is greater (in module) than the values verified in the RCP 4.5 policy scenario. In the baseline scenario, the growth rates of macroeconomic variables are exogenous and follow the recent performance verified by the Brazilian economy. In policy simulations, land productivity is exogenous to allow the implementation of the estimated shocks. The behavior (deviation from the baseline scenario) of the main macroeconomic aggregates, such as national GDP, household consumption and investment, are endogenous.

The period used in the simulations respects the climatological periodization of 30 years, established to cover all-natural climatic variability that can influence the mean of the variables analyzed. In this sense, the variations in agricultural productivity estimated in Tanure (2020), by cultivation and by type of producer, represent projections of variation for 30 years, carried out between the years 2021 to 2050. For the construction of the shocks in the model, these productivity variations were transformed into five-year rates. Section B in the Appendix presents the data used as shock in the simulations.

The agricultural sectors are directly affected by climate shocks. The land productivity shock alters the cost of the land factor, causing the sectors to refocus their primary production factors in order to minimize costs. Sectors with land productivity gain (positive shocks), will replace labor and capital by land, reducing costs. Sectors with productivity decrease (negative shocks) will replace land with labor and capital, resulting in rising costs. The magnitude of

substitution is determined by the substitution elasticities¹⁷⁵ of primary factors and by the intensity of use of each factor. The size of this substitution effect between primary factors is guided by the productive structure extracted from the model database, being distinct between family farming and large-scale agriculture sectors and regions.

4. RESULTS AND DISCUSSION

The results of the simulations performed with RCP 4.5 and RCP 8.5 policy scenarios are interpreted as deviations from the baseline scenario, in which the shocks of land productivity caused by climate change are not considered. The projections in 2050 represent the accumulated results related to the productivity shocks between the years 2021 and 2050.

4.1 Sectorial results

Table 1 presents the results of simulations for national sectoral production in RCP 4.5 and RCP 8.5 scenarios. Climate change directly affects agricultural sectors, via productivity shock, and indirectly other sectors of the economy. The greater the proximity to the agricultural sectors, the greater the indirect effects of the phenomenon. Moreover, the effects of CM on sectoral production, on average, intensify over time and in the RCP 8.5 scenario. Tables C1 and C2, in the Appendix section, shows the level of economic activity of the agricultural sectors, by UF. 3

Table 1: National Sectoral Production (Accumulated % variation in relation to baseline scenario)

Sector	RCP 4.5			RCP 8.5

Source: Own elaboration based on model results.

In the RCP 4.5 scenario, economically relevant sectors for family farming would perform negatively. The Cassava, Coffee, and Banana sectors would accumulate losses of 3.26%, 3.55%, and 2.62%, respectively, in 2050. Soybean production would also be negatively affected, in lower magnitude. On the other hand, Tobacco, Other sectors of temporary tillage, and Corn sectors would show a production increase of 0.9%, 0.7%, 0.18% in 2050. As part of the production originated from family farming is consumed on the property, the negative impacts on the production of cassava, beans, orange, banana, coffee, grape and others of permanent farming, could deteriorate the food security of producers, and consequently increase their condition of vulnerability. This pattern deteriorates in the RCP 8.5 scenario.

Among the large-scale agricultural sectors with the highest share of domestic production, Corn, Cotton and Orange would tend to be negatively affected with a reduction in production by 8.91%, 8.74%, and 6.18%, respectively, in 2050. These sectors, together with Coffee, also with negative performance, have relevant participation in the foreign market, which could contribute to the retraction of supply and increase in international prices, as also verified by Calzadilla *et al.*, (2013) and Nazareth *et al.*, (2020). Among the beneficiaries, we highlight the producers of Wheat and Sugarcane, with projections of a production increase of 5.8% in the year 2050. It is also noteworthy the positive impacts, even if minor, on the Soybean sector, relevant in economic terms. The national performance of soybeans would be guaranteed by the increase in productivity in large producing regions, such as SP, MT, MS, PR, SC, and RS, however, the projections for the MATOPIBA region, the current frontier of crop expansion, are negative, as verified in Zilli *et al.*, (2020). These effects would be intensified in the RCP 8.5 scenario.

Climate change would indirectly affect other economic sectors, with the most pronounced impacts on sectors close to the agricultural sectors. The Cattle and Other Animals, Forestry and Vegetal extraction sectors, by competing for production factors, would be negatively impacted. The replacement of land by capital and labor in the agricultural sectors would reduce the availability of these factors for the others. The Cattle and Other Animals sector, the main responsible for the meat production of beef, pork, and poultry, would be negatively impacted, with possible effects for international trade, since Brazil has the largest cattle herd in the world, being the largest exporter of beef and poultry, and the third-largest exporter of pork (FAO, 2020). Nevertheless, the economic downturn of the agricultural sectors would negatively affect the Pesticides and Fertilizers sectors since these are the main suppliers for the agricultural sectors.

4.2 Regional Results

The impacts of CM on productivity and its consequent economic effects are heterogeneous between sectors and regions. The aggregate performance of the family farming and large-scale agricultural sectors by UF, presented in Table 2, is the net result of the effects on the activity of all agricultural sectors and allows us to evaluate the direction of impacts in regional terms and by type of producer. The family farming sectors of Cassava, Tobacco Leaf, Coffee and Soybean, and the large-scale agriculture sectors of Sugarcane, Soybeans and Coffee, have great economic relevance and therefore play a decisive role in regional results. The results for the RCP 8.5 scenario would indicate higher losses compared to the RCP 4.5 scenario.

Table 2: Aggregate production variation of the family farming and large-scale agriculture sector in 2050 (Accumulated % variation in relation to the baseline scenario)

Source: Own elaboration based on the results of the AGRO-BR model.

The aggregate sector results, by type of producer, reflect the magnitude of the productivity shock and the economic importance of each sector. Thus, crops with great economic participation can contribute positively to the aggregate performance of the sector. In the family farming sector, the states of Maranhão, Piauí, Ceará, São Paulo, Goiás, as well as the states of the Southern region and the Federal District would show growth. All the others would show a fall in the level of economic activity in relation to the baseline scenario. In the large-scale agriculture sector, the states of Amapá, Ceará, Rio Grande do Norte, and São Paulo and all in the Southern region would show growth in the level of sectoral activity. The positive performance in both scenarios of the Southern region is due to the positive shock of agricultural productivity, caused by the increase of the average levels of temperature and precipitation. The region is characterized by milder temperatures. This explains the increase in the level of activity in the pessimistic scenario, with higher temperatures in the region. The positive performance of the state of São Paulo is due to the increase in productivity of sectors whose participation in the state GDP is relevant, such as Soybeans, Coffee, Sugarcane and Cotton for the large-scale agriculture sectors, and Beans, Coffee and Grapes for the family farming sectors. From the perspective of aggregate regions in the RCP 4.5 scenario, the activity of family farming would be negatively affected in the North, Northeast, and Southeast regions of the country. These regions concentrate the largest share of family producers in Brazil. Only the Midwest and South regions would show an increase in the level of activity. Large-scale agriculture production would be negatively affected in the North, Northeast, and Midwest. The Southeast and South regions would benefit in terms of economic activity. These results could contribute to the increase of regional inequalities in Brazil since the negative impacts affect regions that concentrate family farmers with a less developed profile and a focus on subsistence production, while positive impacts would affect the South region, which in turn concentrates mechanized family farmers well established in the market. The simulations of the RCP 8.5 scenario indicate possible intensification of the effects over time, for all regions, except the North region, which would have the negative effects mitigated. Figure 3 shows the effects of climate change in RCP 4.5 and RCP 8.5 scenarios.

Figure 3: Regional Economic Activity Level in RCP 4.5 and RCP 8.5 scenarios in 2050 (Accumulated % variation in relation to baseline scenario)

Source: Own elaboration based on the results of the AGRO-BR model.

The relevance of the participation of the state of São Paulo to the level of activity in the Southeast region would explain the positive performance of the large-scale agriculture sector in the region, given that in the states of Minas Gerais, Espírito Santo, and Rio de Janeiro (the other states that compound the southeast region) the economic performance would be negative in both scenarios. São Paulo stands out in the large-scale production of Cotton, Sugarcane, Wheat, and Others of the Permanent Crop. Some economically expressive sectors would show a decline in the level of activity, such as the large-scale production of Corn and Orange, however, the net effect in terms of activity is positive.

4.3 Macroeconomic results

The impacts of climate change projected by the AGRO-BR model would imply a negative impact on GDP in both scenarios. The retraction would be gradual over time, reaching -0.01% in 2050. Considering the nominal GDP of 2019 in the amount of R\$7 trillion, the climate change represented in the model by the RCP 4.5 scenario could generate, roughly, accumulated losses of R\$105 billion over 30 years, in current values, with annual losses of R\$3.5 billion, reaching R\$243 billion (R\$8.1 billion annually) in the RCP 8.5 scenario. Table 3 presents the projected macroeconomic results.

Table 3: Macroeconomic Results in 2050 (accumulated % variation in relation to the baseline scenario)

Variables / Scenarios	RCP 4.5	RCP 8.5
Household Consumption	-0,010	-0,010
Investment	-0,001	-0,002
Exports	-0,129	-0,154
Imports	-0,092	-0,121
GDP	-0,010	-0,010
Family Farming Production	-0,490	-0,830
Large-Scale Agriculture Production	-0,590	-0,920

Source: Own elaboration based on model results.

Compared to other studies, such as Margulis; Dubeux (2011), the estimated magnitude in terms of impacts on GDP is lower due to being due only to the net result of land productivity changes, while other studies that project larger impacts consider other aspects related to climate change. In the present study, although projections indicate that most crops would be negatively impacted, crops relevant in terms of representativeness in GDP were positively impacted, especially in commodities producing regions such as SP, PR, and RS states, minimizing the aggregate negative effects. Nevertheless, the final impact is negative, for both types of producers in the RCP 4.5 scenario, with a 0,49% accumulated decrease in family farmer's production and a 0,59% decrease in large-scale agricultural production in 2050. The results deteriorate in the RCP 8.5 scenario.

The results presented are similar to studies with similar approaches. Farias (2012) projects the impacts of CC on the economy through the integration of Monash and B-MARIA models and estimates of land-use change according to scenarios A2 and B2, for a group of eleven crops. With projected a accumulated reduction in national GDP between 0.02% in 2039 and 0.11% in 2099 considering scenario A2, and between 0.02% in 2039 and 0.07% in 2099 in scenario B2. The results are also close to those observed by Silva (2018), who estimates the agricultural productivity of five crops and projected a negative impact of 0,05% on GDP considering the RCP 2.6 scenario and a decrease of 0.26% in the RCP 8.5 scenario, accumulated in 2099. Our study advances by providing up-to-date estimates with the most recent scenarios for a higher number of crops and for distinct groups of family farmers and large-scale producers.

On household consumption performance, projected results indicate possible retraction in the same magnitude of GDP. The impact on household consumption would be more intense in the RCP 8.5 scenario. This performance is determined by the closing of the model, with the aggregate consumption following the variation of income and, therefore, GDP. Regarding investment, it is verified that at the aggregate level there is no retraction related to the decline of economic activity in the national economy. In sectoral terms, agriculture would increase the level of investment, especially in sectors with a retraction of land productivity, through the incorporation of capital and labor.

Sectors directly affected by productivity shocks, especially large-scale agriculture sectors, are, on average, exporters. The net effect of shocks on the level of activity is negative, and positive on their costs. In this sense, exports would be negatively affected and would show a sharp decline over time. The decrease in the level of economic activity would determine the reduction in imports. The use of imported productive inputs would be reduced due to decreased production. Moreover, the reduction of income of factors would negatively affect the consumption of families and the volume of imported goods. Therefore, negative impacts on Brazilian trade with the foreign market, as pointed by Calzadilla *et al.*, (2013) and Nazareth *et al.*, (2020), are expected.

Table 4 presents the GDP results at the Federation Units level for RCP 4.5 and RCP 8.5. The performance of each FU, in terms of GDP, reflects the economic importance of agricultural sectors affected by land productivity shocks. Projections indicate heterogeneity of results. On average, there would be a reduction in GDP in most FUs and of greater magnitude in the pessimistic scenario RCP 8.5. The States of the North, Northeast and Midwest regions would be the most affected, meeting the results of Ferreira Filho; Horridge (2010), Moraes (2010) and Farias (2012). It should be emphasized that such regions are the least developed in Brazil. The only FUs that would present positive growth in both scenarios would be RR, TO, AL, RJ, SP, PR and RS.

Table 4: GDP per Federation Unit (Var. % Accumulated in 2050)

Regions	Federation Units / Scenarios	RCP 4.5	RCP 8.5
North	Rondônia	-0,04	-0,03
	Acre	-0,06	-0,07
	Amazonas	-0,01	-0,02
	Roraima	0,16	0,28
	Pará	-0,2	-0,07
	Amapá	-0,09	-0,08
	Tocantins	0,14	0,21
Northeast	Maranhão	-0,05	-0,08
	Piauí	-0,15	-0,21
	Ceará	0,03	-0,02
	Rio Grande do Norte	0,0	-0,08
	Paraíba	-0,04	-0,07
	Pernambuco	-0,01	-0,01
	Alagoas	0,05	0,08
	Sergipe	-0,1	-0,14
Southeast	Bahia	-0,13	-0,16
	Minas Gerais	-0,1	-0,11
	Espírito Santo	-0,13	-0,18
	Rio de Janeiro	0,0	0,0

	Goiás	-0,06	0,01
	Distrito Federal	-0,01	-0,01

Source: Own elaboration based on model results.

Therefore, the simulated macroeconomic results show that the average impacts of land productivity shocks, used in the model as a proxy for the effects of climate change on agricultural productivity, would be negative on the Brazilian economy. However, the effects are heterogeneous. The Southern region would be the least negatively affected in economic terms, with the state of RS as a positive highlight. It is emphasized that part of the UF benefited from economic growth, such as SP, PR and RS, are the most developed in the country. Thus, the advent of CC could widen regional disparities in Brazil.

5. FINAL CONSIDERATIONS

There is a consensus that the impacts of climate change on agriculture in Brazil will be mostly negative, but there are few analyses that assess how the effects would be distributed in sectoral terms and by type of producer. This study is the first to provide projections of how the effects would be distributed over the 27 FUs, considering 21 crops produced by family farmers and large-scale agriculture sectors. We found that family farming production in less developed regions would be

negatively affected, while developed regions would benefit from CC. Therefore, the phenomenon could deteriorate the situation of vulnerability and inequality conditions in the country.

The sectoral results projected for family farming indicate that the production of Cassava, Banana, Soybean, and Coffee would be affected by reduction over time, with negative implications on food security, while Tobacco, Corn, and Others from the Temporary Crop would be affected with increased production. On the part of the large-scale agriculture production, Corn, Cotton, and Orange would decrease, while Sugarcane, Soybeans, and Wheat would benefit from increased production. The pattern of results is similar between scenarios, however, the magnitude of the effects in RCP 8.5 would, on average, be more intense. Table 5 presents the synthesis of the results.

Table 5: Summary of the results

Producers	Family Farming		Large-scale Agriculture	
	Positive	Negative	Positive	Negative
Impacts				
Sector Highlights	Tobacco Leaf, Peanut, Grape, Other. Temporary	Cassava, Coffee, Corn, Banana and Beans	Sugarcane, Grape and Tobacco Leaf	Corn, Cotton, Beans, Coffee
Federation Unit	MA, PI, CE, SP, SC, PR, RS, GO, DF	All the rest of FUs	AP, CE, RN, SP, PR, SC, and RS	All the rest FUs
Regions	South	North, Northeast, Midwest and Southeast	South and Southeast	North, Northeast and Midwest

Source: Own elaboration based on the results of the AGRO-BR model.

In the indirectly affected sectors, the effects on the level of activity of Cattle and Other Animal, Forestry and Vegetal extraction sectors would be negative since they compete for inputs and production factors with the agricultural sectors. As Brazil stands out as one of the world's leading meat exporters, the phenomenon of climate change could bring instability to international meat trade. In addition, the sectors that concentrate their activity on supplying inputs to the agricultural sectors, such as Fertilizers and Pesticides, would also be affected with production retraction in 2050, in both scenarios.

Finally, macroeconomic results would be negative. The magnitude of the variation is small, due to the heterogeneity of the effects, which despite being on the average negative, would be positive for important Federation Units in terms of participation in national GDP, such as SP, PR, and RS. Since the regions benefited are the most developed, such results could contribute to the widening of regional disparities in Brazil. The effect of climate change would generate a negative accumulated impact on GDP of around 0.01% in 2050, in both scenarios. In relation to the GDP of the Federation Units, the greatest variations would be verified in states whose share of agriculture in GDP is more relevant. Mato Grosso, Mato Grosso do Sul, Pará, Bahia, Minas Gerais, Piauí, and Maranhão, are negative highlights, while Tocantins and Rio Grande do Sul, Paraná and São Paulo are positive highlights in both scenarios.

**ECONOMIC IMPACTS OF DROUGHTS UNDER FUTURE PROJECTIONS
OF CLIMATE CHANGE: A CASE STUDY FOR SÃO PAULO
METROPOLITAN AREA**

Karina Simone Sass, Eduardo Amaral Haddad

University of São Paulo, Brazil

ABSTRACT

Drought is one of the biggest challenges climate change can impose on cities. It can cause serious socio-economic problems by affecting water supply, industrial production, the price of food and energy, and actual income. Despite the importance of the evaluation of such impacts, there is a lack of evidence on the effect of climate change and droughts on urban areas, especially on industrial activities. This work aims to fill this gap by evaluating the socioeconomic impacts of projected droughts on the São Paulo Metropolitan Area (SPMA), in Brazil. Currently, this region is in highly critical conditions of water availability and it is subject to the occurrence of hydrological droughts.

The method of the work comprises three stages. Firstly, we estimate a dynamic panel data model to evaluate the direct effect of droughts on the added value of twenty-one industrial sectors. An Annual Weighted Cumulative Drought Severity Index represents the drought conditions in the regressions. Secondly, a frequency analysis identifies the frequency and intensity of future critical drought events using climate change scenarios. Lastly, we combine the result from previous stages to build scenarios representing future drought direct economic impacts. Then, a Spatial Computable General Equilibrium Model (SCGE) performs simulations with those scenarios to measure the economy-wide effects of the projected droughts.

The results show severe droughts are likely to occur soon in SPMA, and they can impose negative impacts on the production of water-intensive sectors, such as food production and metallurgy. Those effects spread through the economy, affecting several other economic activities. The results from the simulations also allow the construction of a local economic vulnerabilities index, which can be useful for implementing climate change adaptation strategies and economic development policies.

**TOWARDS AN INTERPRETATION OF LABOUR PRODUCTIVITY
GROWTH: PATTERNS OF REGIONAL COMPETITIVENESS IN
EUROPEAN REGIONS**

Roberto Camagni, Roberta Capello, Giovanni Perucca

Politecnico di Milano, Italy

ABSTRACT

The increase of labour productivity induced by technological progress is typically interpreted as the main determinant of regional competitiveness. In the last decades, however, the empirical verification of this mechanism provided contradictory results. We claim that labour productivity growth is just one of the sources on which regional competitiveness relies, being increasingly dependent on output quality improvements and that the combination of the different indicators is useful to produce different patterns of regional competitiveness. We offer a methodology for their measurement and an application to European regions. Our analysis shows that, even if structural differences persist, several regions in Eastern countries moved towards competitiveness strategies analogous to those of Western Europe.

REGIONAL REINDUSTRIALIZATION PATTERNS AND PRODUCTIVITY GROWTH IN EUROPE

Roberta Capello, [Silvia Cerisola](#)

Politecnico di Milano, Italy

ABSTRACT

In recent times, and especially after the 2008-2009 economic crisis, we have witnessed a decline in productivity growth in the EU and the literature has often been referring to productivity paradox and/or productivity gap. However, the situation is in fact highly diversified at the regional level. In particular, the industrial structure of GVA has substantially changed over the last two decades and although a decrease in the share of manufacturing VA is a general (almost physiological) trend in advanced economies, it has been recognized that the EU needs to reverse the declining role of industry within its boundaries, strengthening industrial competitiveness to enable the transition to a low-carbon and resource-efficient economy (reindustrialization).

Starting from the critical issues related with the deindustrialization process, the present paper aims at highlighting different possible ways of reindustrializing and at highlighting their role in productivity growth. In more details, a regional reindustrialization may occur either reinforcing those sectors in which the areas were already specialized; or increasing the presence into more dynamic sectors and acquiring new know-how; or exploiting the pre-existing knowledge to reindustrialize in local core sectors, although without strengthening the specialization in those specific sectors; or, finally, reindustrializing in non-core sectors (niches) without improving the specialization in those sectors. After identifying reindustrializing NUTS2 regions in the EU and the associated reindustrialization patterns, this work provides an econometric application meant at highlighting the effects of the different reindustrialization typologies on regional productivity growth at the sectoral, manufacturing, and aggregated level, also considering specialization features in advanced rather than traditional manufacturing sectors.

WHEN YOUR CLIENT MOVES ABROAD: FORCED UPGRADING AND SUBCONTRACTORS' PERFORMANCES IN THE MANUFACTURING SECTOR

Jacopo Canello, Nicoletta Giudice

University of Groningen, Netherlands

ABSTRACT

The aim of this contribution is to assess how small local subcontractors operating in low-tech manufacturing industries accomplish upgrading strategies in response to economic and structural shocks. The main assumption is that, when the local environment becomes more vulnerable as a result of disruptions, subcontractors' upgrading often occurs out of necessity. In such circumstances, local actors are forced to change their status quo operations to survive global competition.

The empirical analysis will focus on the 2008-2015 period and will exploit novel firm-level data extracted from the Italian Ministry of Economics and Finance Annual Survey (IMEFAS), using a sample of Italian subcontractors operating in the clothing and footwear industry. In this research, the shock is represented by production relocation decisions of client firms in the regions where subcontractors are operating. The analysis focuses both on captive offshoring (investments in existing or new production facilities abroad) and on offshore outsourcing (establishment of new subcontracting relationships with foreign suppliers). The aim is to assess whether 'forced' upgrading (i.e. upgrading in response to production relocation) has the same beneficial effects on subcontractors' performance as the standard upgrading processes identified by the literature.

This research aims to integrate the literature on economic resilience and that on Global Value Chains (GVCs), providing a novel perspective on upgrading. Moreover, the IMEFAS database allows to shed light on a 'grey area' of the manufacturing industry which has been overlooked by previous empirical research. This lack of contributions is surprising, considering small subcontractors represent a significant share of manufacturing employment in several European regions. These firms are particularly vulnerable to global transformations: therefore, their ability to cope and react to sudden changes is crucial to increase the resilience of the economic systems in which they operate.

PUBLIC SPENDING AND ECONOMIES OF SCALE IN PARTIAL FISCAL DECENTRALIZED GOVERNMENTS: THE CASE OF CHILE

[Alicia Chavez](#), [Dusan Paredes](#)

Universidad Catolica del Norte (UCN), Chile

ABSTRACT

Economies of scale derived from over-urbanization could affect the average cost of public spending in some cities and, as a consequence, undermine the equal access to local public goods among municipalities. Those that reach economies of scale would be able to supply the basic required local public goods plus other additional benefits and opportunities, while those that do not achieve them would face problems to even provide the basic ones, causing an unequal supply between cities. Under such setting, there should exist redistributive spatial policies that compensate this inequality; if not, people that live in less concentrated regions could see their rights affected. This paper presents a framework for the assessment of economies of scale in local public spending in Chile, which is an interesting case because of its well-known particular geographical features as well as its high fiscal heterogeneity. Chile is characterized by a partial fiscal decentralization model, in which all municipalities receive funds from the central government to satisfy the minimum acceptable standard of living, but they can also complement with own funds generated by local collection to offer additional goods and services.

Empirical evidence of economies of scale has focused on centralized economies, but this issue must also be considered in decentralized economies. The behavior of local governments under a centralized model could differ from the ones under a partial fiscal decentralization model. While the latter, who receive funds from the central government and are in charge of the provision of local public goods, may be interested in achieving economies of scale to use efficiently their resources; the former may not be interested in doing so because the central government is who controls the provision of local public goods. In this sense, it is important to address the presence of economies of scale in local public spending in non-centralized governments; that is, either in decentralized or partial fiscal decentralized governments. Therefore, for the purposes of this paper, we estimate the population level in which a reduction in the average cost of provision of local public goods occurs and we differentiate between municipalities with high and low fiscal dependence from the central government. Furthermore, we follow a theoretical model of cost efficiency that takes into account spatial interactions and spillover effects among neighboring jurisdictions.

Our preliminary results show that Chilean municipalities reach an optimum population level around 700,000 inhabitants, which is very high; in fact, only 2 municipalities would fall into this level. Once we control for the fiscal heterogeneity of Chile, we obtain that municipalities with high fiscal dependence reach their optimum population level around 45,000 inhabitants, while the ones with low fiscal dependence reach it around 700,000 inhabitants. This fact highlights the importance of considering territorial differences when addressing public financial issues and the local provision of local public goods.

THE EFFECT OF SUBWAY EXPANSION ON TRAVEL TIMES IN SANTIAGO-CHILE. EVIDENCE FROM UBER DATA MOVEMENT

[Ariel Arcos](#)¹, [Bernardo Lara](#)², [Dusan Paredes](#)¹

¹Universidad Catolica del Norte, Chile. ²Universidad de Talca, Chile

ABSTRACT

According to the INRIX 2020 report, 3 of the 5 cities with the highest traffic congestion problems belong to Latin America. These problems are related to high urban primacy and lack urban planning characteristic of underdeveloped countries. For example, in the case of Santiago de Chile, Frost & Sullivan estimate economic losses by around 2.5 billion dollars by 2018, in relative terms it exceeds seven times the local public budget the city. To solve the problems of traffic congestion, many of the Latin American countries, including Chile, have implemented transport policies. However, as Yañez-Pagans et al (2018) indicates, in Latin America there is a deficient culture of impact evaluation of transport policies. In this sense, the objective of this research is to evaluate the impact of the expansion of Metro line 6 on travel times to the main employment centers of the city. To achieve the objective, the four main destinations for work reasons are considered according to the SECTRA 2011 origindestination survey. Then, from Uber's vehicular transport services we obtain georeferenced daily travel time information between origin and destination for a period of 20 days prior to and 20 days after the opening date of Metro line 6. Using the opening of the new Metro line as an exogenous shock that modifies travel patterns and that allows evaluating its causal impact on traffic congestion through an interrupted time series regression estimate (ITSR).

The research hypotheses are that the new Metro line had an impact on the reduction of travel times and that this impact follows a spatial pattern. The results show that travel times are reduced after the opening of the new Metro line, but significant only for three of the four main employment centers with reductions of around 7% and 14%. Similarly, it is obtained that the impact of line 6 is spatially heterogeneous, which is reflected in the clusters formation of benefited areas and affected areas with increases in travel times, which are close to the employment centers.

COOPERATIVES AS AN ALTERNATIVE TO REDUCE THE HIGH TERRITORIAL CONCENTRATION OF CAPITAL OWNERSHIP IN THE CHILEAN CASE

Juan Pedro Eberhard, Patricio Aroca

CEPR, Business School, Universidad Adolfo Ibáñez, Chile

ABSTRACT

Many countries struggled with high levels of inequality. Territorial inequality is sometimes overlooked as an important source of inequality. Differences in the territory are associated with the distribution of capital both human and physical. However, a more nuanced source of inequality may play an important role in how to develop local economies.

Studying the value chain of dairy products in Chile, this paper shows how cooperatives can promote redistribution of profits from upstream links (manufacturing) to downstream links (agricultural), which have a territorial impact given that manufacturing ownership is highly concentrated around the Chilean Metropolitan Region.

In addition, the cooperative allows its associates to be more resilient to face an economic downturn, due to this allows the associates to receive revenues from the manufacturing activities of the cooperatives, given that manufacturing profits are larger than the ones generated by agricultural dairy production.

Using an input-output framework, it is shown that the impact is even larger when the indirect and induced effects are taking into account, especially because most of the induced effects are spent in the territory, while in the case of the large company this amount is concentrated around the Metropolitan Region.

EFFECTS OF WIND ENERGY INPUT ON THE SECTORS OF ECONOMIC ACTIVITY IN THE SEMIARID REGION OF BAHIA

[Carolina Ribeiro, Gilca Oliveira](#)

Federal University of Bahia, Brazil

ABSTRACT

Renewable energies have been growing rapidly and gaining more and more space in the world electrical matrix in recent years. The accelerated deployment of energy from wind sources contributes to the annual reductions in CO₂ emissions. In the Brazilian electric matrix, wind energy already represents an 8% share in the country. From 2011 to 2018, 31 billion dollars have already invested in the wind sector. In 2017, investment in the sector represented 58% of the total invested in renewable energy. The State of Bahia has already received a large volume of investments in wind energy. The state's wind generation is located in the semi-arid region. The region has experienced the worst drought in its history in recent years. Therefore, the semi-arid region lacks policies that encourage regional development, the generation of jobs and income and actions to assist in living with the semi-arid region. In this context, it is questioned how the investments in wind energy affect the sectors of economic activity in the semi-arid region of Bahia, promoting development? Thus, the present study aims to investigate how the sectors of economic activities in the region react to investments made in the wind sector. For this purpose, it uses the input-output matrix of the semi-arid region of Bahia for the year 2015 with 40 sectors, prepared from the matrix Bahia 2015, of GERI-UFBA. The analysis uses classic indicators, economic multipliers of employment and production and hypothetical extraction of input-output sectors, in order to investigate the effects on job creation and production. The results show that the effect of wind energy contributions in the economic activity sectors of the Bahian semi-arid region, it was observed that around 18 billion BRL in wind energy has the possibility of influencing the total production of the semi-arid by more than 28 billion BRL in direct impacts and indirect. As expected, the Civil Construction sector had the highest profile. Regarding the generation of jobs, the effects of the contribution can lead to the creation of more than 3,300 jobs. The most impacted sectors were civil construction and others in the extractive industry with the possibility of generating 548 and 348 total jobs, respectively. From the above, given the progress of the wind sector in the region and the contributions made, it is observed that these positively affect several economic sectors, encouraging development. However, even with the effects of the contributions on the sectors being positive, public policies are necessary to provide a more significant development for the region. In addition, these, in turn, must consider the social and economic inequalities present in the semi-arid.

EASING THE EFFECTS OF AUSTERITY WITH REFORMS: A REGIONAL CGE EXPERIMENT ON BRAZILIAN LABOR PRODUCTIVITY

ABSTRACT

This article aims to project the variation in labor productivity in response to structural reforms in Brazil necessary to offset the contractionary impacts of this agenda, considering regional heterogeneities. For this, a dynamic interregional general equilibrium model is used for 27 Brazilian federative units, allowing a bottom-up analysis. The main results show that the increase in labor productivity necessary to mitigate the contractionary effects of fiscal consolidation varies considerably between the Federation Units, relatively more onerous to the Northeast region. Macroeconomic results also follow the same pattern of regional heterogeneity. The increase in labor productivity in the states most affected by the contractionary impacts of austerity is hardly feasible due to the low prospect of household consumption, falling investment and high unemployment in a sectoral composition that has little benefit from the austerity and reforms agenda.

KEYWORDS

Computable General Equilibrium; Fiscal Austerity; Labor Productivity; Structural Reforms.

1. INTRODUCTION

In the current Brazilian public debate, in parallel to the Federal Government's austere measures on the expenditure side and the attempt to adopt fiscal consolidations in the Federative Units (states) via the Federal Government's Tax Recovery Plan, there is a discussion regarding the need to approve structural reforms, such as the liberalization of the labor market, increase in the average time for workers' social security contributions and modification of the tax structure.

According to the extensive compilation of theories and empirical evidence presented in Alesina et al. (2019), fiscal consolidations can achieve expansionary results. For OECD countries, Bouis et al. (2012), Alesina et al. (2018) and Annicchiarico et al. (2013) find, to a greater or lesser extent and time to maturity, the achievement of fiscal consolidations in periods of economic stagnancy. This conclusion, supported mainly by the role of expectations, opposes the Keynesian argument that fiscal consolidations would have a contractionary effect on aggregate demand in the short-run. Thus, expansionist austerity (or expansionary fiscal contraction) can be defined as the positive correlation between fiscal adjustment, either through cutting public spending or increasing taxation, and private consumption and investment.

As this literature argues, one of the contexts that would allow expansionary results due to fiscal consolidations is the one marked by accompanying policies. These policies vary from the concomitant adoption of contractionary monetary policy and the liberalization of the capital market, according to the pioneering analysis of Giavazzi and Pagano (1990), to structural reforms in the labor market and the productive sectors (product market).

For Brazil, the impacts of fiscal austerity are still uncertain, whether at the macroeconomic and sectoral level or on the social spectrum, on the well-being of households and income distribution. Although the implementation of Constitutional Amendment (AC) 95/2016¹⁷⁶ had the goal of anchoring the expectations of economic agents, limiting the growth of public spending in a context of fiscal insolvency, as pointed out by Salto and Barros (2018), some argue on its flexibilization, given the persistence of high idle capacity and unemployment, as well as the lack of public investment in sectors such as health, education and infrastructure (GIAMBIAGI, 2019).

¹⁷⁶ Constitutional Amendment No. 95 (AC 95), of December 15, 2016, established the New Fiscal Regime (NRF) within the scope of the Federal Government's Fiscal and Social Security Budget, which will be in force for twenty financial years. The NRF sets individual limits for the Executive, for the bodies of the Other Powers, the Public Ministry of the Union - MPU and the Public Defender's Office of the Union (DPU) (MINISTRY OF FINANCE, 2018).

The history of reforms in the Brazilian state is wide and old (COSTA, 2008). These reforms, however, differ considerably from one another. If in the 1950s and 1960s they were marked by developmentalism - from the 1980s and, mainly, 1990s, it was influenced by the global liberalism (CARDOSO, 2021). Currently, reforms are constantly brought to the public debate as an essential agenda for the resumption of Brazilian growth, justified by the fact that they act to liberalize and cooperate to the private sector, in order to mitigate the eventual short-run negative impact on economic activity. due to fiscal consolidation, as part of the literature argues.

According to Anderson, Hunt and Snudden (2014), the reforms positively affect labor productivity and the level of employment through the liberalization of the labor and product market. According to Bouis (2012), flexibilities in labor laws, for example, reduce restrictions on hiring and firing employees, which, in turn, can increase labor productivity, despite the reduction in the bargaining power of the worker and increase, most of the time, precariousness and social costs (RUBERY and PIASNA, 2016; SHIN, 2012). Even social security reforms that promote an increase in the retirement age and actuarial neutrality, raise the labor force participation rate to a new balance in about 10 years according to estimates by Bassanini and Duval (2006; 2009), who, from the point of view of view of the worker, are also liable to adverse effects (BOERI et al., 2002; KODAR, 2004).

Less optimistic arguments regarding the achievement of structural reforms can be found in Rodrik (2017), who highlights the fact that despite the goal of raising the potential output of the economy in the long-run, reallocating factors to more productive sectors, its impacts are usually overestimated. For Bardaka et al. (2020), unless structural reforms are carefully planned to support productive sectors (high value-added), these policies may fail even in the long-run.

Discussions on the effects of austerity and structural reforms are scarce of regional analyzes. This is an important feature, in face of heterogeneities common to space, especially in Brazil, a continental country with great regional, social, economic and structural inequalities. These inequalities mean that the importance of public spending for the economies and well-being of households and the dynamics and productive structure itself vary considerably between regions.

For different countries, Caraveli and Tsionas (2012); Beatty and Fothergill (2013); Cabrera, Lustig and Moran (2015); Pearce (2013); Murphy (2017); Green and Lavery (2015); and Tupy and Toyoshima (2013) highlight the central role of public sector performance and government income transfers to households with regard to interregional income inequalities. The greater dependence of smaller and poorer regions on public sector action, either directly, in the administration and provision of services, or indirectly, via income transfers, is a stylized fact in the literature of regional economics, they are the so-called "economies without production".

Regarding fiscal consolidations and their regional effects, Cardoso et. al. (2019) assess the direct and indirect impacts of a fiscal austerity agenda of the Brazilian government on the country's regional and sectoral inequalities. The authors project austere scenarios for the growth of public spending in the Brazilian economy, without and with the recovery of private investment (ie, considering the hypothesis of expansionary fiscal austerity) and conclude that, even if the recovery of private investment was sufficient to offset the negative impacts of the spending cutting on economic growth, there would be worsening macroeconomic and inequality indicators between municipalities and states in the North and Northeast, relative to the rest of Brazil.

Considering the literature favorable to the positive effect of structural reforms, through labor productivity, and the one that discusses the role of the Government in regional inequalities, this article proposes to measure the increase in labor productivity necessary to offset the contractionary effect of the public spending cut on GDP, stemming from the deepening and regional extension of the fiscal austerity agenda in Brazil in the coming years. Still, considering the Brazilian regional structure, it seeks to assess the heterogeneity of eventual productivity gains in the states of the country. For this, a computable general equilibrium model (EGC) with recursive dynamics is used, calibrated for the Brazilian twenty-seven states (Federative Units). The model is based on 2015 data published by the System of National Accounts (SCN) of Brazil (IBGE, 2019) and allows a bottom-up analysis from the state to the national level.

This paper innovates when investigating the regional productivity gain to compensate the contractionary effects of fiscal austerity in Brazil, through the EGC model. Its results are in accordance with the literature on regional convergence in the Brazilian productive structure, as well as regional inequalities. Despite not considering the influence of the pandemic caused by COVID-19, the themes brought here are closely linked to this problem, both in coping with and overcoming the multisystem crisis caused by the virus.

In addition to the present introduction, the work is divided into four more sections: the first, presents the main studies related to structural reforms and their consequences on labor productivity and regional inequalities as well as the recent literature on the Brazilian productivity; then, we describe the methodology, which presents the structure of the model applied to this work, its database and the simulation strategy. In section 4 we present the results and, at last, the final remarks.

2. LITERATURE REVIEW

Assessments of the relation between structural reforms, labor productivity and regional inequalities are also scarce and lack consensus. For Colombia, Eslava et al. (2004) investigate the effects of product market reforms, such as removing import restrictions and foreign direct investment, introduced in Colombia in the early 1990s. Based on longitudinal data at the firm level for the period 1982-1998, they find evidence that the reforms are associated with an increase in general productivity, largely driven by the reallocation of low- and high-productivity companies. These changes had no effect on the persistent history of regional inequality in the country, as assessed by Fergusson et al. (2017). In this sense, for India, Unni, Lalitha and Rani (2001) find that liberal reforms in industry and international trade throughout the 1980s and 1990s only benefited the Gujarat region, which was already the most industrialized in the country before the reforms, in terms of value added, employment, capital and productivity. The authors also observe a general post-reform worsening in the informal sector in relation to the formal sector across the country.

To understand the recent evolution of labor productivity in Brazil, in sectorial and regional terms, as well as an international comparison, we present the following references.

Silva et al. (2016) present an international comparison of the evolution of total productivity in the period from 1965 to 2010 between Brazil, South Korea, the United States and other countries in Latin America, considering the technological effects and structural changes. According to the authors' explanation, this decomposition reveals to us whether the growth of a given economy was due to structural changes - the reallocation of labor from less productive sectors to more productive ones - or technological advances, that is, the fact that the economy is able to produce more with the same amount of inputs. The authors note that, despite the huge total discrepancy between South Korea and other countries, this evolution presents different trajectories when analyzed in shorter periods. If, until 1980, Brazil and South Korea had similar productivity growth, they find that, from the 1980s on, the technological effect was largely responsible for the fall in Brazilian productivity. In the Korean economy, on the other hand, there was a growth of 65.7% in productivity, guided by the outstanding technological effect. For the United States, they observed very low growth in the period 1965-1980, compared to other countries (7%); relative increase in the 1980s (12%); and a considerable recovery in the years extending from 1990 to 2010 (28%).

At the sectorial level, based on data from the National Accounts and the National Household Sample Survey, Veloso et al. (2015) updates the trajectory of the evolution of labor productivity in Brazil over the 1990s and 2000s. The authors show that the average labor productivity grew at a rate of 1.3% p.a. (1995-2013), with a considerable difference between the three main sectors of the economy: Agriculture (6.1% p.a.); Industry (-0.4% p.a.); and Services (0.6% p.a.).

Regionally, Galeano and Feijó (2013) analyze the decomposition of the evolution of labor productivity in industry between 1996 and 2007, considering its participation in national employment using the shift-share method. Of interest to the present study, the regional rates are: Southeast, -12.4%; South, 14.6%; North, 58.3%; Northeast, 23.9%; and Midwest, 55.5%. According to the authors, the general results show that there was a certain rearrangement of some sectors of industry between regions. However, less developed regions are still unable to absorb that portion of the declining sectors in the Southeast region, due to the low representativeness of industrial activities in the regions. With the exception of the Southeast region, the authors argue that the growth in labor productivity in the analyzed years was due more to the residual regional component, that is, to the competitiveness of the sectors themselves in the regions, than to structural changes in the sectorial composition.

In this way, Cruz and Santos (2011) analyze the dynamics of Brazilian industrial employment between 1990 and 2009 and highlight that, despite the regional spillover of industrial employment, the regions that had a relevant industrial base have moved towards specialization in industrial sectors with greater technological content, as a consequence of the externalities of these places, which, according to the authors, was more important than the tax incentives offered for the dispersion. Mendes et al. (2019) evaluate the spatial reorganization of the Brazilian manufacturing industry after 2008 and suggest a spillover of the activity towards low quality jobs, with a greater dispersion of sectors with less technological intensity and jobs with lower educational levels. The authors assume a strong correlation between sectorial technological intensity and the labor level of education and observe the prominence of the Southeast region, mainly in the state of São Paulo, with regard to employment generation of masters and doctors, in sectors of higher technological intensity. In addition to the sectorial issue, the results still suggest a possible productive transition in seek of lower labor costs.

It is important to emphasize that the dynamics of labor productivity over time, in general, was closely related to the countries' growth of product and income. For Brazil, it is worth remembering that this regional convergence has historically resulted from factors related to the action of economic policy and the economic logic of competition and location. As Ferreira and Diniz (1995) point out, the convergence of per capita income between Brazilian states in the 1970s and 1980s, the period of greatest effectiveness for industrial decentralization in the country, was associated with the development and expansion of basic infrastructure; the movement of agricultural and mineral borders; the direct

action of the State in terms of investments and the granting of subsidies and tax incentives; the crises and reversals of industrial polarization in large urban centers like Rio de Janeiro and São Paulo; and migratory movements and changes in the regional distribution of the population. These conditions are in line with the investigations made, more recently, for the Brazilian industry, as indicated by the previously mentioned works.

3. METHODOLOGY, DATABASE AND SIMULATION STRATEGY

The model used for the simulations is a dynamic recursive CGE model calibrated for Brazil. It follows the theoretical structure of The Enormous Regional Model (TERM), which is a model developed by the Center of Policy Studies (CoPS), in Australia, with several applications for the Brazilian economy such as Ferreira Filho and Horridge (2014); Carvalho et al. (2017); Ribeiro et al. (2018); Cardoso et al. (2019). As the following discussion present, this method differs by the version of the database and by the regional details of technological change, improving its analytical potential at the regional level.

3.1 The Enormous Regional Model (TERM)

TERM is a bottom-up Computable General Equilibrium model, which means that each region in the model is considered as a separate economy and the results at the national level are aggregations of regional results. Although demand, supply, price and quantity are computed for each region separately, spatial interdependence is considered in the model through interregional trade. Therefore, the TERM approach is appropriate for analyzes in which the industrial and regional details have a relevant role. The theoretical structure of TERM follows basic neoclassical assumptions. For each Federative Unit (state), a representative household chooses a consumption basket that maximizes the Stone-Geary utility function subject to a budget constraint. Consumption is allowed to be divided between the subsistence and luxury component (supernumerary), in which only expenditures above the subsistence level affect the per capita utility (PETER et al., 1996; STONE, 1954). All economic agents (households, firms, government and investors) are allowed to choose between domestic goods (from different regional sources) and imported goods using a CES specification (Armington hypothesis), based on the differences in the purchase price of each source. The market-clearing condition is valid for all markets in all periods, adjusting prices and quantities each year.

The equation that models the production technology is the main transmission mechanism of the exercise presented in this study. Its structure defines the production of each industry and region by minimizing the production costs, following a production function in fixed proportions (Leontief type), which establishes the use of intermediate inputs and primary factors (1). Hierarchically combined with the production function, a function of constant elasticity of substitution (CES) defines the composition of the primary factors, labor and capital, employed in production (2). Associated with the inputs, intermediate or primary factors, the variables of technological change are the ones that make it possible to capture the effects of gains or losses in productivity. In this sense, productivity gains can be understood as savers of inputs / factors.

$$tot_{ir}^q = \frac{1}{tot_{ir}^t} \times MIN \left\{ \frac{int_{ir}^q}{int_{ir}^t}, \frac{prim_{ir}^q}{prim_{ir}^t}, \frac{oth_{ir}^q}{oth_{ir}^t} \right\} \quad (1)$$

$$prim_{ir}^q = CES \left\{ \frac{lab_{ir}^q}{lab_{ir}^t}, \frac{cap_{ir}^q}{cap_{ir}^t} \right\} \quad (2)$$

Where q is for quantity; t , for technology; i , for industry and r , for region. int , $prim$, and oth indicates the intermediate inputs, primary factors and other production costs, respectively; lab and cap indicate the use of labor and capital factors, respectively; tot_{ir}^q denotes the total production of industry i , in region r ; and tot_{ir}^t is the technological variation in the total use of inputs in industry i in region r .

The dynamics adjustment is based on the accumulation of investments and capital stock at the regional and industry levels. According to Dixon and Rimmer (2002), for each year of the simulation, it is assumed that the rates of capital growth are determined by the willingness of investors to invest resources in an industry based on the expected rate of return. Basically, if the rate of return expected by investors is higher than the pre-established normal rate of return, the capital accumulation will be above the normal rate (Dixon and Rimmer 2002).

In this sense, the proposed exercise is favored by the ability of the method to capture, over the time, the effects of differentiated technological changes at the regional level on the economic system, as well as by the possibility of decomposing its effects among the main macroeconomic aggregates such as consumption, investment, employment, exports and imports.

3.2 Database

The model's database is made up of 27 regions, corresponding to the Brazilian's states, and 127 sectors, listed in the Input-Output Matrix of 2015 released by the Brazilian Institute of Geography and Statistics (IBGE) (IBGE, 2018). The model's database was regionalized through a method developed by Horridge (2012), in addition to information from the System of National Accounts (SNA) of Brazil. Information on consumption is from the Brazilian 2008–2009 Household

Budget Survey (IBGE, 2011); on employment, from the Annual Report of Social Information (RAIS) (BRASIL, 2020); and on international trade, from the Comex Stat (2019), from the Foreign Trade System (SISCOMEX). Next, we exhibit some variables from the database that are important for this study: the Gross Regional Product (GRP), by state (Figure 1), the wage bill of the labor factor in the states (Figure 2) and the representativeness of Government expenditure, by government sector, in relation to GRP in each state (Figures 3 and 4).

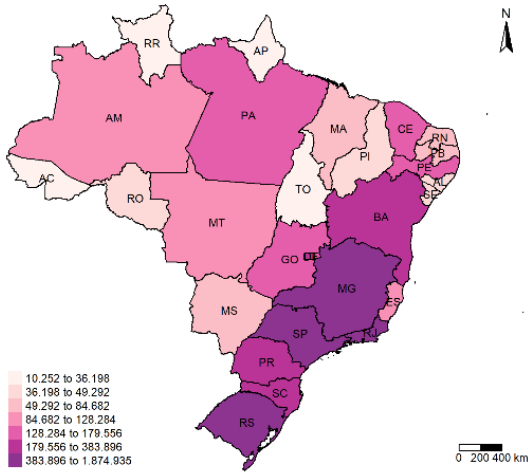

Figure 1: Gross Regional Product (R\$ million), Brazil, 2015

Source: Model's database.

Average exchange rate in 2015: 1 US\$ = 3,33 R\$.

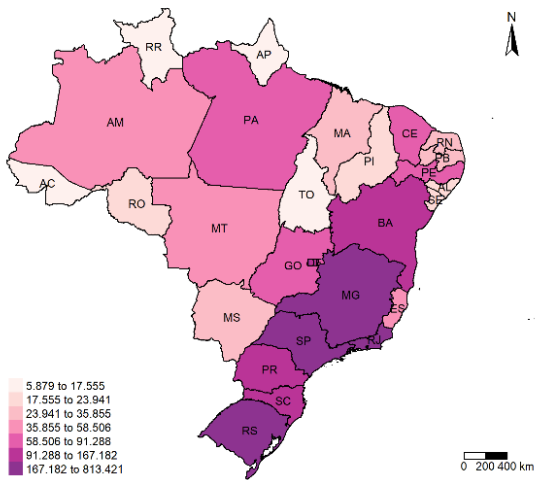

Figure 2: Labor force remuneration on each state (R\$ million), Brazil, 2015

Source: Model's database.

Average exchange rate in 2015: 1 US\$ = 3,33 R\$.

Figure 3 provides an overview of the Government's general role. In our model, public expenditure is taken under the concept of General Government, that is, it represents the total expenditure at the Federal, State and Municipal levels. Part (a) illustrates the composition of the main purchasing flows of the government sectors; in (b), we show the weight of spending on GRP of each, by sector.

Figure 3: Main demands of Government sectors for products (a) and the share of Government sectors expenditures in the total production of the states (b)

Source: Model's database.

It is notable that, while Government spending has a greater share in the total production of the North and Northeast of the country the wage bill is concentrated in the states with the highest GDP, mainly in the South and Southeast regions. Figure 4 illustrates the share of the General Government expenditure component in the GRP of each state.

Figure 4: Representativeness of General Government expenditure on each Federative Unit (% of GRP), Brazil, 2015

Source: Model's database.

In general, the illustrations indicate that the greater share of public sector consumption (spending on goods and services) in these regions makes their economic dynamics more dependent on this component of final demand. In addition, the

Government sector has a high influence in employment and consequently in the wage bill of these regions, which also affects the dynamics of the economy of these states.

3.3 Simulation Strategy

In order to assess the response of labor productivity required to offset the contractionary impact of the Government's shrinkage, influenced by the lasting fiscal austerity agenda currently adopted in the country, the simulation is divided into a base scenario (baseline) and a policy scenario. The simulation of the baseline updates the database as follows: for the observed period (2016–2019), we use the main official macroeconomic data for real GDP, investment, household consumption, government spending, exports, import prices and consumer price index. For the 2020-2021 period, we used a homogeneous scenario of growth at 1% and 1.5%, for these years, respectively, and, from 2022 onwards, we assumed a scenario of stationary growth of 2.5% per year. From 2020, the hypothesis that the growth of government spending follows the growth rate of household consumption is also adopted in the base scenario.

For the policy simulation, the growth in real Government consumption, exogenous, was set at a zero-percentage change, exactly representing the commitment of the fiscal adjustments initiated in 2017, according to the Constitutional Amendment (CA) 95/2016. In other words, there is no real growth in government spending on the policy scene. This assumption is kept constant throughout the simulation period (2019 to 2030). The policy scenario does not intend to strictly simulate the performance of the CA 95/2016, but of a hypothetical austerity agenda, represented by the absence of real growth in General Government spending. This implies that the General Government institutional sector loses its share in the regions' GRP over the simulation period.

The fiscal concept of the General Government gathers the intermediate consumption expenditures of the Government and personnel from the Federal, State and Municipal spheres. The policy scenario therefore represents an illustrative scenario for reducing the size of the state in relation to the economy, since states and municipalities are not, at first, under the expenditure ceiling.¹⁷⁷

In addition to the database, the operation of CGE models depends on a large system of equations, which establishes the behavior of the variables and their interrelations. The main equation involved in the policy shock to be studied is simple:

$$GRP_r = C_r + G_r + I_r + X_r - M_r \quad 3)$$

As previously explained, the simulation consists of a relative reduction in Government spending (G) compared to the baseline, for each region *r*. However, to assess the reaction of labor productivity in face of such a contraction, we modify the closure of the model.

The closure is the set of hypotheses of the model, in which is defined the exogenous and endogenous variables of the system of equations. In order to simulate the expected effect of the structural reforms adopted in parallel to the fiscal consolidation, we modify the closure of the policy scenario in order to exchange the real GDP of each state, exogenous, with the respective labor productivity, endogenous, while we kept the growth of the first variable unchanged (in relation to that observed in the baseline).

In other words – we avoid an ad hoc definition by endogenously calculating the labor productivity necessary to maintain GDP growth as projected in the baseline. So, according to equation 3, the policy scenario establishes zero growth in Government spending (G) and zero deviation of GDP in relation to the baseline, supported by the other components of the equation that adjust to the expected increase in productivity described in equations 1 and 2.¹⁷⁸

It is important to emphasize that, intrinsic to this methodology, the details of the dynamics of the labor market and real wages, referring to the recursive dynamics of the model, indicate that the intertemporal adjustment of real wages responds to fluctuations in current employment, in face of an employment trend defined by projections of the workforce growth, present in the baseline. Another important issue is that, in this CGE model, the mere announcement of this policy has only the effect of changing aggregate demand, but not expectations regarding interest and investment rates. Therefore, it can be said that our policy scenario simulates what would happen if the government maintained its commitment to zero growth in real spending, but families and companies, however, did not change their expectations regarding the future.

177 There was pressure for States to adhere to the ceiling in exchange for the postponement of payment of debt maturities with the Union. The Tax Recovery Plan, for example, was being proposed by the Union to States in exchange for negotiations regarding federal aid to the fiscal situation of the States. This plan basically followed the CA 95/2016 strategies, such as the zero real growth of the expenses. However, given the difficulty of decision by the States' legislature and the arrival of the Covid-19 pandemic crisis, nothing concrete has been established. On March 3rd of 2021, Proposal of Constitutional Amendment 189 (Emergency PCA) was approved, which sets out austerity rules for States and municipalities, which must be taken if the current expenses of this entity in relation to current revenues exceed 95%.

178 According to Cardoso (2019) and Cardoso et al. (2019), due to the relative contraction of aggregate demand, a policy scenario with Government spending growing below that projected in a baseline leads to the negative deviation of GDP and its components, with the exception of Exports, in a long-run result. In the baseline, the Government's expenditure component follows the GDP dynamics in each region.

4. RESULTS

In this section, we organize the results from three perspectives: i) at the national and regional macroeconomic level, showing the cumulative impact on the final demand and employment (2019-2030); ii) labor productivity at the state level; and iii) sectoral results at the state level. All the results are exhibited as the accumulated percentage deviation from the baseline scenario, in which the policy of austerity is not applied. Figure 5 shows the results of the national GDP and its components over the projection. Figure 6 shows the evolution of other macroeconomic variables, important for the interpretation of the results of Figure 5.

Figure 5: Macroeconomic Results - Policy Scenario - Accumulated deviation (%) to the Baseline (2019-2030)

Source: Own elaboration based on the simulation results.

Figure 6: Other macroeconomic results - Policy Scenario - Accumulated deviation (%) to the Baseline (2019-2030)

Source: Own elaboration based on the simulation results.

As shown in the previous graphs, a shock of retraction of total government demand (Figure 5) would contribute to the fall in aggregate demand. To adjust to this fall, domestic prices adjust. This reduction in prices has two consequences: On the one hand, there is a reduction in the remuneration of factors, which generates a reduction in household consumption, contributing to amplify the contractionary effect of the cut in public spending and, on the other hand, given that international prices do not change and that exports demand responds negatively to the exchange rate (local currency/\$world), there is a change in relative prices favorable to Brazilian exports, leading to an increase in this aggregate in GDP. Here, it is assumed that the country has no influence on the global market prices, this means that Brazil has a terms of trade decline, which leads to export growth relative to imports and a trade surplus. To this condition, it is also added the fact that the increase in labor productivity contributes to the reduction of production costs.

As we can observe in Figure 5, however, household consumption remains almost equivalent to that projected in the baseline (final accumulated deviation of -0.02%), despite the employment fall (Figure 6). This result is due to the fact that the gain in labor productivity sustains the average level of wages each year, detaching them from the level of domestic prices (Figure 6).

The real constraint of the public expenditure with a positive response of the labor productivity also does not drive significant growth in investment (Figure 7). Thus, even with cheaper inputs and growth in exporting sectors, the levels of income and consumption influence the rate of return on capital and contribute to keeping investment at levels similar to the base scenario, although there is a small negative deviation in the final years of the simulation. The state level results in Table 1 show that the variables vary considerably between them.

Table 1: Macroeconomic Results by Federative Unit - Policy Scenario - Accumulated Deviation (%) from the Baseline (2030)

Sections: North; Northeast; Southeast; South and Center-West.

At the state level, the results in Table 1 indicate a significant worsening in household consumption and investment in states in the North region, such as Acre (AC), Roraima (RO) and Amapá (AP), and in the Northeast, which, with the exception of Bahia (BA), have significant numbers below 9% of accumulated negative deviation from the baseline. As can be seen, the real stagnation of Government expenditure is of equal magnitude between states; however, its impacts are different given the different share of the public sectors (public education, public health and public administration and social security) in each one, as indicated in the previous section. Exports grow more in the states most affected by the policy, in which unemployment and the fall in consumption and investment are also greater, inducing a fall in domestic prices and, therefore, in export prices. The regional heterogeneities of the results imply that the response of the labor productivity necessary to keep GDP constant is also heterogeneous in the country's states, as shown in Figure 7.

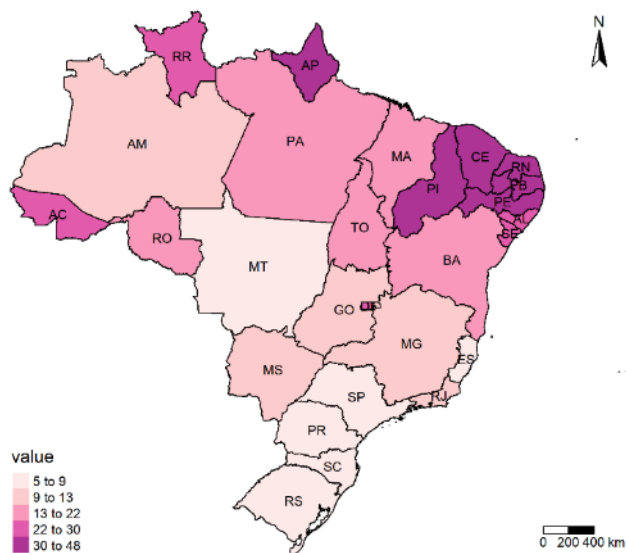

Figure 7: Labor productivity accumulated growth, by Federative Unit (%) - Policy scenario (2030)

Source: Own elaboration based on the simulation results.

In the model structure, the increase in productivity is given in negative values, which implies the need for less work to produce a certain quantity of product. In a similar way, we can interpret the positive values as an increase in the quantity of product that the same number of workers will be able to produce.

As can be seen in Figure 7, the results of the simulation show that the labor productivity necessary to sustain GDP in the face of reduced government spending is heterogeneous in the country. The low magnitude of accumulated growth in the states of the South, Southeast and Center-West (with the exception of the Federal District - DF) and high in most of the North and especially the Northeast regions, points out that, in relative terms, the limitation of the real growth in Government expenditure in São Paulo (SP) and Piauí (PI), for example, it is more expressive in the second, because the representativeness of Government expenditure in its GDP is much higher than in the former, in order to demand even greater growth in labor productivity in those regions most affected by fiscal austerity.

As described in the mechanisms of the shock, the positive impacts in terms of variation in production, employment and investment must occur in the sectors whose production is mainly export-oriented, especially commodities sectors. Thus, another justification for the regional heterogeneity of the results is supported by the regional distribution of the industries.

Table 2 highlights the 20 industries with the highest and lowest accumulated growth after the implementation of the policy. The list of industries that have benefited the most from the policy is more diversified and presents sectors predominantly oriented to the foreign market, with the majority belonging to the extractive and processing industries. The industries with the worst accumulated result, on the other hand, have activities aimed at the domestic market, such as public services, infrastructure, rents and other services and supply goods.

Table 2: Industrial Results - Policy scenario - Accumulated deviation (%) compared to the baseline (2030)

Top 20 Industries		Bottom 20 Industries	
Non-ferrous metal minerals	28,3	Public administration collective services	-21,6
Hotel and similar accommodation	28,3	Public education	-17,7
Non-ferrous metallurgy products	28,1	Social Security and Assistance Services	-16,6
Naphtha for petrochemicals	26,9	Public health	-13,6
Mineral coal	25,5	Buildings sector	-5,4
Cellulose	25,4	Infrastructure works	-4,2
Iron ore	24,7	Private health	-3,8
Pesticides and household disinfectants	24,6	Imputed rent	-3,5
Organic chemicals	24,2	Research and Development	-2
Fabrics	23,7	Employers' organizations, trade unions and other	-1,7
Electronic components	23,3	Gasalcohol	-0,7
Pig iron and ferroalloys	22,6	Trucks and buses, including cabins, bodies and trailers	-0,6
Inorganic chemicals	22,1	Water transportation	-0,3
Non-real estate rentals and	21,4	Other dairy products	-0,1
Motor vehicle parts and accessories	21,2	Other food products	-0,1
Resins, elastomers and artificial and	20,9	Food services	0
Machinery for mineral extraction and	20,8	Furniture	0,5
Legal, accounting and consulting	20,7	Other products and services of temporary crops	0,9
Aviation fuels	20,5	Specialized construction services	1
Storage and auxiliary transport services	19,9	Products derived from wheat, cassava or maize	1,1

Source: Own elaboration based on the simulation results.

The representativeness of the production of these selected sectors in each state before the implementation of the policy is an important indicator to justify the different levels of labor productivity necessary to sustain economic activity, as shown in the previous result. Figure 8 shows the share of the two groups of sectors in the matrix that considers the entire production of the economy, in the model database, for each state (highest growth and lowest growth, respectively).

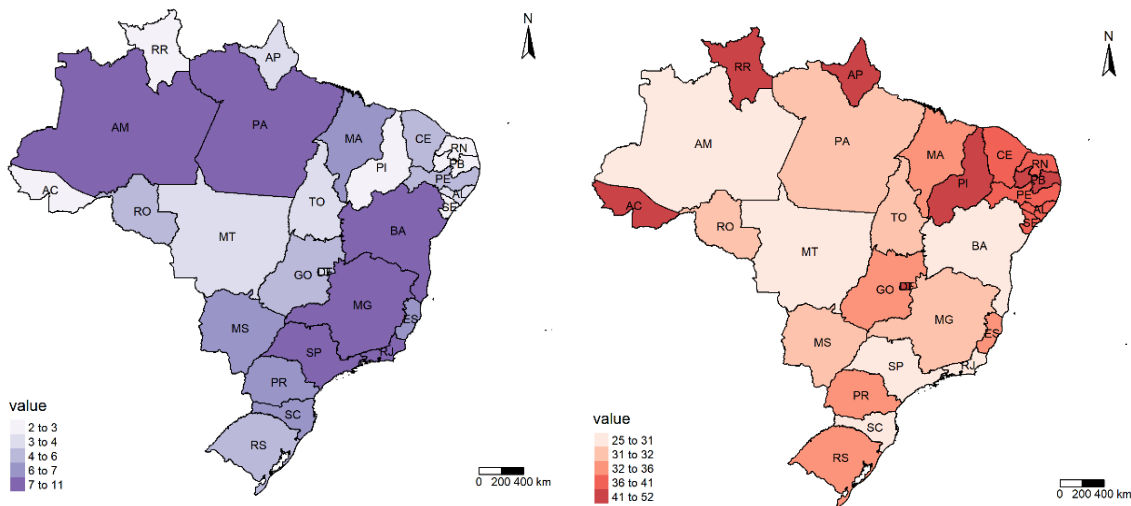

Figure 8: Representativeness of the post-policy 20 Top/Bottom industries on each Federal Unit (% of the total Output) - 2015

Source: Model's database, own elaboration.

As can be seen, the distribution of the share of the two groups has some important differences. While the activities that benefited most after the policy simulation were already relatively more important in the states of São Paulo (SP), Rio de Janeiro (RJ), Minas Gerais (MG), Bahia (BA), Amazonas (AM) and Pará (PA), the most affected industries appear with greater representation in the Federal District (DF), Piauí (PI), Rio Grande do Norte (RN), Paraíba (PB), Acre (AC), Amapá (AP) and Roraima (RO). While the group of industries most benefited from the policy scenario reaches up to 10% of production in some states, those less benefited can reach representativeness of up to 50% - a representative result of the inequality of diversification between the economies of the states.

Overall, the results are consistent with the literature. Since the 1970s, a convergence of income and productive activities can be observed in parallel with the increase in labor productivity in the North, Northeast and, mainly, Midwest regions above that observed for the South and Southeast regions, the most industrialized ones. This result can be explained by the rearrangement of some industrial sectors between regions. However, as authors such as Galeano and Feijó (2013) and Mendes et al., (2019) argue, the less developed regions would not be able to absorb the share of the declining sectors in the Southeast region, due to the low representativeness of the most technological activities in these regions, once the dispersion of activities has occurred in search of lower labor costs in the country.

In the current scenario, as demonstrated in this exercise, the level of labor productivity required to supply fiscal consolidation is relatively more feasible for regions where Government expenditure is less relevant and the productive structure is more diversified and more abundant, in terms of job creation; or more benefited by the fall in relative prices (or both). However, such a gain in productivity does not seem feasible in regions where the opposite occurs: the states of the North and Northeast regions, along with the Federal District, are the ones that suffer most from the cumulative drop in household consumption, unemployment and, mainly, investment - key factor in the history of convergence of production and income between the country's regions.

5. FINAL REMARKS

The present work aimed to measure the increase in labor productivity necessary to offset the contraction of public spending in Brazil arising from the current agenda of fiscal austerity and structural reforms. The objective is supported by the hypothesis that structural reforms can mitigate the effect of austerity by increasing labor productivity. On the other hand, there was a need to consider Brazilian regionalities, since the productive structure - quite uneven in the country - plays an important role in the reaction and recovery of economies in the face of multidimensional shocks such as those seen in fiscal consolidations.

The economic literature is permeated by arguments in favor of and against the achievement of structural reforms in terms of labor productivity and the level of production in the economy. Factors such as the difficulty in planning and orienting reforms, as well as the slow process of growth recovery in periods of austerity, are the main obstacles listed in the literature. At the regional level, there are also arguments that value the State's development and investment strategies with regard to the convergence of production and productivity. In Brazil, these were the factors that marked the industrialization of historically less developed regions, such as the North, Northeast and Center-West of the country. In this sense, the ability to sustain convergence is a common alert among the authors, who highlight the low infrastructure and education necessary to consolidate the high-tech industry in these emerging regions.

The results of the simulation strategy are consistent with the literature. The labor productivity required to sustain GDP in face of the reduced government spending is spatially heterogeneous in the country.

In addition to the justification supported by the heterogeneity of the representativeness of Government spending in the GDP of each state and the distribution of labor in the country, sectoral performance is also an important factor for the uneven results of the productivity response in each state. The list of sectors that would most benefit from the simulated policy is more diversified, with most activities belonging to the extractive and manufacturing industry, and most representative in the states where the need for compensating labor productivity is less. As for the sectors with the worst accumulated performance, which presents, in general, activities more directed to the domestic market, they are more representative in the states most affected, negatively, by politics.

The rearrangement of production and labor between the regions of the country has been historically related to the action of economic policy and the economic logic of competition and location. More recently, for the Brazilian industry, it can be said that the pre-existing economies of agglomerations and industrial bases were fundamental for its expansion, biasing possible deconcentrations of the economic activity to low jobs of worse quality. Therefore, the low perspective of household consumption coupled with the combination of lack of investment and high unemployment in a sectoral composition that has little benefit from the austerity and reforms agenda makes such an increase in labor productivity in some of the states unviable, suggesting a worsening of Brazilian regional inequality.

To the extent that austerity has an effect on variables such as interest rates, inflation and debt control, according to part of the literature, the results presented here show regional vulnerability due mainly to the productive structure - combined with high unemployment and falling consumption of families. Thus, the conclusion of the present study joins those of those who defend the flexibility of austerity policies regarding public investment aimed at sectoral diversification and expansion of infrastructure, especially in the North and Northeast regions of the country. In addition, it suggests the need to maintain income generation policies through social assistance and formal jobs.

It is worth mentioning some limitations of the work. The CGE model used does not have a fiscal module. Therefore, we do not have transfers between governments and institutions (such as households) and local governments. In addition, there is no direct connection between tax revenues and public expenditure, which are determined exogenously. Due to

the specificities of the statistics of the System of National Accounts, the model also does not capture the direct effects of cuts in public services in the household consumption basket, only the indirect effects, via economic activity. Therefore, it is not considered an extended income concept, as proposed in Atkinson (2016), in which the consumption of public goods is counted in the families' income. This can be a starting point for future work.

Finally, we emphasize the fact that the current crisis caused by the pandemic COVID-19 has exposed the vulnerabilities of countries whose role of the State has been mitigated by austerity policies is highlighted. The effects of the pandemic are systemic, but require special attention in relation to the already fragile labor market and labor productivity in some peripheral economies, as well as access to basic health services and public policies to deal with adverse situations.

ABSTRACT

This work sought to identify the factors that influence the stoppage of public works carried out in the municipalities of Pernambuco in the years 2016 to 2018. For this, it was proposed the use of a Probit Spatial model, and its extensions, in order to investigate the effects of various controls used and possible spatial spillover. The main variable of interest was the value of the contributions received voluntarily by the municipal governments of the governments of the other spheres of public power through the signing of an agreement from the perspective of fiscal decentralization. However, as a way to control the endogeneity present in the data, instrumental variables were used based on the hypothesis of vertical interaction between governments, which would lead local governments with the same party affiliation as state and federal governments to receive higher values through agreements and, thus, have less chance of suffering work stoppages. The results showed that works located in municipalities that receive greater compensation from other governments are less likely to be paralyzed when party affiliation in common between governments is used as instruments. Additionally, there was a spillover effect of stoppage of public works, where works located in municipalities surrounded by others with a large number of paralyzed works tend to have an increase in their chances of stoppage.

KEYWORDS

Public works shutdown. Spillover effect. Instrumental variable.

1. INTRODUCTION

A government concern is to provide public goods and services in order to maximize social welfare. For this, it is necessary that the government seeks efficiency in the provision of such services. This efficiency will ensure that the government will provide public goods at the lowest possible expense.

In Brazil, governments are hierarchically distributed from the federal to the state, and finally to the municipal. The latter, according to the theory of fiscal decentralization, has several advantages when providing public goods, because, being closer to the population in a given location, it knows its demands and priorities. In addition, it is recognized that the local government can use public resources more efficiently, since such resources do not have to go a long way within the public bureaucracy to reach their final destination. In this way, fiscal decentralization would be an effective way to promote the efficient use of public resources (AMARAL FILHO, 2001).

Several empirical evidence has shown that the simple decentralization of resources does not guarantee the maximization of social well-being, as efficiency in the use of public resources is not always achieved (GUCCIO; PIGNATARO; RIZZO, 2014). Specific characteristics of the localities can be decisive in the good management of public money.

The local government, based on the decentralization of resources, carries out several public works with resources originating from the state and federal governments. However, this occurs in an asymmetric environment in terms of information, since the governments of higher spheres have no information about the contracted companies or about the social benefits of the works (BESFAMILLE, 2003). In this way, the central governments can influence the execution of a public work, at the municipal level, through the amount of compensation that they make available to the municipal governments so that they can execute the work according to the agreement agreed between them.

The availability of resources from central governments to the positions of local managers does not always translate into greater efficiency in the use of such resources. In this way, the simple fact that there are additional resources coming from the higher entities may not be decisive for the completion of a work (SOUSA; CRIBARI-NETO; STOSIC, 2005).

Several works are simply paralyzed because they do not meet different technical and legal criteria. Corruption acts during the bidding and execution phases of the work are also responsible for the several stoppages that occurred (CHEAITOU; LARBI; HOUSANI, 2019; SALOMÃO et al., 2019; OHASHI, 2009).

Another effect investigated by several empirical studies concerns the spillover effect of public spending on works, where local governments look at the behavior of neighboring governments to make a decision on the amount of works they should carry out in their municipality (BRUECKNER, 2003; MADIES; PATY, 2008; LEROUX; CARR, 2007).

In view of the above, this research sought to investigate which factors explain the probability of stopping public works, with emphasis on the influence of the amounts voluntarily received from the state and / or federal governments as a counterpart for carrying out the works. For this, the party affiliation in common between the local government and the higher governments was used as instruments for the values received through an agreement through a two-stage estimation process under the hypothesis of an interaction strategy between the governments of the different spheres of public power (vertical interaction) (BRUECKNER, 2003; KELLY, 2000).

Additionally, we investigated the occurrence of a spillover effect in the stoppage of public works, because, in this case, the behavior of a given local government, with regard to the execution of works, can be influenced by the actions of the governments of the neighboring localities. This control at the spatial level proved to be a significant predictor of the chance of a work stoppage, and contributed to obtain consistent estimates of the various estimated parameters, given that its absence implies bias of the omitted spatial variable.

The results obtained showed that the probability of paralysis of a work performed by the government decreases for a given increase in the values of the counterparts received from the state and federal governments when instrumented by the party affiliation in common between the governments. The estimation of the spillover effect was also statistically significant, indicating that public works located in municipalities surrounded by others with a large number of paralyzed public works suffer an increase in their chance of paralysis.

This article is divided into 5 more sections in addition to this introduction. In section 2, the empirical evidence that guided this research is discussed. Section 3 presents the proposed methodology and the data used in the investigation of the research problem mentioned above. Section 4 presents the results obtained from the estimation of the proposed econometric models. Section 5 presents the discussion about the main findings of this work, comparing them with other findings in the recent literature. Finally, in section 6, the research conclusion is made.

2. EMPIRICAL EVIDENCE

The efficiency of the public sector in the provision of goods and services has been investigated from the most diverse perspectives, since an efficient allocation of public resources generates significant impacts on the population's quality of life. Thus, efficiency in the allocation of public resources implies maximizing the public services offered or, to put it another way, it implies minimizing public expenditure for a given level of public service offered (SOUZA; RAMOS, 1999). One way to achieve efficiency in the allocation of public resources is through fiscal decentralization, where the central government delegates to the local government the task of providing certain public goods with the argument that the local government, due to its proximity to the population, takes advantage of the supply of such goods, as it knows the needs and preferences of the population better (AMARAL FILHO, 2001).

A counterpoint to the argument of effectiveness of the use of public resources by fiscal decentralization and made by Guccio, Pignataro, Rizzo (2014) for the case of carrying out public works in Italy where they showed that local governments are less efficient in the execution phase, vis - vis-à-vis the central government, as they suffer greater delays. They also emphasize that the case becomes more evident the smaller the size of the municipality and the greater the external value received for the execution of the work. A similar result was observed in Souza and Ramos (1999) that the decentralization of resources per se does not generate efficiency in the use of public resources and that inefficiency is greater in municipalities with less than 15 thousand inhabitants.

The decision to carry out public works by local governments occurs in an environment of asymmetric information for the central government, since the local government has information about the contracted company and about the potential benefits of public works for the locality. The central government, in turn, will only finance part or all of the project without prior knowledge of the benefits for the population (BESFAMILLE, 2003).

The realization of public works has a double benefit for the population, as it has the power to transfer income to the poorest strata while creating an improvement in public infrastructure. Thus, the realization of public works, being used as a variable of fiscal policy, achieves the objective of increasing the level of income, bringing the salaries of the private sector to equilibrium levels and the improvement of infrastructure has effects on economic growth (GEHRKE; HARTWIG, 2018). A similar conclusion is reached by Berg et al. (2018) which showed that the public works program in India (National Rural Employment Guarantee Scheme of India (NREGS)) increased the average levels of the growth rate of agricultural income by 4.3% per year.

The interaction between governments occurs both between governments of different spheres, as in the case of central government and local government, and between governments of the same sphere. In this sense, strategies for interactions between governments may arise (BRUECKNER, 2003). In this case, government spending in neighboring locations may

influence government spending in a given location, characterizing a spillover effect of public works (FRIGIO; KOPLIN; REID, 1999). The interdependence of public spending, when verified, leads to the conclusion that there is “imitation of behavior” of the mayors in relation to the fiscal and tax policy according to Foucault, Madies and Paty (2008) who verified this effect in the French municipalities, while Leroux and Carr (2007) verified this interaction of local governments in the cities of the state of Michigan in the United States.

The stoppage of a public work is due to the non-compliance with the laws that regulate this matter, in addition to the lack of compliance with technical procedures that may or may not be due to acts of corruption such as fraud in tenders, changes in rules, changes in technical specifications, among other things (SALOMÃO et al., 2019).

Ohashi (2009) examined the effect of greater transparency in the bidder's qualification process. He found that improved transparency reduces the acquisition cost by a maximum of three percent, as transparency in the bidding process weakens collusion between bidders.

In Brazil, there are six types of bidding modalities: competition, price taking, invitation, auction and auction. The bidding modality may imply greater or lesser probability of a work stoppage because, according to them, the efficiency in the execution of a public work can be influenced by the bidding modality, concluding that the competition modality can reduce the waste of public resources by reducing the acts of corruption inherent in the bidding processes (CASTRO; GUCCIO; PIGNATARO, 2018). For Cheaitou, Larbi and Housani (2019), the choice of who will carry out the work is crucial for the success of the efficient use of public resources. Therefore, they argued that the price-taking at the “lowest price” may be responsible for low quality and delays in public works.

Efficiency in the use of public resources can be influenced by several socioeconomic characteristics of the localities such as the population's educational level (AFONSO, SCHUKNECHT; TANZI, 2010), urbanization rate and number of residents, among others (SOUSA; CRIBARI-NETO; STOSIC, 2005). Thus, these characteristics, in addition to those inherent to the work, can be important predictors of the probability of a public work stoppage (CAMPOS; COSTA, 2017).

3. METHODOLOGY

3.1 Data

For this research, data from public works that took place in the municipalities of Pernambuco, in the years 2016 to 2018, from the Court of Auditors of the State of Pernambuco (TCE-PE) will be used. The socioeconomic data of the municipalities of Pernambuco originate from Condepe Fidem and the Brazilian Institute of Geography and Statistics (IBGE): unemployment rate, demographic density, urbanization rate, municipal human development index (MHDI), Gini index, proportion of people with higher education, household income per capita. The party affiliation data of the mayors of the municipalities of Pernambuco come from the Superior Electoral Court (TSE), while the data referring to public works such as number of stoppages, contracted amount, counterpart amount and bidding modality are from the TCE-PE. The FIRJAN Tax Management Index (IFGF) was also used by the Federation of Industries of the State of Rio de Janeiro with the data declared by the municipalities to the National Treasury Secretariat (STN).

3.2 Descriptive Statistics

Table 1 - Descriptive statistics of socioeconomic variables in the municipalities of Pernambuco.

Variables	Description	Mean	S. errors	Min.	Max.
Paralyzed	Dummy = 1 if public works were stopped	0.0609	0.101	0	0.476
Valcont	Per capita value of contracted works	31.15	84.93	0	1,116
Contpart	Per capita amount of consideration received from the federal and state governments	1.686	12.58	0	169.3
Tipo_Licit	Dummy = 1 if the type of bidding for the work was taken at a price	0.412	0.228	0	0.920
IFGF	Municipal tax management FIRJAN index	0.265	0.148	0.022	0.671
Por_Ens_Sup	Percentage of people with higher education	3.653	2.049	1.040	19.11
Partgov	Dummy = 1 if the mayor is from the same political party as the state governor	0.343	0.377	0	1
Partpres	Dummy = 1 if the mayor is from the same political party as the president of the republic	0.122	0.273	0	1
Income	Per capita household income	296,0	104,5	155,5	1.144
Txdesoc	Unemployed rate	9.417	4.694	1.450	23.61
Dens	Demographic density in km2	247,0	906,0	7,790	9.068
Txurban	Urbanization rate	61,79	20,28	12,38	100
Gini	Gini Index	0,520	0,0452	0,420	0,680
Reelei	Dummy = 1 if the mayor is in the second term	0.207	0.406	0	1
Sex_Pref	Dummy = 1 if the mayor is male	0.885	0.252	0	1
P_vot_pref	Proportion of votes of the mayor	0.538	0.118	0.026	0.806
P_ver_pref	Proportion of councilors from the same party as the mayor	0.218	0.137	0.014	0.727

Total Municipalities: 184

Source: Own elaboration.

3.3 Econometric strategy

3.3.1 Spatial Models for Qualitative Data

To test empirically what are the factors that affect the probability of a public work being paralyzed in the municipalities of Pernambuco, the *Spatial Lag Probit Model* (SAR) model was used. The justification for the use of this is due to the fact that the dependent variable is qualitative, assuming the value one (1) if the work was paralyzed and zero (0), otherwise (BALTAGI; EGGER; KESINA, 2018; ELHORST, 2017; ARIMA, 2016; WANG; IGLESIAS; WOOLDRIDGE, 2013).

$$Y^* = \rho WY + X\beta + \varepsilon \tag{1}$$

Y^* is a binary variable that assumes a value equal to one (1) if public works i were paralyzed in municipality j and zero (0) otherwise;

WY is the average proportion of public works paralyzed in the municipalities neighboring the municipality j where the construction work i takes place.

X is the vector of the explanatory variables used as controls.

Another fact to consider is the existence of spatial spillover of the covariables included in the model. To verify this hypothesis, the *Spatial Durbin Probit Model* (SDM) model was used, which includes the first order spatial lags of the independent variables represented by the term WX (LACOMBE; LESAGE, 2015; LESAGE; PACE, 2009).

$$Y^* = \rho WY + X\beta + WX\theta + \varepsilon \tag{2}$$

The vertical interaction between governments - the one where there is interaction between governments at different levels of administrative hierarchy - when it is analyzed at the level of public works, occurs through the signing of agreements. These are characterized as a tool that aims to discipline the transfer of resources and the execution of the expense object. The rendering of accounts must be carried out by the municipalities that receive the resources, proving, even, the fulfillment of the deadlines and other formalities agreed in the agreement. Thus, there may be a strong correlation between the party affiliation of the municipal manager, when it is the same as that of the state and federal governments, and the amount of resources obtained through the signing of agreements. In this case, party affiliation will affect the likelihood of a particular public work stoppage only because it affects the amount of resources available to the local government to carry out the work. In this way, party affiliation between governments at different levels of public power was used as an instrument for the value of the consideration received through the estimation of the two-stage probabilistic model (KELLY, 2000).

Thus, the model in equation (2) will be modified so that the party affiliation variables are included in the first stage of the regression.

$$Y^* = \gamma contpart + \rho WY + X\beta + WX\theta + \varepsilon \tag{3}$$

$$\gamma contpart = \rho WY + X\beta + WX\theta + \lambda part_gov + \pi part_pres + v \tag{4}$$

4. RESULTS

The results with the instrumental variables are shown in Table 1. In all the proposed models, the value of the consideration received from the state and/or federal governments has a negative and statistically significant effect, showing that increases in the value of the consideration received cause a decrease in the probability public works come to a standstill and that the mayor's party affiliation is decisive for the value of the consideration received.

The decrease in the probability of stopping public works due to the compensation received by the local government, from the state and federal governments, is due to the fact that the failure to provide the public good can cause the population to associate the party affiliation of the heads of the government. executive at each administrative level to the poor provision of public service. In addition to this, compliance with the legislation is also another factor that forces the local government to strive for the work to be effectively delivered within the scheduled schedule so that it does not suffer the sanctions provided for in the laws governing the signing of agreements.

The occurrence of the effect of work stoppages across space was verified through the variable $Wparalysed$ which had the value of its estimated coefficient positive and significant in all proposed models, indicating a spillover effect of work stoppage across space, that is, works located in cities surrounded by others with a large number of paralyzed public works tend to have an increased probability of suffering paralysis, which shows an "imitation of behavior" among neighboring governments (FOUCAULT, MADIES; PATY, 2008; LEROUX; CARR, 2007; BRUECKNER, 2003; FRIGIO; KOPLIN; REID, 1999).

A usual test for measuring the spatial autocorrelation between the shutdown of works in a given municipality and the shutdowns that occurred in neighboring municipalities is done through the Moran Index. The result of this positive index (Moran's $I = 0.1512$ and $p\text{-value} < 1\%$) points out that public works located in municipalities surrounded by others with a large number of paralyzed works are more likely to also be paralyzed.

Among the models proposed in Table 2, the SDM model with IV (column 3) was the model selected according to the Akaike selection criterion, as it presented the lowest value of this statistic. The Wald test was performed under the null hypothesis of exogeneity of the regressors, which was rejected in all models proposed at the usual level of 5%, indicating that the use of instruments was adequate to solve the problems of endogeneity present in the data.

According to the SDM model in Table 2, works of higher value and those whose bidding was carried out using the price taking modality have a greater chance of stoppage, since there is a positive relationship between the variables *logvalcont* and *tipo_licit* with the dependent variable. Works carried out in municipalities with a higher number of unemployed people, greater income inequality, as measured by the Gini index, and higher per capita income are more likely to stop, while works located in municipalities with a higher rate of urbanization, a higher proportion of people with higher level and where the mayors were reelected, are male, had a higher percentage of valid votes and have a higher percentage of councilors from the same party as the city mayor suffers a reduction in their probability of stoppage. The tax management index prepared by Firjan, on the other hand, was not statistically significant in any of the years in which it was measured. The first order spatial lags of the covariates that were shown to be statistically significant to explain the average probability of stoppage of public works were those related to the urbanization rate and the proportion of votes that mayors had in the elections, which were negatively correlated with stoppage of works public, while those referring to the unemployment rate in the population of cities, the sex of the mayor were positively correlated indicating an increase in the probability of stoppage of government works.

Table 2. Results of the estimations of the probabilistic spatial models with instrumental variables.

In Figure 1, the ability of the model to discriminate the categories of the slope variable was measured using the Receiver Operating Characterist (ROC) curve. If the area under the curve is less than or equal to 0.5, the model cannot discriminate between the categories of the variable explained. The results show that the models SAR (IV), SAR2 (IV) and SDM (IV) discriminate acceptably the categories of the dependent variable, since the values under the ROC curve were in the order of 0.71, 0.77, and 0.79, respectively.

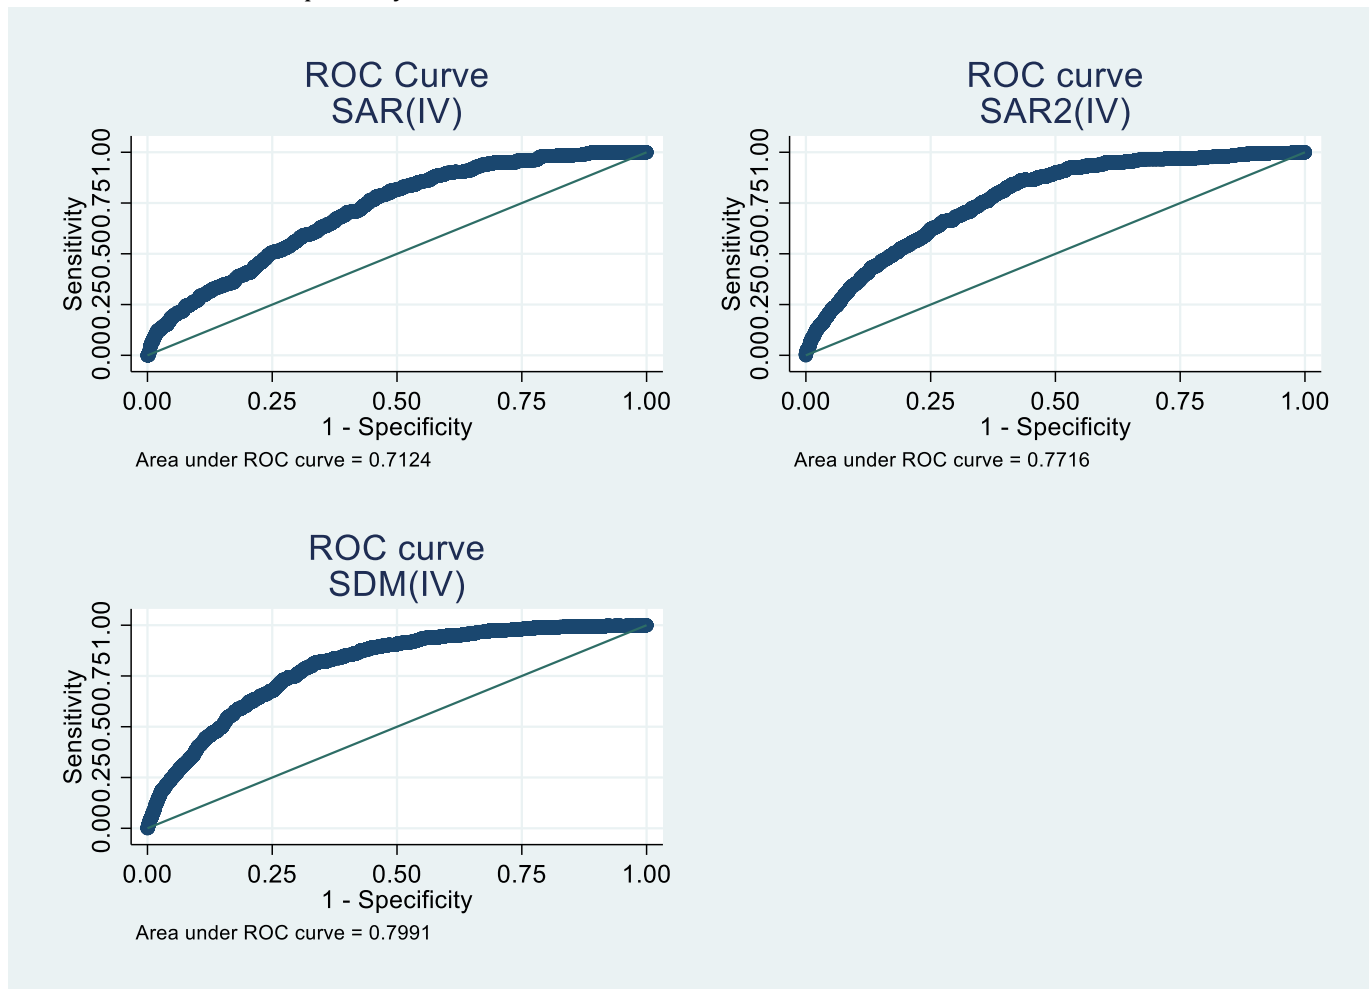

Figure 1. ROC curve of the SAR (IV), SAR2 (IV) and DURBIN (IV) models

Source: Own elaboration.

The quality of the adjustment between the estimated average probability of stoppage of the works carried out by the government and the amount received from the state and federal entities is shown in Figure 2. Here, we have a view of the negative relationship between the value of the consideration received by the local government for carrying out public works and the probability of their stoppage.

Figure 2. Dispersion graph of the relationship between the value of the counterparts and the probabilities of stoppage estimated in the models SAR (IV), SAR2 (IV) and DURBIN (IV), respectively

Source: Own elaboration.

The hypothesis raised in this paper is that the party affiliation of the mayor of the municipalities of Pernambuco affects the amounts received as a counterpart from the federal and state governments for carrying out public works and this would lead to an effect on the probability of stopping such works. Table 3 shows the result of the reduced form of the SAR (IV), SR2 (IV) AND SDM (IV) models. It is possible to see a positive correlation between the party affiliation of the mayors and the value of the consideration received, indicating that mayors who are from the same parties as the state governor and/or the president of the republic receive, on average, greater voluntary transfers of resources to public works.

4.1 Robustness

To test the relevance of the hypothesis that governments at different levels of power use a vertical interaction strategy, which would imply greater transfers of resources to municipalities where mayors have common party affiliation with other government officials, it was considered that mayors are political parties different from those of the state and federal government, which implies the absence of vertical interaction between the governments of the different spheres of public power through party affiliation.

Table 4 shows the results of the estimations of the spatial probabilistic models, considering the absence of partisan interaction between local governments and the higher spheres. In all the proposed models, there was no statistical significance of the effect of the values of the counterparts received on the probability of stopping public works in the municipalities of Pernambuco. The contagion effect, which occurs when the probability of a work being paralyzed in a given region is affected by the number of works paralyzed in neighboring regions, was only significant in the first model proposed, where there was no control of the other variables that affect the probability of occurrence. work stoppage.

5. DISCUSSION

The provision of public goods and services by government officials aims to provide a higher level of social welfare, observing the principle of efficiency in the allocation of public resources. This allocative efficiency implies a decrease in public expenditure with the performance of the various services provided by governments to the population.

Under the argument of allocative advantage, local governments receive public resources from the state and federal governments to carry out works of common interest, as they know the needs of the region better than the hierarchically superior governments. Thus, due to informational asymmetry, central governments delegate to local governments the mission of offering public goods and services according to local needs and preferences (BESFAMILLE, 2003; AMARAL FILHO, 2001).

The impacts of carrying out public works in a given location go beyond the provision of the service that underlies the execution of the work. There is an improvement in the infrastructure of the sites that receive the works and the poorest people achieve an improvement in their income levels (BERG et al., 2018). However, the execution of a public work must obey several technical and legal criteria for its realization. Failure to comply with these criteria will result in work stoppages and the waste of public money, in addition to failure to reach the objective of offering the public service (SALOMÃO et al., 2019).

The results obtained showed that the compensation received in each public work decreases its probability of paralysis when instructed by the party affiliation of the mayors, indicating that the voluntary transfer of resources between

governments vertically distributed in the structure of the public power affects the amounts received in compensation for the realization of the actions. works and, consequently, the chance of them being paralyzed (KELLY, 2000). This stems from a possible strategy of vertical interaction between governments, indicating that local governments receive, on average, a greater amount of resources when they have the same party affiliation as higher hierarchical governments, as shown in the first stage of regression (BRUECKNER, 2003).

The results also showed the existence of a spatial interaction based on a spillover effect of paralysis of public works, indicating that the chance of a public work being paralyzed increases in places where the neighboring municipalities have large amounts of paralysis of these works. This result indicates that the behavior of public managers, with regard to public works, can be influenced by the behavior of managers in neighboring municipalities (FOUCAULT; MADIES; PATY, 2008; LEROUX; CARR, 2007).

Other factors inherent to public works also affect its probability of stoppage, such as, for example, the bidding modality where it was verified that the price taking is a modality that increases the chance of a work being paralyzed. This result is in line with other findings, such as in Cheaitou, Larbi and Housani (2019) and Castro, Guccio and Pignataro (2018).

Municipalities' characteristics were also shown to be relevant in predicting the probability of stoppage of the works carried out by the local government. Municipalities with higher income inequalities and a higher percentage of unemployed people are more likely to have government works paralyzed, while municipalities with higher percentages of people with higher education and a higher rate of urbanization are less likely (AFONSO, SCHUKNECHT; TANZI, 2010; SOUSA, CRIBARI-NETO; STOSIC, 2005). The characteristics of local government officials also made up the list of variables that affect the likelihood of stopping public works. Works located in a city where the mayors are male, are in the second term, had a higher proportion of votes and have a higher percentage of councilors from the same party as yours, are less likely to suffer stoppages (CAMPOS; COSTA, 2017).

6. CONCLUSION

The present research sought to investigate the factors that may contribute to a public work being paralyzed, which results in delays in the supply of the public good or objective service of that work and in waste of public resources. For this, a spatial probabilistic model was used in order to control overflowing effects of the shutdown of such works. Among the various factors that affect the likelihood of a public work being paralyzed, the highlights were the amounts passed on voluntarily by the state and federal governments through agreements for the mayors under the argument of fiscal decentralization that advocates that the local government, for knowing better, the needs and preferences of your region, would use public resources more efficiently and, therefore, generate a higher level of social well-being.

This work contributes to the economics literature of the public sector by identifying a causal effect of the values passed on voluntarily by the state and federal governments to the local governments, through the signing of agreements, on the probability of stoppage of public works destined to the supply of goods and services to the population. In order to measure the impact of the amounts received in return from the hierarchically superior governments on the chances of work stoppage, the party affiliation of the mayors was used as an instrument, on the grounds that there is vertical interaction between governments of different hierarchies. In this case, mayors with the same party affiliation as the state and/or federal governments would receive a greater volume of voluntary resources from these governments to use in public works, thus decreasing the likelihood of their paralysis. The results showed that the probability of a work being paralyzed in a given municipality decreases when the values received in return from central governments are increased, using common party affiliations as instruments.

To test the validity of the hypothesis of a vertical interaction strategy between governments, it was considered that the mayors no longer had the same party affiliation as the state and / or federal governments, which in this case would result in a transfer of voluntary resources from arbitrary way. The results obtained showed that the values of the consideration received through agreements were not statistically significant to affect the chances of stopping a public work.

Additionally, the spatially correlated factors were controlled under the hypothesis that a "behavior imitation" effect could occur between local governments, which, in this case, occurs when the probability of a work being paralyzed in a given city is affected by the amount of works paralyzed in neighboring cities. The results showed that an increase in the number of works paralyzed in neighboring cities increases the probability of a work being paralyzed in a given city.

Other controls were added as a way to measure the effects of several factors that can affect the likelihood of stopping public works. Public works carried out in cities with higher rates of urbanization and a higher proportion of people with higher education are less likely to be paralyzed, while increases in income inequality and the unemployment rate of the population are factors that increase the chances of paralysis of public works. Already works located in cities where mayors are in the second term, received a higher proportion of votes and have a greater number of councilors affiliated to their parties, have less chance of being paralyzed.

BRAZILIAN EXPORTS AND INCOME DISTRIBUTION: AN INPUT-OUTPUT ANALYSIS FOR 2002-2014

Mariana Catharin Velludo, Vinicius de Almeida Vale, Kenia Barreiro de Souza

Federal University of Parana, Brazil

ABSTRACT

The impacts of international trade on income distribution have presented conflicting results. Empirical studies found that the direction and magnitude of this relation differ for each country and time, depending on factors such as development and income level, productive, social and institutional structure, and trade reforms specificities (GOLDBERG and PAVKNIK, 2007; MESCHI and VIVARELLI, 2008; BERGH and NILSSON, 2010; ÇELIK and BASDAS, 2010; BENSIDOUN, JEAN and SZTULMAN, 2011; ATIF et al.; 2012). These papers, like most of the literature, used econometric approaches. Otherwise, Alsamawi et al. (2014) used input-output analysis to calculate the inequality footprint, i.e., the income distribution (measured by Gini index) that each country produces elsewhere in the world, for importing goods. Their main finding was that most developed countries (more egalitarian) import from developing countries (more unequal). Brazil presents the fourth highest Gini index of upper-middle-income countries (World Bank, 2020), which makes the matter especially relevant for the country. An important question remains unanswered: what is the inequality footprint of Brazilian exports? To answer that, this paper aims to assess the domestic income inequality linked to Brazilian exports. That is, how the income yielded, direct and indirectly, from exports, is distributed among households. To this end, we adapted the approach proposed by Los et al. (2016), based on "hypothetical extraction". We consider a hypothetical world where Brazil does not export anything to region n (Extraction I). We used the World Input-Output Database (WIOD) 2002-2014, which covers 43 countries plus the "Rest of the World" and 56 sectors. Additionally, we disaggregated the vector of wages in the input-output table into ten income classes based on the National Household Sample Survey (PNAD), for the same period.

Considering total exports demand (all countries available in the WIOD table), we found an income Gini index of 0.304 for 2014, which is lower than the generated from domestic demand (0.376). This shows that, in general, the income required to satisfy all external demand is more egalitarian than the income created by domestic demand. Evaluating the exports to each trading partner separately, the only country whose demand generates more inequality than the domestic demand is India, presenting a 0.464 Gini index. Thus, we did not find evidence that production for international trade worsens Brazilian income inequality. Otherwise, it could be improving the country's economy, by creating jobs with less unequal wages.

The next steps of this study include creating a relative measure that considers the volume of trade. Moreover, these results will be explicit by sector, which could allow us to understand which industries from each country are responsible for such results. Thus, we propose another extraction (Extraction II), considering a hypothetical world where Brazil does not export anything to sector s from region n. Finally, the results will be extended to the 2002-2014. Thus, we will be able to observe how the income inequality in exports behaved over the time, given the changes that Brazil's export agenda has undergone.

TRIGGERING THE INTEGRATION OF MINORITIES RESIDING IN A DEMOGRAPHICALLY MIXED REGION INTO HIGH-TECH ACTIVITIES

[Ronen Harel](#)¹, [Dafna Schwartz](#)², [Dan Kaufmann](#)³

¹Peres Academic center, Israel. ²Interdisciplinary Center Herzliya, Israel. ³Sapir College, Israel

ABSTRACT

This study attempts to identify the conditions necessary to promote the integration of very low socioeconomically disadvantaged minorities in mixed majority-minority regions into technological entrepreneurship and high-tech activities. We also look at how the smart specialization model can be adapted to these situations.

This experimental study was conducted in Israel and focused on the mixed region of Beersheva-Rahat and the surrounding Bedouin dispersion, where the minority population is ranked extremely low on the socioeconomic scale – on the lowest level.

The current study is a continuation of an earlier study conducted in the mixed region of Haifa-Nazareth, where the minority is ranked higher on the socioeconomic scale. The findings in that case show that smart specialization in mixed regions requires a pre-phase of social-relationship and business-network building between the majority and minority populations.

The findings of the present study indicate that in mixed regions with a minority population that is ranked very low on the socioeconomic scale and has low level of readiness for technological entrepreneurship and high-tech activities, a pre-preliminary-phase is needed in order for smart specialization to work – a phase in which educational and training infrastructures are improved and the population gains awareness of its own potential for future integration in the high-tech sector. This phase constitutes an addition to the smart specialization model.

The study findings also point to the important role of the local and regional entrepreneurial initiatives in improving the minority population readiness to take part in that technological entrepreneurship and high-tech activities.

The study employs qualitative methodology. Primary and secondary data were gathered and analyzed, and in-depth interviews conducted.

The study findings have a theoretical and practical contribution by expanding the smart specialization model for implementation in mixed majority-minority regions with a population that ranks very low on the socioeconomic scale, while showing the need for preliminary phases and for governmental policy tools that promote these pre-phases.

INDUSTRIES, OCCUPATIONS, AND ENTREPRENEURSHIP IN RURAL REGIONS

Zachary Keeler, [Heather Stephens](#)

West Virginia University, USA

ABSTRACT

Economic development strategies aimed at fostering regional growth through entrepreneurship are increasingly important in lagging regions. While previous research suggests that having more entrepreneurs or self-employed can lead to higher levels of economic growth in rural and distressed regions, not all entrepreneurs are created equally. Some people may become self-employed due to a lack of other opportunities, while others may be more innovative, exploiting new opportunities and contributing to growth. Additionally, entrepreneurship in certain industries may be more beneficial to growth than in other industries. At the same time, another strain of research has linked industrial and occupational diversity to entrepreneurship and regional growth, especially in urban areas, due to the cross-fertilization of ideas. However, rural regions may lack agglomeration economies and other factors conducive to growth that make the relationship between industrial and occupational diversity and entrepreneurship in rural areas less clear. Therefore, a clear understanding of the linkages between industries, occupations, and entrepreneurship in rural regions is needed. Unfortunately, the publicly available data on detailed industry-level employment are often suppressed in small and rural counties. Thus, to examine these relationships in the United States, we have obtained detailed county-level and industry-level data from Economic Modeling LLC (EMSI) on employment and self-employment. We first estimate models where we look at local economic growth in terms of growth in employment and population and assess whether entrepreneurs from certain industries contribute more to growth. We also use these detailed data to construct measures of industrial diversity to see how that affects economic growth. We estimate models for the entire United States, for rural and urban areas separately, and also separately for distressed regions, such as the Appalachian Regional Commission Region in the eastern United States. Our models include controls for historic economic performance and industrial composition, as well as controls for other factors that have been shown to influence regional economic growth. Finally, we estimate models where our dependent variable is the share of self-employed (overall) and the share of self-employed in key industries that initial analysis suggests may be important to regional growth. In these models, we are especially interested in whether the propensity to be self-employed is affected by industrial diversity and may explain why some regions have more self-employment (or more self-employment in industries that support growth) than others. Initial results suggest that self-employment in some industries does matter more for growth and that places with more industrial diversity have more self-employed. When complete, our analysis will provide guidance to help rural regions better target scarce resources in order to support regional prosperity.

ARE THERE MARSHALLIAN INDUSTRIAL DISTRICTS IN PORTUGAL? REVISITING THE CANELLO AND PAVONE ALGORITHM

João Leitão, Joaquim Ferreira

University of Beira Interior, Portugal

ABSTRACT

Mapping and classifying Industrial Districts is an important instrument of analysis of industrial activity and regional competitiveness, which allows identifying the nature of the specialization of the manufacturing activity, as well as the current state of industrialization of the regions. In this line of analysis, the present study makes an attempt to map, identify and classify the Industrial Districts in Portugal, making use of an adaptation of the Canello & Pavone (2016) algorithm, which allow finding that only 20 of the municipalities in Portugal show an organization model of the Industrial District type, among which, 13 are located in the North region, 6 in the Centre region and, only, 1 is in the Alentejo region. The evidence obtained reveals that the manufacturing activity with higher specialization focuses on the clothing industry. In turn, the transformative activity that denotes, in average terms, a greater concentration of employed population and production units, is that of the leather industry. These results unveil weak and dispersed industrialization of the Portuguese industry, still focused on activities of low value-added, based on a passive outsourcing mode targeted to international corporate clients, which constrains the competitive scale and internationalization capacity to the national companies distributed, in a very unbalanced way, in the Portuguese regional space.

DETERMINANTS OF ENTREPRENEURIAL BEHAVIOR: AGRICULTURAL AND NON-AGRICULTURAL HOUSEHOLDS IN INDONESIA

Evi Noor Afifah, Vitriyani Tri Purwaningsih, Ririn Nopiah

Department of Economics, Universitas Gadjah Mada, Indonesia

ABSTRACT

Entrepreneurship is the greatest employment opportunity that can be entered by all groups of young and old alike. To have an entrepreneur may be a diploma and academic performance is not the main prescription. This sector can become a type of formal work if the business undertaken develops by involving permanent employees in it. However, the work done by most people tends to be informal work because it is done without permanent employees or even the business is done alone. Many factors are behind a person to open a business or become an entrepreneur, so this research was conducted to see the determinants of entrepreneurial behavior. Using data from the fifth wave of the Indonesia Family Life Survey (IFLS) in 2014, this study looked at two business models namely agricultural and non-agricultural businesses. The unit of analysis of this research is households in Indonesia with a lot of involving variables related to the Head of the Household. The model used is a cross section with logistic regression and marginal effects.

For the agricultural business model, this study uses several dummy variables such as gender, the main employment status variable whether having a job as an employee / laborer in the government/private sector. Health variables which is health/physical care, then ownership of mobile phones, ownership of internet access, ownership of electricity in the household, and location of residence whether in the village or city. It also uses the variables age, marital status, ethnicity whether Bugis, Minang, Chinese, Javanese, or others, and length of education and number of household members. In the second model, the model for non-agricultural businesses, the variables used are more similar to the agricultural business model, only slightly different by adding the ownership of the building/other buildings occupied.

REASSESSING THE PENALTY IN COMMUTING FOR IMMIGRANTS: NEW EVIDENCE FROM SPAIN

José Manuel Casado Díaz, [Raquel Simón Albert](#), [Hipólito Simón](#)

University of Alicante, Spain

ABSTRACT

This article examines the differences in commuting length between native and immigrant employees in Spain, a relevant issue since immigrants' longer commuting times may reflect an imperfect spatial matching of their labour supply and demand with negative implications for their relative labour outcomes and their individual well-being. The research differentiates immigrants according to their origin and is based on a rich, nationally representative database, the Survey on Quality of Life at Work (in Spanish Encuesta de Calidad de Vida en el Trabajo) that covers the period 2007 to 2010. One of the main novelties, as regards previous studies on the topic, is the novel use of decomposition econometric techniques, the Oaxaca-Blinder decomposition, that allow quantifying the joint and individual influence of a wide range of explanatory factors. This is relevant insofar they permit quantifying which part of the raw differences in commuting times between immigrant and natives is explained by their different characteristics and which part remains unexplained, reflecting actual differences in the patterns of commuting for individuals otherwise observationally similar. The evidence obtained shows that, although a relevant part of the explanation of the greater commuting observed for immigrants is related to observed elements such as a different use of modes of transport, they make overall significantly longer journeys when comparing with observationally similar natives. This commuting penalty occurs yet only in the case of immigrants from emerging countries as it does not exist for those from advanced economies, which are more similar to natives. Although the penalty is overall rather similar along several sociodemographic and occupational lines, it is much more pronounced for individuals living in large municipalities and in the region of Madrid, respectively, which implies that the vast majority of previous studies on the commuting of immigrants focused in specific highly populated geographical environments could offer a biased perspective and could not be nationally representative. To conclude, we offer additional novel evidence about the potential explanations of the commuting penalty of immigrants by testing the hypothesis that the unexplained differences in the commuting times between immigrants and natives are due to contrasting attitudes towards this phenomenon. Given that commuting has a similar negative impact on satisfaction in different domains of life for immigrants and natives, immigrants' longer commutes are not apparently associated to a greater tolerance to commuting, which helps to discriminate against potential competing explanations of the phenomenon.

SPATIALIZATION OF MIGRATION IN THE CONCEPT OF TRANS-LOCALISM

Ahmet Türel, Sinan Mert Şener

Istanbul Technical University, Turkey

ABSTRACT

The concepts of space and displacement are in constant development in the globalizing world. Migration mobility that comes with globalization also increases the interaction between space and subject. Thus, it causes displacements to be visible from the outside. Today, migration is the movement of displacement that occurs in different forms all over the world. Reasons and results of migration are influenced by many other variables: sociological, economic, political, environmental, etc. Migration research has been carried out on many different concepts, such as identity, belonging, ethnicity, culture, and financial.

Along with these concepts, migration has a spatial/locational dimension that is often overlooked. With the ideas of transnational migration and transnational migration space, discussions on migration have started. In the study context, the spatiality of migration is discussed within transnational spaces and translocal places. Within the framework of daily life practices put forward by Certau, migrants' positions in the city and their experiences until reaching the endpoint are deciphered. Also, the resistance and reactions of immigration mobility against the city are questioned. While migration is localized in a sense, on the other hand, it is the situation of being a non-places, as Auge mentioned.

The migration spaces caused by environmental interactions occurring in immigrant memory during the migration process are essential issues. The study discussed how migration space is affected by forced migration and how migrants create solutions to these changes. However, the migration process is reconsidered in adaptation to the migrated location and dependence on the origin region. The study aims to propose a changing and developing place and place setup for potential immigrants or potential immigrants by creating an algorithm of migration and immigration. Here, physical preferences and social and the networks that come with digitalization, which has a game-changing effect today, will be included as an input, and the location selection criteria will be deciphered in depth.

Turkey, a "border gate" country between Europe and Asia, is strategically positioned geographically and symbolically. Turkey, which has evolved from the most immigrant country to a migrant country, has become the most desired European side country in recent years. In this context, Istanbul, which has been the most attractive city to migrants because of the cosmopolitan city, was chosen as a suitable case study for this study. In addition to the literature research, migration and spatial relations are deciphered through the migration route with the cognitive mapping method and in-depth interviews with immigrants in Turkey.

The study aims to create new perspectives on migration and evaluate migration as "multiple places" beyond the destination or origin. It also intends to increase added value regionally by transforming forced migration into an input that contributes to the labour market and social and social structure. Additionally, it enables the creation of urban and regional projections through the role of migration spaces that come with migration in creating trans-local spaces at the intersection of temporality and permanence.

CLUSTER ANALYSIS OF ONLINE VACANCIES BASED ON ATTRIBUTE ASSOCIATIONS

[Carlos Usabiaga](#)¹, [Fernando Núñez](#)², [Lukasz Arendt](#)³, [Ewa Gałecka-Burdziak](#)⁴, [Robert Pater](#)⁵

ABSTRACT

This paper develops a new smoothing procedure for contingency tables which is based on models of partial association. Our methodology is tested on a database of online job offers published on selected Polish job portals in the period 2017-2019. First, we build a contingency table by cross-classifying some descriptive variables of the job vacancies (for example, region, occupation and activity). Second, we use our methodological proposal to smooth the contingency table, correcting in this way the sparsity problem which affects highly segmented tables. Third, we use the smoothed table as an input to generate a table of association factors between rows and columns that can be clustered on both sides giving rise to a bicluster "heatmap". Our application allows to contrast the existence of polarisation in the Polish labour market by using data on online job offers, an interesting proposal given that most of the studies on the polarisation hypothesis are based on employment data. The study reveals that a cluster of semi-transversal skills – self-organisational, technical, interpersonal and availability skills – constitutes an important requirement in most of job offers. Since these skills are mainly developed within the educational system, these results put even more pressure on this system, which is not sufficiently effective in providing skills in line with labour market needs. We also show that office skills do not offer a particular advantage in the labour market, in accordance with the polarisation hypothesis, while ICT skills and communication skills seem to have a positive effect on employability in times of accelerating automation.

THE GEOSTRATEGIC POSITION OF ROMANIA FROM THE PERSPECTIVE OF ENERGY RESOURCES

[Alexandra Colcer](#)¹, [Mihail Paduraru](#)², [Irimuş Ioan Aurel](#)¹

¹Babeş Bolyai University, Faculty of Geography, Romania. ²University of Economic Studies Bucharest, Romania

ABSTRACT

The conflict from Ukraine created increasingly tense relations between the states of the European Union amid an energy crisis. For this reason, the article aims to demonstrate how energy resources have become a key element in the security architecture of a state. Therefore, the dynamics of international economic relations require a careful analysis of the geographical position of Romania from the natural resources perspective. It should be mentioned that the authors come from different fields, so the study will have different approaches. The purpose of the research is to demonstrate the importance of energy resources in the security architecture of Romania. In the context of a constantly changing international security architecture, energy resources are still a basic element in ensuring security. Due to the geopolitical and geostrategic events happened on the international stage, the states increased the importance of possession, capitalization, and access to the energy resources. The present study is an interdisciplinary one, carried out by a mixed team, between a geographer and an intelligence practitioner, which makes the subject to be approached from several angles. The objectives of this paper are the evaluation of the resources from the qualitative and quantitative point of view, and the way these resources are capitalized. Also, we will analyze the trade with resources and the policies in the field. In addition, we will also emphasize how the resources are strategically capitalized. The documentary sources were verified for a high degree of credibility and aimed at scientific works of geography, economy, law; visual materials (maps, graphs, sketches), legislative documents and public statements of the people in the field. The statistical data were collected from the website of the National Institute of Statistics and EUROSTAT. We used bibliographic methods for collecting information from both printed (books, scientific papers) and electronic formats (scientific articles, online newspapers). For texts, we used the method of semantic analysis and the message contained, according to criteria such as credibility, relevance, objectivity, accuracy, completeness. Also, the cartographic method was used to make the cartograms. The research started from the premise that the development and stability of a state depends exclusively on the management of these resources. Given the importance of the energy resources from Romania, the present study will highlight how this advantage can be enhanced depending on the way they will be used.

THE EFFECT OF A FREE TRADE AGREEMENT WITH THE UNITED STATES ON MEMBER COUNTRIES' PER CAPITA GDP: A SYNTHETIC CONTROL ANALYSIS

Esteban Colla-de-Robertis, Rafael Garduno-Rivera

Universidad Panamericana, Mexico

ABSTRACT

This article aims to evaluate the impact of signing a free trade agreement (FTA) on per capita gross domestic product (GDPPC). Although the immediate objective of a FTA is to increase trade between the signatory countries (Dür et al. 2014), from the perspective of evaluating public policy, it is important to evaluate its impact on citizens' well-being, and the GDPPC is a better measure of said impact than measures that pertain to trade alone.

In particular, we focus on the GDPPC of the 20 countries that have signed a FTA with the United States. This focus is motivated by the fact that the U.S. is the biggest, most developed economy in the world and has signed the most extensive trade agreements of any country. North-South agreements tend to be the most extensive, whereas South-South agreements tend to be the least far-reaching (Dür et al. 2014). Hence, this study helps shed light on the development effects of North-South agreements for Southern (developing) countries.

The United States has been an ardent supporter of trade liberalization. Since President Roosevelt's administration, the U.S. has assumed that trade openness guarantees stable economic growth. In that line, during the last century, the U.S. has traded with a variety of countries across the globe, becoming a leader and a role model on trade openness in this era of global economic integration.

The main trade agreement explosion occurred during the early 2000s, after agreements with Israel (1985), Canada (1988) and Canada and Mexico (1994). At the time of this study, the United States had signed FTAs with 20 countries. Two of these FTAs were multilateral (NAFTA and CAFTA); NAFTA includes Canada and Mexico, while CAFTA includes countries in Central America and the Caribbean (2004). The rest of the agreements were bilateral.

This study employs the synthetic control method (SCM) to estimate the economic effects of signing free trade agreements (FTAs) with the United States. This method allows for a counterfactual –the country's per capita GDP had it not signed a FTA–, which can be compared with the observed per capita GDP. This difference speaks to the causal impact of the FTA. We principally find that FTAs seem to have a heterogeneous impact. In particular, there is evidence that signing a FTA with the U.S. had a positive effect on the per capita GDP of Chile and Jordan and that NAFTA had an adverse impact on Mexico's per capita GDP. In several other cases, no significant economic impact is discernible. In addition, the more a country depends on the U.S. for its trade, the less beneficial signing a FTA with the U.S. is.

This article contributes to the debate on the effectiveness of trade as a development strategy. In particular, the SCM opens up the possibility of a "case-by-case" analysis, ultimately revealing that a free trade agreement with the U.S.–a country situated at the world's technology frontier–has heterogeneous outcomes and, by itself, does not guarantee economic development (obtained through a higher per capita GDP).

REGIONAL AND GLOBAL PATTERNS OF PARTICIPATION IN VALUE CHAINS: EVIDENCE FROM BRAZIL

ABSTRACT

The main objective of this paper is to verify Brazil's role in global value chains considering its participation in global and regional trade blocs. The hypothesis is that Brazil has different roles in global value chains and regional value chains. Brazil carries out international trade with several countries, regions and trade blocs. However, the country's trade with the other Mercosur members has a different pattern compared to other countries and trade blocs. Thus, this paper intends to verify the trade pattern differences between Brazil and South America and Brazil and other regions and trade blocs. We also seek to verify the role of Brazil as a reference center for conducting international trade in South American countries, that is, the role of Brazil as a regional hub in international trade. To achieve these stated goals, we perform a spatial decomposition of foreign value-added content, by taking into account the upstream and downstream segments of value chains. The regional and global participation patterns in the value chains are analyzed through the geographic extension of the stages of production. These patterns are assessed using indicators of global and regional fragmentation of global value chains. To measure the linkages of global value chains, the value-added content is decomposed using the inter-country input-output model over the period from 1990 to 2015. We use the full Eora Global Supply Chain Database's multiregional input-output table (MRIO), which contains data for 190 countries and specifies 26 activity sectors. The chosen period of investigation allows us to evaluate Brazil's participation in global value chains relative to different scenarios and changes in its commercial and industrial policies. Thus, we assess if Brazil's integration process with internationally fragmented production chains follows a worldwide trend or presents a pattern distinct from other economies. Our findings suggest that between 1990 and 2015 Brazil's production became more fragmented internationally and consequently its participation in global value chains increased. However, its regional insertion increased more than its global insertion. Although South America has a small share in value-added trade, it was found that Brazil operates both as a regional hub and serves as a reference for international trade in that region. In the global context, Brazil has the role of supplier of intermediate inputs, while in the regional context, Brazil plays the role of an important production center. This regional production center proved to be well integrated with the principal hubs of the global value chains.

KEYWORDS

International fragmentation; Global value chains; Global and regional fragmentation; Input-output; Brazil.

1. INTRODUCTION

Since the 1970s, Brazil's commercial and industrial policies have been oriented towards the formation of a vertically-integrated national industrial park and the establishment of all stages of production. These policies have been formulated to preserve Brazil's limited exposure to imports, with a strong protectionist tendency (Veiga and Rios, 2017). The main instrument of this trade policy is the collection of high import tariffs (Messa and Oliveira, 2017). Tariff barriers have a significant effect on blocking trade in value chains, as intermediate inputs cross national borders many times before they become final products.

The initial and limited trade policies of the Brazilian economy arising since the 1970s were the creation of the Southern Common Market (Mercosur) in 1991 (agreement between Brazil, Argentina, Paraguay and Uruguay), the trade agreement between Mercosur, Chile and Bolivia in 1996 and extended to include Colombia, Ecuador, and Peru in 2003. Since then, Brazil has been relatively closed to new trade agreements (Thorstensen and Ferraz, 2014).

Given this context, commercial opening in Brazil began in the early 1990s, such that changes in the structure of production and international trade in the Brazilian economy necessarily changed its role in global value chains. The growth of the Brazilian economy since then, mainly in the 2000s, has attracted foreign investments and made the Brazilian economy more heterogeneous in terms of sectors compared to prior periods. In fact, the existence of Mercosur had a spillover effect on the development of international trade in other South American countries also. Many companies

sought to obtain or expand access to South American markets, which led to an increase of foreign investments in Brazil and the region in recent decades.

The main objective of this paper is to verify Brazil's role in global value chains considering its participation in global and regional trade blocs. The hypothesis is that Brazil has different roles in global value chains and regional value chains. Brazil carries out international trade with several countries, regions and trade blocs. However, the country's trade with the other Mercosur members has a different pattern compared to other countries and trade blocs. Thus, this paper intends to verify the trade pattern differences between Brazil and South America and Brazil and other regions and trade blocs. We also seek to verify the role of Brazil as a reference center for conducting international trade in South American countries, that is, the role of Brazil as a regional hub in international trade (Baldwin and Lopez-Gonzalez, 2015).

To achieve these stated goals, we perform a spatial decomposition of foreign value-added content, by taking into account the upstream and downstream segments of value chains. The regional and global participation patterns in the value chains are analyzed through the geographic extension of the stages of production. These patterns are assessed using indicators of global and regional fragmentation of global value chains. To measure the linkages of global value chains, the value-added content is decomposed using the inter-country input-output model over the period from 1990 to 2015. We use the full Eora Global Supply Chain Database's multiregional input-output table (MRIO), which contains data for 190 countries and specifies 26 activity sectors. The chosen period of investigation allows us to evaluate Brazil's participation in global value chains relative to different scenarios and changes in its commercial and industrial policies. Thus, we assess if Brazil's integration process with internationally fragmented production chains follows a worldwide trend or presents a pattern distinct from other economies.

Some relevant prior studies conducted on the Brazilian economy are focused on discussing value chains based on evidence supported by gross export statistics, even though such statistics are not appropriate in this context (Johnson and Noguera, 2012a; Koopman, Wang and Wei, 2014). Dietzenbacher, Guilhoto and Imori (2013), Guilhoto and Imori (2014), Ferraz, Gutierrez and Cabral (2015), Callegari et al. (2018), Magacho et al. (2018), Perobelli et al. (2019), Haddad (2019) and Haddad and Araújo (2020) analyze the insertion of Brazil into global value chains based on the trade of value-added content. This paper differs from the existing literature in that we analyze the role that Brazil can play in the trade relations of global value chains from two perspectives – global and regional. As such the paper contributes to the literature by explaining the differences that the Brazilian economy plays in relative terms in the international fragmentation of production both globally and regionally – that is, we focus on the geographic extension of its value chains.

Our findings suggest that between 1990 and 2015 Brazil's production became more fragmented internationally and consequently its participation in global value chains increased. However, its regional insertion increased more than its global insertion. Although South America has a small share in value-added trade, it was found that Brazil operates both as a regional hub and serves as a reference for international trade in that region. In the global context, Brazil has the role of supplier of intermediate inputs, while in the regional context, Brazil plays the role of an important production center. This regional production center proved to be well integrated with the principal hubs of the global value chains (United States, China and Germany).

The paper is structured as follows. Section two presents a literature review about vertical specialization and the challenges of measuring the participation of countries in global production chains. Section three presents the vertical specialization measures used in this study. Section four provides the source of the data used in the analysis. Section five presents and discusses the results. Finally, section six provides conclusions and suggestions for policymaking.

2. DECOMPOSING PARTICIPATION IN GLOBAL PRODUCTION CHAINS

Foreign value-added content is used to evaluate integration into global value chains. The method used in this paper to measure the value-added content of trade follows that of Johnson and Noguera (2012a) and Los, Timmer and de Vries (2016), which is adapted to assess the integration in upstream and downstream segments of supply chains, emphasizing the regional and global participation patterns in these chains.

The contribution of each country in the production chain can be broken down using an inter-country input-output table. This table contains the values of the flows of intermediate inputs and final goods among all the countries' industries – i.e., the s industries ($s = 1, \dots, S$) in each of the n countries ($n = 1, \dots, N$). By combining information on the values of transactions of intermediate inputs (\mathbf{Z}), final demand (\mathbf{F}), sectoral production (\mathbf{x}), and remuneration of primary production factors (\mathbf{w}), it is possible to estimate the value generated in each of the SN industries. The intermediate inputs required per unit of production are defined in the matrix $\mathbf{A} = \mathbf{Z}(\hat{\mathbf{x}})^{-1}$, and the value added per unit of product is defined in the vector $\mathbf{v} = \mathbf{w}(\mathbf{x})^{-1}$. The term $\hat{\mathbf{x}}$ corresponds to the diagonal matrix formed by the vector \mathbf{x} .

To produce the good (i, s) , a combination of local primary inputs and national and imported intermediary inputs from different sectors and countries is required. Then, the good (i, s) is absorbed in the final demand or used as an intermediate input in production. To break down its value, it is necessary to find the product levels associated with the good (i, s) at each stage of production, measured through inter-country input-output tables. To do so, the value chains are identified by the last stage of production of the final good $f_{ij}(s)$. The participation of each country in the international fragmentation of production is measured by its value-added content inserted in the value chains, following the formulation proposed by Los, Timmer and de Vries (2015). Thus, the value generated in the production of the good (i, s) is derived from the remuneration of capital and labor in the country-industry of production. This is equivalent to

identifying the extent to which the country of completion of the final good $f_{ij}(s)$ contributes to the production of that good, which can be decomposed as follows:

$$\mathbf{g} = \hat{\mathbf{v}}(\mathbf{I} - \mathbf{A})^{-1}\mathbf{F} \quad (1)$$

where the matrix $\hat{\mathbf{v}}$ is formed by the diagonalization of the value added per unit of product. The use of the Leontief inverse matrix, $(\mathbf{I} - \mathbf{A})^{-1}$, ensures that value-added contributions at all stages of supply through direct and indirect requirements in the productive chain structure are taken into account. The final demand vector ($SN \times 1$) \mathbf{F} has its real values only in the cells that represent the final demand for the country-industry (i, s) , while all other values in the final demand are set to zero. The vector \mathbf{F} is equal to the final internal and external demand for the final products $f_{ij}(s)$. The choice of a specific vector \mathbf{F} by country of origin of the production of final goods determines the value chain being analyzed.

The vector ($SN \times 1$) \mathbf{g} contains the value-added contributions generated in each of the country-industries that can be assigned to the value chains of the final products $f_{ij}(s)$.¹⁷⁹ To obtain the origin of the value added to the final good $f_{ij}(s)$ in the production chain by country, the elements of \mathbf{g} , which correspond to the industries in each country, are added to each other. Los, Timmer and de Vries (2015) show that the main result of this calculation is the possibility of decomposing the value of a final product by the value-added contributions made in any country.

2.1. Downstream integration into global chains

The integration of countries into global production chains may occur differently when considering the downstream or upstream tracking of such production chains. Therefore, this study measures the downstream integration into global value chains, defined as Sourcing_s. This measure is calculated taking as a starting point the proposed decomposition by Los, Timmer and de Vries (2015).

The Sourcing_s measure is calculated using the vector \mathbf{g} , defined in Equation (1), from its replication for each country of completion of the final good $f_{ij}(s)$. Value added from the country of completion in vector \mathbf{g} is set to zero. The sum of the value-added contributions provided by each country i for the other completion country j is defined as:

$$SVA_s = \sum_{j \neq i} VA_{ij}(s), \forall j \quad (2)$$

The participation of each country in the supply of value-added content for the global production chains, from Equation (2), is defined as follows:

$$\text{Sourcing}_s = \frac{SVA_s}{\sum_i \sum_{j \neq i} VA_{ij}(s)} \quad (3)$$

where $\sum_i \sum_{j \neq i} VA_{ij}(s)$ is the sum of the foreign value added in global production. The sum of Sourcing_s for each country i belonging to the global production chain is equal to 1.

2.2. Upstream integration into global chains

The upstream integration in global chains focuses on the provenance of the value added for the last stage of production, that is, the country-of-completion. In this regard, the value added in the final goods produced in Brazil is decomposed, per the approach developed in Los, Timmer and de Vries (2015). Thus, the vector \mathbf{F} of Equation (1) includes the final demand values only for Brazil, with the other cells specified as zero. The value of the final good produced by industry s in Brazil is indicated by FINO_s. The value added from country j is defined by $VA_{(j)}(s)$. The vector \mathbf{g} contains the corresponding levels $VA_{(j)}(s)$ for each final good produced in Brazil $f_{ij}(s)$, such that:

$$\text{FINO}_s = \sum_s VA_{(j)}(s) \quad (4)$$

The contribution of all countries to the value added in the production of (i, s) is equal to the value of the final product (i, s) . The FINO_s measure allows for the definition of the value added throughout the production chain in which Brazil is integrated, minus the value-added content produced in Brazil:

$$\text{FVA}_s = \sum_{j \neq \text{Brazil}} VA_{(j)}(s) = \text{FINO}_s - VA_{(\text{Brazil})}(s) \quad (5)$$

The term FVA_s measures the international fragmentation of production chains.¹⁸⁰ FVA_s, unlike SVA_s, defined in Equation (2), is the sum of the value added from the N countries in the production of country i . SVA_s, in turn, is the sum of the contribution of country i to the value added inserted in the production of the N countries belonging to the global production chain. To measure the importance of foreign value added, FVA_s is expressed as the share of value added in the production of s :

$$\text{FVAS}_s = \text{FVA}_s / \text{FINO}_s \quad (6)$$

The foreign value-added share (FVAS) is used to measure the extent of the international fragmentation of the value chains in which Brazil is inserted. This share is an index that varies between zero and one. FVAS assumes zero value when all value added is produced internally, assuming larger values as international fragmentation increases.¹⁸¹ FVAS includes the value added at each stage of production. Thus, this measure does not pose the problem of double counting, defined by Koopman, Wang and Wei, (2014), which is present in the other vertical specialization metrics that use intermediate inputs imported into production.

179 The final demand for the good (i, j) includes household and government consumption as well as the demand for investment in domestic and foreign markets.

180 The approach to international fragmentation measuring from FVA_s is based on tracking the value chain, starting from the final product and tracing the added value, at all stages, needed to produce the final good.

181 By definition, FVAS cannot be equal to one, because the final stage of production must involve some activity in the country of completion of production.

3. DATABASE

The regional and global fragmentation of value chains is analyzed using the data provided by the full Eora MRIO. The construction of this database is described in Lenzen et al. (2012a) and Lenzen et al. (2013a). The full Eora MRIO contains data for 190 regions of the world, specifying 26 sectors of activity,¹⁸² and covers the period from 1990 to 2015.¹⁸³ The data for the construction of the Eora MRIO database derive from national statistical offices. Bilateral trade data comes from the UN Comtrade Database and UN Service Trade Database. The Eora database assumes that its regional specification sufficiently covers the global economy.

Changes in the national accounts system may cause interruptions in the continuity of the input-output tables of Brazil estimated by Eora. However, Lenzen et al. (2013b) show that this does not generate imbalances in sectoral aggregated analyses – which are the focus of this study. A detailed description of the price corrections and of all the discontinuities and corrections implemented in the input-output tables for the Brazilian economy, used in the estimation of the full Eora MRIO, is found in Lenzen et al. (2012b) and Lenzen et al. (2013b).

The choice of using the Eora other than other databases of inter-country input-output tables is motivated by its complete regional specification for the South American countries. This allows us to measure the geographical origin of all regional trade flows in Brazil. In addition, the historical series of the full Eora MRIO makes it possible to evaluate the evolution of Brazil’s participation into global value chains.

4. RESULTS

The measures of foreign value-added share (FVAS) and Sourcing are used to quantify the Brazilian economy participation in regional and global trade blocs. FVAS is a measure of upstream integration into global chains, that is, in terms of the purchase of inputs. The Sourcing measure, defined by the share of value added produced by Brazil in relation to total foreign value added in all value chains, evaluates the downstream integration into production chains.

Table 1 shows the distribution of value added in the final goods produced in Brazil in two groups: for all activity sectors and for the sectors related to agriculture, mining, manufacturing and tradable services.¹⁸⁴ The regional and global foreign value-added share (FVAS) in the final goods produced in Brazil increased from 1990 to 2015. This suggests that production in Brazil became more internationally fragmented. Brazil ranks 157th out of 188 countries¹⁸⁵ in terms of FVAS in final products (Table A1 in the Appendix).¹⁸⁶ South American countries have a small share in the production of final goods in Brazil – the regional trade bloc provided 2.06% (RFVAS) and the global trade bloc contributed 8.98% (GFVAS) of the foreign value added in Brazilian production in 2015.

Table 1. Origin of value added in final goods produced in Brazil (%)

	All sectors		Agriculture, mining, manufacturing and tradable services	
	1990	2015	1990	2015
Domestic value added	93.731	92.014	92.004	88.957
Foreign value added (FVAS),	6.269	7.986	7.996	11.043
of which				
Regional (RFVAS)	0.646	1.476	0.858	2.059
Global (GFVAS)	5.623	6.510	7.138	8.985

Source: Authors' calculations.

The downstream integration of Brazil into value chains in regional and global trade blocs is measured by Regional Sourcing and Global Sourcing. The Sourcing measure assesses the importance of the Brazilian economy for the production chains, that is, the value added with origin in Brazil in relation to the foreign value added included in the final goods produced anywhere in the world. Table 2 shows Brazil’s share in world exports of value added and its regional and global participation between 1990 and 2015. In 2015, Brazil contributed 1.39% of foreign value added in the final products of all production chains – 0.24% for the production of South American countries (Regional Sourcing) and 1.14% for the

182 The Eora MRIO provides data from the inter-country input-output table with the breakdown of 56 sectors of activity into the Brazilian economy. However, this matrix does not have a harmonized version for all world economies, making it impossible to aggregate foreign value-added results at the industrial level.

183 Owen et al. (2016), Steen-Olsen et al. (2016) and Owen (2017) analyzed the results of economic indicators constructed from the Interregional Input-Output Tables of the Global Trade Analysis Project (GTAP), World Input-Output Database (WIOD), Multi-region Input-Output Table (EORA) and Inter-country Input-Output (OECD-ICIO) and found that global added value accounts are similar between these databases, although differences exist at the country and individual sector levels.

184 Non-transactional services are not included in the analysis because their production is not traded internationally. These sectors are characterized by services rendered locally.

185 The Eora MRIO database has information on 190 regions, including one called "statistical discrepancy" and another for the former USSR. Thus, the ranking has information on 188 countries.

186 One of the reasons for the low FVAS in the Brazilian economy is the high import tariffs practiced in the country. They have been aimed at intensifying the protection of the national industry (Veiga and Rios, 2017a) and increasing domestic content in production. However, we cannot merely analyze the FVAS to assess participation in value chains. For example, the United States and Japan also have low FVAS. The FVAS is influenced by the stage of technological development and its dependence on imports of foreign technologies, and the linkages of the industrial structure with the rest of the world—that is, the industrial specialization in the country and the stages of production that are outsourced abroad.

production in the rest of the world (Global Sourcing). Brazil is 20th of 188 countries in a ranking which assesses shares in the supply of value added for global production chains, (Table A2 in the Appendix).

Table 2. Share of value added with origin in Brazil in relation to total foreign value added in all value chains (%)

	All sectors		Agriculture, mining, manufacturing and tradable services	
	1990	2015	1990	2015
Sourcing, of which	0.963	1.373	0.985	1.386
Regional Sourcing (RS)	0.096	0.240	0.099	0.244
Global Sourcing (GS)	0.867	1.133	0.886	1.142

Source: Authors' calculations.

Table 3 shows Brazil's regional and global patterns of participation in value chains through the decomposition of the geographical origin of the value-added trade by industry. The participation of the Brazilian economy in international trade is marked by distinct characteristics when considering its global or regional integration. Agriculture (13.56%) and mining (17.49%) make up 31.05% of the regional foreign value added (RFVAS), while manufacturing represents 46.8% of global foreign value added (GFVAS) in 2015. Brazilian value-added exports to South America (Regional Sourcing) consisted mainly of manufacture (44.49%) and services (46.36%), whereas Global Sourcing has become resource-intensive and agriculture and mining increased participation from 12.82% in 1990 to 16.70% in 2015. Table 4 also shows the importance of services in value-added exports in both Regional Sourcing (46.36%) and Global Sourcing (45.22%). Haddad and Araújo (2020) found that the value added to services in exports account for 48.23% of Brazilian exports of value added, despite the fact that services represent only 17.39% of total gross exports in 2015.

Figure 1 shows the relative importance of regional insertion in relation to global insertion for the tradable activity sectors between 1990 and 2015. These results allow us to identify the change in the pattern of international fragmentation over time. The RFVAS and Regional Sourcing have increased in relation to the global share. Therefore, although Brazil's participation in the value chains has been driven mainly by the global fragmentation of production, its regional insertion has increased more than its global insertion. This result may have been driven by trade agreements signed during this period, which Brazil prioritized to conclude with neighboring countries. Johnson and Noguera (2017) show that participation in bilateral free trade agreements positively affects countries' vertical specialization.

Table 3. Regional and global patterns of participation in value chains: Brazil

		Year	Agriculture	Mining	Manufacture	Services	Total
Foreign Value Added	Regional	1990	15.317	12.554	27.524	44.605	100.000
		2015	13.560	17.495	28.238	40.706	100.000
	Global	1990	1.806	4.403	35.218	58.574	100.000
		2015	1.798	8.472	46.938	42.791	100.000
Sourcing	Regional	1990	4.168	5.844	35.701	54.287	100.000
		2015	3.499	5.650	44.492	46.358	100.000
	Global	1990	7.012	5.807	26.995	60.187	100.000
		2015	6.722	9.980	38.079	45.219	100.000

Source: Authors' calculations.

5.1 Comparison between Brazil and other economies

The fragmentation of production occurs differently at the regional or global level of value chains. In this context, Baldwin and Lopez-Gonzalez (2015), Lejour et al. (2017) and Li et al. (2019) identify the hubs in the global trading system. Lejour et al. (2017) show that value-added trade follows supply lines between groups of regions specialized in specific stages of global value chains. These supply lines are formed by groups of geographically close and highly integrated regions that provide value-added to other groups of regions defined as global production centers.

To identify the main regional value chains and global production hubs, the value-added trade flow, measured using Equation (4), is shown in Figure 2. The size of the circle represents the amount of foreign value added in the production of final goods. The width of the arrows represents the flow of value added between countries. The colors represent the regional production chains: South America (orange), North America (dark green), Asia-Pacific region¹⁸⁷ (blue), Europe (light green) and the rest of the world (lilac). The link arrow shows the direction of the value-added flow. The figure shows only the main value-added flows. This figure allows for visualization of the supply chains highlighting the main production hubs.

The structural pattern of the production chains is maintained between 1990 (Fig. 2a) and 2015 (Fig. 2b). Production chains have become more integrated, reflected in the increased share of foreign added value in production. Li et al. (2019) also show that value chains still remain largely regional; China is increasingly playing a relevant role as a hub in simple global value chain networks, although the United States and Germany are still the main hubs in complex global value chain networks.

Even though they are poorly integrated, South American countries act as a regional production center for Brazil, which in turn is more interconnected with the main hubs of the global value chains. Brazil is the main trade reference for these countries. This regional production center mainly supplies the production chain in North America and Europe, which serve as global production centers. Brazil at the global level plays a role as a supplier of intermediate inputs, while at the regional level it plays a role as a main production center. We should note that Brazil has the potential to significantly affect the economies of neighboring countries, assuming a position of regional leadership (Adler and Sosa, 2014).

Table 4 shows FVAS and Sourcing in product value chains for Brazil and the major global manufacturing hubs (United States, China, and Germany).¹⁸⁸ Columns (3) and (6) present the difference between 2015 and 1990. All countries increased their foreign value-added share (FVAS). Meanwhile, the United States and Germany have lost share in Sourcing (column 6). In the 1990s and 2000s, there was a relocation of global manufacturing from the United States, Europe, and Japan toward Southeast Asia (Baldwin and Lopez-Gonzalez, 2015); column (6) shows that the main beneficiary of this process is China (7.82%).

Table 4. FVAS and Sourcing in product value chains by country, 1990 and 2015

	FVAS			Sourcing		
	1990	2015	2015-1990	1990	2015	2015-1990
	(1)	(2)	(3)	(4)	(5)	(6)
Brazil	7.996	11.043	3.047	0.985	1.386	0.401
United States	6.593	11.932	5.339	15.435	9.799	-5.637
China	8.093	12.629	4.536	2.635	10.460	7.825
Germany	13.575	21.894	8.319	10.475	7.880	-2.595

Source: Authors' calculations.

Geographic proximity is crucial in global value chains because the trade is intensified between economies that share a border. Brazilian participation in global value chains occurs mainly by trade with geographically distant countries. China and Germany mostly have regional trade. These countries are hubs in the global value chain and have a trade pattern for hub-and-spoke networks with their neighboring countries (Baldwin, Lopez-Gonzalez, 2015). Thus, there is an intense

¹⁸⁸ Tables A1 and A2 in the Appendix present FVAS and Sourcing in product value chains by country of completion for the 188 countries specified in the Eora MRIO database.

trade of intermediate inputs in regional production chain, with Chinese and German firms performing some intermediate stages of production in neighboring countries.

Figure 3 shows the origin of the foreign value added in the final products of Brazil as well as for the major production hubs (United States, China, and Germany). Brazil's share of total value-added exports increased from 0.98% in 1990 to 1.38% in 2015. Although the Brazilian economy occupies a prominent position in South America, its participation in global production chains is still discreet. Brazil contributes only a small share of the foreign value added in the final products of global hubs. Between 1990 and 2015, there was an increase in the interdependence between global hubs, although this interdependence has remained small. Baldwin (2020) also shows that the interdependence of the three global manufacturing hubs – China, Germany and the US – has increased with respect to international supply chains.

Figure 3. Global manufacturing hubs' interdependence

Source: Authors' calculations.

The value-added originating in South America represented 4.22% (1.38% only in Brazil) of the global trade in 2015. The small size of the economy of the countries in the region justifies Brazil's greater dependence on foreign value added with global origin. Brazil and other South American countries depend heavily on trade with countries that are geographically distant. Poor integration between South American countries potentially reduces the benefits that they could obtain from global trade, since the geographic distance still matters in globally fragmented production (Li et al., 2019).

5. CONCLUSIONS

This study has undertaken a spatial decomposition of foreign value added in the downstream and upstream segments of value chains. The focus of the analysis is the Brazilian economy, since its pattern of participation in international trade has distinct characteristics with reference to its global or regional integration. This analysis presents evidence with respect to the position that Brazil occupies in the value chains and the spatial extent of this productive fragmentation. The main results show that the participation of the Brazilian economy in value chains occurs differently when considering their geographic scope and downstream and upstream production stages. We find that the downstream and upstream participation of Brazil in value chains is driven mainly by the global fragmentation of production. However, its regional insertion has increased more than its global insertion. The results also suggest that Brazil operates as a regional hub, as it is a reference for international trade in in this region. This regional production center proved to be more integrated with the main hubs of the global value chains (United States, China and Germany). Additionally, in the global context, Brazil plays the role of supplier of intermediate inputs, while in the regional context, Brazil plays the role of an important production center.

The Brazilian economy is relatively closed to international trade and minimally inserted in value chains. Protectionist policies have been directed for all stages of production in the national territory. Thus, Brazilian industry has remained minimally integrated into the international fragmentation of production. Additionally, the reduced number of trade agreements hinders the country's participation into value chains. However, the results also indicate that Brazil plays a strategic role in the fragmentation of South American production. This role, if well explored, could be a strategic mechanism to increase its participation in global fragmentation.

One of Brazil's greatest challenges in the context of international trade, as well as with reference to some developing countries, is to break the prevailing policy of protecting domestic industry. A greater integration with international trade

through openness, trade agreements, and other measures that reduce tariffs and barriers, in the short term can be expected to cause a reduction in the level of activity, employment and income generated by some sectors of the economy. However, over the long term the same sectors are expected to achieve gains in industrial competitiveness. In the context of growing international outsourcing, the formulation of policies should take into account that the production processes are increasingly fragmented in different territories. Mapping the dimensions of value chains is crucial to an increased understanding of Brazil's participation in the international fragmentation of production, which can be useful for the formulation of external and industrial policies. Hence, the evaluation of the productive structure considering the geographic extension of the value chain may bring objective elements to support the discussion of new trade agreements. The results of this study provide information that can be considered in planning policies that aim to increase Brazil's participation in global value chains. A strategy that could be used for this would be via greater regional insertion considering the negotiation of unilateral agreements (via Mercosur or not) with other countries in South and Central America.

CAPITAL INCREASE AND LAND PRICES: AN ESSAY AMONG BRAZIL AND UNITED STATES OF AMERICA

[Guilherme Asai](#)

University of Illinois at Urbana-Champaign, Urbana, USA, guilherme.asai@alumni.usp.br

ABSTRACT

In the past decade, Brazil and the USA take turns in the position of the largest producers of agricultural commodities, such as soybeans. One way to reach this position was to increase the planted area. The need for more areas of plantation caused an increase in the value of land, which caused an increase in the capital employed (invested capital). Therefore, all agriculture and livestock were affected by this increase in land values. In this scenario, this paper aims to quantify the influences in import, export, prices, and production value by the increase in invested capital, due to an increase in land prices. The methodology used was based on computable general equilibrium. The results indicated that there was a positive influence in all analyzed variables (importations, exportations, commodity prices, and production value). Thus, this paper deals with a current and important theme, that can help making efforts and decisions by measure the impacts in increasing the planted area in the medium and long term.

KEYWORDS

Agriculture, Computable General Equilibrium; Land market; Land values; PAEG.

1. INTRODUCTION

Over time, agriculture has played an important role in the globalized world as one of the most important sectors in the economy, as reported by Gilis et. al. (1992) the agriculture sector is responsible for food security and international trades. Despite the fact of nutrition question, the benefit of this sector could provide economic development for regions, countries, nations, and even people.

In some cases, larger producer of agriculture commodities previously develops their economies build primarily in the agriculture sector, like the United States of America (USA). Others, with emerging markets, like Brazil, structure their net trade balance based on the export of agriculture commodities. Besides, the export of agricultural commodities is responsible for keeping the trade balance in surplus, and employment in the countryside is important to maintain a stable employment level and ensure food security for the country.

By 2015 years the Brazilian agriculture has undergone several changes and raised the agribusiness sector to one of the most important in Brazil. According to the Federation of Industries of the State of São Paulo (FIESP, 2017), Brazil has the second-largest soybean production in the world with more than 104 million tons for the 2016/2017 crop, only behind the USA, which, according to United States Department of Agriculture (USDA, 2018) the production in 2016/2017 crop was about 107 million tons of soybeans.

Regarding the exportation of soybeans, Brazil is the main exporting country with around 59 million tons, while the US export was about 50 million tons for the 2016/2017 crop. As the main destination for these exports was China that received more than 92 million tons of soybeans across the globe, consolidating itself as the largest soybean importing country (FIESP, 2017; USDA, 2018b).

All this increase in grain production and export reflects the Brazilian economy in positive ways. The agribusiness sector, which includes all the livestock and agriculture, is responsible for more than 21% of the total Gross Domestic Product (GDP) in 2017 (CENTER FOR ADVANCED STUDIES ON APPLIED ECONOMICS, 2017). Likewise, the US agriculture and food sector had a 5.5% in weight in the composition of the GDP, which represents US\$ 992 billion in 2016 (USDA, 2016). However, the importance of the agriculture sector for Brazil and the US remains always the same over the years. Concurring with the World Bank (2018) the valued added percentage of the GDP for the agriculture, forestry, and fishing sectors are almost the same during the past 20 years for Brazil and the US, in terms of 4.70% and 1.14%, respectively. In terms of currency production value, both nations grew up to 5% per year between 2000 and 2015.

Figure 1 indicates the percentage of agriculture and forestry valued added in total country value-added comparing US and Brazil.

Figure 1: Percentage of agriculture and forestry value-added for US and Brazil

Source: Research data.

Note: data extract from World Bank (2018).

For those countries with a strong economy, the weight of the agribusiness sector must be not larger due to the third sector, where most of GDP is concentrated. Nevertheless, in emerging markets, like Brazil, the agribusiness sector has an important weight in GDP's composition.

The expansion of agricultural and livestock production goes together with an increase of planted area in all Brazilian regions. This increase in the area planted leads to the need to expand new areas of cultivation and new agricultural frontiers (Sampaio, Sampaio & Bertrand, 2012). Not only the soybeans and the corn beans had their area planted increase, but the area for agriculture was raised in all regions of Brazil.

In the meantime, the USA also increased its soybean planted and harvested area. According to the USDA (2018), the USA increases the planted area by more than 20% from 2000 to 2018. This was a prerogative to become the largest soybean producer in the world. However, unlike Brazil, the USA increased its production also based on the use of high technology, research, public policy, and crop substitution (DABERKOW & MCBRIDE, 2003; MASUDA & GOLDSMITH, 2009).

By mutual agreement, the fastest way to increase agriculture production is an increase in fields and expanded agricultural crop area. This happened on a larger scale in Brazil which raises the country as one of the top producers and exporters for these grains. To reach this position, was necessary to increase the planted area, by doing this the grain production expanded for unexplored areas that create a new agricultural frontier between the States of Maranhão, Piauí, Tocantins, and Bahia, all in the Brazilian Northeast, region known as Mapitoba. At the same time, consolidated grains planting areas were modernized and consolidated in Midwest and South.

As a fair comparison between the USA and Brazil of the growth in soybean planted area, Figure 2 demonstrates what happened to the level of the total planted area over the last years.

Figure 2: The planted area between 2006 and 2018

By analyzing Figure 2 the gap of soybean planted area between those countries is decreasing, going from up to 8.5 million hectares to less than 1.5 million difference. Thus, the increase of soybean planted area is visible over the years and this could indicate how Brazil approached USA soybean production.

Parallel to the increase in soybean production, export, and planted area, there is an increase in the price of land due to the need to obtain more areas for planting. Some authors as Ferro & Castro (2013) and Asai & Piffer (2016) indicate that land has been appreciated in the last decades, both in areas of traditional soybean cultivation areas and in the new agricultural frontier.

As Plantinga, Lubowski & Stavins (2002) land prices reflect more than just the land use proposes. There are a series of variables, among them can be cited, for example, the potential use of the expected net returns obtained by allocating the land to its most profitable use, the potential development of the land in that region, or even the rent of them. The authors indicated that is important to how the land prices for public policies and prevent loss of productive agricultural land and even loss incapacity to produce food.

Although, the increase in land price appreciation forces the farmers to produce more with the same quantities of output due to the maintain profitability (FLOYD, 1968). The land prices impact in a negative way when the returns taxes were calculated, as more the land costs, more returns were expected. Thereby, Floyd (1968) and Alston, Beddow & Pardey (2009) indicate that more capital and labor are needed in agriculture.

Therefore, agriculture and livestock are affected by this increase in land values. In this scenario, what are the economic impacts (commodity prices, production value, and quantity exported and imported) that the increase in the land value causes in the agriculture sector for the USA and Brazil?

To answer this question, the present paper will use a Computable General Equilibrium (CGE) model, simulating three scenarios: (i) capital increase in land value for Brazil only; (ii) capital increase in land value for the USA only; and (iii) capital increase in land value for both countries. Hence, this paper deals with a current and important theme that can help to make efforts and decisions by measure the impacts in increasing the planted area in the medium and long term. The paper is structured into four main chapters include this one introduction. The second one is to introduce de CGE model which will be used to capture the influences in the agriculture sector due to land appreciations. The third part is dedicated to present the results of the CGE model and describe the economic impacts caused in agriculture. To the end, the fourth chapter is the final considerations.

2. METHODOLOGY

The Computable General Equilibrium Model is the ability to represent the economy of a country and your commercial relationships with others inside a set of algebraic equations or accounting identities. To Sadoulet & De Janvry (1995) and Partridge & Rickman (1998), CGE models can capture the relationships among economic agents through the macroeconomic and microeconomic aspects present in the Input-Output Table.

To fulfill the objective of this paper the CGE model chosen was the PAEG which uses part of the GTAP model and its database. The next session will introduce a brief description of the PAEG model.

2.1 General Equilibrium Analysis Project for the Brazilian Economy – PAEG

The General Equilibrium Analysis Project for the Brazilian Economy is a static, multi-regional, and multi-sector model, structured to represent the Brazilian economy and its interactions with other economies around the globe (GURGEL et al., 2011).

PAEG's structure is based on the *GTAPinGAMS* (Rutherford & Paltsev, 2000; Rutherford, 2005), adopting a nonlinear complementarity problem in the General Algebraic Modeling System (GAMS) developed by Brooke et al. (1998), and uses a Modeling Programming System for General Equilibrium syntax (MPSGE).

The database used is the Global Trade Analysis Project (GTAP) and was disaggregated to portray the Brazilian economy in its five different macro-regions – Center-West, North, Northeast, South, and Southeast. However, the GTAP database has been preserved the other countries and of trade flows identically to the original ones. The regions, sectors, and the factors of production considered in the PAEG are described in Figure 3.

Sectors	Acronym	Regions	Acronym

Figure 3: Regions and sectors present in the PAEG model

As Gurgel et al. (2011) and Teixeira et al. (2013) defines, PAEG model represents the way goods and services are produced in Brazilian and world economies. The regions are represented by a final demand structure and the behavior of the players is that of an optimizer in that they maximize their welfare.

To combine the database, regions, and sectors is created some variables to represents the regional economy into the model. The variables of the economic model are Y_{ir} , as production of good i in region r . The C_r , I_r , and G_r , are private consumption, investment, and public consumption in region r . The M_{jr} represents the importation of good j by the region r , as well the HH_r is the variable for representative consumers. The public sector or government in region r is the variable $GOVT_r$ and the activity through which specific inputs are allocated to private sectors is the FT_{sr} .

To exemplify how the regional economy is structured in PAEG model the Figure 5 illustrated the structure and the economic flows.

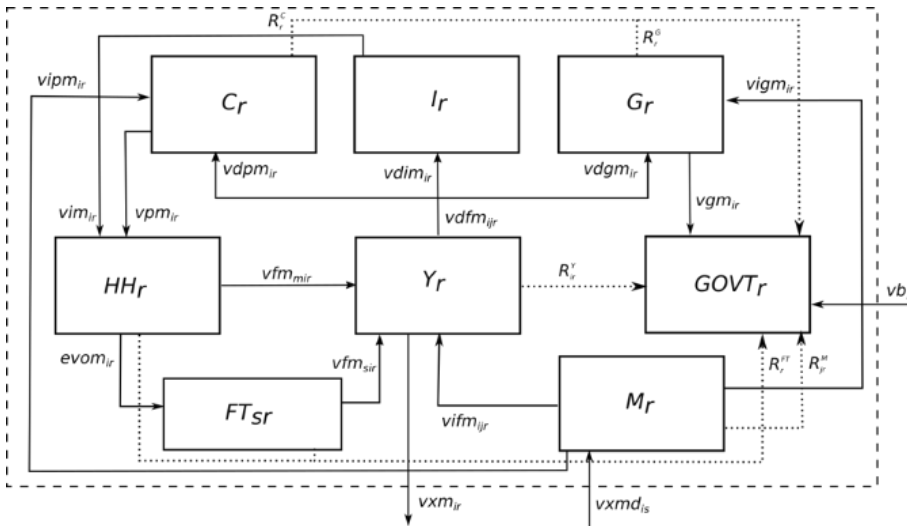

Figure 4: Regional economic structure and economic flow of the PAEG model

Source: Pinto, et al. (2016).

In Figure 4, the dashed line defines a region r , the solid line indicates the flows of the variables and the dotted lines determine the tax flow. Besides that, it is possible to see the variables - Y_i , C_r , I_r , G_r , M_{jr} , HH_r , $GOVT_r$, and FT_{sr} - and the other parameters. These other parameters are the indirect taxes represents for the letter "R" and affects production (R_{ir}^Y); consumption (R_r^C); public demand (R_r^G); factors of production (R_r^{FT}); and imports (R_{jr}^M). The base accounting identity for the variables in the model is indicated in Equation 1 through 7.

$$Y_{ir}: \quad \sum_f vfm_{fir} + \sum_j (vifm_{jir} + vdfm_{jir}) + R_{ir}^Y = vom_{ir} \quad (1)$$

$$M_{ir}: \quad \sum_s (vxmd_{isr} + \sum_j vtwr_{jisr}) + R_{ir}^M = vim_{ir} \quad (2)$$

$$C_r: \quad \sum_i (vdpm_{ir} + vipm_{ir}) + R_{ir}^C = vpm_r \quad (3)$$

$$Gr: \quad \sum_i (vdgm_{ir} + vigm_{ir}) + R_{ir}^G = vgm_r \quad (4)$$

$$I_r: \quad \sum_i v \dim_{ir} = vim_r \quad (5)$$

$$FT_{fr}: \quad evom_{fr} = \sum_i vfm_{fir} \quad f \in s \quad (6)$$

$$YT_j: \quad \sum_r vst_{jr} = vt_j = \sum_{irs} vtwr_{jirs} \quad (7)$$

Gurgel et al. (2011) describes step by step each how these accounting identities are calculated which are composed of: domestic production (vom_{ir}); exportation ($vxmd_{irs}$); international transportation services (vst_{ir}); intermediate demand ($vdvm_{ijr}$); private consumption ($vdpm_{ir}$); government consumption ($vdgm_{ir}$); investment ($v \dim_{ir}$); imported goods (vim_{ir}); goods used in the intermediate consumption ($vifm_{ijr}$); private consumption ($vipm_{ir}$); government consumption ($vigm_{ir}$); consumption of public agent ($vigm_{ir}$); exportation of good i by region r (vxm_{ir}); importations of good i by region r ($vxmd_{irs}$); international transport services (vt_j); a value of transport service exportation (vst_{jr}); bilateral transport service flows acquired in the importation of goods ($vtwr_{jirs}$); budget constraint of government (vgm_r); and budget constraint of representative agent ($evom_{fr}$).

Presented the basic structure of the model and its accounting identities, the main use of the CGE occurs through simulation and scenario analysis. In this paper, scenarios of an increase in invested capital in agriculture will be simulated, due to the increase of land prices during the last year. This scenario is possible because the land is considered a productive factor and is exclusively for agriculture in PAEG model.

2.2 Land prices data overview

The historical data used as an assumption in growth capital into de CGE model were obtained from secondary sources like Informa Economics FNP (FNP, 2002 – 2017); Instituto Brasileiro de Economia (IBRE, 2017), and USDA (2018), which was selected only the agricultural and livestock land prices, despite the other land uses, such as urban area. In this form, there were encounter a homogeneous type for comparison between USA and Brazil.

Those raw data have been distributed as agricultural and livestock land prices for each region and, but for the analyses, all data were aggregate as an average of all. Figure 5 illustrated an index for the average for 2002 until 2017.

Figure 5: Index base 100 in 2002 for average agricultural and livestock land price in Brazil between 2002 and 2017

The index was constructed due to currency difference and for observed the behavior with the land prices in those countries through time. Note that the land prices increase even in the USA and Brazil, between 150% and 630%, respectively. However, even with the highest growth in Brazil may not directly reflect an increased production which will be investigated throughout the paper.

To verify the adherence between the two historical data some statistical analyzes were performed and the result is indicated in Table 1.

Table 1: Stats for the land prices data

	USA	BRA
Average	5.450	22.878
Median	5.337	17.635
Std deviation	1.586	13.572
Minimum	2.990	6.862
Maximum	7.611	50.034
Stat t	0.008	
Stat t critical	1.753	
Pearson correlation	0.937	

Through this brief statistical analysis, it is observed that there is no significant difference between those historical data and there is a high correlation mid them. Thus, the data can provide statistical information to the CGE model leading to a more reliable scenario modeling.

2.3 Scenarios: increase on invested capital in agriculture

To reach the objective of this paper and quantify the influences of land appreciation in Brazilian agriculture, a scenario is simulated through a productivity shock by capital increase into agriculture sectors. Through the scenario simulation, it will be possible to quantify the changes in imports, exports, and agriculture and livestock prices.

The increase in land prices will reflect in the expansion of the cultivated area since it will be necessary a superior investment in the purchase of new areas for openness and planting. The expansion of the agricultural frontier and, both planted and harvested area, indicates the need to acquire new areas by farmers from all macro-regions. If the land prices grow up, more expensive is to expand the agricultural areas by the acquisition of new ones. Thus, a scenario of increased invested capital inland brings the possibility of analyzing the impacts of the agricultural sector by the CGE.

Meanwhile, the land is considered a production factor. Authors such as Pindyck & Rubinfeld (2009), Belik (2014), and Hoffmann & Ney (2016) comments that in agriculture the land is a productive input, such as capital and labor, whose land is a determining factor for Brazilian agricultural production according to Rahal (2003). Also, Gardi et al. (2015) indicate that the land is a natural resource that is a multifunctional and non-renewable natural resource and carries out multiple functions, including the support of food production.

In the classical microeconomic theory, the value of the land can also be interpreted by the theory of fixed factors. In the long run, Varian (2003) places that certain factors are fixed for the economy. In the agriculture sector, the field of plantation is limited by the amount of land available and is fixed in the long term, since there is no way to produce more land artificially.

Consequently, the demand for new arable areas increases the price of land as occurs over the last decades. The Compound Annual Growth Rate (CAGR¹⁸⁹) for agricultural lands in the USA is around 6.02% and for Brazil is about 13.23%, which is established in Table 2.

Table 2: CAGR for agricultural land price in Brazil between 2002 and 2017.

	USA (US\$/acre)	BRA (R\$/ha)
2002	1,210	1,828
2003	1,270	2,533
2004	1,340	3,226
2005	1,610	3,036
2006	1,830	3,027
2007	2,010	3,497
2008	2,170	4,202
2009	2,090	4,499
2010	2,150	4,896
2011	2,300	5,919
2012	2,520	7,128
2013	2,730	8,148
2014	2,950	9,969
2015	3,020	10,659
2016	3,010	11,607
2017	3,080	13,327
CAGR	6.02%	13.23%

189 The CAGR is calculated by equation $CAGR = \left(\frac{value_t}{value_{t-n}} \right)^{\frac{1}{n}} - 1$.

To simulate the scenario with the shock on invested capital into the agriculture sector, the CAGR will be considered imputing these values of Table 2 in the PAEG model. The incidence of the capital increase will occur into a factor of production named capital (cap) in the agricultural sector.

This scenario is justified with the ideas of technical change and the aggregate production function. The capital increase will affect directly the Y_{ir} where the region r (USA and Brazil) and goods i which is the selected agricultural products (pdr, gro, osd, c_b, oap and agr). Therefore, those depends on the interaction of capital (K) and labor (L) over time (t), following the Solow's (1957) idea which the aggregate production function is calculated by Equation 8.

$$Q = F(K, L; t) \tag{8}$$

At this point, the technologic structure to produce some amount of agriculture goods required a fixed combination of intermediate inputs, even domestic or imported, and primary factors as capital and labor. An increase in capital Figure 7 illustrated the structure to produce on PAEG's model.

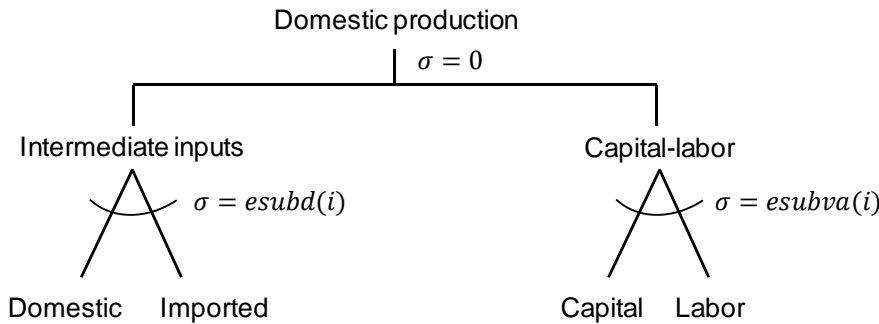

Figure 7: Structure to produce with a production function

In Figure 7, the intermediate inputs are a combination of domestic and imported under elasticity of substitution $esubd$, and the primary factors are combined under elasticity of substitution $esubva$, calculated by Cobb-Douglas function. Satisfying all the conditions above, the PAEG model creates the scenario with an increase of invested capital in the USA and Brazilian agriculture.

According to Goodman et al. (1985) and Frederico (2013), the agriculture is considered a capital-intensive sector. Under these circumstances and following the production function of Solow (1957), the productivity shock into the PAEG's model will respect the newer conditions of the production function for each region and each selected good indicated in Equations 9 and 10.

$$\text{USA: } Y_{ir_USA} = F(1.0602 * K, L; t) \tag{9}$$

$$\text{BRA: } Y_{ir} = F(1.1323 * K, L; t) \tag{10}$$

Through this land appreciation, a simulated scenario will show an increase of invested capital in the formation and expansion of the agricultural area (harvested and planted area) for the USA and Brazil. The need for this capital is due to the increase in land prices and required 1.06 more capital for the USA and 1.123 times more for Brazil.

Therefore, will be simulated three different scenarios for comparison: (i) capital increase in land value for Brazil only; (ii) increase in land value for the USA only; and (iii) increase in land value for both countries.

Thus, with this CGE simulation will be possible to know and quantify the influences of the increase in land prices for the USA and Brazilian economy. Through the productivity shock directly affecting the agricultural sector that resulted in effects on the entire world economic balance.

3. IMPACTS OF LAND APPRECIATION IN AGRICULTURE SECTOR FOR ECONOMY

Over the years, land appreciation and its determinants have been studied. To contribute to the discussion of the topic, this work aims to represent the land value appreciation as a capital invested in agriculture sectors for the economy in the USA and Brazil by simulating scenarios through a GCE model which will represent the behavior of these countries in the world economy. The results for the simulated scenarios are presented in Table 3.

Table 3: Results on equilibrium after GCE's simulated scenario of capital increase in the agriculture sector (%)

Parameter	Sector	Scenario 1	Scenario 2	Scenario 3

	agr	-0.01	0.08	0.60	

Analyzing the change in production value for the agriculture sectors before the shock in the equilibrium the only negative change was in rice production in Scenario 2. This could be justified because Brazil imported a portion of their consumption of rice, there was a compensation in the volume of rice imported, as observed by an increase in 0.10% in import rate.

In Scenario 3, the USA only decreases the production value of the sugar cane sector, in contrast to Brazil, in which the value falls in the corn and rice sectors. Notes that the decrease or even increase in the sectors had a greater impact than in Scenarios 1 and 2, which indicates that the two countries together are stronger and can move the world economy more than separated.

Nevertheless, the increase in soybean production value has an important change when the USA and Brazil increase their capital invested in agriculture because these countries have the largest soybean production and hold the highest export rates as well. The increased amount of 0.14% (USA) and 0.15% (BRA) is sufficient to keep the two in their positions. To prove this, Figure 7 indicates the rates for all regions present in the model for the soybean production value for Scenario 3.

Figure 7: Structure to produce with a production function

The behavior on exports and imports was predictable. In most cases occur fall in imports and the increase in exports in all three scenarios. The only exceptions were in the exportation of corn and livestock, also in importations for rice and milk sectors, in both cases for Brazil during the simulated Scenarios 2 and 3.

In general terms, it can be inferred that the greater production of the agriculture and livestock sectors succeeds, even more, the need for domestic consumption of these products, reducing the need to import. The search for self-sufficiency can be interpreted as a positive point since the dependence on food imports can cause an imbalance in the region's trade and supply. Be self-sufficiency in agriculture and livestock products, also, can provide food security. Through this, it becomes important to the development of these regions by reducing the poverty as Shiferaw et al. (2011) indicate in their study.

The rice, soybean, sugar industry, and milk sectors had an increase in exports both in the USA and Brazil. The sectors that had an increase in exports are those that are prominent in those countries' export agenda. As commodity-exporting soybean, livestock and sugar stand out among agricultural commodities obtains prominence in exports, placing Brazil among the largest players in the international market.

Leading to commodity prices an opposite movement was found in equilibrium. In every analyzed sector in Scenario 1 the prices have decreased, except in milk and dairy products that maintain stability. Nevertheless, in Scenario 2 all prices have increased. There is another controversy in prices when the results of Scenario 3 are presented. The price stability in practically all sectors can be justified because the commodity prices are governed by numerous factors of which, land value is one of its determinants, and more variables make the price oscillation.

At this level, it can be inferred that agriculture price gains can be derived from other variables against land price, such as employment of technology or improvement in the field. Because they are commodities, price is governed by global demand and supply, which in the long term, there is a balance in prices due to international market regulation.

The way the model is structured, it is possible to evaluate the set of scenarios in terms of microeconomy relating production value and commodity prices. With the scenarios, supply and demand curves move, causing a new equilibrium. In Scenario 1 increase in production value allied with a decrease in commodity price indicates supply curve shift right and static demand curve. In Scenarios 2 and 3, an increase in production value and prices causes a shift right in both demand and supply curves.

By shifting the right demand and supply curves in these scenarios, it can be said that there is more production and consumption of agriproducts in Brazil and the USA. It can be taken to a level of consumption that maintains or increase the population welfare in both countries, however, this cannot be verified in this research.

Generally, the impacts of land appreciation in the agriculture sectors are positive. There is an increase in export and decrease in importation goods which indicates a positive balance trade, which is beneficial to the economy of the country attracting foreign exchange. The rise of commodity prices implies a greater number of resources for Brazil being a commodity exporter.

Therefore, the production values of agriculture and livestock were harmed by an increase in invested capital. This fact is comprehensive because the needed more investment to maintain the agriculture production, or even maintain the same level of welfare state which cause, and effect is not analyzing in this paper.

4. FINAL REMARKS

This paper aims to investigate what are the impacts on Brazil and the USA economy due to an increase in land values, especially in the agribusiness sector. To verify and compare both countries, a CGE model to simulated scenarios was used in: (i) increase in land value for Brazil only; (ii) increase in land value for the USA only; and (iii) increase in land value for both countries.

In all these three scenarios the impacts in the agribusiness sector are positive, in both Brazil and the USA. The production value increases which means there are more intensive economic activities for the agribusiness sector. Even the need for more capital in agriculture and livestock production, for land expansion, for example, the land prices interfere so as not to negatively impact the economy.

By increasing the import and exports, it means that more international trades are being made, especially with increased production (higher production value in simulated scenarios). Still, with the increase in production, there was an increase in consumption as observed in the results of scenarios 2 and 3.

Thus, the land market influences agribusiness in Brazil and the USA. Increasing the land prices causes the need to increase the use of capital in agricultural activities, however, this higher capital is positively reflected with the increase in exports, the value of production, and the increase in prices. From the microeconomics point of view, there is an increase in demand and consumption of agricultural products.

ABSTRACT

For years, many studies point that cargo transportation services were responsible for the loss of efficiency of several sectors of the Brazilian economy, including agriculture. The Brazilian agriculture sector is dependent on transportation services for the flow of production from the point of origin to the final consumer, as well as the distribution of inputs and implements, such as fertilizers and agricultural machinery. However, some bottlenecks shrink the transport and cause inefficiency. The objective of this paper is to investigate the impacts for the Brazilian economy given some change efficiency at agricultural cargo transportation service. The main hypothesis that guide this paper was: cargo transportation is a limiting factor for the development of the Brazilian economy. Using a computable general equilibrium model which represents the interactions of the five Brazilian macro-regions with other regions around the globe. As a result, it was found that the agricultural cargo transportation service influences the economic growth and regional development of the country through the increase in GDP and the well-being of the population. However, the simple improvement in the transport service does not bring significant growth or development to the country, showing that there are other factors that limit this development.

KEYWORDS

Agriculture; cargo transportation; computable general equilibrium; transportation services.

1. INTRODUCTION

In a globalized world, the flow of goods, people and services is increasingly active. In the world economy, Ballou (2010) indicates that logistics is a part of this economy by encompassing activities related to the flow of goods and services, such as transportation, storage, and communication.

Logistics may be understood as the link between producers and consumers, or vice-versa, that uses resources and activities to plan, implement, control and assure, efficiently, the flow and storage of services and goods all the way to the consumption point, being essential to all business. The entire process of goods management and follow up, services and information for the distribution of goods and services is considered part of logistics (RUTNER e LANGLEY, 2000; MOURA, 2006; BOSONA and GEBRESENBET, 2013; CROUCHER and BAKER, 2014; NOVAES, 2016).

In Brazil, where the agribusiness has been increasingly important over the last few years, logistics represent the main communication and production market of the agricultural and cattle ranching production, becoming important for the flowing of agricultural goods and services. Beyond that, logistics are an important topic for the rural sector, given that the logistics costs and losses throughout the system have high weight in the cost of agricultural production, according to studies by Martins et al. (2005), Martins (2011), Kussano and Batalha (2009; 2012) and Costabile et al. (2016).

In the Brazilian country, countless logistics infrastructure bottlenecks are found. Capdeville (2010) lists a few, such as those caused by the organizational environment, by the road structure status, by the facilities status, by the lack of environmental permits, by the deficiencies of the energy sector, by the elevated costs – of operation, transactions, and capital – and by the employed technology.

The existence of bottlenecks in the infrastructure of the logistics system in Brazil cause efficiency loss and a rise in the costs for the entire national productive chain, in addition of being a barrier for the competitiveness of the Brazilian goods in the international market (BARAT, 2009; PONTES et al., 2009; CAPDEVILLE, 2010; SOUZA, 2012).

With this perspective, the objective of this paper is to investigate the impacts for the Brazilian economy given some change efficiency at agricultural cargo transportation service. To complete this purpose, there is a main hypothesis: cargo transportation is a limiting factor for the development of the Brazilian economy.

To fulfill the proposed objective and answer the hypothesis, the present paper will use a computable general equilibrium (CGE) model with the main data input as a Brazilian input-output table for the five macro-regions of Brazil and those interactions around the globe. With this model is possible to capture the impacts in agricultural cargo transportation due

to efficiency shocks. Through the transport efficiency, shocks will be possible to indicate the impacts in the GDP, welfare, and value of production.

Therefore, this study is organized in five main sections, being this the introduction. The second section is dedicated to contextualizing the limiting factors in Brazilian agricultural cargo transportation; the third addresses the analytical referential, introducing the CGE model used in the analysis of the transportation services in the five Brazilian macro-regions; the fourth bring the results of the efficiency shocks; and lastly, the fifth lists the final considerations.

2. BRIEF OVERVIEW OF THE LIMITING FACTORS IN BRAZIL'S CARGO TRANSPORTATION

The limiting factors, or bottlenecks, in logistic sector are characterized by Bacarat (2009) and Capdeville (2010), as a difficult or even prevent logistics to happen in an efficient way, similar to the definition found at the Council of Supply Chain Management Professionals (2013), where the bottleneck is "a constraint, obstacle or planned control that limits throughput or the utilization of capacity" (CSCMP, 2013, p.22).

The inefficiency of the transportation services caused by the bottlenecks in the logistics system may negatively interfere with the logistics cost, with the loss of comparative advantage and with the increase in inefficiency that hurts the economy of a country (BALLOU, 2001; RODRIGUES, 2008; BARAT, 2009; KUSSANO and BATALHA, 2009; CAPDEVILLE, 2010; FERNANDES, 2011; KATO, 2016).

When it comes to the agricultural sector, Caixeta Filho (2010) and Mascarenhas et al. (2014) remark the difficulty in achieving a cost compatible with the spatiality in production, given that Brazil has continental proportions and there is a certain difficulty in the transportation of supplies from region to region.

The dependence of a single transportation mode was subject of a study by Ledyard et al. (2002), a case study in which cost is a factor of competitiveness to the transportation services, especially for truck freight. In this study, authors indicate that a solution to reduce costs is to promote auctions with a combined price per route, offering options to the suppliers that are economically beneficial to both buyers and sellers.

This dependency or unbalance in the transportation matrix is regarded by Keil and Young (2008), Kawano et al. (2015), Pacheco and Pereira Jr (2015), Lima (2015) e Branco et al. (2016) as harmful to the transportation services, as the market of the production to reach the consumer markets gets harmed and may directly affect the comparative and competitive advantage achieved in certain goods. As a way of attenuating the effects of dependency, Kawano et al. (2015) also explores the possibility of using multimodal to diversify the transportation matrix of a production region.

Regarding the logistics infrastructure, the works of Fujita et al. (2000), Castro (2002), Kussano and Batalha (2009; 2012), Capdeville (2010), Mitsutani (2010), Freitas et al. (2011), Lopes (2015), Schalch (2016) and Aritua (2016) are unanimous to point deficiencies, lacks or failures in the transportation infrastructure. The logistics and transportation infrastructure emphasized by the authors range from accesses to roads or drainage issues (for example, holes, poor road signs and access difficulties) to failures in the communication system (information technology), damaging the logistics system as a whole and not only the transportation system.

The importance of the freight services in the transportation of agricultural goods is even more critical when considering the time sensitivity of these. According to Behar and Venables (2011), Attavanich et al. (2013) e Redding and Turner (2014), the perishability of vegetable and animal origin goods increase the transportation costs, requiring a greater care and service quality in transportation, turning this service narrower when compared with the transportation of other goods.

The political questions are also limiting factors to logistics. Laws, regulations, institutional policies and organizational environment are pointed by Correa and Ramos (2010), Capdeville (2010); Machado (2013); Cruz (2015) as an obstacle to the logistics system. Such factors are not limited to Brazil, but also appear in other locations, as in the Netherlands, where political questions regarding the implementation of roads in Rotterdam became an obstacle to de development of logistics (DREWELLO e GÜNTHER, 2012).

Finally, social dilemmas start to affect the transportation services. Psaraftis (2015) e Proskurina et al. (2016) report the concern with environmental characteristics, such as pollution and environment degradation, barriers to improve the logistics infrastructure of a region.

Consequently, the limiting factors or bottlenecks negatively affect the competitiveness, interfere with the acquired comparative advantages and mitigate the logistics and freight services development. However, measures can be taken, for example, investments to reduce said bottlenecks.

3. ANALYTICAL APPROACH

Computable general equilibrium models have, in their essence, conditions to capture all the relationships present in a hole economic system. The CGE combining macroeconomic models and their interactions present in the input-output matrix.

In the literature, there are CGE models for different purposes, and types. For this paper, the CGE model chosen is the Project of Analysis of General Equilibrium of the Brazilian Economy (PAEG) that bring an analytical set of static, multiregional and multisectoral general equilibrium to the Brazilian economy.

The PAEG is an economic model capable of representing the economies of large Brazilian regions and their partner countries, examining trade flows and trade protections, considering the interrelations of the various sectors, markets, and agents (families, governments, companies) of economies, besides allowing complementarity between diverse sectors to be captured. The PAEG model also allows the calculation of aggregate effects on well-being and factor markets. Therefore, for these reasons, the PAEG model is in the class of models applied as general equilibrium (GURGEL, PEREIRA and TEIXEIRA, 2011).

The representation of the PAEG's regional economy is given by the following parameters: (i) Y_{jr} is the production of good i in region r ; (ii) C_r, I_r, G_r are private consumption, investment and public consumption in region r , respectively; (iii) M_{jr} represents the import of good j by region r ; (iv) HH_r is the representative consumer variable; (v) public sector or government in region r is the variable $GOVT_r$; and (vi) FT_{sr} represents the activity through which specific inputs are allocated to private sectors. Figure 3 shows the structure and economic flows present in the PAEG.

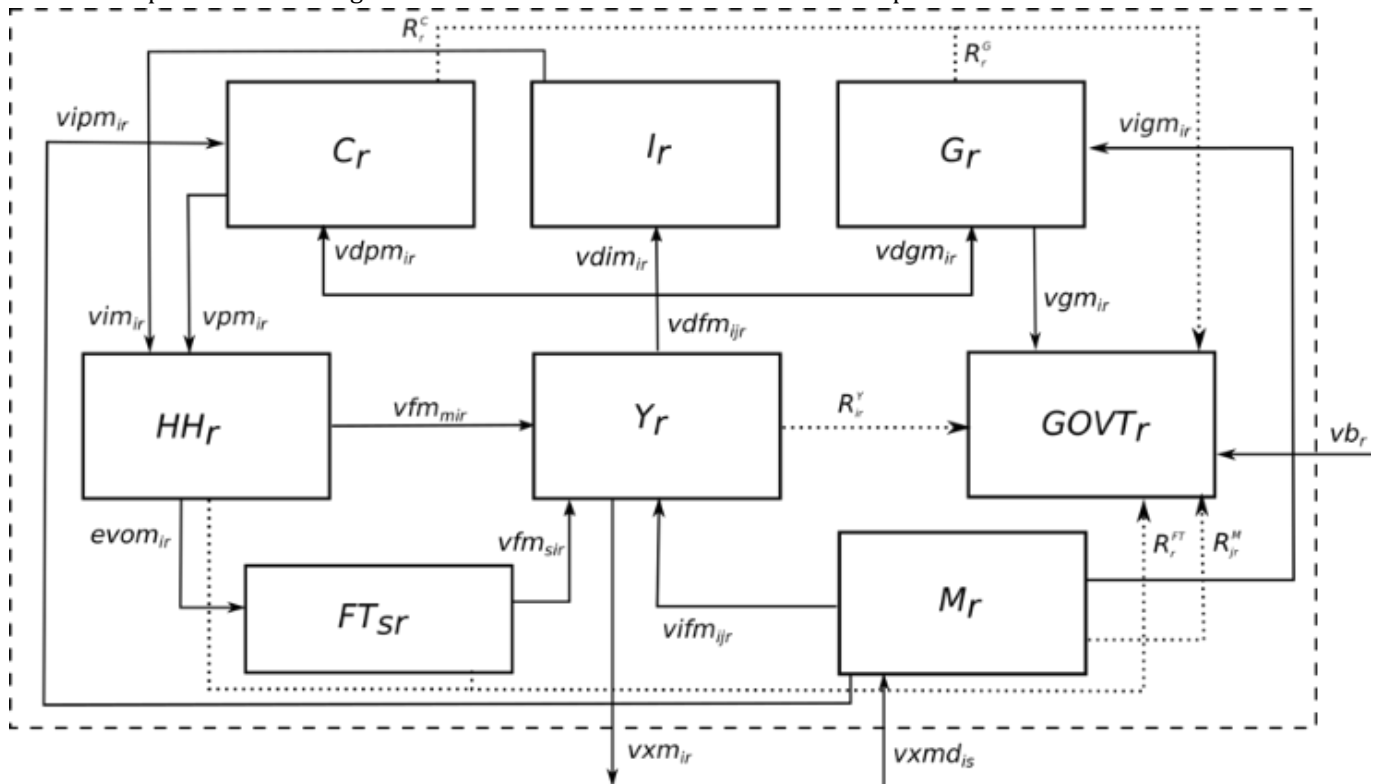

Figure 1: Regional economic structure and economic flow of the PAEG model

Source: Pinto et al., 2016.

To analyze the efficiency gains in the transport of agricultural cargo the PAEG model was structured to support the agricultural cargo transportation sector whose sector will receive efficiency shocks.

By dissociate the cargo transport service of the traditional PAEG model, the PAEG Transportation (PAEG-T) was structured and this description, with the accounting identities, can be found in the Asai (2019). The PAEG-T assemble the transportation service across Brazilian regions was conducted out of a new productive sector in Y_{jr} that refers to transportation services across regions and countries worldwide. Table 1 indicates all the regions and sectors presents in the model.

Table 1: Regions and sectors present in the PAEG model

Regions	Sectors
1. Brazil-Northern region	1. Rice
2. Brazil-Northeast region	2. Corn and other cereals, grain
3. Brazil-Midwest region	3. Soybeans and other oilseeds
4. Brazil-Southeast region	4. Sugarcane, sugar beet
5. Brazil-Southern region	5. Meat and live animals
6. Rest of Mercosur	6. Milk and dairy products
7. United States	7. Other agricultural products – wheat, fiber, fruits, vegetables etc.
8. Rest of NAFTA	8. Food products - Other food, beverages and tobacco products
9. Rest of America	9. Textile industry
10. European Union	10. Clothing and footwear
11. China	11. Wood and furniture
12. Rest of the World	12. Paper, cellulose and ind. Graphics
	13. Chemicals, ind. rubber and plastics
	14. Manufactured: non-metallic minerals, metal mechanics, mining, various industries
	15. SIUP
	16. Construction
	17. Trade
	18. Transport
	19. Services and public administration (being)

Source: Teixeira, Pereira and Gurgel, 2013.

Being regarded as a new sector in the model, the parameter in the PAEG-T that will guide the shocks is the $ytbr(j)vtwbr(j)$, where the $ytbr(j)$ sector only will be created to model calculations when the parameter $vtwbr(j)$ is present, that is, regarding the transportation margins across Brazilian regions that characterizes a flow present in the model according Diagram 1.

$\$prod: ytbr(j)vtwbr(j) s: 1$

$o: ptbra(j) \quad q: vtwbr(j)$

$i: py(j, r) \quad q: vstbr(j, r)$

Diagram 1

The Diagram 1 illustrates the production of transport services in Brazil, combining supplies of the sector j in the different regions r , precified by $py(j, r)$, the initial value of which is given by $vstbr(j, r)$ to the production of the supply of interregional transportation services, precified by $ptbra(j)$, the initial value of which in the database is given by $vtwbr(j)$. The $vstbr(j, r)$ e $vtwbr(j)$ parameters only exist for the transportation j sector.

The accounting identity of the parameters may be observed in Equations 1 and 2.

$$vtwbr_j = \sum_r vstbr_{jr} \tag{11}$$

$$vtwbr_j = \sum_j vtwr_{jisr} \tag{12}$$

For these identities, $vtwbr_j$ is the total offer of interregional transport services, the $vstbr_{jr}$ is quantity that each Brazilian region contributes to the total supply, and the $vtwr_{jisr}$ is the service demanded for bilateral trade in each region.

3.1 Shock level and simulated scenarios in PAEG-T

To simulate a scenario that exemplifies the efficiency of the transportation services, the efficiency shocks will be applied under the parameter $vtwr_{jirs}$. Therefore, a shock in the cost of transportation. The $vtwr_{jirs}$ parameter has the following configuration in the model: $vtwr(otp, agro, bra, r)$. Where j and i are the transportation services (otp) and the agribusiness sector (agro), respectively; s is the Brazilian macroregions (bra); and r means all other regions.

The shock determination occurs in the transportation cost of agricultural commodities, produced in the Brazilian macroregions, that will be transported to other regions, comprehending the rest of the country and the further regions present in the model.

To restrict the agricultural sector (agro) eight activities will be impacted due to efficient gains in transportation. These sectors are: (i) rice (pdr); (ii) corn and other grain cereals (gro); (iii) soybeans and other oleaginous fruits (osd); (iv) sugar cane, sugar beet, sugar industry (sgr); (v) meat and living animals (oap); (vi) milk and dairy (rmk); (vii) other agricultural products such as wheat, fibers, fruits, vegetables, etc. (agr); and (viii) food products, liquor, and tobacco (foo). The shock was defined in 2.7% in efficiency gains, this magnitude is based on the variation of the infrastructure investment during 2010 and 2017, which has an average annual growth of roundly 2.7% as show in Figure 2.

Figure 2: Investment in transportation sector

Source: National Transport Confederation (2020).

Therefore, the changes in the interregional transportation’s costs, simulating the efficiency gains of the transport sector, which allowed to analyze the impacts in Brazilian economy under the activity level, balance of trade (export minus import), production factors usage, GDP and welfare perspectives.

4. IMPACTS IN BRAZILIAN ECONOMY

In general terms, the impact on Brazil's economy with the improvement of agricultural cargo transport service was positive, demonstrated by the positive variation in GDP and welfare. These benefits were measured with the increase of these indicators for all macro-regions.

Projected GDP and welfare provide an initial trend of balance between them, departing as efficiency increases. Thus, the positive variation by changing the efficiency of the cost of transporting agricultural loads, that is, the decrease in freight in the EGC model caused efficiency gains that generate an increase in GDP, an indicative of economic growth.

Despite noting an almost linear and constant variation in GDP, this directly impacts on improving the regional economy. Thus, by varying the level of transport losses and efficiency gains, the observed trend of GDP is increasing. Table 1 shows the post-GDP and welfare shock result.

Figure 3: Welfare and GDP after the shock

The GDP of the southeast region, despite presenting behavior similar to that of other regions, the economic impact for Brazil is greater. This indicates a significant improvement in the Brazilian economy because the economy of the southeast is the most representative of the country, starting from a higher comparison base among the other macro-regions. With GDP and welfare as elements of regional analysis, the Brazilian midwest region has positive trends of economic growth with the lowest cost of transporting agricultural cargo.

Through the shock a proportion of GDP and welfare remain constantly. Regarding welfare, the behavior is similar to that observed by GDP, with the exception of the northern region, where no change is observed. In general terms, by varying

the cost of transport negatively the impacts on GDP and well-being are negative, just as when efficiency varies positively, the response becomes positive.

As the only region which has not suffered any influence on GDP, the northern region behaves differently from the others, with no change in GDP but positive change in welfare. This indicates that the transport service is not a significant sector for the region to the point of altering, in itself, the generation of wealth in the region.

The impact on the level of welfare is most evident when increasing transport efficiency. In absolute terms, GDP growth is composed of a share of household consumption which indirectly translates into well-being. Given that the welfare variable grows more than GDP, when considering the other variables, it can be inferred that GDP is high due to increased consumption.

After verifying the macro-regions, it becomes possible a broad view of the impact on the Brazilian economy in changing the cost of transporting agricultural cargo.

As already observed, GDP has a positive response to the change in freight prices. When one observes the Brazilian economy, without the breakdown by macro-region, the variation becomes smoother, since there are other components in which they can impact at the national level.

It is possible to correlate GDP with the gains projected by the shocks in order to estimate a value for the different transport costs, given Equation 3.

$$GDP_{projected} = GDP_{current} \times (1 + shock\ variation) \tag{13}$$

Therefore, the projected GDP at the different simulated levels is exposed in Table 17, whose calculation of the variation is consistent in the respective shock.

Table 2: Brazilian’s projected GDP post-shocks (base 2018)

Efficiency level	Post-shock GDP change (%)	GDP (R\$ trillion)	Potential GDP (R\$ trillion)
2.7%	0.002	6.827	6.839

Through this projection, it is already possible to observe that the service of transport of agricultural cargo, by itself, is an influencing factor of the country's economy. This proves what is observed throughout the scenario in each region.

In summary, with this projected scenario from the perspective of efficiency gains in agricultural cargo transportation services indicate a slight improvement for GDP and welfare, resulting in a positive economic impact and some regional development. However, because it demonstrates a minimal impact on the economy, the cargo transportation service cannot be characterized as a major barrier in the economic and regional development of Brazil.

5. FINAL REMARKS

The present study analyzed the transport services of agricultural cargo and aimed to investigate and quantify the economic impact of its efficiency for Brazil.

As the projected scenarios the economic with the simulation in efficiency shocks indicates positive variation in GDP and welfare, characterizing economic growth and development for the macro-regions. The trend of GDP and welfare growth is noted in all regions.

In the shock, it was validated that logistics is a limiting factor for the development of the Brazilian economy, but not unique. The low variation in the results, in the third decimal place symbolize a small variation, and points to the existence of more obstacles to the economic development of the country. With that said, the agricultural cargo transportation service does not directly impact the country's economic growth.

It is concluded that the transport service of agricultural cargo has its limitations and prevents the economic development of Brazil but should not be considered as one of the main obstacles to this.

AN ANALYSIS OF SUPPLY- SIDE INEQUALITIES IN EDUCATION SECTOR IN SRI LANKA

[Ayesha Wickramanayaka](#)¹, [N.P. D. Padmakanthi](#)²

¹ University of Kelaniya, Dalugama, Kelaniya, Sri Lanka, ayshaamadumali@gmail.com; ² University of Kelaniya, Dalugama, Kelaniya, Sri Lanka, dammikap@kln.ac.lk

ABSTRACT

Education is the most prominent factor that determines personal wellbeing and economic development. As well, education is a basic human right. United Nation's Sustainable Development Goals also have emphasized the importance of provide quality education for all. Sri Lanka provides free education for all school aged children. However, there are huge inequalities in micro level. These inequalities limit the development of human capital which is the essential factor for economic development. Hence, the main objective of this study is to identify the supply side inequalities in school education in Sri Lanka. To analyze this objective secondary data are used. Data are analyzed using descriptive statistical methods. The results indicate huge inequality in distribution of National Schools in district and provincial level. Although there are considerable number of National Schools in some districts, the students' enrollment rate is low because those schools have located only in the main cities. Students from remote area have limited access those schools. Further, results highlighted that students in remote areas have limited chance to follow Mathematics and Science scheme subjects for Advanced Level. This barrier negatively affects the economic development since some human resources move out from their potential path. Availability of adequate teachers also important to ensure quality education. However, distribution of teachers according to their specialized subjects and education level are highly unequal. Especially schools located in remote areas suffer from trained and graduate teachers and teachers for subjects such as English, Mathematics, and Science. Unequal distribution of infrastructure facilities also hindered the right for quality education. All these inequalities negatively affect for passing rate of the benchmark examinations of the students. Policymakers and government should properly involve to reduce inequalities in education sector by providing equal facilities for every and each student.

KEYWORDS

Inequality, School Education, Sri Lanka, Supply -Side

1. INTRODUCTION

Education is essential factor in economic development and social development of any country. Every person has right to get quality education. The importance of equal access to education has been emphasized in international conventions and national policies. United Nation's Sustainable Development Goals (SDGs) also have emphasized the importance of providing quality education for all. The fourth SDG especially focus on equality in education ensuring "inclusive and equitable quality education and promote lifelong learning opportunities for all" (undp.org.com, 2015).

Sri Lanka's national free education policy is designed to provide a common and equitable education for all. As a result, commendable educational achievements such as high literacy rate, the higher enrollment rate for primary and secondary education, and decent Human Development Index (HDI) have been achieved. In 2018, the school enrolment for primary education in Sri Lanka was 99.11 per cent and that was 100 per cent for secondary education (World Bank, 2020). As well, the literacy rate in Sri Lanka is 91.7 per cent reflecting the value of providing free education (Central Bank, 2020). But, there are micro-level disparities in accessing education, quality, and performance of education. This difference can be seen according to type of schools and according to available human and physical resource facilities. Those disparities have associated with a range of negative outcomes, such as lower economic growth and high risk of violence and conflict because of lower labor market returns and low social mobility. Therefore, it is more important to assure equitable and quality education to accelerate economic growth, reduce social and economic vulnerabilities and social violence.

Inequalities in education are caused by supply-side reasons as well as demand-side reasons. Government expenditure and policies can be identified as supply-side reasons. These inequalities limit the development of human capital which is the essential factor for economic development. Therefore, it is very important to identify and address supply-side inequalities in Sri Lankan education system.

2. LITERATURE REVIEW

Many researchers have analyzed the inequalities of education in different prospective. Taylor (2001) has found that socio-economic-status of a family in Canada is the one of the strongest indicators of a child's educational outcomes. Low socioeconomic status not only is associated with poor grades but also is a strong predictor of dropping out of school and skipping school. This research has shown that an achievement gap exists between children in low-income families and other families. Emma and Elaine (2017) have concluded that children's social class is one of the most significant predictors if not the single most significant predictor of their educational success using the data from two academic cohorts, the kindergarten classes of 1998 and 2010 in America. Baisla, (2020) has analyzed the causes of education inequality in India. This research found that regional inequality, gender-based inequality, caste, and social group's parental income and occupation are affecting factors for the education inequality in India. He recommends to plan education policies by addressing factors of educational inequalities so as to assure equal education for every student. Agrawal (2014) has analyzed educational inequality in rural and urban India and have pointed out that income of the parents has closely affect to students' achievements. This study found high inequalities in education in majour Indian state by calculating Gini Index separately for the rural and urban sectors. Although inequality declined from 1993 to 2009 period the Gini index is above 50 per cent in 2009. Tilak, (1989) has found educational inequalities affect for economic growth and unequal distribution of income based on primary data that collected from sample of 400 households in West Godavari district, Andhra Pradesh. He has pointed out that investment in education sector by targeting backward castes and women is essential for achieving equality in education. Kalmijn (2005) has analyzed educational inequality and family relationships based on contact and proximity in the family. The results have shown sharp but nonlinear educational effects on proximity and distance, although most of the educational effect on contact is indirect. This research has found that educational differences within family relationships lead to greater distances and less contact. Francisco (2014) has pointed out that inequalities in education is caused to educational achievement and opportunities using 57 countries based on Programme for International Student Assessment survey which was conducted in 2006. He indicated that 35 per cent of disparities in educational achievement are related inequality of opportunities and, this inequality is higher in continental Europe and Latin America than in Asia, Scandinavia, and North America. Stiglitz, (1923) has mentioned that differences in the education have been led to income inequality in any country. Furthermore, Lee (2013) has indicated that family background of the students is the most influential factor in educational inequality. Sarma et al, (2018), have analyzed inequalities in education in Sri Lanka using data collected from Monaragala, Batticaloa, and Mullaitivu districts. The results indicated that poverty and rurality are key contributors of educational inequalities. Differences in the types of schools and their congeniality especially limit poor and rural children's learning and educational outcomes and possibly put away later life opportunities. Although Sri Lanka is on the path to achieving universal primary and secondary enrolment across the island, evidence have pointed out that inequalities between rural and urban, and rich and poor areas are much worst especially when consider the quality of education. Although many researchers have analyzed the inequalities in education and it consequent to economy, research that analyzed the education inequalities in Sri Lanka is limited. Especially research that focus on supply side inequalities. Therefore, this research attempt to fil this gap. The finding of this research will help to policy makers to take decision to reduce inequalities in education sector.

3. OBJECTIVES

The objective of this study is to identify the supply-side inequalities in education sector in Sri Lanka.

4. METHODOLOGY

This analysis is based on secondary data. Secondary data are collected from various reports of the Central Bank in Sri Lanka, Ministry of Education, Department of Examination, Department of Census and Statistics (DCS), Centre for Poverty Analysis (CEPA), published research articles and websites, etc.

Collected data from secondary sources were analyzed using descriptive statistical methods. Data were analyzed using Microsoft Excel.

5. RESULTS AND DISCUSSION

This study mainly focusses on supply -side inequalities of education sector in Sir Lanka. Within the context supply-side inequalities are analyzed according to distribution of type of schools, availability of physical facilities and human resource facilities.

5.1 Unequal Distribution of Different Type of Schools in Sri Lanka

In Sri Lanka, the type of schools plays an important role in determining the quality of education. Education facilities such as availability of different subjects, medium of teaching and other facilities vastly vary according to the type of schools. Unequal geographical distribution of type of schools cause to inequality in education and prevent some students getting quality education especially in remote areas.

The school system in Sri Lanka has consisted of government schools, private schools, special schools, and Pirivens. In terms of the level of schools, there are two main categories of government schools in Sri Lanka such that national schools and provincial schools. Out of total number of government schools (10,175) 353 are national schools and 9,822 are provincial schools (Ministry of Education (MOE), 2019). The schools administrated by the central government are designated as national schools and schools administrated by the provincial councils are named as provincial schools. National schools are recognized as providing the best primary and secondary education out of the government schools and their disproportionate distribution can lead to spatial disparities in education (MOE, 2017).

Following graph shows the distribution of national schools and total number of students in each district.

Figure 01: Distribution of National Schools and Total Student Population in 2017

Source: MOE, 2018.

According to the graph, Colombo district has the highest percentage of national schools (10.4 per cent) in Sri Lanka. Kilinochchi district has the lowest percentage of national schools (0.5 per cent). About 54 per cent of national schools are centered in Western, Southern, and Central provinces in Sri Lanka while remaining six provinces have 46 per cent of national schools (MOE, 2018). There is a big difference between percentage of national schools and percentage of students’ population in Gampaha and Anuradhapura districts. Especially Anuradhapura district is one of the largest district in Sri Lanka. Although in some districts such as Killinochchi and Mullaitivu, have reasonable percentage of national schools compared to percentage of students. However, students’ enrollment in national schools in these districts is very low (MOE, 2018). As a percentage the students’ enrolments rate of Killinochchi district is 0.2 per cent and Mullaitivu district is 0.3 per cent (MOE, 2018). The wide geographical spread and the highest distribution of rural sector may reasoned for low students’ enrollment in national schools (DCS, 2018) (CEPA, 2018). Most of the national schools are located in urban areas (CEPA, 2018).

It is more clearly understand the unequal distribution of national schools by calculating National Schools Students Ratio (NSSR).

Table 01: National School Student Ratio in 2017

District	The national school student ratio	District	The national school student ratio
Colombo	10,279	Kilinochchi	16,225
Gampaha	21,406	Batticaloa	13,056
Kalutara	12,849	Ampara	14,981
Kandy	8,159	Trincomalee	10,913
Matale	8,812	Kurunegala	12,401
Nuwara eliya	23,658	Puttalam	24,246
Galle	8,113	Anuradhapura	34,578
Matara	7,743	Polonnaruwa	23,091
Hambantota	8,818	Badulla	6,910
Jaffna	16,118	Moneragala	11,980
Mannar	5,418	Rathnapura	16,285
Vavunia	7,512	Kegalle	12,307
Mullaitivu	9,564		

Source: Author calculation based on MOE, 2018.

The NSSR is the number of students in each district divided by the number of national schools. It was calculated by using following equation.

$$\text{National school student ratio} = \frac{\text{Number of total students}}{\text{Number of national schools}}$$

According to this table, NSSR in Anuradhapura district is 1: 34,578 which is the highest ratio. Anuradhapura is one of the largest district in Sri Lanka and compared that there are few number of national schools are located in this district. The lowest ratio shows in Mannar district (1:5,418). NSSR is more than 1: 20,000 in five out of twenty-five districts. However, when compared to available physical facilities and human resources the capacity of school is around 3000 to 4000 students for the school which have highest facilities. Although class room facilities are enough for 35 students most national schools have around 60 students in each class room. Entrance for national school is very competitive. It is very difficult to enter low income people since political influence, other personal relationship and corruption deprived their right to enter national schools. The main solution for this is increase the facilities and quality of education equally in all the schools in Sri Lanka.

In addition to the unequal distribution of national schools among districts, types of schools are also unequally located in Sri Lanka. The government schools are classified by type depending on the terminal grade of the school and according to subjects offered for Advanced Level. There are four main types of schools 1AB, 1C, Type 2 and Type 3. 1AB type schools have Advanced Level Science (Bio Science and/ or Physical Science) stream classes with or without primary sections. The schools having Advanced Level classes at least one stream of Arts and/or Commerce and/or Technology streams and/ or Vocational with or without primary sections are defined as 1C schools ((MOE, 2017). Following graph shows the distribution of type 1AB and 1C schools.

Figure 02: Distribution of 1AB and 1C Schools in 2017

Source: Author calculation based on MOE, 2018.

Out of total government schools 10 per cent are 1AB schools (MOE, 2018). This graph shows that distribution of type 1AB and 1C schools according to district. It has been calculated by using following formula.

$$\text{Percentage of 1AB schools} = \frac{\text{Total Number of 1AB schools in district}}{\text{Total number of 1AB schools in the country}} * 100$$

Same formula was applied to calculate 1C schools. As shown in graph 02 the highest percentage of total 1AB type schools are located in Colombo (7.5 per cent) and Kurunegala (7.4 per cent) districts. Kilinochchi district has the lowest percentage (1.1 per cent) of 1 AB schools. The highest numbers of IAB schools are located in the Western, Southern, and Central provinces compared to other six provinces in Sri Lanka (MOE, 2018). Also 91.5 per cent of 1AB schools belong to national schools (MOE, 2018). Out of total number of government schools only 18 per cent of government schools are belong to 1C schools (MOE, 2018). Kurunegala district has the highest percentage of 1C type schools which is 9.9 per cent. Both Mullativu and Kilinochchi districts have the least percentage of 1C type schools. When 1AB and 1C schools are taken together, Colombo, Gampaha, Kandy, Galle, Matara, and Hambantota districts have more than 30 per cent 1AB and 1C schools out of the 25 districts in Sri Lanka. Exception of these six districts, nineteen out of twenty-five districts has less than 30 per cent 1AB and 1C schools (MOE, 2018). According to this, it is clear that less than two-thirds of the existing government schools (only 28 per cent) do not offer Advanced Level.

Unavailability of Advanced Level class in schools prevent some students to continue their education after finishing Ordinary Level examination especially in remote areas and student with financial problems. Those students may not have opportunity to enter government universities which offer free undergraduate courses. In some cases, students have to spend lot of time to go to school that located in far from their area because of unavailability of Advanced Level class in rural area especially which offer Bio-Science or Physical Science subjects for Advanced Level. This situation may worsen with poor transportation facilities in remote areas. This cause to reduce their time that has to spend on education and finally end with low results and cannot continue higher education. Not only that, unavailability of Bio- Science and Physical Science subjects for Advanced Level prevent some students to select other subjects other than their preference and this may violent basic human right. As an example Killinochchi, Mannar, and Mullativu districts, each had approximately 1 per cent of the Type 1AB schools in 2015 and had no students entering university via the science stream on merit in 2016/2017 (Department of Examination (DOE), 2017). This may reason for deprive some potential labour for specific field in future and cause for many more social and economic problem in the country. Finally, unequal distribution of schools causes for economic development in the country.

5.2 Unequal Distribution of Teachers

Inequalities in education sector exist in terms of teacher’s distribution and qualification of the teachers. The qualifications of the teachers are measured according to their level of education and training to the types of subjects they qualified to teach. In terms of qualification of the teachers there are five main categories such that graduate, trained, untrained, trainee, and other teachers.

- Graduate teachers – teachers having a 3 or 4 years’ degree by recognized university and postgraduate degree
- Trained teachers – teachers trained in teachers’ training colleges/ National Colleges of Education and teachers having 2 years’ diploma in science/mathematics.
- Untrained – untrained teachers and 2-3 years’ diploma holders (absorbed to Sri Lanka teacher service)
- Trainee – teachers not absorbed to Sri Lanka teacher service
- Other – teachers paid by other government institutes and teachers paid by nongovernment institutes / organizations.

Source: MOE, 2017.

Following table shows the distribution of the teachers according to their qualifications.

Table 02: Distribution of Teachers in 2017

Province	Graduate teachers (%)	Trained teachers (%)	Trainee teachers (%)	Untrained teachers (%)	Other teachers (%)
Western	9.8	7.2	0.1	0.0	0.03
Central	5.7	8.3	0.4	0.3	0.01
Southern	5.3	5.8	0.1	0.1	0.01
Nothern	3.1	4.6	0.1	0.0	0.00
Eastern	3.9	5.7	0.3	0.0	0.00
North Western	5.6	6.3	0.3	0.0	0.01
North Central	3.7	4.1	0.1	0.0	0.00
Uva	3.2	4.8	0.2	0.1	0.05
Sabaragamuwa	4.7	5.5	0.2	0.1	0.00
Total	45.0	52.4	1.8	0.7	0.11

Source: Author calculation based on MOE, 2018.

As showing in the table, about 97.4 per cent of the teachers in government schools are either graduates or trained teachers. The highest number of graduate (9.8 per cent) and trained (8.3 per cent) teachers are in Western and Central provinces. The highest number of trainee (0.4 per cent) and untrained (0.3 per cent) teachers are in the Central province. However, the lowest percentages of all graduate and trained teachers are in Northern (3.1 per cent) and North Central province (4.1 per cent), respectively. Northern Province has recorded the lowest percentage (7.8 per cent) of all teachers. Furthermore, teachers have been recruited to schools on the basis of difficulty service by the Ministry of Education and the Provincial/Zonal Educational Departments in Sri Lanka. This rule may cause for some dissimilarities compared to requirement of the school. Because it is mandatory for a teacher to serve in a 'difficult' or 'very difficult' school for a period determined by the government (minimum of three years). As well, some teachers use political and other influences to transfer to a school of their preference.

The gross student-teacher ratio is the number of students per teacher. The Western province has the highest student-teacher ratio (1:21) while Northern Province have the lowest student-teacher ratio (1:13). However, there is no huge disparity in student-teacher ratio in Sri Lanka, that is stayed average level in each district. Also, Type 1AB schools compared to other schools categories have the highest student teacher ratio (1:21) (MOE, 2017).

Unequal distribution of teachers in education sector negatively affect for student's education. When students' teachers' ratio is high it is difficult to manage one teacher to lot of students and pay their attention to students individually. Especially this badly affect primary education of the students who need more attention at their early age. Further, lack of trained teachers in some schools especially in remote area badly affect for quality of the education. Especially, schools located in remote areas suffer from lack of teachers who trained specific subjects such as English, Science, and Mathematics. So, the failing rate of those subjects in Ordinary Level examination is high in schools which do not have enough teachers for English, Science and Mathematics. However, it is mandatory to pass Mathematics to follow Advanced Level according to the education system of Sri Lanka. Because of this reason most of students have to stop their school education without following Advanced Level which is mediatory to enter university. Further, there are no teachers who qualified for teaching English in most schools (Ranasinghe et al. 2016). He states that by 2012 there were 205 students per English teacher. Therefore, students are poor with English which is the international language. This negatively affect for them to find good job and follow higher education since most higher education institutes offer programs in English medium. As well, very few government schools in Sri Lanka offer education in English medium because of lack of teachers to teach in English medium and lack of class rooms facilities in schools. Hence, students have limited opportunity to follow school education in English medium and it is very competitive to enter the English medium class. This may negatively affect to their language skill and job market opportunities.

Some schools in Sri Lanka severely suffer with lack of teachers. Following table illustrates the schools which have only one teacher two teachers.

Table 03: Student-Teacher Ratio in School with One Teacher and Two Teachers in 2016

<i>Student per teacher</i>	<i>Number of schools with one Teacher</i>	<i>Number of schools with two Teachers</i>
1 student per teacher	5	3
2 student per teacher	13	7
3 student per teacher	2	6
4 student per teacher	7	11
5 student per teacher	6	10
6 student per teacher	1	8
7 student per teacher	-	12
8 student per teacher	2	8
9 student per teacher	3	1
10 - 20 student per teacher	8	20
21 - 30 student per teacher	-	6
31 - 40 student per teacher	-	3
41 - 50 student per teacher	1	1
51 - 75 student per teacher	5	1
76 -100 student per teacher	-	-
101 or more student per teacher	1	-
All schools	54	97

Source: MOE, 2017.

According to above table, 54 schools have one teacher and 97 schools have only two teachers. Out of the 54 schools which have one-teacher, five had one student and one school had 101 or above students. However, as shown in this table, 47

schools have student per teacher ratio less than 1:20. Teachers are the main resource in the school. Students have to find another school because of lack of teachers. Especially schools in remote area suffer from lack of teachers because of poor infrastructure facilities. Students have to find schools far from their areas which may costly and time consuming for them to access since lack of teachers. In some cases, assigned teachers also rarely come to schools. Number of leave days entitle for the teachers are 15 per cent of total school working days and student achievements being low as the days of leave taken by teachers are high (Institute of Policy Studies of Sri Lanka (IPS), 2017). Because of those reasons some financially destitute people do not continue their children’s education. These inequalities lead some social and economic problems in future. Further, in 2016, there were 262 schools with 15 students or less (MOE, 2017). Accordingly, this has highlighted the poor management of resources in the country.

5.3 Unequal Distribution of Infrastructures Facilities

Infrastructure facilities and other facilities that essential for maintain the quality education are also shown the inequality of education facilities in Sri Lanka. Out of total number of schools, 5,643 schools (55 per cent) have computer facilities for students. The highest percentage of computer facilities which is 69 per cent recorded from western province and the lowest percentage of computer facilities record from North Western province which is 47 per cent. More than 50 per cent of computer facilities have secondary schools, 1AB, and 1C schools (MOE, 2017). Lack of computer facilities prevent the students get new knowledge and working with new technologies. Especially in the current situation such that COVID-19 pandemic it is essential to use the computers to access online learning. However, without basic knowledge of computers it is very difficult for students to access it. Therefore, lack of computer facilities may lead inequality in education and limit the labour market participation.

Availability of basic facilities such as water, electricity and toilet facilities also cause for better education. However, there are some schools which lack even basic facilities, such as water, electricity and toilet facilities.

Table 04: Percentage of Schools by Drinking Water Facilities in 2016

<i>Province</i>	<i>Wells/Tube Wells in school premises (%)</i>	<i>Piped Water Facility (Municipal & Urban Councils/Water Supply & Drainage Board) (%)</i>	<i>Water from Streams/Springs (%)</i>	<i>Bowser (%)</i>
<i>Western</i>	40	54	2	0
<i>Central</i>	21	35	20	0
<i>Southern</i>	36	52	4	0
<i>Nothern</i>	73	12	0	5
<i>Eastern</i>	29	57	0	1
<i>North Western</i>	57	18	0	0
<i>North Central</i>	46	32	0	1
<i>Uva</i>	25	27	21	1
<i>Sabaragamuwa</i>	36	25	20	0
Total	40	35	8	1

Source: MOE, 2017.

According to table 04, main drinking water sources of the schools are wells/tube wells in school premises, piped water facility (Municipal & Urban Councils/Water Supply & Drainage Board), water from streams/springs, and bowser. Out of total schools 40 per cent of schools fulfil their drinking water requirement from wells/tube wells in school while most of other schools use piped water which is provided by Municipal & Urban Councils/Water Supply & Drainage Board. Most schools in Northern and North Western province used wells/tube wells in school premises and it is because rural areas are more widespread. Only 84 per cent of schools have any kind of drinking water facilities. According to this, 16 per cent of the government schools in Sri Lanka have no water facilities (uninterrupted water facilities).

Following graph shows the schools which do not have dirking water facilities according to province.

Figure 03: Percentage of Schools which do not have Water Facilities according to Provinces of Sri Lanka in 2016

Source: MOE, 2017.

As shown in this graph, there are no water facilities approximately one-fifth of the schools in Central (23 per cent), North Western (25 per cent), North Central (21 per cent), and Uva (26 per cent) provinces. However, most of schools in Western and Southern provinces have water facilities.

Schools in Sri Lanka have been divided into five categories according to available basic infrastructure and other necessary equipment. Those categories are very congenial, congenial, not congenial, difficult, and very difficult. Factors considered to measure congeniality include the availability of basic resources (electricity, water, telephone, library facilities), the durability of existing equipment (such as photocopy machines, televisions, and computers), the number of usable toilets, the size of the school buildings, availability of a principal’s office, teachers’ common rooms, the number of teachers and qualification composition (vocational and graduate), distance from school to the nearest bus stop or train station and the number of trips available towards the school between 7–8 am, and distance from the school to key education ministry offices, the nearest bank, post office, and government hospital (Sarma et al,2018). Following graph illustrate the percentage of school according to available basic facilities.

Figure 04: School Congeniality by Province in 2016

Source: Author calculation based on MOE, 2017.

As shown in above graph, according to total number of schools in province the majority of very congenial schools and congenial schools are located in Western and Southern provinces. Most of the not congenial schools can be seen in Central province. The lowest percentage of very congenial schools is in North Central province. As well, the majority of difficult and very difficult schools are centred in Eastern and Northern provinces in Sri Lanka. However, in the former war-torn provinces of Kilinochchi, Mannar, Mullaitivu, and Vavuniya close to 50 per cent of the schools are non-congenial, less accessible, and less conducive as a learning environment due to insufficient facilities (MOE, 2017). This is in sharp contrast to schools in Colombo where approximately 70 percent of the schools are congenial (MOE, 2017). Lack of basic facilities hinders the welfare of the students and negatively affect for education increasing inequality in education sector.

6. CONCLUSION

Free education policy in Sri Lanka has made it one of the most literate countries in South Asia. However, there are lot of inequalities in education sector in Sri Lanka because of supply-side reason. Therefore, this study attempt to evaluate the supply side factors that cause for education inequality in Sri Lanka.

The results of the study indicate national schools are distributed across the country unequally. Especially in some districts there are very few national schools compared to students. The student ratio compared to national schools are very high and not affordable to existing facilities of the school.

Further results indicate that there are limited opportunities for students to follow Bio-Science and Physical Science subjects for Advanced Level because of unequal distribution of 1AB schools which offer Bio-Science and Physical Science subjects for Advanced Level across the country and this type of schools are rarely located in remote areas. As well, the IC type schools that offer Advanced Level except Bio-Science and Physical Science subjects are also unequally distributed among the districts and among the sectors. Hence, some students have stopped their education without following Advanced Level which is the university entrance examination in Sri Lanka. Further, there are lack of graduate and trained teachers in some schools limiting students right to have quality education. Especially lack of trained teachers for English, Mathematics, and Sciences affect the equality and quality of the education in remote areas. Further limited schools in Sri Lanka offer English medium learning facilities creating another inequality in education sector.

There are considerable number of school do not have enough drinking water facilities in each province. Out of total number of schools 16 per cent of school do not have enough drinking water facilities. Schools in Northern and Eastern province highly suffer with lack of basic facilities that need to get quality education compared to other provinces.

Unequal opportunities and resources to access education can be translated into low learning outcomes. As well, disadvantaged groups will face later life disadvantages, which affect for lower labor market returns, low social mobility and slow economic growth.

7. SUGGESTIONS

According to findings of this study it can be recommended to increase equal physical and human resource facilities in both urban and remote areas so as to every student get equal quality education. Policymaker should take necessary steps for training teachers especially for subjects such as English, Mathematics and Science. As well, it is important to provide opportunities for every student who like to follow their school education in English medium since it cause for positive outcome in future. In this regards it is essential to train teachers for English medium subjects.

It is basic human right to have school education for all students. However, limited number of schools that offer Advanced Level class prevent some students to continue their education. Hence, policymakers should pay attention to expand the schools that provide Advanced Level class so that every student able to get quality education equally.

Basic facilities such as water, electricity, toilet, library, and other necessary facilities for education is essential for quality education. However, most of schools in Sri Lanka do not have such facilities. Therefore, it is necessary pay attention by policy makers to improve those facilities in every school so as to consider all the schools in same level.

ACKNOWLEDGEMENT

This study is a part of the project of 'Impact of Social Protection on Sustainable Development Goals: An Empirical Analysis' funded by the AHEAD research grant (AHEAD R2 DOR HEMS KLN No.12). Authors would like to acknowledge the AHEAD project for providing financial support for this project

DISPARITIES AND DETERMINANTS OF REGIONAL UNEMPLOYMENT RATE: EMPIRICAL EVIDENCE FROM MOROCCO

labrane Amaghous, Aomar Ibourk

Department of Economics, FSJES, Cadi Ayyad University, Morocco

ABSTRACT

Unemployment is one of the most important macroeconomic indicators of an economy. Its analysis, in Morocco, was carried out mainly by referring to national data while neglecting regional aspects. Although the unemployment rate at the regional level is considered as one of the socio-economic indicators of a region, the disparities in unemployment and its determinants are little debated in Morocco.

The objective of this paper is, first, to describe the spatial configuration of the unemployment rate. Then, we study the factors likely to explain the disparities in unemployment between the regions of the country.

There is a growing interest in studying unemployment in the literature. Thus, many studies are carried out in this field. While some analyze unemployment disparities between countries, others focus on unemployment disparities within a country (Marukawa, 2017; Dixon et al., 2001; Rios, 2017).

The theoretical literature puts forward several factors to analyze unemployment at the regional level. Thus, regional disparities in unemployment are due to regional problems and specificities. Furthermore, the variables used to explain unemployment disparities between countries are not valid for describing regional unemployment disparities. Indeed, the social security system and the tax system are mentioned as explanatory factors of the unemployment disparities between countries but have little or no value at the regional level because there are no large ones within the country. 'a country (Elhorst, 2003).

The estimation of the determinants of regional disparities in the unemployment rate will be made using the techniques of exploratory spatial data analysis. The models of spatial econometrics are needed to justify, through their lessons in terms of analyzing spatial disparities, why geographic should be taken into account in the framework of the analysis of regional determinants of the unemployment rate (the participation in the labor market, the rate of the young population (aged between 15 and 24, the level of education, the rate of industrialization). It is important to point out that developing countries lack unemployment data by regions over several years. Morocco is no exception to this situation. In this study, we use the spatial data of the general census of population and habitat (RGPH) of 2014.

More precisely, it is a question of showing that the taking into account of spatial disparities renews the debate on the effectiveness of regional development policies. These inequalities cannot be neglected and they allow an improvement in the understanding of the process of convergence between the provinces.

A SPATIAL ANALYSIS OF EDUCATION INEQUALITY DETERMINANTS: THE CASE OF MOROCCO

[Iabrane Amaghous](#)

Department of Economics, FSJES, Cadi Ayyad University, Morocco

ABSTRACT

Since its independence, the Moroccan economy has been characterized by a fluctuation in growth rates (Agénor and El Aynaoui, 2015), despite the successive reforms adopted (Ben Ali and Cherkaoui, 2007). Dictated by the World Bank, Morocco has adopted a structural adjustment program aimed at maintaining its macroeconomic balance, the main guidelines of which are austerity affecting largely social investments (Ben Ali, 1998). The latter were assigned to so-called regions with high growth potential, neglecting the other regions of "useless Morocco", thus reinforcing territorial inequalities (Achy and Sekkat, 2008), including in the field of education. Indeed, the analysis of the performance of the Moroccan education system reveals asymmetries and territorial imbalances hiding disparities between regions. This problem manifests itself, in particular, by the existence of a large number of "poor" regions whose educational performance is low. It should also be noted that the Moroccan provinces are characterized by the persistence of a dual structure between the Kenitra-Settat axis, developed, and a periphery in difficulty.

From a theoretical point of view, there is a broad consensus that socio-economic determinants contribute substantially to the reinforcement of educational inequalities. Paradoxically, despite this reality and the challenges that individual, socio-economic and institutional factors may pose, very few theoretical and empirical studies have focused on the spatial dimension of observations. It is therefore not surprising to note that research on spatial inequalities in Morocco remains very marginal.

The estimation of the determinants of educational inequalities is carried out using the techniques of the exploratory analysis of spatial data. These are techniques that make it possible to visualize spatial distributions, to identify atypical locations and extreme observations, to detect patterns of spatial association and to suggest spatial regimes or other forms of spatial heterogeneity. Models of spatial econometrics are needed to justify, by their lessons in the analysis of spatial disparities, why the geographical should be taken into account in the context of the analysis of the determinants of educational inequalities. It is important to note that developing countries lack educational data by region over several years. Morocco is not immune to this situation. In this study, we use spatial data from the recent 2014 General Population and Housing Census (RGPH). More specifically, the aim is to show that taking into account spatial disparities renews the debate on the effectiveness of regional development policies. These inequalities can not be neglected and they allow an improvement in the understanding of the process of inequalities between the provinces. We seek to show that educational inequalities are related to patterns of distribution of poverty.

**GEOGRAPHY MATTERS FOR SMALL ADVANCED ECONOMIES: THE
IMPLICATIONS FOR AN ECONOMIC STRATEGY**

Paul Dalziel, Caroline Saunders

AERU, Lincoln University, New Zealand

ABSTRACT

New Zealand is a small advanced economy (SAE) in the South Pacific Ocean. Policy advisers often compare New Zealand's economic performance with those of other SAEs: Austria; Belgium; Denmark; Finland; Hong Kong; Ireland; Israel; Netherlands; Norway, Singapore; Sweden; and Switzerland. These comparisons generally recognise that among SAEs, New Zealand is uniquely distant from the world's largest and highest income markets. Nevertheless, it has become commonplace for policy advisers to say "Geography is not destiny: New Zealand can do better" (the heading of a section in a 2020 New Zealand Productivity Commission draft report). This paper draws on standard regional economic development analysis to conclude that geography matters for economic strategies. It frames that analysis with the insights of endogenous growth theory to lay foundations for an economic strategy relevant to the New Zealand region of the South Pacific Ocean in the global economy.

THE EFFECT OF UPZONING ON HOUSE PRICES AND REDEVELOPMENT PREMIUMS IN AUCKLAND, NEW ZEALAND

[Ryan Greenaway-McGrevy](#)¹, [Gail Pacheco](#)², [Kade Sorensen](#)¹

¹The University of Auckland, New Zealand. ²Auckland University of Technology, New Zealand

ABSTRACT

We study the short-run effects of a large-scale upzoning on house prices and redevelopment premiums in Auckland, New Zealand. Upzoning significantly increases the redevelopment premium but the overall effect on house prices depends on the economic potential for site redevelopment, with underdeveloped properties appreciating relative to intensively developed properties. Notably, intensively developed properties decrease in value relative to similar dwellings that were not upzoned, showing that the large-scale upzoning had an immediate depreciative effect on pre-existing intensive housing. Our results show that the economic potential for site redevelopment is fundamental to understanding the impact of changes in land use regulations on property values.

THE CONNECTION OF RENTAL AND HOUSE PRICE AFFORDABILITY MEASURES IN NEW ZEALAND

[Graham Squires](#)¹, [Hai Trinh](#)¹, [Don Webber](#)², [Arshad Javed](#)¹

¹Massey University, New Zealand. ²University of Sheffield, United Kingdom

ABSTRACT

The aim of this paper is to examine the cointegration and long-run relation between affordability measures of house ownership prices and house rental prices in New Zealand. Using the approaches by Westerlund (2007) and Dumitrescu and Hurlin (2012), the study shows that there is an existence of cointegration and unidirectional causality effects between house price affordability (HPA) and rental price affordability (RPA) across 11 regions. Auckland, Wellington and Canterbury are the three regions in which the results detect the most extreme effects among HPA and RPA compared to other places in the country.

We extend our study by examining the lead-lag correlation between those two affordability measures. Our extended empirical work shows interesting results that the lead-lag effects of HPA and RPA on each other and mortgage rate have been discovered in New Zealand using GLS approach and for each of 11 regions via OLS model. Those effects are consistent for both methods but are changed at individual lead-lag variables and among different regions. The study empirically provides useful insight for both academia and practitioners in examining the long-run effects and cointegration between house price and rental price affordability.

Application of the bootstrap robust Westerlund technique confirms the presence of strong cointegration between these two housing affordability indicators. Application of Dumitrescu and Hurlin's (2012) Granger non-causality panel tests reveal that the statistically optimal lag length is equal to one quarter with house price affordability Granger-causing rental price affordability over the period 2000q1 to 2017q4. Application of Dumitrescu and Hurlin's (2012) Granger non-causality test results to individual regions suggest that house price affordability Granger-causes rental price affordability in Wellington, Auckland, Canterbury, Nelson and Hawkes Bay and that rental price affordability Granger-causes house price affordability in Wellington only.

VULNERABLE PEOPLE, LOCAL LABOUR MARKET RESILIENCE AND GLOBAL SHOCKS: NEW ZEALAND EVIDENCE FROM THE COVID-19 PANDEMIC AND THE GLOBAL FINANCIAL CRISIS

William Cochrane¹, Jacques Poot^{1,2}, Matthew Roskrug³

¹University of Waikato, New Zealand. ²Vrije Universiteit Amsterdam, Netherlands. ³Massey University, New Zealand

ABSTRACT

Despite its remote location in the South Pacific, New Zealand is tightly integrated in the global economy through trade, tourism, capital & migration flows, and strong digital connectivity. Nonetheless, the country weathered the Global Financial Crisis (GFC) relatively well. More recently, exemplary public health policies have muted the economic impact of the Covid-19 pandemic to date. Despite these favourable national outcomes, there are large differences across people and places in the impact of these exogenous shocks, although the shocks themselves occurred nationally with virtually no spatial differentiation. There are interesting similarities and differences between the socio-economic impact of the GFC shock and Covid-19 pandemic shock. In this paper we focus on one key outcome of public policy concern: the uptake of social security benefits in the short-run (first 12 months) after the onset of the shock. We construct a two-wave panel of 66 regions observed in 2008-09 and 2020-21. We link the corresponding social security data with regional characteristics mainly obtained from the preceding censuses. Using data reduction and model selection methodologies we find that pre-shock vulnerability in terms of unemployment is a key predictors of post-shock growth in social security uptake. This conclusion is robust to accounting for interregional spatial spillovers. There is notable similarity between the impact of the two shocks in terms of demographic composition (age and ethnicity), and the extent to which the self-employed and those in the private sector are relatively more exposed to the shocks. Income and wealth differences and the regional sectoral mix matter too but in a different way when comparing the GFC shock with the Covid-19 shock.

HOW DO PANDEMICS AFFECT ECONOMIC GROWTH? LESSONS FROM THE 1968 H3N2 INFLUENZA AND 2003 SARS

[Ilan Noy](#)

Victoria University of Wellington, New Zealand

ABSTRACT

We evaluate the 1968 H3N2 Flu pandemic's economic cost in a cross-section of 52 countries. Using excess mortality rates as a proxy for the country-specific severity of the pandemic, we find that the average mortality rate (0.0062% per pandemic wave) was associated with declines in consumption (-1.9%), investment (-1.2%), output (-2.4%), and productivity (-1.9%). Our main findings highlight the role of both negative demand-side and supply-side shocks in the flu pandemic's aftermath. We also assess the impact of SARS on the 4 most-affected economies (Taiwan, China, Hong Kong, and Singapore).

THE WELLBEING IMPACT OF EXOGENOUS SHOCKS. NEW ZEALANDERS' REACTION TO COVID-19.

[Philip Morrison](#)¹, [Stephanié Rossouw](#)², [Talita Greyling](#)³

¹Victoria University of Wellington, New Zealand. ²AUT, New Zealand. ³University of Johannesburg, South Africa

ABSTRACT

While several studies have explored the wellbeing consequences of crises, particularly economic recessions and natural disasters, investigations of countries wellbeing responses to epidemics remain relatively scarce. Several disciplines offer theoretical priors in the case of individuals but there is little in the way of theory or historical evidence that addresses the wellbeing response to epidemics at the level of the nation.

In this paper we explore the sensitivity of a national wellbeing index to the arrival and passage of COVID-19 in a small, physically separate economy in the South Pacific. The index is constructed from daily tweets originating within New Zealand which captured the daily mood of the country several weeks before the first domestic case of Covid-19 was recorded until several weeks after the number of cases had dropped to zero.

We find distinct reactions to the epidemic: a marked drop in national wellbeing generated by a descent in positive emotions which exceeded the fall in negative sentiment. We find the reduction in national wellbeing to be short-lived due in large part to the rapid and effective response by the New Zealand government whose actions saw the national mood return to 'normal' within a month.

Although our time series paper complements cross-sectional micro-level studies of the New Zealand experience, our average measures of wellbeing are unable to reveal the distributional consequences of the epidemic. We add this limitation to a number of challenges facing the growing literature employing tweets to monitor changes in national wellbeing.

THE DISTRIBUTIONAL IMPLICATIONS OF COVID-19 IN AOTEAROA NEW ZEALAND

[Daniel Exeter](#), [Janine Paynter](#), [Vili Nosa](#), [Matire Harwood](#), [Chris Bullen](#)

The University of Auckland, New Zealand

ABSTRACT

Aotearoa New Zealand has experienced the re-emergence of COVID-19 in the community, prompting an initial 3-day shift to Level 3 restrictions for Auckland and Level 2 for the rest of the country from 23:59 on Sunday 14 February 2021. At the time of writing the country returned to these alert levels at 06:00 on Sunday 28 February, for at least 7 days, continuing the goal of eliminating the Auckland's second COVID-19 cluster since the re-emergence of COVID-19 in August 2020.

While the New Zealand Government continues its drive to eliminate COVID-19, the economic and societal impacts of lockdown are becoming apparent. The new-found sense of community experienced during the March 2020 lockdown must continue to ensure vulnerable populations are not further marginalized.

In this paper, we explore the socio-spatial distributions of COVID-19 testing and cases in NZ. We also investigate the geography of those most impacted by the prioritization of the COVID19 vaccination rollout, in addition to healthcare during lockdown and the economic realities of a new life after lockdown.

REGIONAL PATTERNS OF WELLBEING THROUGH PANDEMIC LOCKDOWNS

[Arthur Grimes](#)

Victoria University of Wellington, New Zealand. Motu Research, New Zealand

ABSTRACT

Several papers have tracked wellbeing patterns through lockdowns across multiple countries since the onset of COVID-19. Findings have been diverse, reflecting different lockdown experiences and differing country and societal characteristics.

Much less work, however, has examined regional patterns of wellbeing through the pandemic. New Zealand's official statistical agency (Stats NZ) has collected a range of data on wellbeing before and through the pandemic which this paper utilises.

The paper provides a (largely descriptive) analysis of wellbeing developments across 12 regions of New Zealand which vary in their degree of rurality. It focuses on four wellbeing metrics: overall life satisfaction, self-rated health, self-rated financial situation, and loneliness. The analysis relies on both temporal variation in the wellbeing metrics and on variation according to lockdown experience. The first lockdown was shared equally across all regions, but subsequent lockdowns have affected northern regions (particularly the largest city, Auckland) more than elsewhere.

The New Zealand experience of virtual elimination of the virus in the community (through the first nationwide lockdown) is unusual internationally; hence the national-level findings may not be generalisable to many other countries. The unique regional perspective provided here does, however, add a rich extra perspective on how lockdowns may affect different places within a country.

THE SOLOW GROWTH MODEL AND TRADE: THE LATEST EMPIRICS FOR THE WORLD AND ASEAN ECONOMIES

[Yuri Mansury](#)¹, [Jingwen Li](#)²

¹Illinois Institute of Technology, USA. ²Cornell University, USA

ABSTRACT

We revisit the relationship at the nexus of innovation, savings, and living standards by estimating the productivity impact of accumulation in physical and human capital. Based on the latest Penn World Table (PWT version 9.1), we found that the augmented Solow growth model remains consistent with the international variation in both the level and growth of worker productivity. While the canonical Solow model still provides a reasonable approximation, the fit with the PWT data is weaker than in previous studies that make use of older and less comprehensive datasets. Furthermore, the evidence indicates that member countries of the Association of Southeast Asian Nations (ASEAN) as a group converge at about the same rate as the rest of the world. That is, holding accumulation in physical and human capital constant, ASEAN countries grow at the rate predicted by the augmented Solow growth model. We then examine the implications of regional trading arrangements for convergence in standards of living using data assembled from the United Nations Conference on Trade and Development (UNCTAD) and the World Integrated Trade Solutions (WITS). To control for the presence of spatial effects, we adopt a spatial econometric modeling approach that incorporates both spatial lag and spatial error components. Preliminary results from spatial panel data analyses suggest that ASEAN countries tends to benefit from trading with the less developed neighbors while experiencing slower GDP growth as a result of trading with developed neighbors. Our study thus challenges the conventional wisdom touting trade with developed economies as the path to faster growth through innovation and knowledge spillovers. Furthermore, trade agreements with developed economies could actually lead to a slower growth path than a strategy that focuses on strengthening trade links with emerging, neighboring economies.

COORDINATED DEVELOPMENT OF INDUSTRIAL STRUCTURE AND EMPLOYMENT STRUCTURE: EVIDENCE FROM QINGHAI PROVINCE, CHINA

Ma Xiao

China University of Geosciences, China

ABSTRACT

Under the background of the digital age, how to study the coordination of industrial structure and employment structure is an important driving force to solve the problem of regional development, promote regional coordinated development and achieve sustainable development. This study selects the relevant data of industrial structure and employment structure in Qinghai Province from 1990 to 2019 as the research object, and makes a systematic analysis on the coordination of industrial structure and employment structure in Qinghai Province. Based on the Aitchison geometry and logarithmic ratio transformation of component data theory, this paper improves the existing coordination coefficient index to measure the coordination relationship between industrial structure and employment structure, puts forward the improved coordination coefficient index, and verifies the rationality of the coordination coefficient through the empirical analysis of Qinghai Province. In addition, in order to further measure the coordination degree of industrial structure and employment structure in Qinghai Province, this study takes the Moore structure value as the basic data. The method of grey relational analysis is used to calculate the lag time of employment structure. The research shows that: (1) compared with the existing coordination coefficient, the improved coordination coefficient has the advantages of theoretical and practical application. The improved coordination coefficient can measure whether the evolution direction of industrial structure and employment structure is the same or not, and can reasonably explain the change of the coordinated relationship between industrial structure and employment structure. (2) the evolution trend of industrial structure and employment structure in Qinghai Province is basically in line with the law of modern economic development. However, there is still a certain gap between the development of the ideal industrial structure and employment structure. (3) the economic development strategy has a long-lasting impact on the industrial structure and employment structure of Qinghai Province. The low quality of labor force and the low degree of labor marketization are formed in Qinghai under many factors, such as history, population, nationality, geomorphology and so on. In addition, the degree of opening to the outside world is not high, the pace of urbanization is slow, and the investment and consumption mainly depends on the transfer payment of the central government, which is also an important factor restricting the industrial structure and employment structure of Qinghai Province. It is also an important issue that we should think deeply about how to achieve regional coordinated development and sustainable development in the digital era.

REGIONAL DISPARITIES AND HETEROGENEOUS CONVERGENCE IN INDONESIA: A MULTISCALE GEOGRAPHICALLY WEIGHTED REGRESSION APPROACH

Carlos Mendez

Nagoya University, Japan

ABSTRACT

Large and persistent income disparities characterize the subnational regions of Indonesia. The study of regional income dynamics and convergence is important for both scholars and policymakers. Many scholars find the evolution of regional disparities in Indonesia particularly appealing due to its complex and rich geographical structure. Indonesia is the world's largest island country composed of more than seventeen thousand islands. It is also the world's fourth-most populous country with most of its population located on Java island. Indonesian policymakers are also greatly concerned with the evolution of spatial disparities. Aiming to foster regional development and inequality reduction, Indonesia has implemented large-scale decentralization reforms since the late 1990s. District-level governments now have larger political discretion and economic resources to design and implement development plans that respond to the local needs and interests of their constituents. After two decades of a decentralized government system, however, there are few studies that examine the evolution of regional disparities and convergence in Indonesia using recent methods from the spatial statistics and econometrics literature.

Motivated by this context, this paper employs a Multiscale Geographically Weighted Regression (MGWR) model to examine the spatial variation of regional income convergence across Indonesia. This new MGWR model provides a multiscale analysis of spatial heterogeneity. Given the large socioeconomic, demographic, and geographic differences across Indonesian islands, models based on spatial heterogeneity are likely to provide a more accurate and realistic assessment of a regional convergence process. Most previous studies have largely ignored the role of spatial heterogeneity. They usually report a common convergence speed for all subnational regions. In contrast, this paper departs from the assumption of a common convergence speed and aims to identify multiple spatial clusters that characterize the heterogeneity of the regional convergence process of Indonesia.

Regional studies about Indonesia are usually constrained by a modifiable areal unit problem (MAUP). Specifically, the number of districts, as well as provinces, have largely increased in the post-decentralization era. To handle this issue, most previous studies have used smaller samples based on the initial number of provinces and districts. In this paper, however, a larger sample is used based on a novel dataset that is constructed for the current number of provinces and districts. This sample covers 514 districts over the 2010-2018 period.

Preliminary results indicate that spatial heterogeneity plays a significant role in the process of regional convergence in Indonesia. Specifically, there are location-specific convergence speeds. The MGWR model also identifies significant spatial non-stationarity in both the speed of regional convergence and the determinants of regional growth. The marginal effects and spatial scale of the growth determinants clearly indicate an east-west divide in the evolution of regional disparities. Taken together, these results indicate a multi-speed convergence process that has a marked spatial distribution. These results also highlight the need to re-evaluate policies of spatial cohesion and territorial development in Indonesia.

**REGIONAL PUBLIC INFRASTRUCTURES AND DEVELOPMENT ON
DECENTRALIZED INDONESIA**

Benedictus Raksaka Mahi¹, Budy P. Resosudarmo²

¹Faculty of Economics and Business, University of Indonesia, Indonesia. ²Arndt-Corden Department of Economics, Australian National University, Australia

ABSTRACT

Empirical evidence on how different types of regional investment in public capital plays a role in influencing economic and social development within the context of a decentralized government system in developing country been relatively limited. Using a case study of Indonesia, this paper aims to analyse the impacts of regional infrastructures development for different types of government regional infrastructure spending, which are: (1) district/city governments' infrastructure spending, (2) provincial governments' infrastructure spending, (3) the national government's deconcentrated budget on infrastructure to district/city governments and (4) the national government's deconcentrated budget on infrastructure to provincial governments on district/city's economic and social development. Such disaggregation is a unique feature of this paper. The main conclusion obtained is that, compared to district/city governments, provincial governments seem to be better at allocating their infrastructure spending and utilizing national government infrastructure spending deconcentrated to them to induce regional economic and social development in their regions.

CAN CARBON EMISSION TRADING MARKET INTEGRATION RESHAPE ECONOMIC GEOGRAPHY OF CHINA?

Ling Xue, Xiaolin Zhang, Tianjiao Zhang

Peking University, China

ABSTRACT

The emergence of emission trading system is expected to improve low carbon development, but its design and effect on economic agents should be analyzed carefully by policy makers. As carbon trading in China is about to commence, the effect of carbon market integration on China's industrial relocation and economic geography calls for theoretical research. Combining "new" new economic geography (NNEG) and agent-based Modeling (ABM), this paper incorporated production and location decision-making of heterogeneous companies, as well as carbon emission trading, into a dual-region economic geography model on a computational platform based on agent. The paper set different policy scenarios to discuss the dynamic effects of carbon quota constraint, carbon trading and carbon quota allocation on location decision-making, efficiency, regional development equality and trading vitality in the context of carbon market integration. Results showed: 1) without carbon emission trading or carbon quota allocation favoring the western China, carbon emission reduction policy (carbon quota) doesn't necessarily alter firm location choices, but may increase efficiency of firms through competition; 2) without carbon emission trading, carbon quota allocation favoring the western China may influence firm location choices, bridging the gap between the western and the eastern, but the effect gets weaker when tighter carbon constraint; 3) with both carbon emission trading and carbon quota allocation favoring the western China, firms agglomerate in the eastern China, increasing social welfare with marginal costs decreased and firm number increased; 4) the allocation of carbon quota determines vitality of trading activity, and firm heterogeneity should be taken into account. These results contribute to literature in spatial economics, ABM and carbon market integration in China. The related methodological issue such as integrating spatial economic model with agent-based simulation as well as empirical analysis and econometric test is also discussed. The paper innovatively combines ABM and NNEG and may set a paradigm for future work in micro level ex ante research on the nexus between economic geography and carbon emission policies.

DEPICTING THE BLURRED REGIONAL BOUNDARIES IN CHINA USING INDIVIDUAL MOBILITY DATA

[Hongmou Zhang](#)¹, [Liu Liu](#)²

¹School of Government, Peking University, China. ²CitoryTech, China

ABSTRACT

Delineating the boundary or impact area of an economic, cultural, or life-style region has been a long-lasting problem in regional studies. The fundamental difficulty lies in the exact definition of a region, and what criteria need to be considered. Existing methods either use the strength of macro-level connections to evaluate the affiliation of a city to a region, e.g., the proportion of commuters in between, or use network science methods to “cluster” cities into regions. However, both types of methods only give static and definitive results but ignore the dynamism and graduality between regions—it could be debatable to include the so-called periphery cities to either side of the regional boundary. In this paper, we propose a Singular Value Decomposition (SVD)-based method to depict the impact areas of regions in China using individual-level connections among cities. Using the individual mobility data from a mobile map service, we decompose the mobility patterns of China into a series of eigen-mobility patterns—each corresponds to the impact area of a city, or a mobility-based region. The overlay of multiple eigen-mobility patterns depicts the “blurred” boundary between the respective regions—or their competing hinterlands. With the blurred mobility region boundaries as an example, we hope the method could be used to help understand the complexity of drawing regional boundaries and help policy makers to identify the non-confined but blurred economic and cultural landscape of various contexts in regional governance.

RESEARCH ON THE ASSESSMENT OF CITIES' ADAPTATION TO CLIMATE CHANGE AND ITS RELATIONSHIP WITH URBANIZATION IN CHINA

Xiaodong Pei^{1,2}, Jing Wu^{1,2}, Junbo Xue^{1,2}, Jincai Zhao³, Changxin Liu^{1,2}, Yuan Tian¹

¹ Institutes of Science and Development, Chinese Academy of Sciences, Beijing 100190, China, wujing@casisd.cn; ² School of Public Policy and Management, University of Chinese Academy of Sciences, Beijing 100049, China; ³ School of Business, Henan Normal University, Xinxiang, Henan 453007, China

ABSTRACT

With the aggravation of climate change, extreme climate events occur frequently in urban areas, resulting in great loss of human life and property. Therefore it is urgent to enhance the cities' adaptation to climate change. Focusing on the impact of high temperature, low temperature, drought, and flood, multi-dimensional assessment systems covering natural, economic, social elements for cities' climate change adaptation are established. Based on the assessment systems, the studies of adaptation to climate change are conducted in 248 cities in China with using entropy weight method, coefficient of variation method, exploratory spatial data analysis. And with the help of geographically weighted regression (GWR), the relationships among the four types of urbanization and cities' adaptation to climate events are explored. The results showed: (1) High-administrative-level cities have stronger adaptation, lower vulnerability and higher readiness than ordinary-prefecture-level cities. (2) The differences of adaptation to the four types of climate events among cities within each of the seven regions in China present different spatial patterns. The gaps of adaptation among cities within Southern China and Southwestern China are very prominent. (3) Compared with Southern China, Northern China has a wider advantage in adapting to climate change and climate events, and the gap among different regions in adapting to low temperature is relatively small, while there is a significant adaptation gap in coping with high temperature. The key to improving balanced adaptation to climate change in all regions of China lies in narrowing the gap of adaptation to high temperature. (4) The adaptation to high temperature and flood are characteristic of high-in-north and low-in-south. Cities with high adaptation to low temperature mainly belong to high-administrative-level, forming a high-low agglomeration area centered on cities of this level, and cities with low adaptation to low temperature are mainly distributed in Southwestern China, Central China and Huaihe River Basin. Cities' adaptation to drought shows a significant trend of decreasing from southeast to northwest, with high adaptation cities mainly concentrated in Jiangsu, Zhejiang, Anhui and Pearl River Delta, while adaptation in Northwestern China is generally low and shows the characteristics of low-low agglomeration. (5) Under the four types of climate events, the global spatial correlations of cities' adaptation in China are positive, and the agglomeration characteristics of adaptation are mainly H-H and L-L agglomerations. (6) When analyzing the impacts of four types of urbanization on cities' adaptation to climate events, the fitting effects of GWR models are far better than those of OLS models. Population urbanization affects cities' adaptation to four types of climate events, economic urbanization on low temperature, drought and flood, industrial urbanization on drought, and land urbanization on flood. Population, economic and industrial urbanization have positive impacts on adaptation of most cities. Population urbanization can improve adaptation of all cities to high temperature, while land urbanization hinders adaptation of most cities to flood. Under the influence of social and economic development, the urbanization regression coefficients of different cities have significant spatial differences.

KEYWORDS

Adaptation; assessment system; climate change; GWR model; urbanization

1. INTRODUCTION

Since the Industrial Revolution, the amount of GHGs in the atmosphere has been rising, and the global climate is now changing at an unprecedented rate. According to the IPCC Fifth Assessment Report (IPCC 2013), the global average land and ocean surface temperature increased by 0.85°C from 1880 to 2012, and climate warming has caused glacial retreat, sea level rise, ocean acidification, imbalance of water resources distribution, and serious negative effects on natural ecosystems and biodiversity; meanwhile, with the increasing frequency, impact scope and damage degree of extreme weather events, people's lives and property have suffered heavy losses, and the sustainable development of the socio-economic system is also facing serious challenges. Cities, as the main gathering place for human activities, occupy just 2% of the Earth's land, but account for more than 60% of energy consumption and 75% of carbon emissions (Akbari et al., 2016). As regions with high risk of global climate change disasters, cities have also become the main battlefield of human response to climate change, which need to be paid more attention to.

In terms of coping with climate change, the formulation of countermeasures has changed from prevention and mitigation in the 1970s and mitigation in the 1980s to adaptation, which is widely accepted today (Chen, 2004). Adaptation, which

first originated in the field of ecology, is now widely used in climate research and has become one of the core concepts of global change science. In the field of climate change, different scholars have different conceptualizations or definitions of adaptation according to their own academic background or research objects (Smith et al., 1996; Roger et al., 1998; Doria et al., 2009; O'Brien et al., 2012), but all of them emphasize the adjustment of systems to reduce vulnerability and enhance coping capacity in the face of adverse climate change impacts. Research on adaptation to climate change is diverse, but mainly focuses on two aspects: **(1) Policy formulation and framework design.** Based on the evaluation of the effectiveness and benefit of the adaptation measures of related projects, UNDP has designed a comprehensive monitoring and evaluation framework for climate change adaptation, which is suitable for research at various scales (UNDP 2007); Brink et al. (2016) proposed an analytical framework of urban ecosystem adaptation based on the relationship among climate change adaptation, ecosystem services and sustainability theories; Kuang et al. (2018) proposed a decision-making assessment tool for climate change impacts by discussing the framework of adaptation assessment and management of international rivers under climate change; Aguiar et al. (2018) investigated 147 local adaptation policies in Europe, and found that the main obstacles that needed to be overcome to promote the formulation and implementation of climate adaptation plans are insufficient resources, lack of capacity, unreliable commitments and uncertain risks. **(2) Quantitative analysis of adaptation.** Araya-Munoz et al. (2016) constructed an indicators system from three aspects of awareness, capacity and action to evaluate the adaptation to climate change in the Concepcion metropolitan area in Chile and found that the adaptability of all cities had improved significantly from 1992 to 2002, but the relative differences among cities had not changed significantly; Zhao et al. (2020) combined the SPRR model and the IPCC assessment framework to establish an exposure-sensitivity-resilience indicators system and evaluated the adaptation capacity of 12 urban agglomerations in China by using set-pair analysis, and found that adaptation capacity level of different regions varied greatly, and the level of economic development played a key role; Bachner et al. (2019) proposed a general modeling framework to comprehensively analyze how public adaptation to climate change affects the federal budget, and found that it could have substantial positive macroeconomic effects on GDP, welfare and employment; R et al. (2020) conducted a cost-benefit analysis of the proposed climate change adaptation measures in Bosnia and Herzegovina, and explored their feasibility; Huang-Lachmann et al. (2018) conducted an empirical study on 63 cities through multi factor analysis and logistic regression model, which showed that the climate change adaptation plan had a positive impact on the economic opportunities of cities.

Under the background of human sustainable development, the close relationship between climate change and urbanization has been widely concerned. Many studies (Liddle 2013; Wang et al., 2016; Lu 2017; Nyangena et al., 2019; Zhou et al., 2021) have shown that, in the process of urbanization, the rising energy consumption and land use changes increase GHGs emissions, and then exacerbate climate change. There are also studies focusing on the relationship between urbanization and climate change vulnerability (Romero-Lankao and Dodman, 2011; Mutizwamangiza et al., 2011; Friend and Macclune, 2013; He et al., 2019). For example, the SREX report (Murray and Ebi, 2012) finds with high confidence that urbanization along with settlement patterns and changes in socio-economic conditions have all influenced observed trends in risk and vulnerability to climate extremes. Nowadays, the mainstream perspective in the literature tends to focus on urbanization as a driver of climate change and urban vulnerability, and few studies have explored the relationship between urbanization and climate change adaptation. In fact, urbanization is likely to have both positive and negative consequences for overall adaptive capacity of cities and regions (Agrawala et al., 2007). Applying the urban environment transitional model, researchers found that although wealthy cities in the Global North generate large amounts of GHGs emissions, urbanization and urban economic growth have made them rich enough to develop adaptive systems to counteract the adverse affects of climate change (Mcgranahan and Songsore, 1994; Jacobi et al., 2010). Urbanization can also offer opportunities for disaster risk management, which can be the main driving force to enhance the ability to cope with climate change (Garschagen and Romero-Lankao, 2015). In view of these facts, it is very necessary to further explore the relationship between urbanization and adaptation to climate change.

In general, there are still relatively few studies on the assessment of urban adaptation to climate change. The existing literature on climate system change and its indicators selection is relatively single and simple, with limited coverage. In addition, the mechanism of urbanization affecting climate change adaptation is not fully explored. As one of the most vulnerable countries to climate change and extreme events in the world, China has a large number of cities with different geographical conditions and climate backgrounds, and therefore these cities differ in types and occurrence probabilities of climate events they face. Meanwhile, since the implementation of the economic reform in late 1978, China has experienced rapid economic growth and urbanization (Wang 2014; Li and Lin, 2015), and there are great disparities in the urbanization process among China's cities, which make the mechanism and impact degree of urban adaptation to climate change different. Therefore, it is necessary to evaluate cities' adaptation to various specific climate events, and analyze the driving force of adaptation from the perspective of urbanization. Focusing on the four most common climate events including high temperature, low temperature, drought and flood in China, this paper constructs comprehensive assessment systems covering natural, economic and social factors to carry out the assessment of cities' adaptation to climate change, and discusses the spatial patterns of and impact factors (four urbanization types) on adaptation. The research results have certain guiding significance and reference value for the development of climate change adaptation assessment methods in cities and the formulation of adaptation policies tailored to local conditions.

2. DATA AND METHODS

2.1 Study area and data sources

In this study, we chose 248 cities in China as the research objects: 4 municipalities, 5 state-plan cities, 27 provincial capital cities and 212 ordinary prefecture-level cities. Cities in Hong Kong, Macau and Taiwan were excluded from this study due to the limitation of data availability. As shown in **Figure 1**, these cities are distributed in seven major regions of China, with the total population and GDP accounting for 83.30% and 92.92% of the whole country respectively. And they have differences in social, economic, cultural and climate conditions with the average population ranging from 0.25 to 30.75 million. Therefore, the exploration results of these cities can basically represent the overall pattern of the whole country.

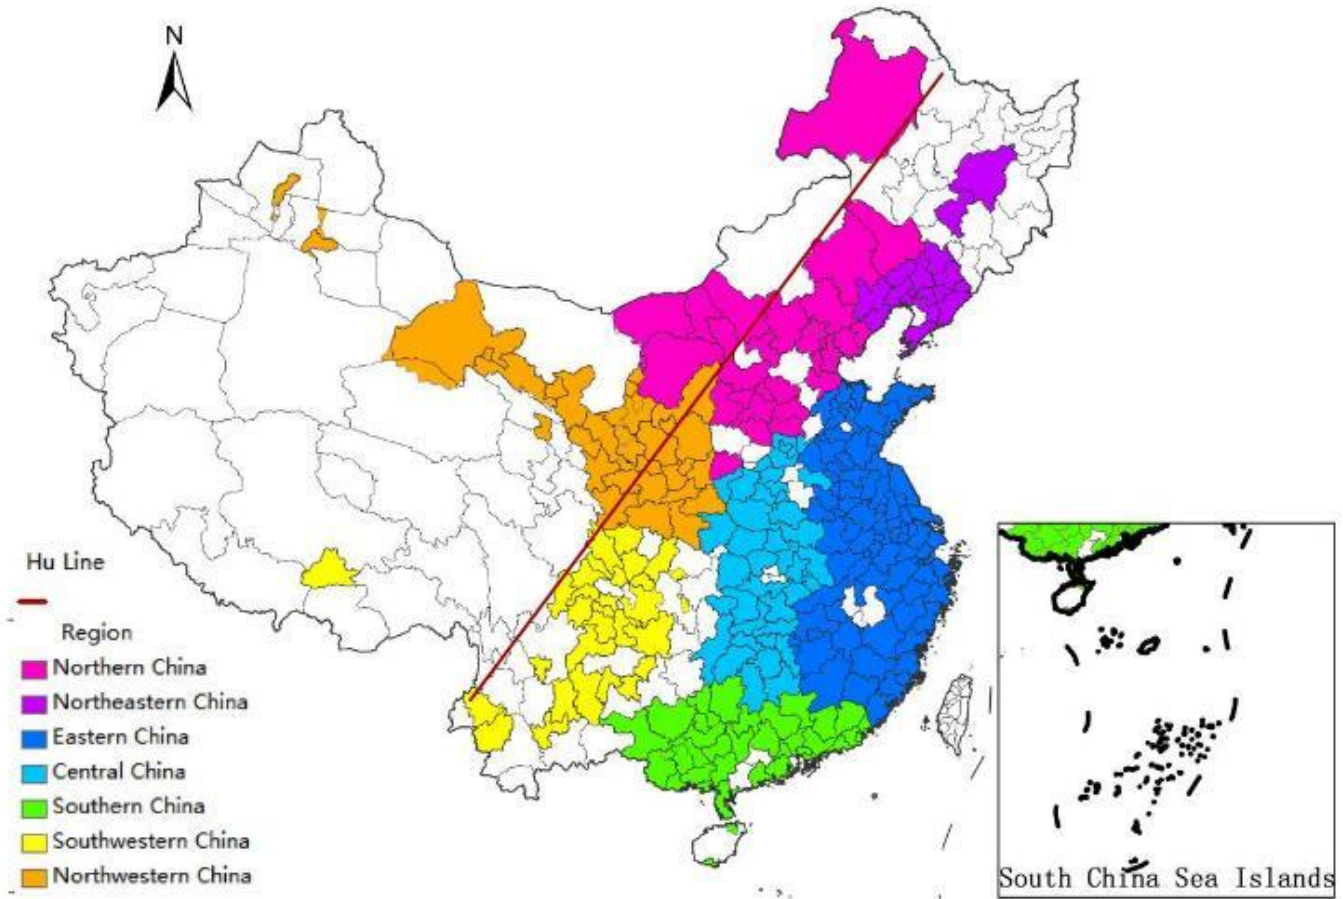

Figure 1 Regional distributions of 248 Chinese cities

The population, economic and social data (infrastructures, patents, etc.) involved in this study were mainly obtained from the Sixth Population Census of various cities, China City Statistical Yearbook 2018, China Real Estate Information and Everbright Securities Research Report; the meteorological data were derived from China Meteorological Data Service Centre, which was obtained by spatial interpolation of meteorological station observation data. For some missing parts of the data, statistical methods such as data fitting and forecasting were used or searching through the Internet to supplement them. For details, see **Appendix Table 1**.

2.2 The framework

The purpose of this study is to conduct a comprehensive assessment of cities’ adaptation to climate change, find out the differences of adaptation in different cities and regions, and explore the impacts of urbanization on adaptation. Based on the previous literature research, combined with the actual situation in China, this paper constructs indicators systems, collects and standardizes the data required for each dimension, determines the weight of each indicator by entropy weight method, calculates the values of cities’ adaptation to climate change by weighted comprehensive evaluation method, classifies the cities and analyzes the spatial distribution features of adaptation based on spatial econometric approaches, and finally explores the role of urbanization in cities’ adaptation to climate change by GWR model. Based on the research ideas depicted in **Figure 2**, the main research methods of each step are introduced below.

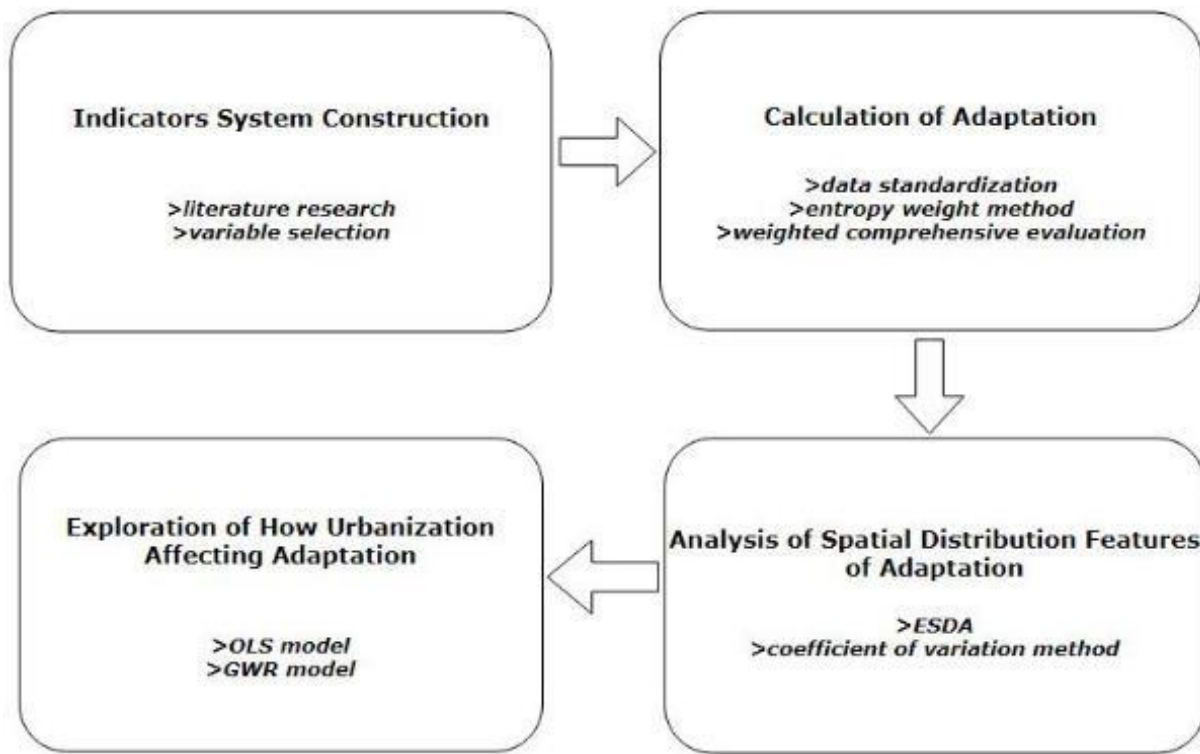

Figure 2 Research ideas and technical routes

2.3 The assessment indicators system

Referring to the climate adaptation assessment framework (ND-GAIN 2018; Chen et al., 2015a) established by the Notre Dame Global Adaptation Initiative (ND-GAIN) and considering the actual situation in China and the availability of data, three-level structural assessment indicators systems for cities' adaptation to high temperature, low temperature, drought and flood were constructed in this paper. ND-GAIN climate adaptation assessment indicators system consists of two dimensions: vulnerability assessment and readiness assessment. Compared with IPCC's indicators system (IPCC 2014), ND-GAIN adds readiness assessment, which can make the system more comprehensively reflect cities' adaptation characteristics, and the framework is now widely used in adaptation studies (Nagy et al., 2018; Aydin et al., 2021; Tan and Ho, 2020).

Vulnerability reflects the sensitive reaction and self-recovery ability of the research object to the disturbance of climate events in a specific space-time environment, which is composed by exposure, sensitivity and adaptive capacity; readiness, which is composed of social readiness, governance readiness and economic readiness, reflects the defense characteristics of the research object to the disturbance of climate events in a complex society-economy system and the capacity of to mobilize adaptation investments from private sectors, and to target investments more effectively. The adaptation indicators under different climate events are different to reflect the impact characteristics of each event, as shown in Appendix Figure 1.

2.4 Entropy weight method

The key step of assessing cities' adaptation to climate change is to determine the weight of indicators. As an objective assignment method, the entropy weight method is more scientific and reliable than subjective methods, which determines the weight of each indicator according to the difference of data disorder degree. If the indicator information entropy is smaller, it means that the indicator has higher disorder degree and greater range of change, so it has a greater impact on the comprehensive assessment. See (Liu et al., 2021) for the specific calculation formula.

After calculating the weight w_j of each indicator using entropy weight method, the adaptation assessment model is constructed based on weighted comprehensive evaluation method commonly used in multiple indicators assessment, and the degree of adaptation is expressed by the adaptation score. The specific assessment model is:

$$Ai = \sum_j^n w_j Y_{ij} \tag{6}$$

where Ai is the adaptation score of city i . The calculation methods of vulnerability VI and readiness RI are the same as that of adaptation, but the indicators sets are different.

2.5 Coefficient of variation method

Coefficient of variation can objectively reflect the degree of difference within a set of data, and avoid the deviation effect of absolute difference. Compared with range, variance, standard deviation and other statistical indicators, it has the advantage of more accurately reflecting the degree of data dispersion. From the regional perspective, this paper will use the coefficient of variation to explore the unbalanced state of the internal adaptation differences in each region. The calculation formula is:

$$CVi = \frac{1}{\bar{x}_i} \sqrt{\frac{1}{n-1} \sum_{j=1}^n (x_{ij} - \bar{x}_i)^2} \tag{7}$$

where CVi is the coefficient of variation of region i ; n_i is the number of research units in region i ; x_{ij} is the adaptation value of the j research unit in region i ; \bar{x}_i is the average value of all research units in region i .

2.6 Exploratory spatial data analysis

Exploratory spatial data analysis (ESDA) is the collection of a series of spatial data analysis methods and techniques, with the measurement of spatial association as the core, through description and visualization of the spatial distribution pattern of things or phenomena, to discover spatial agglomeration and anomalies, so as to reveal the mechanism of spatial interactions among research objects. The common methods are Moran I index and Moran scatter plot.

Moran I index ranges from -1 to 1 . A value greater than 0 indicates spatial positive correlation and the larger the value is, the stronger the spatial aggregation will be. By contrast, a value less than 0 is a spatial negative correlation and the smaller the value is, the stronger the spatial difference will be. A value equal to 0 is irrelevant, that is, the spatial units are randomly distributed. See (Moran and Ap, 1950) for the specific calculation. Moran scatter plot can further explore the differences in adaptation to climate change among cities from a spatial perspective, which is divided into four quadrants corresponding to four types of local spatial association between a city and its cities: H-H (Quadrant I in the upper right) indicates a city with a high value surrounded by cities with high values; L-H (Quadrant II in the upper left) indicates a city with a low value surrounded by cities with high values; L-L (Quadrant III in the lower left) indicates a city with a low value surrounded by cities with low values; H-L (Quadrant IV in the lower right) indicates a city with a high value surrounded by cities with low values. H-H and L-L (resp. LH and HL) refer to positive (resp. negative) spatial autocorrelation, which indicate spatial clustering of similar (resp. dissimilar) values.

2.7 Geographically weighted regression model

In contemporary research, regression analysis is often used to explain the influencing factors. Geographically weighted regression model (GWR) is an extended local regression model based on the classical multiple linear regression model (OLS), which considers the spatial characteristics of observation indicators, and can explore the non-stationarity of spatial relations according to the change of parameter estimation values with geographical location, and explore the spatial differentiation characteristics of the influence of various factors on explanatory variables in the study area. By using this method, the results are more realistic and accurate. The model can be shown as:

$$y_i = \beta_0(u_i, v_i) + \sum_k \beta_k(u_i, v_i) x_{ik} + \varepsilon_i \tag{8}$$

where y_i are the dependent variables; x_{ik} are the independent variables; (u_i, v_i) is the geographic coordinate of sample spatial unit i ; $\beta_0(u_i, v_i)$ are the intercept terms; $\beta_k(u_i, v_i)$ are the regression coefficients; k is the number of independent variables; ε_i are the error terms.

3 SPATIAL PATTERN ANALYSIS OF ADAPTATION

3.1 Perspective of cities administrative level

Based on the calculation results of adaptation to climate change of 248 cities, it is found that the average adaptation scores of each type of climate events in high-administrative-level (HAL) cities (municipalities, state-plan cities, provincial capital cities) are higher than those of ordinary-prefecture-level (OPL) cities, and the average vulnerability scores are lower and the average readiness scores are higher, as shown in **Table 1**. In fact, high-administrative-level cities are more advantageous in adapting to climate change because of their advanced economic development level, superior social security system and mature governance institution. Besides, when setting up high-administrative-level cities, China fully takes into account the climatic conditions, resource endowments and location conditions of the candidate cities, and the cities with lower risk of being affected by disasters are more likely to be selected. In addition to the ability to attract large amounts of investment and financing in the field of climate, these cities are more likely to be favored by national policies and financial support.

Table 1 AI, VI and RI scores of HAL cities and OPL cities

Climate events	AI		VI		RI	
	HAL cities	OPL cities	HAL cities	OPL cities	HAL cities	OPL cities
High Temperature	0.6015	0.5009	0.4008	0.3522	0.2007	0.1488
Low Temperature	0.6141	0.5254	0.4131	0.3766	0.2010	0.1488
Drought	0.5829	0.4825	0.3294	0.2950	0.2535	0.1876
Flood	0.5558	0.4847	0.3753	0.3508	0.1805	0.1339

Note: The greater VI indicates the lower vulnerability.

3.2 Perspective of regions

According to the coefficient of variation formula, the degree of difference of adaptation to climate change within each of the seven major regions of China was calculated, as shown in **sub-figures (a)-(d) of Figure 3**. As can be seen from the figure, the high temperature (low temperature) adaptation gap between cities shows an overall decreasing spatial pattern from south to north. The coefficients of variation for high and low temperature adaptation in Southern China are the largest, reaching 0.142517 and 0.115093 , respectively, indicating that there is a large difference in high temperature

(low temperature) adaptation among cities within the region, and the adaptation ability is extremely uneven. Comparatively speaking, the internal differences in Northeastern China are the smallest, showing a good and balanced adaptation ability. The overall spatial pattern of drought adaptation gap among cities decreases from west to east, with the largest coefficient of variation in Southwestern China and the smallest in Eastern China, but the differences in coefficients of variation among regions are not significant, indicating that the adaptation gap among cities within each of the regions shows a similar pattern. And the coefficient of variation of adaptation to flood is still the largest in Southwestern China and the smallest in Northeastern China. Comparing the four sub-figures, Southern China and Southwestern China need to be focused on: cities within the former face uneven adaptation to high temperature, low temperature, and flood, and cities within the latter face uneven adaptation to high temperature, drought, and flood, indicating that the adaptation gaps of cities within each of the two regions are very significant. The high-adaptation cities should provide technology, experience and knowledge of adaptation to low-adaptation cities. Meanwhile, higher-level administrative units should strengthen financial and policy support to cities with low adaptation to enhance their readiness.

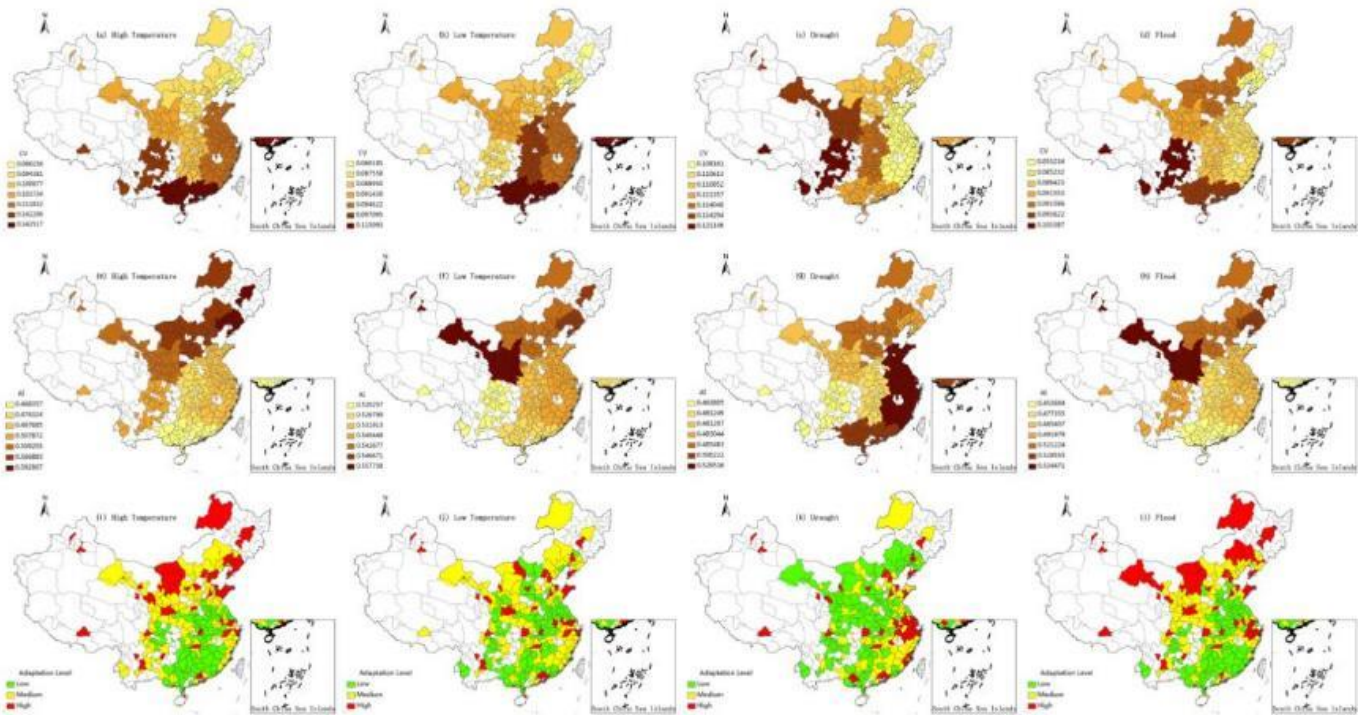

Figure 3 Spatial pattern of adaptation from the regions and cities perspectives

The coefficient of variation only reflects the gaps among cities within each of the regions. Besides, the adaptation gaps among regions are also worth exploring. The average adaptation scores of cities covered by each region are used to represent the regional score, as shown in **sub-figures (e)-(h) of Figure 3**. It can be found that the scores of adaptation to high temperature, low temperature and flood in Northern China, Northeastern China and Northwestern China are always ranked in the top three of the seven regions, and the scores of adaptation to low temperature and flood in Northwestern China are the highest, and the top two regions of adapting to drought are Eastern China and Southern China; the scores of adaptation to high temperature and flood are the lowest in Southern China, and the scores of adaptation to low temperature and drought are the lowest in Southwestern China. To some extent, it suggests that the north has a broader advantage in adapting to climate change and climate events compared to the southern regions of China. Meanwhile, the scores range of adaptation to climate events in seven major regions are: high temperature 0.1245, low temperature 0.0375, drought 0.0657, and flood 0.0808. The range of adaptation to high temperature is 3.32 times of that of low temperature, which indicates that there is a small gap in adaptation to low temperature among regions, but there is a significant gap in high temperature. The key to promoting balanced adaptation to climate change in all regions of China lies in narrowing the gap of adaptation to high temperature.

3.3 Spatial distribution pattern at cities level

Adaptation analysis from the regional perspective only reflects the macro spatial distribution pattern. In order to more accurately explore the characteristics of cities' adaptation and carry out climate policies based on cities' conditions, it is very necessary to conduct analysis and discussion at the cities level, as shown in **sub-figures (i)-(l) of Figure 3**.

High temperature. The overall pattern can be described high in the north and low in the south. High-level cities are mainly concentrated in the three northeastern provinces (Heilongjiang, Jilin, and Liaoning), Inner Mongolia, Shandong and Beijing-Tianjin-Hebei region. Medium-level cities are mainly distributed in Eastern China, Southwestern China and the vast areas north of Huaihe River-Qinling Mountain Line. In addition, some cities in southern Shaanxi near Huaihe River-Qinling Mountain Line and some in Hunan and Hubei are also in this level. Low-level cities are mainly located in

Guangdong, Guangxi, Sichuan, Chongqing, Henan and Eastern China region. In addition, it can be observed from the figure that the vast majority of coastal cities are in medium and high level of adaptation.

Low temperature. Most of high-level cities are high-administrative-level, which are widely distributed, but scattered in spots. Both medium-level and low-level cities form a relatively obvious agglomeration. The former mainly located in Eastern China, Northwestern China, the three northeastern provinces and Inner Mongolia, which is due to the improvement of adaptation ability to low temperature by heating in winter in these areas. Relatively speaking, cities located in Southwestern China, Huaihe River Basin and Central China are less adaptable.

Drought. Cities' adaptation shows an obvious decreasing trend from southeast to northwest, forming a significant agglomeration characteristics. Jiangsu-Zhejiang-Anhui region and Pearl River Delta region present two high-level clusters. In addition, Fuzhou, Quanzhou and Xiamen in Fujian province are also cities of high-level adaptation to drought. And the medium-level cities are mainly concentrated in the southeast coastal areas and Pearl River Basin. The majority of cities located in China's Second Ladder show low adaptation characteristics to drought, especially the Northwestern China has the significant agglomeration characteristics.

Flood. The spatial clustering characteristics of adaptation to flood are also very prominent, especially in Pearl River Basin, Huaihe River Basin, Hunan and Jiangxi, where the large hydrographic networks, copious rainfall and low-lying flat terrain make them face greater risks. From south to north, the adaptation gradually increases, and the cities with high adaptation ability are mainly distributed in Inner Mongolia, the three northeast provinces and the northwest area of Gansu province.

Besides, as shown in **Table 2**, there are 50 cities with low adaptation under the four types of climate events, which indicates that these cities are facing greater climate risks, and it is urgent to carry out research and development, integration and promotion of adaptation technology, so as to effectively improve their adaptation level. These cities account for 20.16% of the study sample, covering a population of 230.901 million, mainly distributed in the southern region of China. Hunan, Hubei, Anhui, Henan, Guangdong, Sichuan and Guangxi contain a large number of the above-mentioned cities, affecting more than 20 million people respectively, which should be paid more attention to. To advance the construction of adaptation ability to a higher level, it is extremely necessary to coordinate the work of adaptation to climate change, strengthen communication and exchanges, deepen cooperation actively among cities.

Table 2 List of cities with low adaptation under four types of climate events

Provinces	Cities	Total population(million)
Jiangsu	Yancheng	7.2422
Shandong	Heze	8.7360
Jiangxi	Pingxiang, Ji'an	6.8669
Hunan	Hengyang, Shaoyang, Yongzhou, Loudi	23.9780
Hubei	Ezhou, Xiaogan, Jingzhou, Huanggang, Xianning, Suizhou	22.7202
Anhui	Huainan, Huaibei, Anqing, Chuzhou, Fuyang, Suzhou, Bozhou	33.3530
Henan	Pingdingshan, Puyang, Luohe, Nanyang, Shangqiu, Xinyang, Zhumadian	42.0900
Guangdong	Shaoguan, Shantou, Zhanjiang, Meizhou, Shanwei, Chaozhou, Jieyang	32.0568
Sichuan	Zigong, Luzhou, Suining, Neijiang, Nanchong, Guang'an, Dazhou	29.5659
Guangxi	Fangchenggang, Qinzhou, Guigang, Yulin, Hezhou, Hechi, Laibin, Chongzuo	24.2920

3.4 Spatial correlation features

By using GeoDA software, the values of Moran I index of cities' adaptation to four types of climate events were calculated , as shown in **Figure 4**. It can be seen from the figure that the values are all greater than 0, respectively: high temperature 0.503, low temperature 0.219, drought 0.351 and flood 0.425, all of which are positively correlated in space. In order to enhance the robustness of the results, the Moran I values were tested by Monte Carlo simulation, and the P values are all significant at 0.01 level, indicating that the spatial agglomerations of adaptation are significant. That's to say, cities with higher adaptation to climate change have a positive impact on the improvement of adaptation of neighboring cities, and vice versa. Meanwhile, according to Moran I values, it can be found that there are differences in the agglomeration characteristics of cities' adaptation to the four types of climate events. For high temperature, the spatial positive correlation is the most significant and the degree of spatial agglomeration is the highest, followed by flood, and the positive correlation of low temperature is the weakest. The cities' adaptation to climate change in China shows four spatial patterns of H-H, L-H, L-L and H-L, and the distribution quadrants of these cities are also shown in the figure. In general, these cities are mainly distributed in the first and third quadrants under all four types of climate events, indicating that the agglomeration characteristics of adaptation are mainly H-H and L-L agglomerations, which further validates the conclusion that the global spatial correlations are positive. In addition, it can be found that most of the cities in Yangtze River Delta region are located in the first quadrant (H-H). The geographical location of this region is superior, the degree of economic integration is very high, and the development of cities in the region is fully coordinated and integrated. Therefore, the cities in the fourth quadrant (H-L) have strong adaptation to climate change, and the adaptation gap is small. And most of the cities in the fourth quadrant (H-L) are high-administrative-level cities, which indicates that these cities have stronger social, economic and governance capabilities than surrounding cities, and have more significant advantages in coping with climate events.

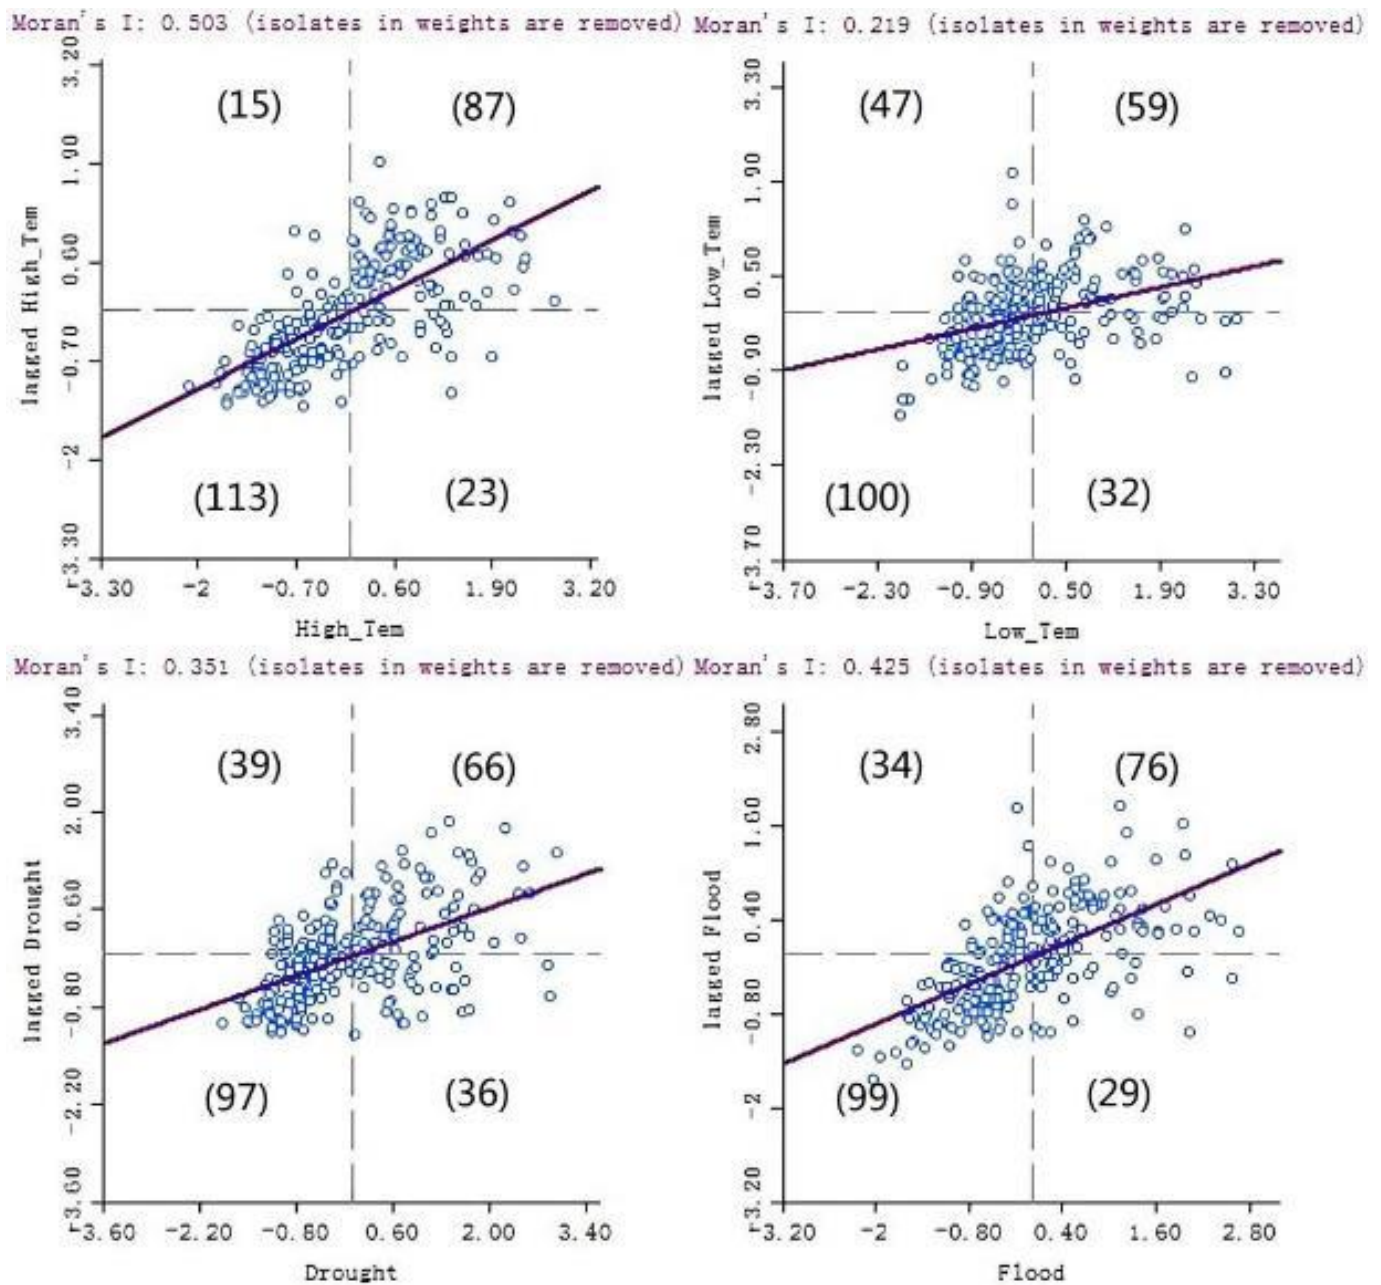

Figure 4 Spatial correlation features of adaptation

Note: 10 cities were removed due to the non-existence of adjacent samples, but this does not affect the reliability of the conclusions.

The above analysis shows that it is meaningful to explore the characteristics of adaptation differences and the underlying reasons from the spatial perspective, and it also paves the way for later analysis of the impact factors on cities' adaptation to climate change in China by using spatial econometric methods to construct models.

4. ANALYSIS ON HOW URBANIZATION AFFECTING ADAPTATION

4.1 Variables selection

Based on the interpretation and summary of the connotation of urbanization by existing literatures (Shi et al., 2013; Zhu et al., 2017; Zhu et al., 2019; Chen et al., 2015b) and considering the availability and scientificity of data, this paper selects independent variables from four aspects of population urbanization (PU), economic urbanization (EU), land urbanization (LU) and industrial urbanization (IU) to explore the impact factors on spatial differentiation of cities' adaptation to climate change in China, which are expressed by the four indicators: the proportion of urban residents, per capita disposable income of urban residents, the ratio of urban built up area to total city area, and the proportion of secondary and tertiary industries, respectively.

One of the prerequisites for multiple regression is that there is no multicollinearity among independent variables. In the regression analysis, after standardizing the four indicators, the variance inflation factor (VIF) method was used to diagnose the existence of multicollinearity. The regression results in **Table 3** show that the VIF values of all indicators are less than 3 indicating that there is no multicollinearity or very weak covariance among independent variables (Zuur et al., 2010), which meets the basic requirements of regression analysis.

Table 3 Multicollinearity test of influencing factors on adaptation

Impact factors	Selected variables	Collinearity statistics	
		Tolerance	VIF
population urbanization (PU)	the proportion of urban residents	0.345	2.896
economic urbanization (EU)	per capita disposable income of urban residents	0.462	2.164
land urbanization (LU)	the ratio of urban built up area to total city area	0.648	1.544
industrial urbanization (IU)	the proportion of secondary and tertiary industries	0.436	2.292

4.2 Analysis of regression results

With adaptation scores of all cities under four types of climate events as dependent variables and four indicators as independent variables, the OLS stepwise regression analysis was conducted. The regression results show that at the 1% significance level, only the proportion of urban residents is included in high temperature OLS model; the proportion of urban residents and per capita disposable income of urban residents are included in low temperature OLS model; the proportion of urban residents, per capita disposable income of urban residents and the proportion of secondary and tertiary industries are included in drought OLS model; the proportion of urban residents, per capita disposable income of urban residents and the ratio of urban built up area to total city area are included in flood OLS model. In the above OLS models, all included independent variables have positive coefficients except for the ratio of urban built up area to total city area, indicating that all the three variables contribute positively to cities' adaptation to climate events.

However, from the previous spatial autocorrelation analysis, it can be seen that the spatial distribution pattern of adaptation is not completely random, but shows significant characteristics of spatial agglomeration and heterogeneity, which shows that cities' adaptation no longer meets the assumption that samples must be independent of each other required by OLS model. In other words, the results and inferences estimated by the classical linear regression model are likely to be less reliable, and it must be modified by introducing spatial factors (spatial differences and dependencies). Therefore, on the basis of OLS model, the component (coordinates) reflecting heterogeneity were included, and the GWR models were used for regression analysis. The results of OLS and GWR models were compared in **Table 4**, and the regression parameters of GWR model were statistically described in **Table 5**

It can be seen from **Table 4** that adjusted goodness-of-fit indexes (R_{adj}^2) of GWR models for four types of climate events are 0.744, 0.695, 0.680 and 0.733 respectively, which are greater than the values of corresponding OLS models. Meanwhile, the RSS values of GWR models are far less than those of OLS models, indicating that the fitting effects of GWR models are better than OLS models, with small error and better interpretation effect. Also, the AICcs of GWR models are smaller, and the differences with OLS models are much greater than 3, which further shows that GWR models have better performance (Cuevas et al., 2013).

Table 4 Comparison of statistics between OLS and GWR models

Climate events	Model	AICc	R ²	R _{adj} ²	RSS
High Temperature	OLS	-724.861585	0.354301	0.349030	0.761955
	GWR	-932.710281	0.784834	0.743669	0.253906
Low Temperature	OLS	-959.812847	0.549487	0.543948	0.293000
	GWR	-1030.611852	0.751280	0.694895	0.161760
Drought	OLS	-910.294683	0.597264	0.590635	0.037822
	GWR	-949.188338	0.730269	0.679576	0.237600
Flood	OLS	-886.657301	0.375056	0.364769	0.390237
	GWR	-1056.719260	0.798689	0.733256	0.125705

Table 5 shows the quintile statistics results. The mean values reflect the average level of contribution of the impact factors to cities' adaptation to climate change, and it can be seen that all factors, except for the land urbanization factor, contribute positively to adaptation in general, which is consistent with the analysis results of the OLS models. Meanwhile, it can be found that there are significant directional heterogeneities in the maximum and minimum values of the regression coefficients of some impact factors, which also indicates that the regression coefficients are non-stationary according to the geographical locations of cities, that is, there are significant spatial differences in the degree and direction of the role of different impact factors on cities' adaptation to climate change.

Table 5 The estimation results of GWR models

Climate event	Urbanization	Upper quartile	Median	Lower quartile	Max	Min	Mean
High Temperature	PU	0.003969	0.003603	0.00285	0.006340	0.001620	0.003490
Low Temperature	PU	0.002654	0.001833	0.001136	0.004500	-0.000300	0.001883
	EU	0.042054	0.029774	0.016489	0.077246	-0.030578	0.027998
Drought	PU	0.002260	0.001134	0.000362	0.003704	-0.001385	0.001303
	EU	0.039992	0.029926	0.013831	0.061970	-0.010707	0.026198
	IU	0.002715	0.001678	0.000829	0.005290	-0.001081	0.001824
Flood	PU	0.002978	0.001999	0.000715	0.005129	-0.001514	0.001923
	EU	0.033977	0.022143	0.011767	0.067194	-0.036343	0.022239
	LU	-0.067807	-0.565335	-0.291919	1.110860	-1.957615	-0.281499

The positive and negative distributions of the regression coefficients of the four types of urbanization are statistically presented in **Figure 5**. It can be seen that PU, EU and IU have positive impacts on adaptation to climate events in most cities, where PU plays a positive role in enhancing adaptation to high temperature in all cities, while land urbanization has a negative impact, i.e., a hindering effect, on adaptation to flood in most cities.

Figure 5 Positive and negative statistics of the regression coefficients

However, simple statistical analysis cannot reflect the specific differences among cities. In order to more intuitively analyze the spatial variations of the impact factors on cities' adaptation to climate change in China, ArcGIS was used to draw the spatial distribution maps (**Figure 6**) of the regression coefficients of each variable in the GWR models.

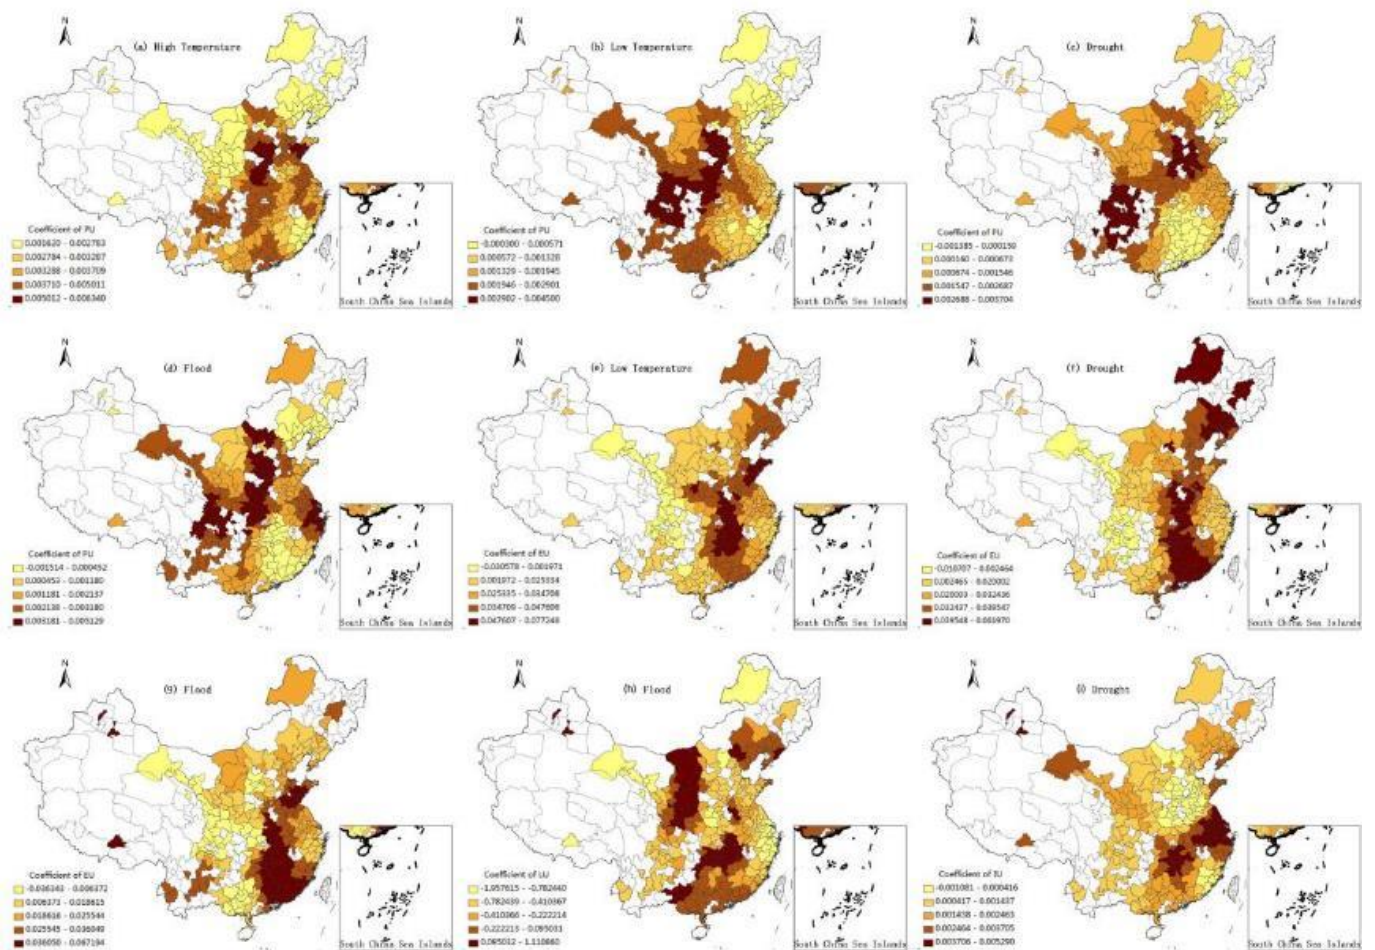

Figure 6 Regression coefficients of urbanization

(1) **Population urbanization.** In the four sub-figures (a)-(d) of Figure 6, the regression coefficients of PU are decreasing from southwest to northeast. The Central Plains region connecting the two directions is always at a high value, while the economically developed Pearl River Delta region is always at a low-medium value. It is not difficult to find that Northeastern China takes the lead in industrialization and has an early and high starting point in urbanization development, and as the vanguard of China's reform and opening up, the Pearl River Delta region has a high level of economic integration and complete infrastructure, both of which are highly attractive to the population. Therefore, their urbanization rates of permanent resident population rank among the top in China. While Southwestern China and Central Plains are both underdeveloped areas, and the urbanization rates still lags behind the national average level, but currently in the stage of rapid development. Population over-urbanization is characterized by massive population inflow or natural population growth that outpaces the development of urban infrastructure, systems, and services, making city governance will become more difficult, thereby increasing vulnerability or decreasing readiness to climate change. The floating population in the Pearl River Delta is mainly educated at the junior high school level, and most of them are engaged in labor-intensive industries and business services industries, rather than scientific and technological industries, which does not help to improve adaptation level from the technical aspect. Meanwhile, a large number of urban villages pose challenges to land use, urban landscape, planning and management, and community security. Nowadays, the overall economy of Northeastern China is in recession, and the mismatch between economic development level and urbanization level makes climate change may bring greater risks and challenges (Sudmeier-Rieux et al., 2015). Due to the existence of Marginal Diminishing Effect, PU has weak and even negative effects on the adaptation of the two regions, while it has positive effects on Southwestern China and Central Plains. Besides, it is worth noting that PU has a limited role in enhancing cities' adaptation to high temperature in Northwestern China, while it has a significant positive contribution to their adaptation to low temperature and flood, which also indicates that the PU sensitivity of cities' adaptation varies significantly depending on climate events.

(2) **Economic urbanization.** We can see from sub-figures (e)-(g) of Figure 6 that the regression coefficients of PU of adaptation to low temperature, drought and flood show highly similar distribution trends: the middle-high value areas are mainly located to the east of Hu Line, while the low value areas are distributed to the west of the line with most cities negative coefficients. West of Hu Line is the less developed area in China, where the economic development is relatively backward. Therefore the disposable income of urban residents there is not high, and the adaptation to low temperature and drought are also at low level, which indicates that the development of EU in this area has limited pulling power and weak impact on the level of adaptation to low temperature and drought. The cities with high values are located in the belt-shaped region consisting of Southern China, Central China, Northern China and Northeastern China, and the development of EU has a significant positive impact on the improvement of their adaptation level. Since the EU is expressed by per capita disposable income of urban residents, it is possible that with more income, residents can buy more facilities and services to protect against climate events, thereby reducing personal and property damage and improving adaptation ability.

(3) **Land urbanization.** As shown in sub-figure (h) of Figure 6, the coefficients of LU vary greatly among cities with the range reaching 3.07, indicating that process of LU varies greatly among these cities. LU plays an extremely critical role in cities' adaptatio to flood, which needs to be paid more attention to. High-value cities are clustered in Northwestern China, Southern China, Central China and Northeastern China; most cities with low coefficient are located in Eastern China, especially in coastal provinces, and the coefficients are even negative. The eastern cities have superior geographical locations, rapid economic development, and early urban planning and infrastructure construction, which has lasted for a long time. However, in recent years, the continuous expansion of urban boundaries has accelerated the concentrated outbreak of urban diseases such as traffic congestion and housing shortage. The resources and environment of these cities are under great pressure, and the disaster resistance abilities and disaster management level are significantly inadequate. In this context, it is not surprising that LU has a negative impact on these cities' adaptation to flood.

(4) **Industrial urbanization.** sub-figure (i) of Figure 6 shows that the high value areas present a belt-shaped distribution, mainly located in Jiangsu, Zhejiang, Shanghai, Anhui and Jiangxi in Eastern China and Hunan and Hubei in Central China, while the low value areas are mainly located in Fujian province and Shanxi-Hebei-Henan region. Besides, some cities in Xinjiang, Gansu and Shandong are also at a high value level. The high coefficient cities have a high level of IU in the country with a diversified industrial pattern or a large proportion of the output value of the dominant industry, and thus IU has a significant positive driving impact on their adaptation to drought. For example, the city of Karamay in Xinjiang is an industrial city with petroleum and petrochemical industries as the main industry. In 2019, the secondary industry accounted for 70%, while agriculture only accounted for 1.5%. In comparison, low value areas are either weak in industrial economy or single in industrial structure. For example, Henan is a typical agricultural province, and the level of secondary and tertiary industries in its cities is relatively backward. From the assessment results, most of these cities are with low values, and IU process cannot play a significant role in promoting adaptation to drought. And Hebei is a large industrial province, not a powerful one, which mainly develops the iron and steel industry with high pollution, high energy consumption and low added-value. So the IU of Hebei does not play a significant positive role in economic development and environmental health. The low-quality IU does not improve the adaptation to drought, but becomes an obstacle factor. To a certain extent, this also indicates that it is very urgent to enhance the industrial output values of cities with low IU coefficient and optimize and adjust their single or unreasonable industrial structure.

(5)

5. CONCLUSION AND DISCUSSION

Based on the data of 248 cities in China, this paper constructed the assessment indicators systems of cities' adaptation to climate change under four types of climate events: high temperature, low temperature, flood and drought. And the coefficient of variation method and ESDA were used to analyze the spatial differences characteristics of cities' adaptation, and GWR model was used to explore that how urbanization affects adaptation. The conclusions are as follows:

- (1) In general, high-administrative-level cities have stronger adaptation, lower vulnerability and higher readiness than ordinary-prefecture-level cities, which are determined by their advantages in many aspects.
- (2) The differences of adaptation to high temperature and low temperature among cities generally present spatial patterns of decreasing from south to north, and the difference of adaptation to drought generally presents a spatial pattern of decreasing from west to east. The coefficient of variation of adaptation to flood is the largest in Southwestern China, the smallest in Northeastern China, and the gaps of adaptation among cities within Southern China and Southwestern China are very prominent.
- (3) The scores of adaptation to high temperature, low temperature and flood in Northern China, Northeastern China and Northwestern China consistently rank in the top three, the scores with high temperature and flood in Southern China are the lowest, and the scores of low temperature and drought in Southwestern China are the lowest. Compared with Southern China, Northern China has a wider advantage in adapting to climate change and climate events, and the gap among different regions in adapting to low temperature is relatively small, while there is a significant adaptation gap in coping with high temperature. The key to improving balanced adaptation to climate change in all regions of China lies in narrowing the gap of adaptation to high temperature.
- (4) The adaptation to high temperature is in the opposite distribution between north and south. The cities with high adaptation are mainly concentrated in the three northeastern provinces, Inner Mongolia, Shandong and Beijing-Tianjin-Hebei region, while the cities with low adaptation are mainly distributed in Guangdong, Guangxi, Sichuan, Chongqing, Henan and Eastern China region. Cities with high adaptation to low temperature mainly belong to high-administrative-level, forming a high-low agglomeration area centered on cities of this level, and cities with low adaptation to low temperature are mainly distributed in Southwestern China, Central China and Huaihe River Basin. Cities' adaptation to drought shows a significant trend of decreasing from southeast to northwest, with high adaptation cities mainly concentrated in Jiangsu, Zhejiang, Anhui and Pearl River Delta, while adaptation in Northwestern China is generally low and shows the characteristics of low-low agglomeration. Also, adaptation to flood also shows a distribution trend of higher in the north and lower in the south, with low adaptation cities mainly located in Pearl River Basin and Huaihe River Basin.
- (5) Under the four types of climate events, the global spatial correlations of cities' adaptation in China are positive, and the agglomeration characteristics of adaptation are mainly H-H and L-L agglomerations. Most cities in Yangtze River Delta are H-H agglomeration, and most high-administrative-level cities are H-L agglomeration.
- (6) When analyzing the impacts of four types of urbanization on cities' adaptation to climate events, the fitting effects of GWR models are far better than those of OLS models. Population urbanization affects cities' adaptation to four types of climate events, economic urbanization on low temperature, drought and flood, industrial urbanization on drought, and land urbanization on flood. Population, economic and industrial urbanization have positive impacts on adaptation of most cities. Population urbanization can improve adaptation of all cities to high temperature, while land urbanization hinders adaptation of most cities to flood. Under the influence of social and economic development, the urbanization regression coefficients of different cities have significant spatial differences.

Due to the limitation of time and data acquisition, the above research has the following shortcomings: First, a small part of indicators data are derived from the Internet or estimation, which may make the results not robust enough; second, the cross-sectional data cannot reflect the relative change of cities' adaptation to climate change from the time dimension. More accurate, more comprehensive and in-depth comparative studies need further follow-up.

Appendix Table 1 Details of data sources

Indicators	Abbreviations	Reasons for selection	Source
Population density	PD	The greater the number of people exposed to the disaster-causing factors per unit area, the greater the risk of life and health damage	China City Statistical Yearbook
GDP per square kilometer(economic density)	GPSK	The higher the value of disaster bearing body per unit area is, the greater the economic loss will be	
Percentage of employees working outdoor	PEWO	People who work outdoors are vulnerable to high and low temperatures, leading to health risks	
Proportion of employees in primary industry	PEPI	It reflects the sensitivity of drought susceptible industries to drought at the level of employment structure	
Proportion of primary industry to GDP	PPIG	It reflects the sensitivity of drought susceptible industries to drought at the level of economy	
Number of hospital beds per capita	NHBPC	Medical resources reflect the level of health protection: the more beds per capita, the more favorable post-disaster relief	
Number of doctors per capita	NDPC	Medical resources reflect the level of health protection: the more doctors per capita, the more favorable post-disaster relief	
Greening coverage of built-up areas	GCBA	Green space provides cooling function, which can reduce the impact of extreme heat and biophysical hazards	
Mobile phone ownership rate	MPOR	Reflect the ability of early warning measures, information exchange, etc	
Water resources per capita	WRPC	Reflects the resource endowment to withstand drought, as well as the ability to obtain drinking water after floods	
Number of buses per 10,000 people	NBP	Vehicles provide a more reliable evacuation option in the event of a flood, while also making it easier for cities to recover from weather disasters	
GDP per capita	GPC	The low value may lead to insufficient investment in the construction of climate adaptation infrastructure and affect the implementation of post-disaster recovery	
Percentage of population aged 65 and over	PPA650	The elderly have poor physical resistance ability, weak self-protection and disaster response ability	

Indicators	Abbreviations	Reasons for selection	Source
Percentage of population aged 0-4	PPA0-4	The child have poor physical resistance ability, weak self-protection and disaster response ability	
Percentage of population with high school education and above	PPHSEA	Education helps raise the city's awareness of how to respond to climate events	
Domestic water consumption per capita	DWCPC	It reflects the sensitivity of water demand after climate change and water shortage	city -level Database of China Real Estate Informatio
Density of drainage pipes in built-up areas	DDPBA	It reflects the drainage capacity in case of flood disaster	
Patents granted per capita	PGPC	It reflects innovation ability. The higher the value, the better the ability to find countermeasures against the incident	
Loan-to-deposit ratio of financial institutions	LRFI	An indicator of economic development. If the value is too low, it may indicate that the city is unable to carry out the construction or investment of adaptive projects	
High temperature days	HTD	The number of days with daily maximum temperature $\geq 35^{\circ}\text{C}$ and it is directly proportional to the high temperature risk	
Average value of highest temperature in high temperature days	AVHTHTD	It is proportional to the risk of high temperature	
Low temperature days	LTD	The number of days with daily minimum temperature $\leq 0^{\circ}\text{C}$ and it is directly proportional to the low temperature risk	
Average value of lowest temperature in low temperature days	AVLTLTD	It is proportional to the risk of low temperature	
Average annual precipitation	AAP	The larger the value is, the greater the flood risk is and the smaller the drought risk is	
Average annual temperature	AAT	The larger the value is, the stronger the city is disturbed by drought	
Housing price to income ratio	HPIR	Housing cost burden is a high risk factor for homelessness, and homeless or marginalized populations are most vulnerable to temperature and weather	https://www.creprice.cn/ , China Meteorological Data Service Centre
Percentage of impervious surface area	PISA	The higher the value, the greater the amount of surface runoff, exacerbating flooding	Calculated by the research group
Heating situation	HS	Whether a city has heating or not indicates how well it can cope with cold weather events	Article of "map can talk" on WeChat- -Where is China's heating demarcation line?
Whether a water-saving city	WAWC	It reflects the water management ability, and water-saving cities can rationally allocate, develop and utilize water resources to form a scientific water use system and effectively deal with drought	Baidu Encyclopedia--National water-saving cities
Government debt balance per capita	GDBPC	The higher the value is, the less investment is likely to be put into the infrastructure construction of adaptation to climate events, and the implementation of post-disaster recovery will be affected at the same time	Everbright Securities Research Report-Special Report on Regional Finance
Number of corruption and bribery cases per 10000 people	NCBC	It reflects the level of free from corruption, the transparency and management capacity of local governments, and the level of effective use of climate funds	Harvard University -- China Corruption Survey Dataset

THE EFFICIENCY OF THE EDUCATION SECTOR BUDGET: EVIDENCE FROM INDONESIA

Tri Wibowo, Abdul Aziz, Praptono Djunaedi

Fiscal Policy Agency, Ministry of Finance Republic of Indonesia, Indonesia. 3wibowo@gmail.com, kingabaz@gmail.com, praptono@gmail.com

ABSTRACT

The decentralization of education in Indonesia has been going on for two decades. As mandated by the law, starting in 2010, the education budget has been allocated 20 percent of total state expenditure. In the last 10 years, the education budget in Indonesia has more than doubled. However, the high budget allocation for education has not yet matched its performance. This article wants to find out how efficient the use of budgets at the provincial level in Indonesia is. The descriptive analysis method is used to see the description between budget allocation and education performance in each province. To see the efficiency of the use of the budget on the performance of the education sector, a Data Envelopment Analysis (DEA) analysis is used. The data is sourced from the Ministry of Education, compiled from 510 data at the district/city level spread across 34 provinces in Indonesia. As input used the education budget allocation (national and regional levels), school conditions, teacher quality, accreditation, student-teacher ratios in each province. Meanwhile, the education output uses the net enrollment rate and the school graduation rate. From the analysis, it can be concluded which districts/cities are the most efficient in allocating resources. With a reference to the efficiency of resource use, efficiency in the use of the budget can be made.

KEYWORDS

Performance, Efficiency, Education

1. PRELIMINARY

1.1 Background

Education is one of the key pillars to improve the quality of human resources. There are two important things related to education that the Indonesia's constitution stated. First, the Indonesian people's right to obtain education, and the second, the huge allocation of fund to finance the implementation of national education. At least, in the last decade, the government has allocated fund amounting to 20% of the State Budget each year.

To fulfill education services, the government implemented a 9-year compulsory education program. Based on the 2020-2024 National Medium-Term Development Plan, the program will be completed in the next five years. Currently, mean years of schooling for Indonesian is 8 years. In other words, most of Indonesian had education up to level two junior high school.

The government implemented right policies to encourage the education's sustainability, from elementary to high school. For example, giving educational assistance for children of poor households, providing school operational assistance funds up to the SMA level, and increasing qualified teachers according to the Teacher Law.

As stated in Article 31 paragraph 4 of the 1945 Constitution (fourth amendment), the government is obliged to allocate education spending of at least 20% of the State Budget. The allocation aims to provide educational services to the public, especially basic education, in the implementation of national education.

This mandate has been fulfilled by the government in compiling the State Budget since 2010. The allocation in the 2010-2020 State Budget has never been less than 20%. The allocation is channeled through the central government (National Budget) and local government (Sub National Budget).

In 2010, the overall education budget was Rp225.2 trillion, and then increased to Rp508.1 trillion in 2020, or an increase double over 10 years. The escalation was in line with the increase in the State Budget. Thus, The hike in the State Budget expenditure will automatically enhance the education budget allocation as the mandate of the Constitution.

Figure 1. Education Budget Allocation

Source: Ministry of Finance.

Although the education sector allocation has reached 20% of the total State Budget, the education sector's output is relatively lower than other countries. Based on Program for International Student Assessment (PISA) 2018, Indonesia's rank is at the bottom of the list. Indonesia is ranked 72 out of 77 countries for reading competency score, ranked 72 out of 78 countries for Mathematics score, and ranked 70 out of 78 countries for the Science score. Those scores tend to be stagnant in the last 10 - 15 years.

With the education budget reaching 20% in the last 10 years, how was the education sector's performance, particularly at the basic education level? Which province is the most efficient of the education budget use?

1.2 Research Purpose

The purpose of this research is to observe how the performance and efficiency of the education budget, especially primary and secondary education in Indonesia.

1.3 Research Method

The method used in this research is to measure the efficiency of the use of education sector's input in producing the education's output in all provinces of Indonesia. Indonesia consists of 34 provinces, but the analysis is only carried out in 33 provinces, except DKI Jakarta Province. This province as the capital city was excluded of the analysis to avoid the bias result. Because the central government's education budget is located in the province. The analysis tool used is Data Envelopment Analysis (DEA). DEA analysis uses the CCR model with output oriented.

The main source of data for this study is from the Ministry of Education in 2019. The education sector's input used is the education sector budget allocation consisting of the education budget from the National Budget and Sub National Budget, classroom conditions, school accreditation, teacher quality, teacher and student ratios and teacher's competency. While the education's output used is the Net Enrollment Rate and National Exam's Score. The focus of the input studied is the input of the education budget.

The student teacher ratio means 1 teacher teaches how many students. The bigger the student teacher ratio, the worse it is. In order for the direction to be positive, in the analysis it is converted into the student teacher ratio (1 divided by the student teacher ratio multiplied by 100) which means how many teachers are needed to teach 100 students.

The variables used in the analysis :

Input variables:

I1 = Education budget per student per year (IDR million / student / year)

I2 = Good School Conditions (percentage)

I3 = School Accreditation (percentage)

I4 = Teacher quality (percentage)

I5 = Student-Teacher Ratio

I6 = Teacher Competence (percentage)

Output variables:

O1 = Net Enrollment Rate (NER)

O2 = National Examination

2. LITERATURE REVIEW

Through a long political process, the general government's system in Indonesia has changed drastically since 2000, from centralized system has become decentralized. One of the strategic affairs delegated to the regions is education sector. With the transfer of authority, it is hoped that the education management in each region can be implemented better than the previous era. This is in line with the Cambridge Institute (2021) expressed that decentralization of education cannot

be separated from the broader political process that shapes the empowerment of local institutions. Evidence suggests that the level of local control is slightly high in states such as states that empower local government agencies. The education decentralization policy will work best if it gets support from various parties in the region. Donald R. Winkler (1989) said that decentralization policies are most successfully implemented if there is a tradition of self-reliance by local communities; if local governments or communities have their own sources of tax revenues and voluntary contributions; if the pressure for decentralization originates with the community rather than ministry planners; if all important affected political groups, especially teachers, are involved and informed about development of decentralization plans; and if administrative capacity at the local level either already exists or is trained.

The education system in Indonesia is the third largest in the Asian region and the fourth largest in the world, with more than 50 million students and 2.6 million teachers in more than 250,000 schools. Two ministries are responsible for managing the education system, namely the Ministry of National Education and the Ministry of Religion (WB, 2014). As a country with a large population, which is spread across 34 provinces, there are high hopes that one day Indonesia will be able to grow as a developed country. This is in line with the education's role as stated by Todaro and Smith (2014) that education has a pivotal role in shaping the ability of a developing country to absorb modern technology and to develop capacity to create sustainable growth and development.

Ciro and Garcia's (2018) study measures the efficiency of public secondary education spending in 37 developing and developed countries using a two-step semi-parametric DEA (Data Envelopment Analysis). This study applies two cross-country frontier models for the 2012-2015 period: one using a physical input (i.e. teacher-student ratios) and one using monetary input (i.e. government and private spending per secondary school student as a percentage of GDP). Some important results of this study are 1) developing countries could increase their enrollment rates and PISA scores by approximately 22% and 21%, respectively, by maintaining the same teacher-student ratios and public-private expenditure levels; 2) Australia, Belgium, Finland and Japan are efficient countries in the cross-country frontier; 3) the physical frontier model significantly benefits developing countries, bringing them closer to the efficiency frontier, but it negatively affects developed countries.

Aristovnik (2013) paper on the measurement of the technical efficiency of the public (primary) education sector within the selected education sector in the 1999-2009 period in the wide range of the EU and OECD countries, including new EU member states. The results showed that within a selected group of EU member countries (Denmark, Hungary and Portugal) was the most efficient in the primary education sector. Other countries achieving the level of efficiency are Greece and Romania, however, their primary expenditures per student (in % of GDP) is very low and have averaged of less than 12% (EU /OECD average is 18.7% in the considered period). On the other hand, the least efficient countries are Belgium, Sweden and Croatia. Some less efficient countries should significantly reduce their input (primary expenditure per student) (e.g. Slovenia from 27% to 22%) and/or increase their output, i.e. school enrollment (e.g. Ireland and Poland), primary completion rate (Belgium) and teacher-student ratio (Ireland) in order to become efficient.

Research on the efficiency of the education sector budget in Indonesia varies considerably. Tisrinasari et al (2020) measured efficiency at the level of vocational high school (SMK) in 2018. The results of calculating provincial efficiency with output oriented Variable Return to Scale DEA show that 14 provinces are declared efficient (and 20 provinces declared inefficient). References and improvements for inefficient provinces, one of which is North Maluku Province which has the smallest score. Input variables include per capita student education allocation (ADM), net enrollment rate (APM), teacher/ student ratio (RGM), and class/student ratio (RKM); while the output variables include the continuing school rate (AM) and the non-dropout rate (100-APS).

Research by Mahmudah et al (2018) evaluated the technical efficiency of high schools (SMA) for the 2015/2016 period in 34 provinces of Indonesia using the Robust DEA approach to reduce biased results on traditional DEA. Input variables include the number of schools, the number of students, the number of teachers, the number of libraries, the number of laboratories, the number of graduates, the number of classes, and the number of classrooms. The output variables include the average national exam score for Indonesian, English, Mathematics, Physics, Chemistry, and Biology.

Another study measuring the efficiency of elementary schools (SD) in Indonesia for the 2014/2015 period by applying the two-stage DEA method was conducted by Fatimah and Mahmudah (2017). The first stage is to calculate the efficiency score using the DEA approach. The second stage uses an econometric approach to analyze the impact of environmental variables on school efficiency. The results show that the VRS model of DEA is better than the CRS model in the first stage to measure the efficiency of SD performance. There are 17 provinces with SD performance is efficient in the VRS model, there are also 12 provinces that are efficient for SD performance in the CRS model. In addition, there are three environmental variables that have a significant effect on the efficiency of primary schools in Indonesia, namely the repetition rate, the average of science of national exam and the qualified teachers' rate.

According to Muniroh (2015) that in general, education development consists of three elements, namely (1) educational content/input, process/transformation, and educational goals/outputs. Education input is students as targets/objects in education, processes/transformations are tools/machines that shape students as planned, and goals/outputs are the final results to be achieved. Education input is a main factor so that the educational process can run well. Education input can be in the form of an education budget, and other resources such as schools, teachers, students, regulations, and others. The readiness of input is necessary so that the process can run well. Therefore, the high and low quality of inputs can affect the educational process and output.

3. RESULTS AND DISCUSSION

3.1 Data description

The data description of the lowest value, average value and maximum value of each input and output variable is presented in the following table:

Table 1 Description of input and output variables

Statistic	I1	I2	I3	I4	I5	I6	O1	O2
Min	3.38	25.54	23.69	80.69	4.98	44.48	53.56	41.86
Average	5.98	36.86	36.45	91.98	7.34	54.99	75.96	47.25
Max	8.93	50.70	48.23	96.50	10.82	68.77	83.69	61.84

Source : Author Analysis.

3.2 Educational Input

Allocation of Educational Expenditure in Regional Budget

Although, at in national level the educational budget has reached 20 percent, seen at the provincial level there are still provinces whose educational budgets are below 20 percent. The Provinces whose educational budget allocation is still below 20 percent are province 21, 64, 65, 82, 91, and 94. The highest educational budget allocation is in the 33 provinces of 31.7 percent of the total Regional Revenue and Expenditure Budget (APBD).

Figure 2. Education Budget Allocation (Prosen)

Source: Ministry of Education Republic of Indonesia, 2020.

Classroom Conditions

One of the other forms of educational input that is also very influential at the stages of the educational process and affects the output of education is the condition of the educational facilities and infrastructure available, especially schools (classrooms). The figure 3 below shows that the majority of classrooms are "lightly damaged", this condition occurs at all levels of education, namely at the SD (53%), SMP (49%) and SMA (39%). Even so, for the "lightly damaged" class conditions it can still be used for teaching and learning activities. Meanwhile, the condition of classrooms with "good"

conditions is at the education level: SD (27%), SMP (33%), SMA (40%). This condition reflects that the Government of Indonesia has a very large homework in improving the quality of education infrastructure so that teaching and learning activities can run better so that they can increase the quality of the desired educational output.

Figure 3. Classroom Conditions (Prosen)

Source: Ministry of Education Republic of Indonesia, 2020.

Teacher Qualification and Competence

Teacher qualifications and competencies are the main elements in the learning process to create good educational output. Teacher qualification is measured by the percentage of teachers who have completed their undergraduate education. Meanwhile, teacher competence is measured by the percentage of teachers who have taken the certification exam. As many as 92.2 percent of teachers in 33 provinces have completed their Bachelor's education. In terms of competence, there were 52 percent of elementary school teachers who had completed the certification exam, 56 percent of junior high school teachers and 60 percent of high school teachers.

Figure 4. Teacher qualification and Teacher Competence (Percentage)

Source: Ministry of Education Republic of Indonesia, 2020.

Student Teacher Ratio

The availability of teaching staff is an important factor in educational services for school students. The balance of the teacher's teaching load in dealing with the number of students must be right. If there is too little it will be inefficient, but if it is too large the number of students to be handled will be ineffective. The teacher-student ratio on average at the SD level is 1: 17, one teacher handles 17 students. At the junior high school level of 1: 14; and at the high school level at 1: 15.

3.3 Educational Output

The educational output describes the results of the implementation of educational inputs that have been planned and prepared. The better the educational input, the better the output is expected. The education output also describes the performance of the education process carried out by various parties involved in the process such as the government, teachers, and other parties.

The Net Participation Rate (APM)

According to BPS (2020), the Net Participation Rate (APM) is the proportion of the population of a certain school age group who is currently attending school at the appropriate level of education (according to the age of the population with the provisions of the school age at that level) to the population of the appropriate school age group.

Figure 5. Net Enrolment Rate: Primary School - Senior High School

Source: Ministry of Education Republic of Indonesia, 2020.

National Examination (UN) Results

One indicator of the success of education is by looking at the results of the national exams (UN) that have been taken by students at all levels of education in Indonesia. National exam (UN) results also reflect the quality of teaching and learning activities carried out so far. Below is a description of the Average National Exam Score (UN) held by Public and Private Schools for Junior High School (JHC), Natural Science High School (NSHS), Social Science High School (SSHS), and Vocational High School (VHS) in Indonesia in the 2015-2019 observation year. The types of subjects tested were: Indonesian Language, English, Mathematics, and Natural Sciences (for the JHC level), as for the NSHS level plus Biology, Physics, and Chemistry subjects, and for the SSHS level plus Geography, Sociology subjects, and Economics. The results of the national exam (UN) scores are a combination of the test modes carried out by the Computer-Based National Examination (UNBK) and the Paper and Pencil-Based National Examination (UNKP).

Figure 6. Average National Examination Score of Public and Private in Indonesia 2015 - 2019

Source: Ministry of Education of Indonesia, 2020.

The data in Figure 6 shows that all the average scores for the National Examination (UN) above for all levels of education are still below the value of 70, although from year to year it shows an improving trend. This illustrates that there is still a need for improvements to the input and process of education in Indonesia and to find out what internal and external factors have the most influence on the low scores of this national exam.

3.4 Indonesian Education in the World

Although the education budget has reached 20 percent of total expenditure, when compared to other developed countries, Indonesia's budget allocation per student is still low. Education budget allocation in Indonesia for primary and secondary levels is only 2.2 thousand USD per student. Meanwhile, the United States reached 23.7 thousand USD, or 10 times that of Indonesia. The problem is, how is the performance and efficiency of education in Indonesia after the 20 percent budget allocation as mandated by law is fulfilled

Figure 7. Education Spending Primary and Secondary (US dollar/student)

Source: Education at Glance, OECD.

In terms of budget allocations for the education sector, from 2000 to 2018, the percentage was still below neighboring countries (Singapore, Malaysia, Thailand). However, the percentage of budget allocation for the education sector in Indonesia is still greater than that of Middle Income countries.

Figure 8. Budget allocation in Education Sector, (Percentage, %)

Source: World Development Indicator, 2020.

The OECD has published an international-scale scoring assessment conducted every 3 years through a program for international student assessment (PISA). The result of PISA Indonesia score in 2000 is relatively better than in 2012 after the education budget of 20 percent is fulfilled.

The results of Indonesia's PISA scores from 2000 to 2018 were relatively stagnant. PISA scores in reading, mathematics, and science are far from the average for the country surveyed (blue line). Indonesia's PISA score in 2000 ranks 39 out of 41 countries. in 2018, Indonesia ranks 70 out of 78 countries. This means that since Indonesia has become a participant in PISA, improving Indonesian education has had no impact significant.

Figure 9. PISA Indonesia Scores 2000 – 2018

Source: Education at Glance, OECD.

One of the factors causing the low PISA score is the allocation of the amount of the education budget per student. There is a positive correlation between the education budget per student and the PISA score. Indonesia, which has a population of 270 million and 45 million students from SD to SMA, requires a small budget. Although the Indonesian government has allocated a budget for education of 20 percent, with a large number of students the budget allocation per student is small.

Figure 10. Education budget allocation (primary and secondary) and PISA scores

Source: Education at Glance, OECD.

3.5 Efficiency of the Education Sector

The efficiency of the implementation of the provincial education sector in Indonesia in using inputs to produce education output in this analysis is carried out into 2 parts. The first part is efficiency uses input for Net enrollment rate (NER) output, and the second part is efficiency uses input for National Examination output. In DEA analysis is a data analysis that can use many inputs and many outputs simultaneously. However, in this study, the analysis was carried out separately for each output. The consideration is to do a partial output analysis in order to know the improvement of each output and how much budget could be saved if each region can efficiently produce educational output.

DKI Jakarta Province is not included in the efficiency analysis because it is the center of the Government. The budget for the head office of the Ministry of Education is located in DKI Jakarta Province, if it is included in the analysis it will damage the data (outlier data).

The education budget allocation for 33 provinces in Indonesia is IDR 216 trillion. The budget is used to finance all educational inputs, both for school infrastructure, for teachers, and for improving the quality of education from elementary to high school levels. The total number of students from primary school to senior high school in 33 provinces is 45 million students. If the budget is calculated per student capita, the average value of the education budget is IDR 5.9 million per student per year. Province with the largest budget value is Province 91 with a value of IDR 8.9 million per

student per year. The province with the smallest budget is Province 32 with a value of IDR 3.4 million per student per year.

Net Enrollment Rate (NER) Output

The efficiency analysis of the use of educational inputs to produce educational output in the form of NER using DEA can be seen in the following figure. Provinces with potential NER for improvement are provinces 94. The gap between realization and projection from DEA analysis is the biggest. The realization of NER in Province 94 was 53.56, while the projection result of DEA reached a value of 64.90 or could be increased by 11.35.

Figure 11. DEA analysis for NER output

Source : Author Analysis.

Judging from the value of the efficiency score, there are 12 provinces that have been efficient in using inputs to produce the best NER output. The lowest efficiency is in the province 94 which only reaches 0.83. By using a lower band of 1 standard deviation, there are 5 provinces that are at the bottom, namely 21.63, 71, 73, and provinces 94.

Figure 12. Efficiency Score for NER output

Source: Author Analysis.

If all provinces can use inputs, especially budget inputs efficiently, budget savings can be obtained. Budget observation simulation can be calculated by finding the difference between the budget input realization and the budget input projection. The value of the difference in the per capita budget in each province is multiplied by the number of students in the province concerned. The total savings from budget inputs in each province, the total value is IDR 35 trillion.

National Examination Output

In the efficient analysis of the use of educational inputs to produce educational output in the form of the National Examination, the biggest gap between realization and projection occurs in the province of 75. The realization of the

Provincial National Exam 75 is 43.74, while the projection results of the DEA reach a value of 50.67 or can be increased by 6.94.

Figure 13. DEA analysis for National Examination output

Source: Author Analysis.

Judging from the value of the efficiency score, the use of input to produce the output of the national exam which produces an efficiency of 1 is in 13 provinces. The province with the lowest efficiency was Province 75 with an efficiency score of 0.83. There are 8 provinces whose efficiency scores are still below the lower band with 1 standard deviation, namely the provinces of 11,16,52,63,71,72,73 and 75. Province 94, which has the lowest NER output efficiency, turns out to be in the National Exam it has an efficiency of up to 1 or is efficient in the use of inputs. The simulation of budget savings for the output of the national exam obtained a total savings from the budget input in each province totaling IDR 1.3 trillion.

Figure 14. Efficiency Score for National Examination output

Source: Author Analysis.

4. CONCLUSIONS

The efficiency of management of the Indonesian education sector needs to be continuously evaluated how efficient the use of educational inputs is in its output. By knowing which provinces are inefficient, it will be easier to evaluate so that existing inputs can be allocated appropriately and efficiently.

If the input, especially budgetary input, can be used efficiently, savings will be obtained that can be allocated to increase the education output up from the NER output or increase the results of the national examination.

The results showed that there are 12 provinces that have been efficient to produce the best NER output. On the other hand, there are 5 provinces that are at the bottom, which the lowest efficiency is province 94 (Papua). Besides that, there are 13 provinces that have been efficient to produce the national exam. On the contrary, there are 8 provinces that are at the bottom, which the lowest efficiency is province 75 (Gorontalo).

There are provinces that are good at producing output 1, but not good at producing other outputs. Like Province 94, the use of inputs produced the lowest NER output, but was successful in producing the national exam output. With partial output analysis, it can be obtained more detailed information about which output should be improved.

If all provinces in Indonesia are efficient in managing the input of the education budget, to produce the current output, the education budget can be saved. The potential for savings in the education budget in 33 provinces is up to IDR 36.3 trillion. The government needs to evaluate the performance of the use of inputs, especially the education budget input, so that the educational output, both NER and national exams in the future, can be increased.

ABSTRACT

Brazilian environmental public policy has advanced in an attempt to control illegal deforestation in the administrative political region called the Legal Amazon over the past twenty years. The environmental governance structure in the region was improved, such as the creation of conservation units, tightening environmental legislation, improvement in the systems for monitoring, inspection and control of deforestation, including the performance in illegal deforestation combat carried out by government agencies such as IBAMA, the federal police and the military. In addition, networks and channels for popular participation in civil society councils and associations were strengthened. In spite of this the enforcement capacity is not sufficient to dealing with the deforestation problem in all its dimension and complexity. Considering this scenario, through Factor Analysis and Principal Component Analysis, this article builds an index of territorial (environmental) governance in the Amazon to assess environmental governance in that region. This index was composed by six governance sub-indices estimated to reflect local dimensions, namely: Governance Capacity; Effectiveness and Control of Deforestation; Living Conditions; Productive Structure; Government Intervention and Social Participation. After that these sub-indices was used to study spatial correlations between them, applying the Exploratory Analysis of Spatial Data (Moran's I and Lisa Map.). The main results of this index confirm relative weaknesses in environmental governance in the Amazon region, especially with regard to the dimensions: government capacity and government intervention, but with significant spatial differences in their municipalities. Otherwise, the results also revealed that the municipalities with greater social participation, cooperation and social cohesion (high-high Social Participation) are confused with those with greater ability to govern (governance capacity) and government intervention, with local influences more relevant among the municipalities of the southeast of Pará, southwestern Tocantins and Mato Grosso, and among the municipalities of the metropolitan area of Manaus, mainly.

KEYWORDS

Territorial Governance; Factor Analysis; Principal Component Analysis; Exploratory Analysis of Spatial Data; Brazilian Amazon Region.

1. INTRODUCTION

The word "governance" incorporate many interpretations and connotations within domains in different areas of knowledge. However, there is a convergent sense toward understanding it as different patterns of cooperation and articulation, including formal and informal networks between social actors, under manifold institutional arrangements, that express authority's exercise to coordinate and regulate transactions (transaction costs) and to promote economic development (World Bank, 1992; Santos, 1997; Stoker, 1998; Kauffman, Kraay & Zoido-Lobaton, 2000; Dallabrida & Becker, 2003; Dellabrida, 2011; Kauffman, Kraay & Mastruzzi, 2011).

Adherent to this definition is the governance idea related to the coordination of economic actors, who, within the same geographic proximity, face the problems addressed to these territories (Pecqueur, 2000). This coordination and articulation are also carried out through networks which public policies are manifested (Calmon & Costa, 2013), and can be thought as social capital level expression obtained within the environment of this governance. This means good governance should be thought as goal and, at same time, as a process (Basu, 2002) that accelerates the achievements of individual and society-wide desirable objectives.

The Brazilian territorial development, in general, related to regional development policies has as historical characteristic the centralization of the initiatives and little articulation with the experiences generated by the local agents themselves. This has been the practice of elaborating regional programs and policies for the Amazon in an attempt to create a connection between the region's economy and the national economy, in general, from the interest of the latter.

Thus, the perspective of territorial governance in the Amazon region in Brazil has been conducted toward the exploration and appropriation of its natural resources: forestry, water resources, including for energy purposes and more recently

for ecosystem services uses, especially of biodiversity, as an integration way of local economies into the national economy.

Indicators can be a valuable informational tool to subsidize the managers, detailing the knowledge of facts and processes, allowing the diagnosis of the municipal situation and the evaluation of the results of the public action.

In the specific case of this article, an attempt is made to construct an index that expresses the various dimensions of governance in the region, reflecting, to a certain extent, the very weaknesses of the exercise of governmental authority and its representative institutions. In addition, environmental governance is conceived as the central element in the operation of its construction.

2. METHODOLOGICAL REVISION OF GOVERNANCE INDEX

Social indicators can be grouped based on the objectives they are intended in terms of what they measure and the public policy that underpins them. Thus, there are social indicators that involve, for example, different dimensions of society, such as education, health, quality of life, housing (housing), security, degree of urbanization, environmental sustainability, among others.

On the other hand, one can think of specific indicators in each social dimension, such as indicators of sustainability and environmental quality, urban indicators, health indicators, educational indicators, public safety indicators, indicators of corruption, poverty indicators, among others. However, indicators can be classified by their comprehensiveness in terms of uni or multifaceted aspects or dimensions of reality between those involving elements or macroeconomic aspects of reality and those involving particular elements or aspects.

Broad index examples are: Human Development Index (HDI); FIRJAN Municipal Development Index; Environmental Sustainability Index - ESI; Social Progress Index (SPI), among others.

The starting point for establishing a Territorial Governance Index, which will meet the expectation of good governance, is to establish its relevant dimensions, that is, those that have desirable aspects or characteristics, at least from the normative point of view, so that the existing governance structure at its various scales or levels can work. The experience of other governance indices helps in this direction.

2.1 Governance Index

An international benchmark on governance index is derived from the World Bank Governance Indicators (Kauffman, Kraay & Zoido-Lobaton, 2000; Kauffman, Kraay; Mastruzzi, 2011), in which governance is understood from three dimensions: a) as the process by which governments are selected, monitored, accountable and replaced; b) the capacity of governments to manage resources efficiently, as well as formulate, implement and enforce their policies and regulations; c) respect of citizens and the state itself the institutions that govern the social interactions between them.

Six would be the sub-dimensions forming this indicator: i) Voice and Accountability; (ii) Political Stability and Absence of Violence / terrorism; iii) Government Effectiveness; iv) Regulatory Quality; v) Rule of Law and vi) Control of Corruption, with each group of two corresponding to the dimensions previously mentioned, as described below (Kauffman, Kraay & Mastruzzi, 2011).

In Brazil, the most recent governance index, was elaborated by the Federal Council of Administration and called the Municipal Governance Index (MGI-FCA), which involves three dimensions: public spending and finances, quality of management and performance. The first dimension has two (2) indicators, formed by three variables; the second dimension consists of 7 (seven) indicators, related to 45 (forty five variables), while the last dimension is composed of 6 (six) indicators, generated from 17 (seventeen) variables.

Another index that also has the character of evaluating governance is the Institutional Capacity Index - ICI (Nunes et al., 2014), which has, as a theoretical scope, the New Institutional Economy.

Another experience in the construction of an institutional performance indicator was the elaboration of the Municipal Institutional Quality Index - MIQI, by the Brazilian Ministry of Planning, Budget and Management - MPBM.

The MIQI is composed of three dimensions: degree of participation, financial capacity and managerial capacity, each with equal weight distribution (33.3%).

3. EMPIRICAL STRATEGY

Based on the procedures suggested by Cohen & Franco (1983) and Januzi (2005), the empirical strategy used in the construction of the Territorial Governance Index was divided into three phases. The first phase consisted of the construction of subindex, one for each chosen dimension. In order to do so, we used the Principal Components Analysis and Factor Analysis, to "reduce" the set of selected variables in each dimension. The second phase was established as the compilation of the composite index, which was determined from the simple arithmetic mean of the indices considered. The third phase was composed by the Exploratory Spatial Data Analysis of the subindex and the computed final composite index.

It is observed that, with respect to the qualitative variables, it was adopted as criterion to create a subscript, from the proportion of attributes that the municipality had in relation to the total of possible attributes. This procedure was used with respect to the attribute of belonging or not of the municipality to a rural territory or to a territory of citizenship. Thus, 1 was assigned to municipalities belonging to a rural territory or territory of citizenship and 0, if the municipality does not belong. Another attribute considered was the municipality being or not reached by dams (being in its area of influence). In this case, 1 was assigned to the municipality belonging to the area of influence of the dams and 0, in case the municipality does not belong to this area.

In the dimension of participation, cooperation and social cohesion, as all variables were dichotomous, we assigned 1 has the attribute and 0, otherwise, then the subindex of the dimension itself was calculated as the proportion of attributes, in relation to the total attributes possible, in this case, nineteen, which, therefore, corresponds to the total number of variables used in this dimension.

$$I_i = \frac{a_i^j}{\sum_{i=1}^{n=19} a_i^j} \tag{1}$$

I_i = Attribute Index or Dimension i;

a_i^j = attribute or dimension i in the municipality j, wherein i ranges from 1 to 19.

On the other hand, the mathematical formulation used from which the indices of the continuous variables were elaborated based on the Factor Analysis was:

$$I = \sum_{j=1}^q \left(\frac{\varphi_j}{\sum_j \varphi_j} FP_{ij} \right) \tag{2}$$

where φ_j is the eigenvalue, generated from factorial analysis, so are multiplied the relative participation these eigenvalue in the set of eigenvalues by their characteristic roots FP_{ij} . In addition, to place the variables in the same interval between 0 and 1, normalization of the values of I was performed based on the following expression:

$$I_n = \left(\frac{F_{ij} - F_{ij}^{min}}{F_{ij}^{max} - F_{ij}^{min}} \right) \tag{3}$$

where, F_{ij}^{min} is the minimum value e F_{ij}^{max} is the maximum value between the index.

After findingg the subindex and index, we adopted the Exploratory Spatial Data Analysis – ESDA, with the objective of testing the influence of spatial autocorrelation on the distribution of indexed attributes in Amazonia Lagal geographic space (Anselin, 1996).

In this case, we opted to use LISA (Local Indicators of Spatial Association), also called Local Moran’s I (Anselin; Bera, 1998), to permit evaluate the individual contribution of each municipality to the formation of the global indicator. The local spatial autocorrelation indicators are visualized on a geographic map (LISA map) in order to identify the spatial heterogeneity dimension among the municipalities.

3.1 Data Source

The construction of the data sources used was based on the recognition of the existence of six competing dimensions for the index formation. Three dimensions that express the quality and strength of governance: 1) Governance Capability; 2) Government intervention; and 3) Participation, Collaboration and Social Cohesion. And three dimensions that, in the specific case of the Amazon, converge to its weakness or the lack of robustness of this governance: 1) Effectiveness of the Control of Deforestation; 2) Living Conditions; and 3) Productive Structure.

Governability is related to variables that describe a greater capacity of municipal governments to manage public activities (services) in their sphere, and this is directly linked to their greater autonomy and financial independence in relation to the state, as well as their participation in the economy of the state and even the region. In this dimension, the following variables were tested: relationship between the municipality's GDP and the state's GDP; relation between the GDP of the municipality and the GDP of the Amazon; Firjan Index; Firjan Index Recipe; Firjan Index Investment; Firjan Liquidity Index, whose original data sources were IPEAdata and FIRJAN.

The Government Intervention dimension considers the three main forms and experiences of federal government intervention in the region: through agrarian reform policy; through large public enterprises such as the large dams - hydroelectric power plants; the creation of environmental conservation units and, more recently, the regional development policy of a territorial nature, which gave rise, among other things, to the creation of the Rural Territories and Territories of Citizenship. In this dimension, the following variables were tested, with the respective data sources: household capacity in the settlement (INCRA); number of families living in settlements (INCRA); total settlement area (INCRA); and the relationship between the area of the municipality destined to a Conservation Unit and the total area of the municipality (MMA). In addition, three dummy variables were considered in this dimension - dichotomous, conferring 1 if the municipality had the attribute and 0, otherwise. Here the variables appeared: belonging to a rural territory (MDA); belonging to a territory of citizenship (MDA) and belonging to the area of influence of dams (MMA).

The dimension of Participation, Collaboration and Social Cohesion was formed by a set of variables that express the degree of maturity of the citizens of the municipality in the creation of participatory forums and social representation. Here, also, the variables were considered as attributes and, therefore, are dichotomic, calculated as 1, if the municipality has this attribute, and 0, otherwise. The variables tested were: existence of Municipal Education Council; existence of Municipal Health Council; existence of Municipal Housing Council; existence of Municipal Sanitation Council; existence of Municipal Council of Human Rights; existence of the Municipal Council for Children and Adolescents; existence of an Environmental Service Contract; existence of Municipal Council of Environment; existence of Municipal Environment Fund; the municipality performs environmental licensing at the site; the municipality has some cooperation instrument with state environmental agency; the municipality has specific legislation to address the environmental issue; the municipality is part of the river basin committee; the municipality participates in an intermunicipal public consortium; the municipality participates in a public consortium with the state; the municipality participates in a consortium with the

federal government; the municipality has some partnership with the private sector; the municipality has support from the private sector or the community; the municipality hosted the Cities Conference. All variables were based on IBGE. On the other hand, the detrimental dimensions are related lack of control of deforestation, to the productive structure, in which only variables were considered that are directly connected at some level of influence on the environment - use of natural resources and, in particular, life conditions, whose low quality of life expressed in several development indicators in the municipality, in the areas of health, education, public services, among others, was considered.

Regarding the Effectiveness dimension of Deforestation Control, the following variables were tested, with the respective sources of observations: cattle herd (IPEAdata); area planted with temporary crops (IPEAdata); area planted permanent crop (IPEAdata); area of the municipality (INPE); accumulated deforestation (INPE); proportion of deforestation (INPE); forest area (INPE); proportion of forest area (INPE); and annual deforestation rate (INPE).

As for the Productive Structure dimension, the following variables were tested: percentage of persons employed in the mineral extractive sector; percentage of people employed in the agricultural sector; degree of formalization of the work of the employed persons. All had their source from the data UNDP.

Finally, the list of variables tested in the conditions of Life dimension comprised: life expectancy at birth; infant mortality up to 1 year of age; infant mortality up to 5 years of age; expected years of study (18 years of age); Adult illiteracy rate up to 15 years; Human Development Index; Human Development Index Education; Human Development Index Longevity; Human Development Index Income; Gini index; proportion of extremely poor; proportion of vulnerable to poverty; income ratio of the richest 10% and the poorest 40%; income ratio of the richest 20% and the poorest 40%; average per capita income; average household income per capita of the extremely poor; average per capita household income of the poor; average per capita income of vulnerable to poverty; Theil Index; total population living in permanent private households; percentage of the population living in households with channeled water; percentage of households with inadequate water supply and sewage. Here, also, the original source of the data was UNDP.

The final empirical model that was estimated to generate the Factor Loads of each dimension took into account the commonalities, that is, the measure of how much of a variable's variance is explained by the factors derived by the factorial analysis.

Before we apply the techniques selected here, it is necessary to test how large the correlations between the variables are in order to justify the application of these two methods. In this direction, two tests are usually employed: the Kaiser-Meyer-Olkin (KMO) sample adequacy measure and the Bartlett sphericity test. In the first case, it is verified (Table 2) that not all the KMO tests presented satisfactory results, so that the dimensions Governance Capacity and Productive Structure, presented the test values 0.3607 and 0.4932, respectively. However, in the second case, the variance independence Likelihood Ratio tests (Bartlett's test) checked for each dimension results lower than the 5% test statistic and, therefore, we reject the null hypothesis of correlation identity matrix (Ranher, 2002) (Table 2).

It was adopted as a criterion to define the number of relevant factors, to consider the results of their eigenvalues above the unit or respective individual proportion explained by them, above 5% (Edwards, 1991; Rachman, 2002; Raykok, 2008). It should be noted that a rotated array indicates the best particular combination of the original variables, which further explains the variances of the data as a whole than any other linear combination of variables. The rotation used was by the Varimax method, since this one tries to minimize the number of variables with high loads in a factor, that is, to maximize the variance of the load.

In Table 3, the results of the Factor Analysis, according to the eigenvalue, are presented the individual and accumulated proportion of each factor for the non-rotated and rotated matrix. It is observed that, for the Governance Capability

dimension, both in relation to the non-rotated matrix and in relation to the rotated matrix, only three factors had an eigenvalue / variance above the unit, representing 82.95% of the cumulative proportion / variance.

From the factors selected as relevant in each dimension, the variables were selected, considering the weight in the factorial loads, as well as the respective "uniqueness" (unexplained part of the variance of the variable), from the result of the matrices rotated in each dimension. Thus, from the criteria defined above, the variables selected in each dimension were: 1) Governability: partipibest; partipibamaz; IFGF; IFGF_R; IFGF_I; IFGF_L; 2) Effectiveness in Deforestation Control: Inefebov; Inareaplavtemp; Inarea; Indeflorestmento; Inpdesm; Infloresta; Inpfloresta; Intxdesm; 3) Conditions of Life: Inpespvida; Inmi1; Inmi5; Inanoest; Intxa15; IDHM; IDHM_E; IDHM_L; IDHM_R; gini; Inpind; Inppob; Inpmpob; In1040; In2040; Inrdp; Inrind; Inrmpob; Inrpob; THEIL; Inpop; Inpagua; Inaguaesg; 4) Productive Structure: Inpagro; Inpextr; Inpformal; 5) Government intervention: Incapac; Infam; Inareakm2.

In order to define the subindex, referring to the five dimensions of governance composed only of continuous variables, a matrix of factorial scores was estimated after the orthogonal rotation of the initial factorial structure, considering the weight of each factor along the characteristic roots, constructed from the division of the score of each factor by the sum of all eigenvalues, being the factorial weights are used in combination with the values of the original variable to calculate the score of each variable. Table 8 below shows the correlations of the subindex of territorial governance dimensions.

Tabela 8: Correlation of the Normalized Territorial Governance Subindex

	ICGOV	IEF	ICV	IEP	ITGOV	IPS
ICGOV	1,0000					
IEF	0,0475	1,0000				
ICV	-0,4767	0,0290	1,0000			
IEP	-0,5382	0,0333	0,7859	1,0000		
ITGOV	0,0512	0,4522	0,0516	-0,0389	1,0000	
IPS	0,3233	0,0700	-0,3410	-0,4098	0,1877	1,0000

Source: Prepared by the authors. Stata Program 13.

Table 8 shows that there is a negative correlation between ICV (subscript that expresses living conditions) and ICGOV (subscript that expresses governmental capacity), which indicates a contrary direction of the administrative and management capacity of the municipalities in relation to the improvement of the quality of life of its citizens, and, in addition, this low quality of life (ICV) has a strong positive correlation with the characteristics of the productive structure (IEP) dependent on the natural resources base of the region and low capacity to generate employment and income. It is also observed the characteristics of this archaic and underdeveloped productive structure expressed in IEP present negative correlation with IPS and ITGOV. In the first case, it shows that, in municipalities with greater participation, cooperation and social cohesion, including between federal entities and their citizens, this goes against the productive structure more dependent on the exploitation of natural resources. This is also reinforced by the experiences of government implemented, although with very low negative correlation.

At that point, reinforcing governance capacity through experiences and progress (ITGOV), especially of an environmental nature, seems to suggest, due to the negative correlation between the index, that the pressure for natural resources, control of deforestation (IEF).

4. INTERPRETATION OF RESULTS

As previously mentioned, we seek to describe and identify spatial regimes with similar characteristics, configuring spatial clusters, as well as the identification of atypical localities with discrepant attributes in relation to the mean, typically called spatial outliers. In the scope of this study, such localities assume the geographical dimension of the municipalities of the Legal Amazon, and attributes are the governance sub-indices estimated from six local dimensions, namely:

Governance Capacity (ICGOV), Effectiveness and Control of Deforestation (IEF), Living Conditions (ICV), Productive Structure (IEP), Government Intervention (ITGOV) and Social Participation (IPS).

The first hypothesis to be explored is the absence of spatial dependence. It means that any governance index of a given municipality can not depend on the socioeconomic conditions established in its closest neighbors. If this occurs, fortuitously, then each index would be the exact representation of the socioeconomic relations carried out internally in each municipality, disregarding any kind of external interference. Since the nature of some relationships does not depend on geographic distance, finding evidence to support such a hypothesis is not a trivial exercise. However, it can be conducted through statistics that provide spatially correlated autocorrelation coefficients at local and global levels.

Table 9 shows a matrix with coefficients of global spatial autocorrelation inferred from the Moran (1948) statistic. Its main diagonal contains univariate coefficients that record the spatial correlation of the same index, but distributed in different municipalities. The elements above the main diagonal, in turn, correspond to the bivariate coefficients and record the influence of any index on any other indexed to the nearest neighbors. It is worth mentioning that the spatial connectivity was established through a binary matrix of contiguity that attributes: 1 to the neighbors of first order; and 0 in all other cases. In order to restrict the coefficient of spatial autocorrelation between 0 and 1, this matrix was normalized in the line.

We test the null hypothesis that the variables underlying the dimensions (represented in the sub-indices) are distributed randomly in space, implying in the absence of spatial dependence. As can be seen (Table 9), there is insufficient statistical evidence supporting this hypothesis, either in the univariate or bivariate context. All univariate Moran I coefficients are positive and statistically significant at 5% probability of error, indicating that improving the quality of any index, in most of the municipalities of the Legal Amazon, should generate external benefits that affect first-order neighbors. In this sense, it is worth mentioning the actions of command and control to combat deforestation in the Legal Amazon, represented by the IEF, whose actions will be more effective if spatially coordinated in the regions where this problem is most incident. Another prominent result refers to the bivariate correlation established between ICV and ICGOV (Table 9). Its estimated negative coefficient indicates that improving living conditions reduces not only the cost relative to the municipality's own governance capacity but also generates positive externalities in the neighborhood. An example of this is with hospital medical services of medium-high complexity, which are generally not available everywhere. Better basic health care in the most isolated municipalities (improving quality of life) should reduce the pressure on hospital services offered by large urban centers in the Legal Amazon.

Table 9: Moran's I Spatial Correlation Coefficients

	ICGOV	IEF	ICV	IEP	ITGOV	IPS
ICGOV	0,1921 (8,687) [0,001]	0,0643 (4,151) [0,001]	-0,1961 (-11,636) [0,001]	-0,0991 (-6,048) [0,001]	0,0386 (2,438) [0,008]	0,0951 (5,697) [0,002]
IEF		0,8111 (37,046) [0,001]	0,3181 (18,925) [0,001]	0,4232 (24,436) [0,001]	0,4613 (24,894) [0,001]	0,0425 (2,625) [0,006]
ICV			0,6951 (33,223) [0,001]	0,5823 (30,026) [0,001]	0,2052 (13,255) [0,001]	-0,1092 (-6,576) [0,001]

Based on the six governance sub-indices of the municipalities of the Legal Amazon, the LISA index were estimated. Of the 792 municipalities surveyed, 570 appear with a non-significant LISA index at 5%, 75 municipalities were classified as High-High, and 105, as Low-Low. It should be noted that the Low- Baixo concentrates mainly in the north of the state of Pará, more specifically in the Island of Marajó, and in areas of the state of Maranhão; the Alto-Alto group, in turn, covers mainly municipalities in the state of Mato Grosso and Rondônia.

The High-High group on IEF is the most comprehensive in territorial terms, involving 226 municipalities that share positive externalities. This result refers to the magnitude of the autocorrelation coefficient of Table 13, as well as to the positive cross-correlations investigated in this study. The Low-Low group, in turn, is concentrated in the extreme east of the Legal Amazon, on the border between Maranhão and Tocantins.

The cost of living is relatively higher, or, in other words, quality of life is lower (High-High ICV group), for those residing in the extreme north of the state of Pará, including Marajó Island, in municipalities in the state of Maranhão and in the

extreme west of the state of Amazonas. Those living in areas of Mato Grosso face less precarious living conditions than the regional average.

Given that the IEP reflects the participation of people engaged in extractive activities of agriculture and mining, then, where the productive structure is more dependent on natural resources, living conditions tend to be more precarious. This positive relationship is evidenced by the cross-spatial correlation coefficient between the ICV and the IEP of Table 9, indicating that municipalities with a high IEP value (High-High group) are confused with the areas mentioned in the previous ICV analysis.

It is not by chance that these areas have received greater intervention from the federal government, as shown by the LISA indices and the cross-spatial correlation coefficient between the IEP and the ITGOV in Table 9. The results (ITGOV High-High group in Figure 6) show that families are settled more frequently in southeastern Pará. The index also points to areas on the border between the states of Amazonas, Mato Grosso, Rondônia and southern Pará.

The results showed that municipalities with greater social participation, cooperation and social cohesion (IPS High-High IPS group, cross-spatial correlation of IPS in Table 9) are confused with those with greater governmental capacity (ICGOV) and governmental intervention (ITGOV). In general, these municipalities offer lower cost of living (ICV) and have a less dependent productive structure of extractive activities based on the exploitation of natural resources. Although evidence shows a significant overall effect, although relatively weak (lower I of Moran IPS in Table 9), more relevant local influences are noted among municipalities in the southeast of Pará, southwestern Tocantins and Mato Grosso, and between the municipalities of metropolitan area of Manaus, mainly.

Based on the previous results, it was possible to calculate a general index that aggregates all six dimensions. The Territorial Governance Index (IGT) is set out in Figure 1. In this, it can be seen that the municipalities with the worst governance indices are located in the state of Maranhão, mainly; and the municipalities with the best results are distributed among areas of the states of Pará and Amazonas.

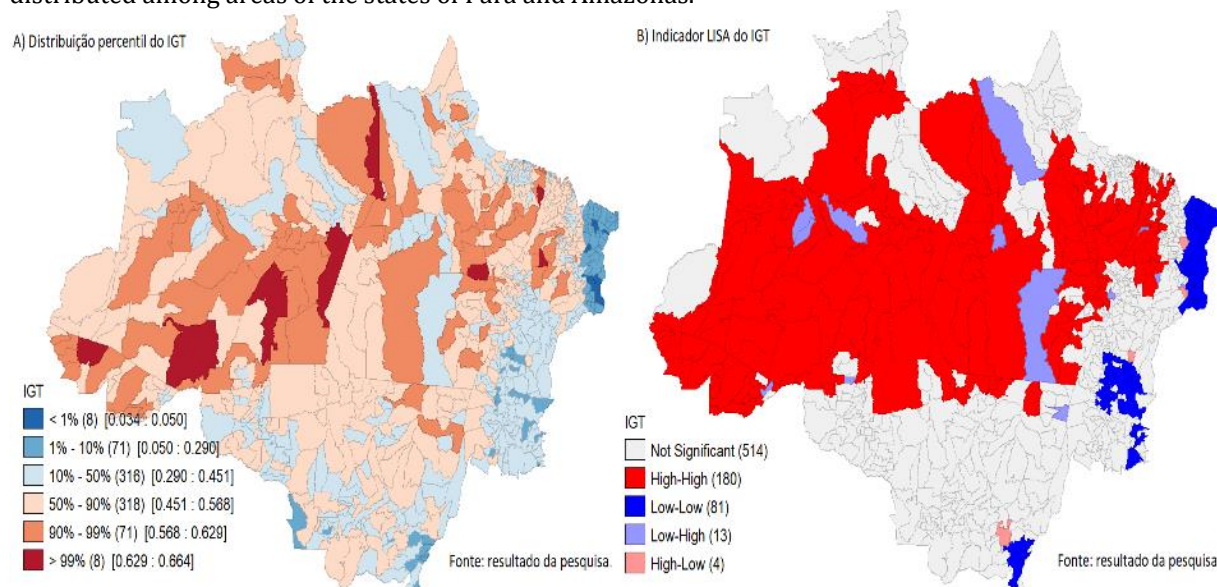

Figure 1: Spatial Distribution of the Territorial Governance Index

Source: Prepared by the authors. R Program.

Finally, it should be noted that the spatial configuration of the global index - IGT is based on positive (good governance) and negative (low governance) forces, the first represented in the subindex governance capacity, government intervention and participation, collaboration and social cohesion. second group integrates the productive structure subindex; effectiveness of deforestation control and living conditions. Thus, it is observed in this general context (IGT) that there is a relatively large number of municipalities that have this indicator low, which indicates a low level of governance in the region, especially to deal with their most emergency problems: deforestation and poor quality of life of the population.

5. CONCLUDING REMARKS

Based on the methodology used here, the index prepared was based on the aggregation of different 6 (six) subindex, each representing a significant dimension of governance in the region, despite factors that contribute to "good governance" and factors that contribute to a fragile governance, or that present weaknesses in relation to one of its main objectives, which is to control illegal deforestation in the region.

The results of the sub-indices, elaborated from the Analysis of Principal Components and Factor Analysis, show a very significant correlation and well adherent to the heterogeneous characteristics of the region. Thus, for example, a negative correlation was observed between ICV (subscript that expresses living conditions) and ICGOV (subscript that expresses governmental capacity), which indicates a contrary direction of the administrative and management capacity of the municipalities in relation to the quality of life of its citizens and, in addition, this low quality of life (ICV) has a strong

positive correlation with the characteristics of the productive structure (IEP), very dependent on the natural resource base.

On the other hand, there was a negative correlation between the archaic and underdeveloped productive structure (IEP) and the efficiency of deforestation control (IEF) with the Social Participation Index (IPS), as well as the experiences of governmental intervention in the region (ITGOV), which indicates that municipalities with greater power of cooperation, collaboration and social cohesion, as well as the own experiences of modification of the territory to increase the environmental governance, as, for example, the creation of units of conservation, are forces contrary to the dependency condition of natural resources and their degradation.

Finally, based on the exploratory analysis of spatial data, the spatial distribution of these subscripts and their spatial dependence were verified using Moran's I and Lisa Map. Thus, for example, it was well-established that the Low-Low group of ICV was concentrated in the Marajó Island and in areas of the state of Maranhão, while the High-High group, in turn, covers mainly municipalities of Mato Grosso and Rondônia.

Otherwise, the High-High group related to the IEF is mainly concentrated in the states of Pará and Mato Grosso, the states of greater deforestation in the region. In addition, the Alto-Alto group of ITGOV shows that families are settled more frequently in southeastern Pará. The index also points to areas on the border between the states of Amazonas, Mato Grosso, Rondônia and southern Pará.

In contrast, the results also revealed that the municipalities with greater social participation, cooperation and social cohesion (high-high group IPS) are confused with those with greater ability to govern (ICGOV) and government intervention (ITGOV), with local influences more relevant among the municipalities of the southeast of Pará, southwestern Tocantins and Mato Grosso, and among the municipalities of the metropolitan area of Manaus, mainly.

All these results contribute to the spatial configuration of the global governance index (IGT), which shows that there is a relatively large number of municipalities that have this indicator low, which indicates a low level of governance in the region, especially to deal with its most urgent problems: control of deforestation and low quality of life of the population.

POLITICAL DYNASTIES AND HUMAN DEVELOPMENT INVESTMENTS: EVIDENCE OF LINKAGE FROM RIZAL PROVINCE, PHILIPPINES

[John Emmanuel Villanueva](#)

University of the Philippines-Diliman, Philippines

ABSTRACT

To test whether dynastic mayors tend to have lower human development investments for their constituents, this study draws inference from a panel data composed of all 13 municipalities in Rizal, a well-known dynastic province in the Philippines, as a preliminary empirical investigation. These municipalities are dichotomized into dynastic or non-dynastic and observed over 17 years (i.e., 2001-2017). All identified political dynasties are categorized as fat dynasties—elected public officials occupying political seats simultaneously with their relatives over several incumbency periods. Based on the results of Panel-corrected Prais–Winsten Generalized Least Squares (GLS) estimation, this research finds that Rizal municipal governments led by fat dynastic mayors tend to have significantly lower human development investments, compared with non-dynastic counterparts. Specifically, they spend less on human development at the (1) aggregate level (i.e., total municipal expenditure on health, education, and social welfare), at the combined levels of (2) education and health, and (3) at the specific sector of education. These findings are in line with the prediction of the predatory view of political dynasties, particularly the fat type. Results are robust to various alternative model specifications and econometric estimation procedures.

political dynasties, fat dynasties, human development investments, health, education, social welfare, municipal government, municipal expenditure

1. INTRODUCTION

A thriving culture of self-perpetuating political families (Rossi, 2017) that manifest elite persistence (Querubin, 2013), hence, the term “political dynasties”, is a hallmark of Philippine politics, particularly at the local level (Teehankee, 2018). Political dynasties in the Philippines are “exceptional in their persistence and scope” (Mendoza, Ong Lopez, & Banaag, 2019, p. 3), so much so that their pervasiveness “is off the chart compared to any other country in the world” (Acemoglu & Robinson, 2013a, para. 3). As it is, nearly 80% of all representatives in the Congress are from political dynasties (Mendoza, Ong Lopez, & Banaag, 2019). At the subnational level, average dynastic share among local government officials stood at 81% for governors and vice-governors, 69% for mayors, and 57% for vice-mayors (Mendoza, 2018).

A political family is considered as political dynasty if it retains political power through maintaining control in at least one elective position over successive electoral cycles (Albert et al., 2015). Alternatively, an elected politician is labeled as “dynastic” if he/she is related by blood (i.e., consanguinity) or by marriage (i.e., affinity) to other politicians currently or previously holding elective public office (Geys & Smith, 2017).

Article II, section 26 of the 1987 Philippine Constitution proscribes political dynasties in the country. However, it requires an enabling legislation to be passed by the Congress to define and implement the said dynastic regulation (Collas-Monsod et al., 2004). Since most representatives in the Congress are members of political dynasties (Mendoza, Ong Lopez, & Banaag, 2019), passing an anti-political dynasty bill remains an uphill battle (Tadem & Tadem, 2016).

Literature on political dynasties is predominantly concerned with why and how they arise and persist (e.g., Dal Bo et al., 2009; Querubin, 2013; 2016). Relatively fewer studies analyze their consequences, particularly with respect to governance, socioeconomic outcomes, and development (Daniele & Geys, 2014; Geys, 2017; Geys & Smith, 2017). Contributing to the latter strand of the literature, this research examines the effect of dynastic presence on human development investments. Specifically, the research investigates the effect of fat political dynasties on human development investments at the municipal level, as reflected in the municipal government expenditure on education, health, and social welfare.

In line with the predatory view of political dynasties, this study posits that fat dynastic municipal governments have significantly lower human development investments compared with non-dynastic counterparts, *ceteris paribus* (i.e., everything else held constant/fixed). To empirically test the theoretical conjecture posed, the study employs a case study approach and draws inference from multivariate panel regression analysis of all 13 municipalities in Rizal province, Philippines observed over a 17-year period (2001-2017). Rizal is a well-known dynastic province in the country.

Based on the results of Panel-corrected Prais–Winsten Generalized Least Squares (GLS) estimation, this research finds that Rizal municipal governments led by fat dynastic mayors tend to have significantly lower human development investments for their constituents, compared with non-dynastic counterparts. These findings are in line with the prediction of the predatory view of political dynasties, particularly the fat type: with wider and deeper entrenchment of

political power due to monopoly of multiple elective positions over consecutive years, fat political dynasties are inherently prone to be predatory—inimical to governance, socioeconomic outcomes, and development.

The rest of the paper is structured as follows: the remaining part of this section provides essential background information; section II presents a review of related literature; section III expounds on the methodology employed; section IV shows the results and offers various plausible explanations; and lastly, section V concludes and outlines several recommendations for further studies.

Human development investments

Human development is about expanding the richness of people's lives, rather than merely the richness of the economy in which they live. It concentrates on "improving the lives people lead rather than assuming that economic growth will lead, automatically, to greater wellbeing for all" (United Nations Development Programme (UNDP), para. 2, n.d.). As a development paradigm, it endeavors to provide people with greater freedom to live the lives they value (UNDP, n.d.).

Central to the pursuit of human development are human capital accumulation and human capabilities expansion (Sen, 1997). Human capital refers to the stock of skills, knowledge, expertise, and other similar attributes that increase an individual's productivity (Becker, n.d., 1962; Goldin, 2016; Schultz, 1961, 1972). Human capital benefits both the individual and his/her society at large (Abrigo et al., 2017; Schultz, 1961). At the individual level, increased productivity associated with human capital is a source of future earnings or of future satisfaction, or both (Schultz, 1972). At the societal level, a large body of theoretical and empirical literature provides evidence that human capital plays a central role in bolstering economic growth and provides other positive externalities (Abrigo et al., 2017; Goldin, 2016). Nonetheless, the concept of human capital is fundamentally economic in nature (Becker, n.d., 1962; Schultz, 1961, 1972) and relates more to human development as a means to an end. To complement the notion of human capital, Sen (1997, p. 1959) introduces the concept of human capabilities: "the ability of human beings to lead lives they have reason to value and to enhance the substantive choices they have." This, in turn, embraces the end aspect of human development.

Human development will not prosper without necessary government investments aimed at enhancing human capital and enlarging human capabilities (UNDP, 1991). In a decentralized representative democracy like the Philippines, LGUs are at the forefront of such public investment initiative (Manasan, 1997). It is in this context that the study operationally defines human development investments as local government investments, reflected in the level of local public expenditure, on policy areas that directly reinforce both human capital and human capabilities. This definition does not discount the importance of private investments on human development, as people do invest in themselves in the form of private spending (Schultz, 1961). Instead, it highlights the government's pivotal role in helping citizens help themselves, because not all individuals have the initial endowments to be able to invest in their own human capital and capabilities. Disparities in income, age, gender, educational background, health status, and social status are just some of many constraints (Beverly & Sherraden, 1997). In essence, government investments on human development are grounded on both efficiency (in relation to economic growth and positive externalities) and social equity (equal opportunity for all) considerations (Abrigo et al., 2017; Goldin, 2016; Beverly & Sherraden, 1997).

There are three (3) major pillars of human development: the ability to (1) live a long, healthy, and creative life; (2) be knowledgeable; and (3) have access to resources necessary for a decent standard of living (UNDP, n.d.). Progress in these fundamental dimensions of human development is measured through a composite index dubbed as the Human Development Index (HDI) (UNDP, 2016). It is unsurprising then, that discourse on human development investments is heavily focused on public spending on health and education.

Nonetheless, there is mounting recognition that public expenditure on social welfare should also be treated as human development investment, especially in terms of providing social protection and support for rehabilitation to disadvantaged and marginalized groups (Ahn & Kim, 2014; Morel et al., 2012; Gonzalez, 2017). The argument is that government investments in education and health is for all citizens, regardless of their constraints, while investment on social welfare is particularly focused on helping disadvantaged and marginalized groups enhance their human capital and expand their human capabilities to be able to participate in employment and social life (European Commission, n.d.; Beverly & Sherraden, 1997).

Collectively, public expenditure on education, health, and social welfare embodies an inclusive government strategy for human development investments as they represent "an essential part of what governments do to improve the quality of life of their citizens and the foundations of human capital in their societies." (Huber et al., 2008, p. 420). In relation to political dynasties that dominate local governance in the Philippines, the focus is on the level of local public expenditure on the said policy areas at the municipal level.

At this point, it is worthy to note that while it is more desirable to examine the effects of political dynasties directly on outcomes pertinent to human development (e.g., through the HDI), this study focusses instead on local public spending where they have direct influence. As explained by Solon et al. (2009), using local government outlays instead of development outcomes is justified because expenditures are more directly controlled by local leaders—thereby reflecting their real priorities. Consequently, given its implications on human development, local government expenditure on health, education, and social welfare represents a reasonable measure of good performance of incumbent local officials who may be dynastic or non-dynastic (Solon et al, 2009; Manasan, 1997).

Good governance and decentralization

In a bid to bring governance closer to the people, the Philippine national government devolved substantial taxing, spending, and borrowing powers to local government units (LGUs) through a wide-ranging decentralization process

embodied in the 1991 Local Government Code (henceforth, 1991 LGC) (Llanto, 2012; Manasan, 2005). The central government institutionalized the transfer of the Internal Revenue Allotment (IRA), a formula-based block grant, to help LGUs finance the additional responsibilities (Labonne et al., 2015; National Tax Research Center (NTRC), 2008).

With the 1991 LGC in place, responsibility for basic services delivery were transferred to LGUs (i.e., provinces, cities, municipalities, and barangays): social welfare services, primary health care, hospital care, and an array of agricultural and environmental services.¹⁹⁰ A special case is basic education, as the primary responsibility for its provision still lies with the national government. LGUs' role is limited to the construction and maintenance of basic education infrastructure (e.g., school buildings) and funding of sports activities. At the municipal level, main devolved functions for basic services that relate to human development are as follows: (1) education – construction and maintenance of public elementary schools; (2) health – primary health care; and (3) social welfare – programs and projects concerning the welfare of vulnerable population (i.e., children, youth, elderly, and disabled persons) (WB, 2016; Labonne et al., 2015; Bautista, 2013; Manasan, 2005).

From an economic standpoint, the Philippines' decentralization drive redounds to increased efficiency and effectiveness in public service delivery, given that local chief executives (LCEs) are in a better position to know and respond (given their relative proximity) to the preferences of their constituents compared with national-level officials (Oates, 1972). But from the view of good governance paradigm, decentralization is more than economic welfare gains (Capuno et al., 2012a; Llanto, 2012): it symbolizes the “logical application of the core characteristics of good governance at the sub-national and local levels” (UNDP, n.d., as cited in Brillantes Jr. & Cuachon, 2002, p. 3).

Governance can be considered “good” at the subnational level when local governments effectively and efficiently allocate and manage public resources to respond to collective problems of their constituents, in general, and in relation to human development, to help them attain individual satisfaction and prosperity by providing them with key public services in the fields of health, education, and social welfare (UN Department of Economic and Social Affairs (UN DESA), 2007).

Political dynasties: Predatory vs. stationary bandit view

Although decentralization (ideally) improves local public service delivery and enhances constituents' overall welfare (Solon et al., 2009), it may also reinforce the dominance and propagation of local hegemonies (UN DESA, 2007). In the Philippines, this is evident in the proliferation and perpetuation of political dynasties among LGUs in the Philippines after the 1991 LGC was enforced (Querubin, 2013, 2016).

In general, political dynasties may be considered as extractive political institutions (Acemoglu & Robinson, 2013b) that effectively concentrate and maintain political power within their families as relatives take turn occupying elective positions successively or simultaneously (Simbulan, 2012). Moreover, they “inherit an electoral advantage from their political forebears” (Daniele & Benny, 2014, p. 2)—in the form of “brand name recall”, wealth, and control of political and economic resources (George & Ponattu, 2017). Aside from these political and financial capital (Ali, 2016), political dynasties benefit from externalities or spillover effects of the so-called incumbency advantage, which claims that incumbent officials running for re-election have electoral advantage and therefore, more likely to win (Querubin, 2013). In the Philippines, Querubin (2016) finds that candidates related to an outgoing incumbent enjoy an electoral advantage over non-dynastic candidates, but such advantage doubles for candidates who run in an election while their relative still sits in office.

Because of these attributes, members of political dynasties have a higher likelihood of winning elections compared with non-dynastic candidates, all things being equal. Hence, political dynasties may: (1) weaken political competition (high-quality non-dynastic candidates are easily defeated in elections); and (2) and worsen governance and negate accountability (moral hazard problems: self-assured of continuous re-election due to deep political entrenchment, incumbent dynastic officials may (a) not have incentives to engage in productive vote courting activities and hence, underperform in office; (b) implement self-serving policies; and (c) perpetuate corruption). These, in turn, may (3) lead to poorer socioeconomic outcomes and development (Bragança et al., 2015; George & Ponattu, 2017; Geys, 2017; Pano, 2016; Tusalem & Pe-Aguirre, 2013).

Essentially, these socially undesirable characteristics of political dynasties embody the more popular perception on them—the so-called “predatory view” of political dynasties (Solon et al., 2009). Consistent with this perspective, political dynasties are usually portrayed as necessarily inimical within the political science and sociology literature (Mendoza et al., 2016).

However, there is an alternative strand in the economics literature that may possibly see political dynasties in a positive light. That is, if political dynasties govern like “stationary bandits”, they may conceivably have positive effects (George & Ponattu, 2017; Mendoza, Jaminola III, & Yap, 2019; Solon et al., 2009). This lesser-known perspective on political dynasties takes off from the idea of economist Mancur Olson (1993). According to Olson (1993, p. 569), a stationary bandit is an autocratic/monarchic-type of leader who has “encompassing interest in the territory he controls and accordingly provides domestic order and other public goods.. at the same time that he extracts the largest possible net surplus for himself.” Further, he/she “anticipates and values dynastic succession that further lengthens the planning horizon and is good for his subject.” (Olson, 1993, p. 571). Hence, although their interests are purely extractive, political dynasties may have the incentive to govern well and thereby induce positive effects on socioeconomic outcomes and development because of longer political horizon and bequest motives (Besley & Reynal-Querol, 2017; George, 2019; George & Ponattu, 2017; Mendoza, Jaminola III, & Yap, 2019; Zheng et al., 2016).

¹⁹⁰ For a full list of devolved functions per LGU, please see Section 17 of the 1991 LGC.

Sequential tenure in office among relatives may reinforce familiarity and continuity that bodes well with performance and bolsters inter-temporal incentives to pursue long-term government projects and programs (Bragança et al., 2015; Tusalem & Pe-Aguirre, 2013). Meanwhile, legacy/reputation concerns ascribed to bequest motives may mitigate or even trump moral hazard problems associated with political dynasties (Besley & Reynal-Querol, 2017). Concern for their relatives' success in upcoming elections may mitigate the opportunistic behavior of incumbent dynastic officials and may likewise provide incentive to govern well and demonstrate good performance in office (Crowley & Reece, 2013; George & Ponattu, 2017; Zheng et al., 2016).

This study dwells on the extractive political institutions (Acemoglu & Robinson, 2013b) nature of political dynasties and therefore, adopts the predatory view of political dynasties (Solon et al., 2009) as the guiding theory behind the hypothesis being tested empirically.

Political dynasties: Fat vs. thin

While political dynasties are typically considered as a monolithic group (Lacroix, et al., 2019), there is a growing body of literature that examines whether political dynasties have divergent effects when disaggregated into various categories (e.g., Ali, 2016; George, 2019). The logic is that perceived effect of political dynasties as a homogenous group is a net effect of its various types—some of which are more inclined to have positive (negative) effects than the others (George, 2019). In the Philippines, Mendoza and colleagues (i.e., Mendoza et al., 2016; Mendoza, Jaminola III, & Yap, 2019; Mendoza, Ong Lopez, & Banaag, 2019) propose a functional typology of political dynasties: (1) thin dynasty – if relatives occupy an elective position sequentially (i.e., family members continuously take turns serving in the same post); or (2) fat dynasty – if family members occupy multiple political seats simultaneously (i.e., at least two family members occupy different elective positions at the same time over consecutive years).

Mendoza and colleagues argue that fat and thin dynasties may possibly have divergent effects owing to fundamental differences in constraints and incentives. On the one hand, fat dynasties have higher proclivity to have deleterious effects, whereas thin dynasties may possibly have desirable effects, *ceteris paribus*. Since fat dynasties are the predominant type in the Philippines (Mendoza, Jaminola III, & Yap, 2019), the perceived net effect of political dynasties in the country in general (as homogeneous group) is logically assumed as malign.

Due to wider and deeper entrenchment of political power (monopoly of multiple elective positions over consecutive years) (Mendoza, Jaminola III, & Yap, 2019), as well as greater incumbency advantage externalities (extends to relatives in several positions) (Querubin, 2016; 2013), fat dynasties may not have the incentive to signal their competence by performing well in office and worse, may be more motivated to pursue self-serving activities to the detriment of their jurisdictions (Ali, 2016; Daniele & Vertier, 2018; George, 2019; George & Ponattu, 2017; Geys, 2017; Tusalem & Pe-Aguirre, 2013).

On the other hand, thin dynasties are constrained with less concentration of power (domination of only one political seat over successive years) (Mendoza, Jaminola III, & Yap, 2019) and limited spillover effect of incumbency advantage (applies to one position only) (Querubin, 2016; 2013). Hence, relative to fat dynasties, thin dynasties will more likely turn to bequest motives to ensure re-election (Mendoza, Jaminola III, & Yap, 2019)—they have the incentive to uphold their family's legacy or reputation by exhibiting good performance in office, which in turn, benefits constituents' welfare (Crowley & Reece, 2013; George & Ponattu, 2017; Olson, 1993; Solon et al., 2009; Zheng et al., 2016).

Since fat dynasties have higher tendency to have inimical effects compared with thin dynasties, studies of Mendoza and colleagues are concentrated on the former, rather than the latter type. This research follows suit by focusing on fat dynasties among municipalities in Rizal province.

The municipal mayor

As the LCE in charge of local governance at the municipal level in the Philippines (1991 LGC), the mayor serves as the principal decisionmaker in setting priority agenda and implementing policies in line with the said agenda within the municipality (Dulay & Go, 2021). Section 444 of the 1991 LGC lists the duties and functions of the municipal mayor: (1) exercise supervision and control over all municipal government policies, programs, projects, services, and activities (PPPSA); (2) enforce all laws and ordinances and implement all approved PPPSAs within the municipality; (3) initiate and maximize generation of revenues and other resources for the implementation of the municipal development plan and other PPPSAs; and (4) ensure the delivery of basic services for the constituents.

Pursuant to the execution of the municipal development plan and provision of basic services, the mayor is primarily responsible for proposing and disbursing the municipal government's annual fiscal budget (Local Government Academy (LGA), 2019). With this power, a mayor can prioritize spending on specific PPPSAs. For instance, a mayor may focus more on expenditure items within the social services sector that includes human development investments in health, education, and social welfare of constituents. Or he/she may seek to spend heavily on general public services which is perceived as a bountiful source of rents in office owing to its less transparent nature (Capuno, 2012b; Diokno-Sicat, 2016). The mayor may likewise utilize discretionary funds to return favors to current supporters and/or win new supporters/allies, subject only to the central government's oversight (Capuno, 2010).

An incumbent mayor in the Philippines is typically supported by the majority of the municipal council, gets to freely appoint allies in key appointive positions (Capuno, 2010), can take advantage of the wide latitude of discretion in fiscal decision making (revenue generation and expenditures) to be re-elected (Solon et al., 2009), and may effectively boost election bids of his/her relatives to the position he/she will vacate and other elective posts via incumbency advantage (Querubin, 2016; 2013; De Dios, 2007).

Indeed, the municipal mayor wields sizable political and administrative powers and thereby, possesses considerable leeway in the use of discretion (Labonne et al., 2015), particularly with respect to prioritization of municipal government expenditures. Therefore, examining the effect of political dynasties on human development investments with the mayoralty seat as reference position is a worthwhile research endeavor.

Case study: Municipalities of Rizal province

Many studies in the Philippines analyze political dynasties at the provincial level (e.g., Collas-Monsod et al., 2004; Virola et al., 2016). However, there is a growing number of researches here and abroad that examine the effects of political dynasties at a lower local government level—at the municipal level where governance is closer to the people (e.g., Capuno et al., 2012a, 2012b and Dulay & Go, 2021 for the Philippines; Asako et al., 2015 for Japan; Bragança et al., 2015 for Brazil; Daniele & Vertier, 2016, 2018 for Italy). This research aims to contribute to this stream in the literature by using the case of municipalities in Rizal province as a preliminary empirical investigation.

Composed of 13 municipalities and one (1) component city (i.e., Antipolo City), Rizal province stands as an interesting case for an initial empirical study on political dynasties on two (2) accounts: firstly, the province itself is considered dynastic, with the Ynares family at the helm of gubernatorial position from 1992-present (Rizal provincial government, 2019); secondly and more importantly, its municipalities¹⁹¹ provide a good mix of dynastic and non-dynastic incumbent politicians, as will be shown in the results section of the study.

2. REVIEW OF RELATED LITERATURE

Viewing political dynasties as a homogeneous group, relevant Philippine literature is dominated by empirical studies pointing to a negative effect of political dynasties on governance, socioeconomic outcomes, and development. Pertinent international literature reflects the same trend. While political dynasties are typically considered as a monolithic group (Lacroix et al., 2019), there is a growing body of literature that examines whether political dynasties behave differently when categorized into various types. At this disaggregated level of analysis, results are mixed—both negative and positive associations are prominent. All studies cited utilized econometric analyses.

Philippine context: Political dynasties as homogeneous group

In the Philippines, Tusalem and Pe-Aguirre (2013) rely on ordinary least squares (OLS) regression and enunciate the pernicious effect of political dynasties on democratic governance in terms of public goods provision. Their results suggest that provinces dominated by political dynasties are less likely to experience good local governance with respect to: (a) health spending; (b) infrastructure development; (c) employment; (d) criminality; and (e) overall quality of government. Meanwhile, Collas-Monsod et al. (2004) observe that political dynasties seemingly constrain the efficient delivery and quality of public services. Their regression analyses suggest that presence of political dynasties among provinces is linked to lower primary education completion rates, lower per-capita income, and higher poverty.

Similarly, Mendoza et al. (2012) find, based on partial correlations, that provinces with higher concentration of political dynasties are associated with lower human development and higher levels of poverty. Using a more nuanced approach via beta-binomial maximum likelihood estimation (MLE-BB), Mendoza et al. (2016) show that presence of political dynasties is correlated with greater poverty, specifically in non-Luzon provinces.

In congruence with Mendoza et al. (2012, 2016), Tusalem (2019) provides evidence that dynastic prevalence among Philippine provinces is linked to higher poverty incidence, as well as lower average family income. Tusalem (2019) employs a panel-corrected standard error (PCSE) estimation.

Philippine context: Political dynasties as various types

While Mendoza and colleagues propose a dichotomous fat-thin classification of political dynasties, their analyses focus more on consequences of fat dynasties since they represent greater political concentration compared with thin dynasties (Mendoza, Ong Lopez, & Banaag, 2019). In their previous studies, Mendoza and colleagues show that “where there are fatter dynasties, there tend to be deeper poverty and underdevelopment.” (Mendoza & Banaag, 2017, p. 1). More recently, Mendoza, Ong Lopez, and Banaag (2019) present a special case of fat dynasties pertaining to provinces where incumbent governor, mayor, and congressman are relatives. Following Mendoza et al.’s (2016) econometric strategy (i.e., MLE-BB), their results reveal a positive association with poverty, with a more pronounced correlation in non-Luzon areas.

Dulay and Go (2021) also investigate the effects of fat dynasties but prefer to call them horizontal dynasties. Banking on a close elections Regression Discontinuity Design (RDD) among municipalities, they find that horizontally dynastic mayors (1) tend to have higher total government spending, (2) a mayor-vice-mayor dynastic linkage is specifically correlated with increased spending in the health and economic services components of total municipal expenditure; (3) but such increased expenditures do not lead to economic growth or lower poverty.

Using Fixed Effects (FE) specification, Capuno et al. (2012b) find evidence suggesting that dynastic mayors on their last term (i.e., last-termer or term-limited) tend to reduce health insurance coverage to the poor but do not appear to have higher or lower expenditure on other local public services, compared with other mayors. On the other hand, Diokno-Sicat (2016) adopts a Random Effects (RE) estimation and finds that last-termer dynastic governors spend more on health, education, labor and employment, and housing and community development, but less on economic services. Meanwhile,

¹⁹¹ Antipolo City is excluded from the sample for comparability among observations.

results of Solon et al. (2009) based on RE logit estimates reveal that dynastic governors aiming for re-election tend to increase spending on economic development services when faced with competition from other political dynasties.

International literature: Political dynasties as homogeneous group

Drawing inference from the flooding incidence across Pakistan in 2010, Ali (2016) employs period FE regression approach and finds that dynastic politicians significantly spend less on development-oriented programs and the expenditure is further dampened in the aftermath of floods. The definition of development expenditure in the study includes spending on education and health, among others.

Similarly, Asako et al. (2015) use instrumental variable (IV) estimation and reveal that Japanese municipalities with dynastic representatives to the Lower House exhibit lower economic performance despite having abundant resources. Meanwhile, Setyaningrum and Saragih (2019) unearth evidence from Indonesia that political dynasties are negatively correlated with local government performance.

Using OLS and quantile regressions, Acemoglu et al. (2007) find that municipalities in Cundinamarca region, Colombia with higher prevalence of dynastic mayors are less developed today. They treat presence of political dynasties as indicator of political concentration, which in turn, is viewed as measure of political inequality.

In India, George and Ponattu (2017) provide evidence that dynastic rule worsens both public goods provision (in terms of health, transport, financial services, and social welfare programs) and local economic development (proxy: night-time luminosity). On the other side, Bragança et al. (2015) show that dynastic municipal governments in Brazil spend more resources on the following expenditure items: (1) education and culture; (2) health and sanitation; (3) housing and urban development; and (4) public transportation. Despite the larger expenditures, they find no significant changes in the quality of public services and improvements in economic growth among dynastic municipalities, compared with non-dynastic counterparts. Both George and Ponattu (2017) and Bragança et al. (2015) rely on close elections RDD strategy.

International literature: Political dynasties as various types

Extending her analysis on political dynasties in Pakistan, Ali (2016) disaggregates dynasties in terms of their sources of power: land owning, business ownership, and connection to a *biradari* (clan). She finds that dynastic representatives whose source of power is landholding (linkage with *biradari*) are more (less) likely to engage in local development spending.

Among Italian city governments, Daniele and Vertier (2016) observe the following based on their results drawn from various specifications (i.e., close elections RDD, FE estimation, and propensity-score matching): (1) among mayors eligible for reelection (on a second term for a two-term limit), dynastic mayors spend relatively much more at the last year of their first term compared with non-dynastic mayors; and (2) among last-termer mayors, dynastic mayors seemingly reduce expenditures at the end of their term, compared with non-dynastic counterparts. In a more recent study using close elections RDD and FE estimation only, Daniele and Vertier (2018) show that dynastic city mayors who are not yet term-limited are more likely to increase capital expenditure in the year before an election.

On the other hand, George (2019, p. 28) continues to use RDD strategy and offers a binary classification of political dynasties: founder and descendant. He finds that founders (descendants) of political dynasties in India have positive (negative) effects on public goods provision: “greater exposure to founders improves the availability of public goods” along categories such as education, healthcare, and connectivity, whereas descendants worsen public goods provision in terms of education, healthcare, and sanitation.

Meanwhile, Lacroix et al. (2019) categorize political dynasties in France as democratic and non-democratic. Taking on the case of the enabling act giving full powers to Marshal Pétain, a dictator, on July 10, 1940, they find that democratic dynastic parliamentarians were more likely to oppose the act (by 7.6-9.0 percentage points margin) than non-democratic dynastic and non-dynastic parliamentarians. Lacroix et al. (2019) bank on a binary logit regression model.

Synthesis

As it appears, the effect of political dynasties on governance, socioeconomic outcomes, and development is not straightforward: findings differ depending on (a) whether political dynasties are viewed as homogeneous group or as various types, (2) what the response variables are, and (3) the specific econometric strategy employed. Nevertheless, the predatory view on political dynasties ostensibly dominates the relevant literature.

Of particular interest to the research at hand, which focuses on the effect of dynastic presence on human development investments, are the following studies: Tusalem and Pe-Aguirre (2013) and Dulay and Go (2021) on health spending, Bragança et al. (2015), Diokno-Sicat (2016), and Ali (2016) on health and education spending, George and Ponattu (2017) and George (2019) on public goods provision in terms of education, health, and social welfare programs, and Capuno et al. (2012b) on health insurance coverage for the poor. The researcher draws from the insights of these studies in discussing the results of the present research.

3. METHODOLOGY

Research design

This work adopts a quantitative, case study approach as a research design and employs multivariate panel regression analysis of publicly available government data as a research method to empirically test the hypothesis posed.

Variables and hypotheses

Main variable of interest: Political dynasties

Akin to how several relevant studies identified family ties among elected public officials, proxy measure for political dynasties in the study is determined through the “family name identification process” (Bragança et al., 2015; Daniele & Vertier, 2016; Mendoza et al., 2016; Querubin, 2013, 2016). However, the primacy of the mayoralty position as a reference point in identifying political dynasties is accentuated, given its power and discretion on municipal government expenditure consistent with the provisions of the LGC of 1991 (Labonne et al., 2015).

Following such modified approach, the family name of an elected municipal mayor (reference position) in Rizal province in 2001 is matched with the family name of elected (1) mayor (in subsequent elections), vice-mayor, and councilors in the same municipality; (2) mayors, vice-mayors, and councilors in other Rizal municipalities and city (Antipolo); (3) governor, vice-governor, and board members of Rizal; and (4) representatives of Rizal’s two (2) legislative districts¹⁹² between election years 2001 and 2016. The levels of matching process are presented in order—from within the municipality up to the legislative districts. If the family names are the same, they are initially considered relatives (whether by consanguinity or affinity). This method is closely related to the strategy of Dulay and Go (2021) and is more expansive compared with other related municipal level researches that restrict family ties matching to within the same municipality only (i.e., Bragança et al., 2015; Daniele & Vertier, 2016, 2018). Meanwhile, familial relations are further verified through desk research and informal interviews. Data is culled from local election results for six (6) electoral years between 2001-2017 (i.e., 2001, 2004, 2007, 2010, 2013, and 2016) collected and maintained by the Commission on Elections (Comelec).

This research considers a municipality/municipal government as “dynastic” if it is led by a “dynastic mayor” (homogeneous view) who may be fat dynastic or thin dynastic (disaggregated view), based on the dichotomized classification proposed by Mendoza and colleagues. A municipality/municipal government is classified as “thin dynastic” if members of the same family hold the mayoralty position continuously from 2001-2017 but do not have kinship ties with other locally elected officials in Rizal in any of the incumbency periods. On the other hand, a municipality/municipal government is categorized as “fat dynastic” if an incumbent mayor and at least one (1) relative who also holds elective office are serving their terms simultaneously for at least two (2) incumbency periods between 2001 and 2017.¹⁹³ This is a stricter characterization of fat dynasties compared with Mendoza, Ong Lopez, and Banaag (2019) who propose a temporal conditionality of at least one (1) election cycle only. The argument rests on the succession and considerable time facets of the “dynastic” nature of political dynasties. The Merriam-Webster dictionary defines dynasty as “a succession of rulers of the same line of descent” and/or “a powerful group or family that maintains its position for a considerable time.” Typical examples are the dynasties that ruled China for hundreds of years. Clearly, relatives who concurrently serve their incumbencies for just one term should not be considered as fat dynasties, or political dynasties at all, unless they demonstrate the “staying power” characteristic of dynasties by being re-elected for at least another term.

Based on the identification procedure cited above, six (6) Rizal municipalities/municipal governments are identified as dynastic and all are categorized as fat dynasties: Baras (Robles family), Binangonan (Ynares), Cardona (San Juan), Jala-Jala (Pillas), San Mateo (Diaz), and Tanay (Tanjuatco). The remaining seven (7) municipal governments are considered non-dynastic: Angono, Cainta, Morong, Pililla, Rodriguez, Taytay, and Teresa. Further details are provided in the results section.

Fat dynastic municipalities/municipal governments are coded=1 in the database, while non-dynasts are coded=0. Such dummy variable treatment of political dynasties is consistent with how relevant studies operationally define dynasties in their regression analyses (e.g., Bragança et al., 2015; Daniele & Vertier, 2016, 2018; Diokno-Sicat, 2016; Dulay & Go, 2021; Lacroix et al., 2019; Mendoza, Ong Lopez, & Banaag, 2019; Tusalem & Pe-Aguirre, 2013). Further, the author concurs with Mendoza, Ong Lopez, and Banaag (2019) who assert that utilizing a dummy variable as indicator of dynastic presence is a much more nuanced approach compared with earlier indicators that simply relied on the share of political dynasties among all locally elected officials. The political dynasty dummy clearly links the familial ties among key incumbent officials. In this case, between the mayor and (a) vice-mayor and councilors in the same Rizal municipality, (b) the same set of local officials in other municipalities and city within the province, (c) the most powerful LCE in the province (i.e., the governor) and other key provincial government officials (i.e., vice-governor and board members); and (d) Congresspeople who represent Rizal municipalities in the Lower House.

Outcome variables: Municipal expenditure on human development

This research examines the effect of dynastic presence on five (5) distinct categories of human development-oriented municipal government expenditures. These categories are clustered into three (3) domains: at the aggregate, combined, and specific sector levels. Firstly, analysis starts at the aggregate level wherein total local public spending on health, education, and social welfare will be collectively called as human development spending/expenditure. This is consistent with the study’s assertion that the three (3) sectors represent an inclusive government strategy for human development investments. Secondly, combined spending on education and health will be analyzed since expenditures on the two (2)

¹⁹² Rizal’s first district covers Angono, Binangonan, Cainta, and Taytay; the second district encompasses Baras, Cardona, Jala-Jala, Morong, Pililla, Rodriguez, San Mateo, Tanay, and Teresa.

¹⁹³ Incumbency periods considered based on the three (3) year term limit provided for LGU officials (LGC of 1991): 2001-2004; 2004-2007; 2007-2010; 2010-2013; 2013-2016; 2016-2019.

sectors are considered primary investments for human development. Lastly, analysis on the specific sector spending among the three (3) expenditure items ensues.

Indicators representing the various categories of LGU expenditure are extracted from the pertinent database compiled and maintained by the Department of Finance-Bureau of Local Government Finance (DOF-BLGF): the Statement of Receipts and Expenditures (SRE) Report which monitors financial performance (income and expenditure) of LGUs (BLGF, n.d.) (Table 1). Missing data, though few and far in between, are addressed through interpolation and extrapolation methods for a balanced panel dataset. Consistent with related researches (e.g., Daniele & Vertier, 2016, 2018; Kelekar & Llanto, 2013, 2015; Manasan, 1997, 1998), this study measures the outcome variables in per capita terms to control for each municipality’s population size.

Table 1. Outcome variables: Indicators and their technical definitions

Outcome variable	Indicator*	Technical definition
Human development expenditure	Total municipal spending on health, education, and social welfare	Sum of municipal government expenditures on education, health, and social welfare
Total education and health expenditure	Not applicable (NA)**	Sum of municipal government expenditures on education and health
Total education expenditure	(Expenditure on) Education, culture & sports/manpower development	Covers sector expenditures for services in support of schools and education facilities; planning and manpower development; sports; and cultural preservation and enrichment*
Total health expenditure	(Expenditure on) Health, nutrition & population control	Covers sector expenditures for health program including medical, dental and health services; planning and administration of nutrition programs; population and family planning programs; and administration of these programs*
Total social welfare expenditure	(Expenditure on) Social services and social welfare	Covers sector expenditures for the upliftment of disadvantaged families and children; the rehabilitation of the physically and socially handicapped; assistance to distressed and displaced individuals and families; care of the aged and other welfare services and payment of retirement pension and other social security benefits. Also included are expenditures for the provision of services and facilities for recreational, religious and other social activities not elsewhere classified*

Notes: *Adopted as is (i.e., verbatim) from the metadata document of SRE (BLGF, n.d.); **Computed by the author from SRE database.

Control variables

Among various determinants of human development expenditures, four (4) factors are selected as control variables (all measured at municipal-level): (1) total local source revenue; (2) total IRA; (3) proportion of young population; and (4) proportion of elderly population. The first two variables belong to the supply side (ability to provide social services to constituency which is tied to income that dictates how much a municipality can spend), while the other two variables represent the demand side (demanded social service component varies depending the age group) of the fundamental equation for human development-oriented basic services provision at the local level (Cantarero & Lago-Peñas, 2012).

In light of the budget constraints theory (Samuelson & Nordhaus, 2010), the ability of an LGU to spend for human development services is largely a function of its total income (Kelekar & Llanto, 2013, 2015) which in turn, is comprised mainly of IRA and local source revenue in the case of the Philippines (Manasan, 1997, 1998). Following Manasan (1997, 1998), IRA and local source revenue are used as distinct explanatory variables in the study’s regression models to capture their individual effects.

Meanwhile, the respective proportions of young and elderly populations are among the standard set of demographic variables utilized in most empirical studies on LGU expenditure (Koppl-Turyna et al., 2015). The rationale for inclusion rests on economic means—or lack of it. Compared with the working age population (ages 15-64) who are likely to be employed and therefore able to spend for their own education, health, and social security needs (private expenditure), young and elderly populations who are not yet working/have already stopped working need and/or demand more publicly funded social services (Kang & Magoncia, 2016).

Both age groups are associated with higher local government expenditures on health and social welfare (Lusky & Weinblatt, 1998, as cited in Žokalj, 2016; Nguyen et al., 2009). However, they have divergent effect on education expenditure owing to substitution effect. Young constituents are direct consumers of publicly provided basic education, while elderly constituents are not, but are high-level consumers of the two other types of basic services, namely, health and social welfare. Hence, the higher the share of young (elderly) age population, the higher (lower) the education expenditure at the local level, *ceteris paribus* (Fernandez & Rogerson, 1997; Guziejewska & Majdzińska, 2018).

This research adopts relevant revenue data from BLGF’s SRE Report and municipal-level population data from the Philippine Statistics Authority (PSA) Census of Population and Housing for years 2000, 2007, 2010, and 2015 as indicators for the four (4) control variables (Table 2). Since the database deals with observations from 2001-2017, population data are interpolated for 2001-2006, 2008-2009, 2011-2014, and extrapolated for 2016-2017.

Table 2. Control variables: Indicators and their technical definitions

Control variable	Indicator	Technical definition
Total local source revenue	Total Local Sources	Sum of the municipality’s total tax revenue and non-tax revenue*
total IRA	IRA	Share of the municipality from national internal revenue taxes collected*
Proportion of young population	NA**	% share of population ages 0-14 to total municipal population***
Proportion of elderly population	NA**	% share of population ages 65-above to total municipal population***

Notes: *Adopted as is from the metadata document of SRE (BLGF, n.d.); **Computed by the author from the PSA population data; ***To fit with the PSA (n.d.) definition of working age population (ages 15-64), the author adopts these age limits, which are also used by Guziejewska & Majdzińska (2018) and Kang & Magoncia (2016).

Dataset: Composition

This research relies on a panel dataset comprised of 13 municipal governments in Rizal province observed over a 17-year period (2001-2017). While limited relative to a national scope, the number of observations analyzed in this study is still statistically viable (e.g., N>30). Owing to the cross-sectional and time-series character of panel data (Wooldridge, 2020), a total of 221 observations are generated for the study (i.e., 13 municipalities X 17 years). The dataset contains information on municipal income, expenditure, population, as well as on whether the municipal governments are governed by dynastic mayors or not.

Econometric Model

The dataset compiled is analyzed based on the linear regression model shown below:

$$Y_{it} = \beta_0 + \beta_1 \text{dynasty}_i + \beta_2 \text{control_var1}_{it} + \dots + \beta_5 \text{control_var4}_{it} + \mu_{it}$$

Where:

- Y_{it}** Outcome variable representing each of the five (5) categories of human development expenditure; **i** = municipality and **t** = year
- β₀** Common intercept (constant)
- dynasty** Main variable of interest representing dynastic presence; dummy variable coded=1 (coded=0) if municipality is deemed fat dynastic (non-dynastic)
- β₁** Coefficient of the main explanatory variable; represents partial effect of dynastic presence on human development investments
- control_var1-control_var4** Vector of control variables applicable to all dependent variables
- β₂ - β₆** Coefficients of control variables
- μ_{it}** error term

With a total of five (5) outcome variables (various categories of human development expenditure), the research estimates a total of five (5) related, but nonetheless, distinct panel regression models where all control variables are kept the same across all specifications.

Data analysis

Akin with Tusalem (2019), this research employs PCSE estimation to analyze the regression model shown above, using the statistical software Stata 16. Particularly, it banks on a Prais–Winsten generalized least-squares (GLS) estimator with PCSEs (henceforth, Panel-corrected Prais–Winsten GLS estimator). Such estimation strategy is chosen over the usual panel data estimators, namely, Ordinary Least Squares (OLS), Random Effects (RE), and Fixed Effects (FE) estimators (Torres-Reyna, 2007; Wooldridge, 2020), based on two key considerations: (1) the peculiarity of the study’s panel data structure; and (2) the need to account for possible spatial dependence among the analyzed municipalities in Rizal province.

Standard model specification tests were conducted to check for specification error, omitted variable bias, and multicollinearity in the study’s regression models. Results of these tests reveal absence of all three. Ergo, the study’s econometric models are properly and sufficiently specified (WSU, 2015). However, supplemental regression diagnostics confirm the presence of “HPAC” disturbances (Blackwell, 2005) in the study’s models: panel heteroskedasticity, panel autocorrelation, and contemporaneous correlation (cross-sectional dependence).¹⁹⁴ Disregarding these nuances in the analysis will lead to biased statistical inference (Hoechle, 2007).

Meanwhile, the panels/cross-sections observed over time in this study are municipalities which are geographical units, hence, spatial dependence is highly likely (Suárez et al., 2018). Spatial dependence pertains to “the propensity for nearby locations to influence each other and to possess similar attributes” (Goodchild, 1992, p. 33). In econometrics parlance, spatial dependence is a form of cross-sectional dependence or contemporaneous correlation among observations (Hoechle, 2007). When such aspect is overlooked, results of any panel data analysis is prone to produce “biased, inefficient, and/or inconsistent coefficient estimates” (Tosun & Skidmore, 2004, p. 172).

Utilizing OLS estimation when HPAC disturbances are present is problematic (Beck & Katz, 1995). In the face of such disturbances, OLS regression estimates will likely be “biased, inefficient and/or inconsistent” due to violations of

¹⁹⁴ Stata commands and results of these diagnostic tests are available upon request.

“standard OLS assumptions about the error process” (Podestà, 2002, p. 9). On the other hand, FE & RE models are inefficient alternatives because they can only address autocorrelation and heteroskedasticity, but not contemporaneous correlation (Hoechle, 2007; Stata Corp., 2019). Further, all three (3) panel data estimators cannot address spatial dependence.

Developed by Beck and Katz (1995), the PCSE method is a robust estimator utilized in social science research when panel regression models have HPAC disturbances (Hoechle, 2007; Sarafidis & Wansbeek, 2012). It has also been used in several studies to specifically account for spatial dependence, for instance, Tosun and Skidmore (2004) for counties in West Virginia, USA, and Diaz-Foncea and Marcuello (2014) for Spanish regions. Within the political dynasty literature, Tusalem (2019) used PCSE estimation to analyze the effect of dynastic prevalence, among other institutional, political, and geographical covariates, on several socioeconomic outcomes in the Philippines. Meanwhile, Martin-Mayoral and Sastre (2017) adopted the PCSE strategy in examining the determinants of aggregate social expenditure, including those for education and health, in Latin America.

If no autocorrelation function is specified, the PCSE strategy only accounts for heteroskedasticity and contemporaneous correlation by relying on OLS regression with PCSEs (Stata Corp., 2019). To address all three (3) disturbances that comprise the HPAC, the author follows the advice of Beck and Katz (1995) and sets a first-order autocorrelation AR(1) common to all panels (i.e., common AR(1) parameter). This approach is embodied in the use of PCSE method’s enhanced version, the so-called Prais-Winsten transformation (Plumper et al., 2005), which is dubbed in the study as Panel-corrected Prais-Winsten GLS estimator (Stata Corp, 2019).

4. RESULTS

Political dynasties among municipalities in Rizal Province

Table 3. Fat dynasties in Rizal province

Municipality	2001	2004	2007	2010	2013	2016
Baras	-	M ₀	M ₀	M ₀ -C ₀	M ₀ -VM ₀ -C ₀	M ₀ -VM ₀ -C ₀
Binangonan	M ₀ -G	M ₀ -C ₀ -G	M ₀ -G	M ₀ -G	M ₀ -G-M ₁	M ₀ -VM ₀ -G-M ₁
Cardona	M ₀	M ₀	M ₀ -VM ₀ -C ₀ -VG-PBM	M ₀ -C ₀ -VG-PBM	M ₀ -C ₀ -VG-PBM	M ₀ -VG
Jala-Jala	-	M ₀	M ₀ -C ₀	M ₀ -C ₀	VM ₀ -C ₀	M ₀ -C ₀
San Mateo	M ₀	M ₀ -VM ₀	M ₀	M ₀	M ₀ -VM ₀ -C ₀	M ₀ -VM ₀ -C ₀
Tanay	M ₀	M ₀	M ₀ -PBM	M ₀ -PBM	M ₀ -PBM	M ₀

Note: M₀, VM₀, C₀=Mayor, Vice-Mayor, and Councilor in a reference municipality; M_{1...n}, VM_{1...n}, C_{1...n}=Mayor, Vice-Mayor, and Councilor in other municipalities/city; G=Governor; VG=Vice-Governor; PBM=Provincial Board Member; Source: Author’s summary based on 2001-2016 local election results (Comelec data).

Upon inspection using the popular “family name identification” approach in the literature and following Mendoza and colleagues’ fat-thin dynasty dichotomy, this research identifies six (6) dynastic mayors, and therefore, six (6) dynastic municipal governments in Rizal: Baras (Robles family), Binangonan (Ynares), Cardona (San Juan), Jala-Jala (Pillas), San Mateo (Diaz), and Tanay (Tanjuatco). All these identified dynastic municipalities are categorized as fat dynasties because they satisfy the following conditions: the incumbent mayor serves his/her term concomitantly with at least one (1) relative also holding elective office in Rizal province for at least two (2) incumbency periods between 2001 and 2017 (i.e., six out of 17 years). The other half, or the seven (7) other municipal governments, are considered non-dynastic because they do not fit the criteria set for categorization into either fat or thin dynasties (i.e., Angono, Cainta, Morong, Pililla, Rodriguez, Taytay, and Teresa).

Table 3 presents the fat dynasties in Rizal province and illustrates how they dominate local elective positions in the province. For example, in Binangonan where the Ynareses hail, the notation “M₀-VM₀-G-M₁” for the 2016 column means that members of the Ynares political dynasty won all four (4) local positions in the 2016 elections, and therefore, will serve their incumbencies simultaneously. The winners are as follows: Cesar Ynares as Binangonan mayor; brother Cecilio “Boyot” Ynares as Binangonan vice-mayor; sister-in-law Rebecca “Nini” Ynares (wife of brother Casimiro “Ito” Ynares Jr.) as Rizal governor; and nephew Casimiro “Jun” Ynares III (son of brother Ito Ynares Jr.) as Antipolo City mayor. Ito Ynares is a former Binangonan mayor from 1972-1986/1988-1992 and Rizal governor from 1992-2001/2004-2007 (Binangonan Municipal Government, 2017b).

A closer look at Table 3 points to several interesting observations. Firstly, between 2001-2017, the mayoralty position among fat dynastic municipalities in Rizal is entirely monopolized by a single political family—except for Baras and Jala-Jala. Secondly, fat dynasties’ extent of political control among elective positions in Rizal ranges from a minimum of three (3) terms or nine (9) years to a maximum of six (6) terms or 18 years.

Elections are far from being competitive among fat dynastic municipalities in the province of Rizal. In fact, fat dynasties in these municipalities not only win by large vote margins, some of them are already winners¹⁹⁵ even before votes are cast—because they don’t have a single competitor. For instance, Cesar Ynares ran unopposed as mayor of Binangonan in the last term of his first three (3) consecutive terms between 1998 and 2007 (i.e., in the 2004 elections) (Binangonan Municipal Government, 2017a). Incidentally, it was in the 2004 elections when the brothers’ tandem of Cesar and Boyet Ynares started in Binangonan when the latter ran and won as a councilor. This is over and above the Ynares family’s

¹⁹⁵ Unopposed local election candidates only need to have one (1) vote to be declared as official winners (Tomacruz, 2019).

unrelenting clout on the Rizal gubernatorial position which started in 1992 and Antipolo City mayoralty seat since 2013. Meanwhile, in the 2016 elections, Bernardo San Juan, Jr. and Ely Pillas won as mayors in Cardona and Jala-Jala, respectively, without any competition (ABS-CBN Investigative and Research Group, 2016).

The political entrenchment of fat dynasties in Rizal province continues beyond the covered period of this research (i.e., from 2001-2017). In the most recent 2019 elections, Cesar Ynares did a repeat of his 2004 electoral dominance and won again unopposed as Binangonan mayor (Rappler, 2019). As he was mayor (again) starting 2016, Cesar Ynares is poised to have a second three (3) consecutive incumbency come 2022 elections (i.e., from 2016-2025). The same trend applies to his brother, Boyet Ynares, who, after being term-limited as mayor from 2007-2016, ran and won as vice-mayor in the 2016 elections and was re-elected in 2019 by an enormous winning margin of 46,002 votes. Boyet Ynares got 61,329 votes while his independent opponent, Manuel Reyes, got a paltry 15,137 votes (Rappler, 2019). Meanwhile, erstwhile San Mateo Mayor Jose Rafael Diaz (i.e., from 2007-2016) won unopposed as Vice-Mayor, while his wife, Cristina Diaz was re-elected mayor via landslide victory over Wilfredo Selga, an independent candidate. The winning margin between Cristina Diaz and Selga was a whopping 47,878 votes, with the former garnering a total of 60,571 votes while the latter got a measly 12,693 votes (Rappler, 2019).

Fat political dynasties and human development investments in Rizal province

Note: ***, **, *=statistically significant at 1%, 5%, and 10% levels, respectively; Panel-Corrected Standard Errors (PCSEs) in parentheses; Dependent variables are in Php per capita terms.

Based on the Panel-corrected Prais–Winsten GLS regression estimates shown in Table 2, it appears that fat dynastic municipal governments in Rizal province considerably invest less on their constituents’ human development compared with their non-dynastic counterparts—controlling for other relevant variables.

At the aggregate level, Rizal municipalities governed by fat dynastic mayors from 2001-2017 tend to have significantly lower human development expenditures as they spend, on the average, around Php 35.77 less per capita. With a probability value (henceforth, p-value) of 0.051, this result is statistically significant at the 90% confidence level and provides moderately strong empirical evidence in support of the study’s hypothesis on the effect of dynastic presence on human development investments.¹⁹⁶

Meanwhile, the disparity in human development investments between dynastic and non-dynastic Rizal municipalities is more pronounced when social welfare spending is excluded, and analysis is focused on the combined expenditures for health and education only. Holding other factors fixed, education and health spending among fat dynastic municipal governments in Rizal is around Php 42.08 lower per capita, compared with non-dynastic municipalities. The relevant coefficient of the dynasty variable here has a p-value of 0.001—statistically significant at the most stringent 99% confidence interval. This offers a rather robust evidence in favor of the study’s hypothesis.

Lastly, Rizal municipalities governed by fat dynastic mayors tend to significantly under-invest in education specifically. Relative to non-dynastic municipalities, dynastic municipal governments in Rizal spend, on the average, about Php 34.53 less per person. This result is likewise statistically significant at the most stringent 1% level (p-value: 0.000), providing a very strong evidence in support of the research hypothesis. As for health and social welfare expenditures, respectively, the study finds no statistically significant effect of dynastic presence among Rizal municipalities.

These findings are hardly surprising given the plethora of related studies that point to the same negative effect of political dynasties on governance, socioeconomic outcomes, and development. In terms of human development-oriented public

196 Interpretation of p-value as evidence against the null hypothesis (i.e., there is no relationship/effect) and in favor of the alternative hypothesis (i.e., there is relationship/effect) is in line with the guidelines recommended by Hartmann et al. (2018): p ≤ 0.01 as very strong evidence; 0.01 < p ≤ 0.05 as strong evidence; 0.05 < p ≤ 0.10 as moderate evidence; and p > 0.10 as weak or no evidence.

expenditures, specifically, results here are in line with the following: Ali (2016) on health and education spending among constituencies in Pakistan; Tusalem and Pe-Aguirre (2013) on health spending among Philippine provinces; Capuno et al. (2012b) on health insurance coverage for the poor among Philippine municipalities and cities; and George and Ponattu (2017) and George (2019) on public goods provision in terms of education, health, and social welfare programs among Indian villages.

But why do dynastic mayors in Rizal perform poorly in terms of local public spending on human development? Does it not adversely affect their chances of staying in power via re-election? As argued in this study, a plausible explanation is the predatory view of political dynasties: ostensibly, they do not have the incentive to invest in human capital enhancement and human capabilities expansion of their constituents as a means to endear themselves to voters and ensure their stay in political power. Reliance on their monopoly of political power coupled with inherited political and financial capital, as well as incumbency advantage externalities is apparently enough to secure votes for them and their relatives during elections.

To recapitulate, members of political dynasties have higher likelihood of winning elections compared with non-dynastic candidates, all things equal (Querubin, 2016). This is ascribed to their key attributes: (1) effective concentration and preservation of political power as relatives take turn occupying elective positions (Simbulan, 2012); (2) bequeathal of massive political and financial capital (Ali, 2016) in the form of “brand name recall”, wealth, and control of political and economic resources (George & Ponattu, 2017); and (3) benefiting from externalities or spillover effects of incumbency advantage. Such substantial electoral advantage may induce dynastic politicians to feel self-assured of continuous re-election, resulting to several moral hazard problems, including underperformance in office (Zheng et al., 2016). Among other mechanisms, this may manifest in terms of the incumbent dynastic mayor’s substantially low human development investments, as shown in the case of municipalities in Rizal province.

Further, this study concurs with Mendoza and colleagues that the deleterious effects of political dynasties are more prominent among fat ones, compared with the thin type. To recall, fat dynasties enjoy wider and deeper entrenchment of political power (monopoly of multiple elective positions over consecutive years) (Mendoza, Jaminola III, & Yap, 2019) and benefit considerably more on incumbency advantage externalities (extends to relatives in several positions) (Querubin, 2013; 2016). These advantages almost ensure continuous re-election for them and their relatives. Following such logic, fat dynastic mayors in Rizal seemingly lack the incentive to signal their competence by performing well in office. Particularly, they appear less motivated to project a caring image to boost their re-election (and/or election of relatives) by spending more on human development-oriented sectors. Inherited and accumulated electoral advantages of fat dynastic mayors in Rizal may so insulate them from the threat of competition from non-dynasts “that they (seemingly) mute performance incentives.” (George & Ponattu, 2017, p. 2)

Beyond its popularity in the relevant literature, the choice of predatory view of political dynasties as a guide in elucidating the results of the research is grounded on the political and electoral realities in Rizal province where fat dynasties are deeply entrenched and are not faced with significant electoral/political competition—as discussed in the previous section. This also helps explain why the study’s findings run counter with Bragança et al. (2015) and Dulay and Go (2021). In Brazil, Bragança et al. (2015) find that dynastic municipalities spend more on health and education, while in the Philippines, Dulay and Go (2021) show that horizontally dynastic municipalities have higher health expenditure. Both studies rely on Regression Discontinuity Design (RDD) anchored on close elections, and therefore applies mainly on localities with high political competition. As Braganca et al. (2015, p. 13) put it, the estimated effects of their political dynasty variable “represent local estimates of dynastic politicians on economic outcomes for municipalities that are highly competitive” and that “*these effects might be quite different in localities where dynasties win by a large vote margin [emphasis added].*” This argument is in sync with Asako et al. (2015) who assert that political dynasties tend to have higher public expenditures only among jurisdictions with competitive elections. As shown in the previous section, elections are far from being competitive among fat dynastic municipalities in the province of Rizal. In fact, fat dynasties in these municipalities not only win by large vote margins, some of them run—and win—totally unopposed. In this section, the study provides empirical evidence that fat dynastic mayors in Rizal significantly invest less on human development of their constituents. The reminder of Braganca et al. (2015, p. 14) is seemingly instructive in this case: “political dynasties facing less electoral competition can be less accountable and therefore perform worse than dynasties facing a lot of competition.”

Control variables and models’ overall significance

Consistent with findings in the literature, all control variables have their expected signs (denoting direction of association) and all are statistically significant predictors of municipal per capita human development investments at various combinations, which justify their inclusion in the study’s regression models.

The R² or coefficient of determination, which represents the “percentage of variation in the dependent variable explained by variation in the independent variables” (Filho, Silva, & Rocha, 2011, p. 60), among the regression specifications above (i.e., between 9-37%) fall within the range of R² values reported by scholars who publish articles on determinants of local government expenditure on health, education, and social welfare (e.g., Araújo et al., 2017; Kelekar & Llanto, 2013, 2015; Manasan, 1998). Moreover, the study’s R² range of 9-37% is a decent result, given that R² values of regression models in the social sciences field are typically low (Wooldridge 2020), with a value of at least 9% considered to be respectable (Itaoka, 2012).

On the other hand, all five (5) regression models are statistically significant at the 99 percent confidence level, based on the Prob>chi2 values—denoting a strong “joint significance” of all explanatory variables in each specified model (Solon et al., 2009; Torres-Reyna, 2007).

Robustness Check: Alternative estimation strategies

Table 5. Alternative estimation strategies: Effect of dynastic presence on human development investments

Estimation Strategy	Dependent Variables					
	Human Spending	Development	Education & Health Spending	Education Spending	Health Spending	Social Welfare Spending
Adopted:						
Prais-Winsten w/ PCSEs	-35.77* (18.34)		-42.08*** (12.31)	-34.53*** (8.37)	-5.05 (6.92)	7.42 (10.55)
Alternatives:						
FGLS	-35.77* (19.74)		-42.08*** (13.61)	-34.53*** (8.13)	-5.05 (7.78)	7.42 (11.26)
FE with Driscoll-Kraay SE	-29.56*** (8.24)		-30.78*** (7.49)	-27.45*** (5.84)	-3.32 (4.34)	1.21 (4.42)

Note: Coefficients shown are those of the political dynasty variable; ***, **, *=statistically significant at 1%, 5%, and 10% levels, respectively; Standard Errors in parentheses; Dependent variables are in Php per capita terms.

Results of the study are robust to two (2) alternative estimation strategies that also address HPAC disturbances: (1) feasible generalized least squares (FGLS) estimator and (2) Fixed Effects (FE) estimator with Driscoll-Kraay Standard Errors (SE). As illustrated in Table 5, coefficients of the dynasty variable stay statistically significant even when estimated using FGLS and Driscoll-Kraay approaches. In fact, the coefficients generated by FGLS are identical to those from the adopted Panel-corrected Prais–Winsten GLS strategy, with slight differences in standard errors. Nevertheless, the latter strategy was adopted because it is superior to the former when focus is on hypothesis testing (Moundigbaye et al., 2017; Reed & Ye, 2011), which is the case for this research. Besides, compared with FGLS, the PCSE approach possesses “finite sample advantage” and generates more accurate standard errors for small panels¹⁹⁷ like the study’s dataset (Beck & Katz, 1995; Hoechle, 2007; Moundigbaye et al., 2017; Stata Corp., 2019; Reed & Ye, 2011). Meanwhile, the Driscoll-Kraay strategy is not used since it is more suitable for panel datasets where cross-sections are larger than the number of time periods (i.e., N>T) (Knight, 2014; Hoechle, 2007). The study’s dataset follows the N<T structure (i.e., 13 municipalities<17 years).

Robustness Check: Alternative specifications

Table 6. Alternative specifications: Effect of dynastic presence on human development investments

Regression Specifications	Dependent Variables					
	Human Spending	Development	Education & Health Spending	Education Spending	Health Spending	Social Welfare Spending
Adopted:						
Linear model	-35.77* (18.34)		-42.08*** (12.31)	-34.53*** (8.37)	-5.05 (6.92)	7.42 (10.55)
Alternatives:						
With unit and period dummies	-84.93 (62.77)		-153.55*** (42.78)	-104.37*** (27.12)	-43.89 (37.05)	8.39 (30.57)
Log-linear model	-0.189** (0.085)		-0.232*** (0.066)	-0.450*** (0.119)	-0.069 (0.067)	0.086 (0.236)
Log-linear with unit and period dummies	-0.813*** (0.158)		-0.408** (0.173)	-1.059*** (0.366)	-0.627*** (0.217)	-0.056 (0.303)

Note: Coefficients shown are those of the political dynasty variable; ***, **, *=statistically significant at 1%, 5%, and 10% levels, respectively; Panel-Corrected Standard Errors (PCSEs) in parentheses; Dependent variables are in Php per capita terms.

Sticking with the PCSE approach, findings are likewise generally robust to three (3) alternative model specifications as depicted in Table 6: (1) adding unit and period dummies to the adopted linear model (i.e., linear model with unit and period dummies); (2) transforming the dependent variable into its natural logarithmic form (i.e., log-linear model); and (3) adding unit and period dummies to the log-transformed specification (i.e., log-linear model with unit and period dummies). Several related studies (e.g., Ali, 2016; Diokno-Sicat, 2016; Dulay & Go, 2021) have employed these alternative specifications to estimate the effect of political dynasties on human development investments. For this research, however, these specifications are found to be saddled with omitted variable bias, specification error, and multicollinearity. This is the primary reason why the study adopts a linear model without unit and period dummies, which is free from the said biases/errors.

Another motivation behind the choice of the adopted specification is the word of caution given by Plumper et al. (2005). When panel data is estimated using the PCSE approach, Plumper et al. (2005) advises against the inclusion of unit and

¹⁹⁷ Composed of 10-20 cross-sections and 10-40 periods (Stata Corp., 2019).

period dummies because unit (period) dummies disproportionately absorb most of the theoretically interesting cross-sectional (time-series) variance in the data. The use of unit dummies is specifically problematic when a level effect of a time invariant variable (e.g., the study's political dynasty dummy) is being tested, since adding unit dummies suppresses the level effects. Meanwhile, including period dummies not only absorb large portions of the trend in the outcome variable, but also tends to bias estimates (Plumper et al., 2005). True enough, the study's alternative regression specifications with unit and period dummies generate unacceptably high coefficients—as can be observed from Table 6.

5. CONCLUSIONS

Local government investments on human development, reflected in their level of expenditure on health, education, and social welfare, are necessary public investments geared towards enhancing human capital and enlarging human capabilities of their constituents. Therefore, human development spending represents a reasonable measure of good performance of incumbent local officials who may be dynastic or non-dynastic (Solon et al, 2009; Manasan, 1997).

To empirically test whether dynastic mayors tend to have lower human development investments for their constituents, this study draws inference from municipalities in Rizal, a well-known dynastic province in the Philippines, as a preliminary empirical investigation. A panel dataset is constructed which consist of all 13 Rizal municipalities, dichotomized into dynastic or non-dynastic, and observed over 17 years (i.e., 2001-2017). All identified dynastic municipalities in the province are categorized as fat dynasties—wherein an incumbent mayor serves his/her term concomitantly with at least one (1) relative also holding elective office in Rizal province for at least two (2) incumbency periods between 2001 and 2017.

Based on the results of Panel-corrected Prais–Winsten GLS estimation, this research finds that Rizal municipal governments led by fat dynastic mayors tend to have lower human development investments for their constituents, compared with non-dynastic counterparts. Specifically, they spend less on human development at the (1) aggregate level (i.e., total municipal expenditure on health, education, and social welfare), at the combined levels of (2) education and health, and (3) at the specific sector of education. These findings are in line with the prediction of the predatory view of political dynasties, particularly the fat type: with wider and deeper entrenchment of political power due to monopoly of multiple elective positions over consecutive years, fat political dynasties are inherently prone to be predatory—inimical to governance, socioeconomic outcomes, and development.

While the study's findings are statistically significant, economically meaningful, and robust to various alternative model specifications and econometric estimation procedures, there are caveats that need to be pointed out. For one, results of this research only apply to Rizal province and therefore, provides only a snapshot of how fat political dynasties affect local governance in the Philippines. A subsequent research analyzing all municipalities in the country is needed to portray a nationally representative empirical evidence. Meanwhile, like Tusalem and Pe-Aguirre (2013), the author recognizes that the study's findings may possibly be affected by endogeneity, since the regression modeling employed “cannot control for unobserved characteristics of politicians, parties, or efforts of mobilization” (Bragança et al., 2015, p. 14). A future research intends to build on the econometric model developed in this study to address possible endogeneity concern.

ECONOMIC DEVELOPMENT PROCESSES OF CENTRAL AND EASTERN EUROPEAN CITIES

Szilard Racz

Centre for Economic and Regional Studies, Hungary

ABSTRACT

The research seeks to explore FDI-driven transformation and development processes in Central and Eastern European (CEE) cities in the post-transition period. The geographical focus of the analysis is limited to post-socialist states, while the scale of the analysis targets the metropolitan and regional level. Research questions: 1) What common specifics characterize the economic development of CEE cities? 2) Can the existence of specifics indicating unique development paths (i.e. Visegrad Group, Western Balkan states; gateway cities, automotive cities) be verified? 3) What are the consequences of capital city centrality and the role of second tier cities? The first part of the study presents the background of the macroregion. In the course of the past three decades, Central and Eastern Europe has witnessed a particularly dynamic transformation process. Central Europe has emerged as a winner of global industrial relocation processes, industrial decline was followed by reindustrialisation, while economic restructuring produced a multi-layered spatial structure. According to Gál and Schmidt (2017), the main specifics of the transition model include a double shift in ownership structure (from state to private, from domestic to foreign) and a double shift in the system model (from state socialism to market capitalism, from industrial capitalism to financialized capitalism). The region's externally driven and financed global economic integration was not the result of bottom-up development, which led to the proliferation of literature challenging core ideas of mainstream theories or presenting their variable geo-economic framework conditions referred to as externally-driven capitalism or the dependent market economy model (Nölke and Vliegthart, 2009). The second part of the study focusing on the examination of individual urban development paths. While FDI was the dominant foreign capital type in the first phase of the transition (privatization), foreign bank capital took over the predominant role of FDI at the turn of the millennium. The unfolding of this process was spatially uneven since capital cities, port cities and western regions adjacent to EU Member States were seen to provide profitable investment opportunities by investors in the first round. Initially, investments targeted only a small number of cities and regions, hence, economic growth was also concentrated in these areas, providing them a source of relative advantage. The global economic crisis has impacted this trend, without, however reversing long-term tendencies. The penetration of advanced services follows the urban hierarchy and in the bulk of the states this sector is concentrated in the capital city. The dominance of capital cities and city regions is a well-established fact. In smaller countries, or in the case of central location, the role of capital cities cannot be overstated. In addition, there is a substantial difference in size between capital cities and second-tier cities in every respect.

INNOVATIVE ACTIVITY OVER SPACE AND TIME - SPATIOTEMPORAL MODELING OF INNOVATION PROMOTING FACTORS

[Imke Rhoden](#)

Ruhr-Universität Bochum, Germany

ABSTRACT

As innovation and innovative activity are regionally bound and prone to spill over not only locally, their development over time is also not negligible. To show determinants for innovative activity over the course of time and stress the importance of considering time series together with spatial indicators is the matter of this paper. A time-dependent geospatial model is able to factor in linear as well as nonlinear innovation-influencing factors, and consider time and space simultaneously. The dataset used is based on data by the German Patent and Trademark Office and is mined according to location and time of the published patents. All analyses are executed in the timeframe 2009-2016 on the map of German administrative districts (NUTS-3 level). The prevailing analytics follow Bayesian statistical reasoning. Results of the model show that time as well as space are relevant dimensions for investigating innovation in Germany. Theoretically motivated covariates like knowledge intensity, R D funding as well as productivity and openness impact innovation favorably. Population density seems to be negligible, and firm size impacts innovation negatively. Incorporating the spatial dimension leads to increased reliability and interpretability of the model. Including the time dimension is necessary, as the effects suffer from overestimation otherwise. The results allow better formulations of future models for innovation activity and allow improvements in targeting regional innovation policy. For the latter the model shows effects specifically for each region and for each type of determinant, so that precise leverage points can be concluded.

DO AGGLOMERATION ECONOMIES INFLUENCE ENVIRONMENTAL REGULATORY COMPETITION? THE CASE OF CHINA

Dan Zheng

University of Chinese Academy of Sciences, China

ABSTRACT

Using panel data of 30 Chinese provinces during the period from 2005 to 2015, this paper empirically examines to what extent agglomeration economies influence environmental regulatory competition. It is found that a province's environmental regulation, which is measured by the enforcement of command and control policy and market-based economic policy, is positively related to the regulation of its competitor provinces. Therefore, Chinese provinces do engage in environmental regulatory competition. It is also found that provinces with different levels of agglomeration economies respond asymmetrically to the change of their competitors' regulations. The more agglomerated a province is, the less responsive is the province's environmental regulation to its competitors' environmental regulation. In particular, the asymmetric response is only significant when provinces adopt a market-based economic policy to engage in regulatory competition.

ON THE DYNAMICS OF PATIENT MIGRATION FLOWS: IS EFFICIENCY PERFORMANCE EXPLAINING INFLOWS FOR NEIGHBORING HOSPITALS? AN APPLICATION TO THE ECUADORIAN HEALTHCARE SYSTEM

Juan Piedra-Peña

Department of Applied Economics, Universitat Autònoma de Barcelona, Campus Bellaterra, 08193 Barcelona, Spain,
Email: juanandres.piedra@uab.cat

ABSTRACT

This study aims to analyze whether higher efficiency performance of Ecuadorian hospitals attracts larger inflows of interregional patients to a given hospital and the existence of spatial dependence in terms of larger inflows of patients for neighboring hospitals in the region. We develop a novel two-stage approach. In the first stage, we use conditional order-m estimations to obtain robust efficiency values for each hospital. In the second stage, we use a spatial Durbin interaction model to estimate the effect of hospital efficiency on patient migration flows and disentangle the spillover effects in the migration dyad. The results show a positive effect of specialized hospitals' efficiency in attracting patients from other regions. In addition, patient inflows present spillover effects not just on neighboring hospitals in the same region but also from hospitals in regions neighboring the origin. Policy implications mostly drive the attention to the importance to elaborate well planned healthcare strategies taking care of territorial externalities. Negative shocks affecting specialized hospitals could imply an adverse effect on the flow of patients to the whole region, affecting the regional public healthcare performance and potential welfare gains. Conversely, more resources could be directed to less-developed regions to incentivize competition.

KEYWORDS

Hospital efficiency, patient migration, spatial dependence, spillover effects.

1. INTRODUCTION

In healthcare system analysis, patient choice of hospitals and the resulting patient mobility has been a topic that has occupied a vast body of the literature over the past two decades (Balía et al. 2014). Models that allow patient choice of hospitals have a wide spread of useful applications both for governments and the hospitals' own governance (Lowe and Sen 1996). In this context, Balía et al (2014) state that the importance to assess patient mobility can be twofold. First, the geography of patient mobility yields indications on the actual level of services provided. This can be particularly useful given that the preferences of the individuals are not perfectly observable. For example, patient outflows might reveal the possible inefficiency or low quality of public healthcare supply in a given region.¹⁹⁸ Second, the flow imbalances across regions may challenge the stability of their healthcare budgets. This kind of information can be useful for central planners and regional authorities interested in correcting inefficiencies in the system as well as improving the healthcare system performance. Understanding the mobility patterns of healthcare consumers may represent an important tool for the central government and regional planners to identify clusters of hospitals and take advantage of spillover effects to better allocate the resources and enhance the efficiency of the system.

Essentially, patients move because they want to get the best hospital treatment that the system can provide, or at least better services than those offered in their local region. They can be expected to move when possible inefficiencies translate into longer waiting lists but also when the perceived quality of the local healthcare services is low (Aiura 2013; Balía et al. 2014). These movements might be permanent over time if the local regions in a country present a certain level of asymmetry in their systems (Balía et al. 2018).

In this sense, there is a strand running through the literature stating that eliminating barriers of access to healthcare, and thus giving patients the ability to choose between hospitals, creates a financial incentive for providers to compete among them, which leads to improvements in quality of care (Gaynor et al. 2012; Gravelle et al. 2014; Bloom et al. 2015). This theory might hold in a country where the healthcare system is rather homogeneous across regions. However, when regional disparities are significant and persistent over time, high-income regions tend to offer a better quality of care. This motivates patients to move from low- to high-income regions seeking better treatment. In turn, the dynamic of such

¹⁹⁸ Throughout this paper, hospital efficiency reflects the ability of a hospital to properly make use of its resources or inputs (e.g., physicians, medical equipment, capacity, etc.) to provide medical attention derived from given outputs (e.g., patients treated, treatments carried out, etc.). In this sense, a fully efficient hospital can maximize its outputs with a given amount of inputs. This is commonly known in the healthcare efficiency measurement literature as *technical efficiency* (Peacock and Hollingsworth 2008).

flows, closely relating with the spatial pattern, could be giving rise to network effects often detected in the data and translating into a structure correlation, known in the literature as spatial dependence (Anselin 2010).

An interesting context of analysis is brought to this setting by Ecuador, whose marked regional disparities offer us a framework of study that can allow us to understand the interregional and intraregional dynamics of patient mobility that can be driven by the performance gaps of their heterogeneous hospitals.

Like other Latin American countries, Ecuador has suffered a continuous process of deterioration of its public healthcare system, which has been exacerbated by the neoliberal reforms of the 1990s and the 2000s, resulting in a widening of the existing territorial disparities in the country. These disparities derived in a concentration of healthcare resources in a few public hospitals (the high-performers), which at the same time were located in developed regions (Piedra-Peña 2020). With the approval of the new constitution in 2008, new healthcare reforms were enhanced to promote free access of medical care and an increase of social security coverage. This gave patients the possibility of choosing the hospital where they wanted to receive treatment.¹⁹⁹ At the same time, this increased the demand for medical attention, promoting a behavior of mobilization to seek treatment in developed regions (Piedra-Peña 2020).

As the barriers of access vanished, patients were expected to seek better treatment in areas where they perceived would get the best possible treatment, leading to patient mobility. Mobility then caused an increase in patient demand, and this can result in two different outcomes. On the one hand, higher demand fuels competition among hospitals in the region, resulting in an increase in quality of care or more efficient use of resources in order to cope with the demand. On the other hand, when demand for hospital treatment increases, hospitals become crowded and additional resources are needed to reduce congestion, entailing eventually inefficiencies like longer waiting times and finally in an underprovision of public services such as healthcare (Aiura 2013). Moreover, if developed regions are the receivers of a bigger share of patients, one can expect that other adjacent hospitals may receive patients driven by the demand at their neighbors.²⁰⁰

So far, the literature on patient mobility has focused on identifying and measuring the effects of the determinants on patient flows either between regions or between healthcare institutions, but there has not been an empirical study that assesses the dynamics of interregional patient mobility in the hospitals within a given region. Understanding these dynamics can help regional planners and hospital managers to understand the patterns of demand as not just interregional but also intraregional patient flows. High-performing hospitals can be prepared for potential boosts in demand generated by new reforms that widen the insured population or allow for the gratuity of medical services. They can account for these demand increases and plan to improve their capacity, medical staff, or technological endowment. Low-performing hospitals can also benefit from this, and enhance their medical resources as well, to increase their performance and avoid possible outflows of patients.

Piedra-Peña (2020) emphasizes the important influence that patient mobility can have on the performance of any given public hospital in Ecuador and that of surrounding hospitals as well, given the spillover effects in hospital efficiency.²⁰¹ Here we seek to understand the patterns of these patient flows and determine the extent to which these performance gaps are driving people to move from different regions to be treated in a (high-performing) hospital, and what the repercussions are for their surrounding hospitals.

Thus, this study aims to analyze whether higher hospitals' efficiency performance encourages larger inflows of interregional patients to a given hospital and whether these are accompanied by larger inflows of patients for neighboring hospitals in the region. So far, the literature on healthcare economics has focused on the measurement of the effects of hospital competition, patterns of access to hospital services, and the determinants of patient migration flows by just accounting for the spatial distance between hospitals or regions, using gravity models (e.g., Congdon 2001; Varkevisser et al. 2012; Moscelli et al. 2016). A large part of the literature has concluded that the healthcare efficient performance of hospitals and regions is a strong driver of patient mobility. But there has not been an attempt—to our understanding—to consider the possible spillover effects that give rise to higher patient migration flows to neighboring hospitals. In this respect, our contribution to the literature is to provide a robust measure of hospital efficiency, consistent with economic theory, that allows us to identify its effect to attract patients. In addition, if spillover effects in the patient migration network are significant, this measure can serve as a reliable tool for decision-making to identify key hospitals that attract demand and foster competition.

To that end, we follow an innovative two-stage approach. In the first stage, we make use of the conditional order-*m* efficiency measurement proposed by Cazals et al (2002), Daraio and Simar (2005), and Daraio and Simar (2007) to obtain robust efficiency measures for Ecuadorian public hospitals in 2014. This method is based upon the economic concept of Pareto efficient allocation and takes into consideration the effect of other environmental variables (related to the region) in the hospital performance. In the second stage, we address patient mobility flows with spatial interaction models proposed by LeSage and Pace (2008) and LeSage and Pace (2009), which take into account traditional origin-destination (OD) models, but incorporate spatial lags of the dependent variable in order to account for spatial dependence, represented by flows from neighboring regions in these models and accommodating for endogenous interactions (i.e.,

¹⁹⁹ The new constitution approved in 2008 (which stated that health is a right guaranteed by the state who will ensure full exercise of the right and access to social insurance) provided reforms aiming at providing higher access to medical treatment, like the gratuity of medical services provided by the Public Ministry of Health (MSP) or laws that deprived the liberty to employers that do not affiliate workers (Orellana et al. 2017; Piedra-Peña and Prior 2020).

²⁰⁰ For example, if a given hospital has a long waiting list, patients could try to receive attention in alternative hospitals in the region.

²⁰¹ Piedra-Peña (2020) provides evidence of the existence of positive spatial dependence in public hospital efficiency deriving from the existence of global and local spillover effects. In other words, the increase in the efficiency of neighboring hospitals is having a positive impact on the efficiency of an observed hospital as well.

global spillovers). In addition, we consider exogenous interaction arising from contextual effects, accommodating for spatial dependence of the explanatory variables, and representing characteristics of the neighboring regions and hospitals (i.e., local spillovers) (LeSage and Fischer 2016). In the applied literature, these models have been used in cases where origins and destinations coincide (LeSage and Thomas-Agnan 2015). However, this is not our case: the list of origins (cantons) differs from the list of destinations (hospitals).²⁰² This calls for a modification in the econometric estimation which has been recently addressed by Laurent et al (2019) that, to our understanding, has not yet been applied, and constitutes an additional contribution of our study.

This paper is structured in the following way. Section 2 reviews the literature on hospital patient migration. Section 3 explains the methodology of the order- m efficiency measurement and the spatial interaction model. Section 4 describes our dataset and Sections 5 present the estimation results. Finally, the main conclusions are presented in Section 6.

2. LITERATURE REVIEW

The aim of our study is to single out the effect that hospital efficiency has on interregional patient mobility. Moreover, we want to disentangle the potential spillover effects found in these mobilization flows between and within regions so, we can identify demand patterns of healthcare treatment that can be used as a tool for decision-making. In so doing, we combine two different strands of the literature: healthcare efficiency measurement and patient mobilization literature. There is a vast body of literature on healthcare efficiency measurement that focuses on obtaining a single value that measures the efficiency performance of an observed unit through parametric and non-parametric methods that combine multiple inputs and outputs. The idea of efficiency is linked to the concept of Pareto efficient allocation, where those efficient units are either minimizing inputs or maximizing outputs in the production of health (i.e. in providing medical attention). The main advantage of these approaches is that we can rely in a single estimated efficiency score, more consistent with economic theory, as it allocates technical or Pareto inefficiencies instead of measuring efficiency based on single averages (Cantor and Poh 2018). A rich review of this literature can be found in O'Neill et al (2008), Hollingsworth (2008) and Cantor and Poh (2018).

Furthermore, we rely on the hypothesis that the performance of a given set of hospitals is going to be determined –to a certain extent– by regional characteristics, and specially by the level of development or income level in the region (Brekke et al. 2016) due to the evident territorial disparities in Ecuador (Piedra-Peña 2020). To avoid the separability assumption and provide meaningful results, we implement a non-parametric method known as the conditional order- m efficiency estimation (Cazals et al. 2002; Daraio and Simar 2005). Recent applications of this technique include Halkos and Tzeremes (2011), who perform a conditional order- m efficiency analysis on Greek prefectures, and find a negative relationship between per-capita GVA and efficiency; whilst population density has a positive effect in hospital performance. Other micro-level approaches such as Mastromarco et al (2019) analyze the cost efficiency of Czech Republic hospitals during the period 2006-2010. They implement an order- m efficiency estimation controlling for non-profit status, teaching status, presence a specialized center (in the hospital) and occupancy rate, finding that non-profit hospitals, university hospitals and hospitals with specialized centers are generally less efficient. Another advantage of conditional order- m estimation is that we do not need to assume a production function in the estimation process. This is particularly important in our study, as the multidimensional nature of public hospitals and regional heterogeneity in the country posits a difficulty at the time of defending the assumption of a single production function for all hospitals in the sample.

However, despite the clear advantages of these methods to provide a robust estimation of efficiency, there has not been an attempt to combine them along with econometric models to study patient mobility patterns. The empirical literature directly focused on patient mobility has been developed in the past decade. Instead of focusing on specific determinants of patient flows, it centers on modeling hospital choices and flows across different jurisdictions (Balia et al. 2014). Some micro-level studies single out potential determinants of mobility. Victoor et al (2012) offer a survey in which they put in evidence that some common determinants of patient mobility can refer to patient characteristics (e.g. education, income, and age) and provider characteristics.

In our setting, we need to take into account macroeconomics (regional) variables since they impact patient decision of seeking care across regional borders. In this respect (macro-level) applied economic studies have mainly been based on gravity models, commonly used to model flows that take many forms, like population migration, commodity flows and traffic flows (Thomas-Agnan and LeSage 2014). These models embed movements of individuals between origin and destination regions. Levaggi and Zanola (2004) look for the determinants of net patient flows from regions of Italy to the rest of the country. They estimate gravity models for a sample of Italian regions from 1995-1997 and conclude that regions characterized by lower outflows are the ones that provide better or faster services. Cantarero (2006) develops the same analysis to patient flows across regions in Spain between 1996 and 1999 and identify that patients from the economically lagged regions move more than those regions that provide better health services.

However, the use of traditional gravity models to explain spatial interaction can be limited. These models rely on a function of the distance of the OD to clear spatial correlation and cross-section independence. As LeSage and Pace (2008, 2009) state, the notion that use of distance functions to effectively capture the spatial dependence of observations can be erroneous. Also, the idea that flows are independent since OD flows are fundamentally spatial in nature. In our framework

²⁰² In Ecuador, cantons are the second-level administrative divisions. The Republic of Ecuador is divided into 24 provinces, which in turn are divided into 221 cantons. The cantons in turn are subdivided into parishes.

of analysis, we expect to find a behavior pattern where high-income regions are the main receivers of patients, following a spatial pattern, that, if not controlled for in the econometric estimation, could lead to biased conclusions.

So far, no studies have tried to account for the spatial dependence in patient mobility. Moreover, even when a big part of the literature implicitly concludes that healthcare performance is a strong driver of patient flows, there has not been an attempt to disentangle its sole effect. The closest paper to our approximation is Balia et al (2018) who account for local spillover effects by incorporating the spatial lags of the exogenous variables in the gravity model. They use a spatial panel data framework of Italian hospital discharges between 2001 and 2010 to assess the effect of the main determinants of interregional patient flows, differentiating between the impacts of regional health policies and other exogenous factors. Their results show that neighboring regions' supply factors, specialization and performance largely affect mobility by generating local externalities that explain OD patient flows; bringing some insights of the inherent spatial-dependent nature of hospital performance, and, its effects on patient mobility.

Our empirical estimation, hence, goes beyond the incorporation of local spillover effects as in Balia et al (2018), and includes potential global spillover effects likely found in OD flows, as stated by LeSage and Pace (2008, 2009). In so doing, we use the extended gravity models developed by LeSage and Pace (2008, 2009) to allow for spatial dependence in the sample, represented by the flows from cantons (regions) to public hospitals in these models. Additionally, we consider exogenous interactions of the explanatory variables (LeSage and Fischer 2016) to accommodate for the contextual effect of the neighboring regions and hospitals in the OD dyad, as in Balia et al (2018).

3. METHODOLOGY

The method used in this study is developed in two stages. First, we need to obtain the efficiency measures for each hospital, conditional to the environmental variables they face and can constrain their performance. In the second stage, we develop a spatial interaction model (based on the conventional gravity specification) to estimate the impact that the efficiency value has on migration flows, accommodating for potential spillover effects.

3.1 Order-m efficiency estimation

The first stage of our strategy uses a nonparametric order- m efficiency estimation approach, introduced by Cazals et al. (2002), Daraio and Simar (2005) and Daraio and Simar (2007) that relies upon the production theory (Debreu 1951; Koopmans 1951). Introducing the notation used in this paper, we assume a set of $y \in \mathbb{R}_+^p$ outputs produced by a set of $x \in \mathbb{R}_+^q$ inputs, the production technology is the set of all feasible input-output combinations:

$$\Psi = \{(x, y) \in \mathbb{R}_+^{p+q} \mid x \text{ can produce } y\} \tag{1}$$

The multidimensional nature of public hospitals, with different functions that are difficult to quantify, plus the impossibility to obtain input and output prices information makes Ψ impossible to observe. To account for this, we need to estimate Ψ from a random sample of production units denoted by $X = \{(x, y) \in \mathbb{R}_+^{p+q} \mid i = 1, \dots, n\}$. Following this framework, an observed production unit (x_i, y_i) defines an individual production possibility set $\Psi(x_i, y_i)$, which under the free disposability of inputs and outputs can be expressed as:

$$\Psi(x_i, y_i) = \{(x, y) \in \mathbb{R}_+^{p+q} \mid (y \geq y_i) x \leq x_i\} \tag{2}$$

Nevertheless, there could be other environmental factors $Z \in \mathbb{R}^r$ exogenous to the production process that could be affecting the production and the distribution of efficiency scores. In this matter, Cazals et al. (2002), Daraio and Simar (2005) and Daraio and Simar (2007) use a probabilistic formulation of the production process to develop a conditional efficiency approach to account for the environmental variables in the efficiency estimation, conditioning the production process to a given value of $Z = z$. This conditional function is given by:

$$S_Y(y|x, z) = Prob(Y \geq y \mid X \leq x, Z = z) \tag{3}$$

Representing the probability of a unit operating at level (x, y) being dominated by other units facing the same environmental conditions z . This way, the conditional output efficiency can be defined as the Farrell (1957) efficiency measure:

$$\theta(x, y|z) = sup\{\theta \mid S_Y(\theta y|x, z) > 0\} \tag{4}$$

Those points where $\theta(x, y|z) = 1$ are the technically efficient ones and correspond to the efficiency frontier, while those with $\theta(x, y|z) > 1$ are technically inefficient. To obtain the nonparametric estimators of the conditional frontier $\theta(x, y|z)$, mitigating the impact of outliers, we use the order- m frontier (Cazals et al. 2002). The order- m frontier considers as a benchmark the expectations of the best practice among m peers randomly drawn from the population of units from which $X \leq x$.²⁰³ The procedure is repeated B times resulting in multiple efficiency measures $(\hat{\theta}_m^1, \dots, \hat{\theta}_m^B)$, where the final order- m efficiency value is the sample mean $(\hat{\theta}_m)$. This way, the efficiency of a decision making unit (DMU)²⁰⁴ can be compared with m potential DMUs that have a production larger or equal to y . The conditional order- m output efficiency estimator can be obtained by the computation of the one-dimensional numerical integral defined as in Daraio and Simar (2007b):

$$\hat{\theta}_m(x_0, y_0|z_0) = \int_0^\infty [1 - (1 - S_{Y|X,Z}(u y_0|X \leq x_0, Z = Z_0))^m] du \tag{5}$$

The efficient frontier corresponds to the DMUs where $\hat{\theta}_m(x, y|z) = 1$. Notice that the efficiency values can take a score lower than one. In this case, the hospitals are labeled as super-efficient, meaning that they exhibit higher levels of outputs than the order- m frontier.

²⁰³ We fix the value of $m = 90$, following the approach of Daraio and Simar (2005) for which the decrease in *super-efficient* observations ($(\theta(x, y|z) < 1)$) stabilizes.

²⁰⁴ We can call DMU to any unit of analysis, say, individuals, departments, firms, municipalities, or in the case of this study, hospitals.

To estimate the conditional order-m model, we need to incorporate smoothing techniques such that in the reference samples of size m units with comparable z -values have a higher probability of being chosen. Hence, we rely on the estimation of nonparametric kernel functions to select the reference observations, and a bandwidth parameter h in the estimated probability function $S_Y(y|x, z)$, given by:

$$\hat{S}_{Y,n}(y|x, z) = \frac{\sum_{i=1}^n I(x_i \leq x, y_i \geq y) K_{\hat{h}}(z, z_i)}{\sum_{i=1}^n I(x_i \leq x) K_{\hat{h}}(z, z_i)} \quad (6)$$

where $K_{\hat{h}}(\cdot)$ represents the kernel function, $I(\cdot)$ is an indicator function, n represent the number of observations and h is the appropriate bandwidth. Considering that our environmental variables Z are continuous, we estimate the appropriate bandwidth h following Daraio and Simar (2005) and use the k-Nearest Neighbor (k-NN) method.

3.2 Spatial Durbin interaction model

In the second stage of our strategy we make use of spatial interaction models, which rely on gravity models to explain OD migrations flows. However, a potential drawback for gravity models is that they rely just on a function of OD distance to account for spatial correlation and ensure cross-section independence (Balía et al. 2018). These assumptions have been challenged by many authors. Porojan (2001) and Lee and Pace (2005) find evidence of spatial dependence in the residuals of international trade and retail sales flows, respectively; while LeSage and Pace (2008, 2009) point out that the assumption of independence among observations might be difficult to defend, as OD flows are fundamentally spatial in nature. The explicit consideration of flow data correlation due to the spatial configuration of the units involved has been drawing much attention in the literature as the so-called network autocorrelation (Patuelli and Arbia 2016).

To embed spatial dependence in a spatial interaction setting, LeSage and Pace (2008) consider spatial spillovers at three dimensions: *origin-based*, *destination-based*, and *origin-destination based*. As described by LeSage and Pace (2009), origin-based spatial dependence reflects the notion that forces leading to flows from any origin to a particular destination may create similar flows from neighboring origins. Destination-based spatial dependence is related to idea that forces leading to flows from the origin to a destination may generate similar flows to nearby destinations. Thus, origin-destination-based spatial dependence reflect those forces that create flows from neighbors to the origin to neighbors to the destination. Using this definition of spatial dependence means that we need to model spatial dependence for flows of patients as a spatial autoregressive specification, accommodating endogenous interactions. This definition will allow us to define spatial spillover effects to hospitals neighboring the destination hospital in the flow of patients.

Additionally, we can accommodate the model for exogenous interactions in a Spatial Durbin Model (SDM) representing a situation where local spillovers arise from changes in the characteristics of neighboring hospitals and environmental features of neighboring regions (cantons). The exogenous interactions can be modeled by including the spatially lagged covariates in the econometric specification (along with the spatial lag of the endogenous variable). If statistically significant, the omission of these interactions can lead to problems of omitted variable bias (LeSage and Fischer 2016). We control for this issue: we begin by defining the model with no spatial interactions (based on the conventional gravity model) and adjust it for exogenous interaction specifications as in LeSage and Fischer (2016), and, then, we move to its SDM extension as illustrated in LeSage and Pace (2008) and Laurent et al (2019).²⁰⁵ We define our final model as follows:

$$y = \rho_d W_d y + \rho_o W_o y + \rho_w W_w y + c\alpha_i + \alpha l_N + e_d \beta_d + X_o \beta_o + X_i \beta_i + W_d e_d \phi_d + W_o X_o \phi_o + W_i X_i \phi_i + \gamma g + W_o g \gamma_o + W_d g \gamma_d + \varepsilon \quad (7)$$

Where y is the $N = n_o n_d$ vector of patient migration (logged) flows, that has been obtained by stacking the columns of the matrix Y of patients' migration flows, whose columns reflect origins (cantons), and rows destinations (hospitals). With n_o being the number of geographical observations at the origin and n_d the number of geographical observations at the destination. The vector of distances g is composed by the euclidean logged distances between origins and destinations. We define a contiguity matrix W_d where hospitals are neighbors if they are located in the same canton. Hence, W_o defines as neighbor those cantons that share a border line. The spatial lag $\rho_d W_d y$ reflects flows from neighbors to each destination observation in the vector of origin-destination flow to form a linear combination of flows from neighboring destinations. While ρ_d captures the strength of destination-based dependence. Similarly, $\rho_o W_o y$ reflects a linear combination of flows from regions neighboring the origin; and ρ_o reflects the strength of origin-based dependence. Hence, $\rho_w W_w y$ forms a linear combination of flows from neighbors to the origin and flows from neighbors to the destination, and the parameter ρ_w represents the strength of this dependence.

The vector e_d contains the robust logged efficiency scores obtained with (5) specific to every hospital. The matrix X_o accounts for economic and demographic regional characteristics that proxy the regional income-level and health conditions, and impact patient choice to seek treatment in other (developed) regions. We use cantonal variables such as the logged Gross Value Added per-capita (GVAp_c), logged population density, logged cantonal mortality, logged unsatisfied basic needs index (NBI),²⁰⁶ and logged insured population rate.²⁰⁷ β_o, β_d are the associated $k \times 1$ parameter vectors. The scalar parameter γ is the effect of the (logged) distance g , and α is the constant with l_N vector of ones.

²⁰⁵ We move in this direction to identify the sources of spatial autocorrelation and avoid model misspecification and omitted variable bias. Following this sequence, we can determine the significant effect of the exogenous interactions by means of an SLX, and, then, those of the endogenous interactions with the SDM model. In such a way, we can select the appropriate framework of analysis that provides the best fit to our data.

²⁰⁶ The NBI is a multidimensional poverty index, commonly used in Latin American countries.

²⁰⁷ In order to avoid taking the log of zero, we have added the unity to the dependent and independent variables as in LeSage and Thomas-Agnan (2015).

The spatial lags of the exogenous variables W_oX_o and W_dX_d help explain variations in flows across dyads coming from changes in the characteristics of the regions neighboring the origin and hospitals neighboring the destination respectively. ϕ_o, ϕ_d are the parameters associated to W_oX_o and W_dX_d . We control for the spatial lags of distance g , so W_dg and $W_o g$ explain the variations in flows arising from changes in the distance of neighboring hospitals in the same canton, and from neighboring cantons respectively. This aligns with the idea that patients will select the hospital to be treated depending not just on their proximity (to a given hospital), but to the that of their neighbors, as well. Finally, γ_d and γ_o are the parameters corresponding to W_dg and $W_o g$; and ε is the vector of disturbances.

A problem that might arise in the application of the model (especially for the regions that present large inflow of patients) is the presence of large flows of patients in the matrix of OD flows, relative to smaller (or zero). This would produce the non-normality in flows and jeopardize the estimations (LeSage and Pace 2008, 2009; Thomas-Agnan and LeSage 2014). In our setting, this would be representing an intraregional flow of patients (e.g. residents of developed regions getting treatment in their local area). To deal with this problem, LeSage and Fischer (2010) propose to modify the independent variables, by replacing with zero the values of the independent variables for the intraregional flows. The intraregional variations will be captured in a new set of explanatory variables X_i, W_iX_i , with non-zero observation for the intraregional observations as well as adding a new intercept term, α_i .

Note that we cannot interpret β_d (nor any other estimated parameter associated with origin-destination characteristics) as the partial derivative on flows arising from changes in the destination-efficiency. As pointed out by LeSage and Pace (2009), in the spatial econometric specification of the interaction model, changes in the k th characteristic of an observation i will produce changes in flows into the i th observation from other observations, as well as flows out of the observation i to other observations. Unlike conventional regression models where it leads to changes only in observation i of the dependent variable, y_i .

LeSage and Thomas-Agnan (2015) propose scalar summary measures of the impacts arising from changes in characteristics of the observations that involves averaging the *cumulative flow impact* associated with changes in all observations, resulting in the so called *origin effects*, *destination effects*, and *network effects*. Origin and destination effects express the mean impact on flows arising from changes in the origin and destination characteristics, respectively. In turn, network effects characterize the mean impact of a change in the characteristics of the origin i on all the flows coming from other origins, different from i to a destination j .

4. DATA

To estimate (7) we collect data for the year of 2014. Hospital information comes from the Annual Survey of Hospital Beds and Discharges and the Survey of Health Activities and Resources provided by the National Institute of Statistics and Census (INEC, by the acronyms in Spanish). We excluded the psychiatric, dermatologic and geriatric hospitals, and took out from the sample those that presented irregularities in the data.²⁰⁸ As described above, the migration flow matrix considers the rows to be the hospital destination, while the columns are the cantons (regions) of origin. We retrieved a sample of 176 destination hospitals and 106 cantons of origin. By vectorizing the flow matrix, we obtain a vector of 18.656 observations.

The cantonal economic and demographic variables were retrieved from the Ecuadorian Central Bank (BCE, by the acronyms in Spanish) and INEC's public statistics, respectively. While the poverty and population insurance data was collected from the 2010 national census.

For the selection of input and output variables to estimate model (5) in the first stage of our strategy, we followed previous literature on efficiency measurement. A complete review of the literature is offered in Hollingsworth (2008), O'Neill et al (2008) and Cantor and Poh (2018).

Regarding the input variables, we use the number of beds, the medical equipment, and infrastructure, widely used as a proxy for hospital size and capital. To proxy labor costs, clinical staff is usually included. To that end, we introduce the number of physicians and healthcare professionals beyond the number of physicians of the hospital.

As for the outputs we use the hospital's patient discharged to measure the final production of health.²⁰⁹ Additionally, we use the total number of morbidity and emergency consults, and the total number emergencies treated. Finally we proxy for the hospital quality using the survival rate after 48 hours of admission.

Finally, we consider three environmental variables that can potentially affect the hospital performance: the cantonal GVApc, cantonal population density and the hospital occupancy rate.

For the second stage of our strategy, we use two sets of variables, at hospital and regional level. First, at the hospital level, we use the efficiency scores obtained in the first stage as a variable of hospital performance. The variable proxies the pulling effect for a hospital to attract patients (e_d in equation (7)). A negative sign of the efficiency variable destination effect means a good performance, attracting patients from other cantons.²¹⁰

We proxy the cantonal level variables (X_o in (7)) that will impact on patients' decision to look for medical treatment with five variables: logged GVApc, logged population density, logged cantonal mortality, logged unsatisfied basic needs index (NBI).

²⁰⁸ We excluded psychiatric, dermatologic and geriatric hospitals as they focus on specific illness and patients that require different treatments that could bias the efficiency values. For example, psychiatric hospitals might require inpatients to stay for long periods of time, wherein our analysis would reflect it as a criteria for less efficiency.

²⁰⁹ We control for the heterogeneity of the disease-case attended using Herr (2008)'s case-mix index.

²¹⁰ Recall that hospitals with efficiency values higher than one are technically inefficient hospitals. Hence, a negative relationship with patient flows would mean that the best-performers are attracting more patients.

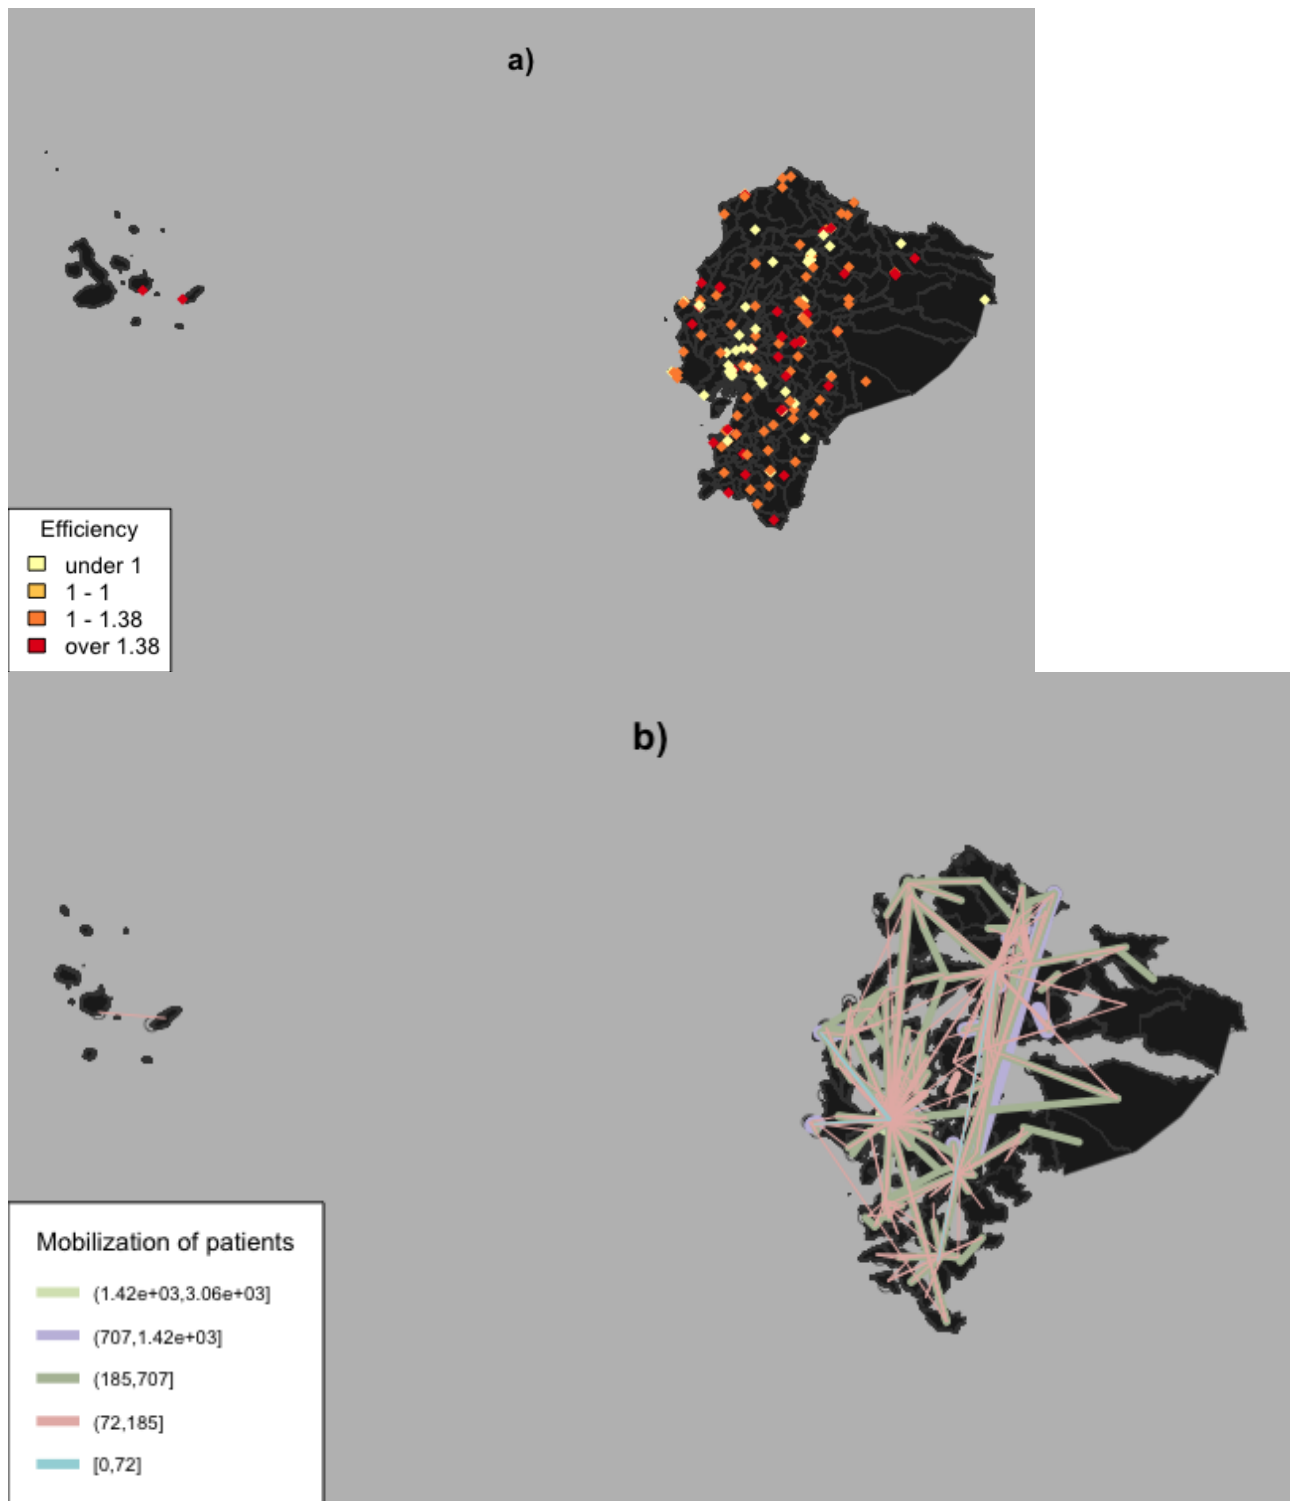

Figure 1: Hospital Efficiency and patient migration flows

Figure 1 shows the distributions of hospitals by efficiency performance (e_d in (7)) at the top panel (a), and the migration flow dynamic of the sample (y in (7)) at the bottom panel (b). Panel a) of the Figure shows the most efficient hospitals (that is, the hospitals with an efficiency value lower than 1, to be mainly concentrated in two of the most developed regions of Ecuador, where most of the healthcare resources are located).²¹¹

The panel b) of Figure 1 shows the patient flows from origin to destination, organized by intervals. We observe that there is a clear dynamic of patients traveling to the regions where the best performing hospitals concentrate. We can appreciate that most of the patient inflow is coming from neighboring cantons, which is a first signal of potential spatial autocorrelation in the migration flow. Hence, we use spatial interaction models that allow to disentangle the spillover effects of this migration dyad.

²¹¹ These hospitals concentrate mainly in Quito and Guayaquil which are the two bigger and most developed cantons in Ecuador Mendieta Muñoz and Pontarollo (2016).

5. ESTIMATION RESULTS

The Bayesian MCMC estimates based on 1000 draws are presented in Table 1. The estimates show not just a high level of destination-based spatial dependence, but origin-based and origin-destination-based spatial dependence as well. The coefficients ρ_d and ρ_o are 0.31 and 0.53, respectively. The estimated parameter $\rho_w = -\rho_d\rho_o$ is -0.11 and statistically different from zero.

These results provide evidence of the existence of spillover effects arriving from patient migration flows. Destination-based spatial dependence posits that flows coming from a given canton of origin to a destination hospital creates similar flows to neighboring hospitals (located in the same destination canton). In addition, origin-based spatial dependence shows that flows from any origin canton to a destination hospital creates similar flows from neighboring origins. Finally, origin-destination spatial dependence evidence that larger outflows from cantons neighboring the origin generate larger inflows to hospitals neighboring the destination. These findings point out the existence of spillovers steaming not just among cantons, but within cantons.

Table 1: Scalar summary effects

	Mean	t-value

Table 1 also reports the scalar summary effects for the model (7). In terms of hospital efficiency, the estimates show a significant expected negative effect. The increase in efficiency of an observed hospital leads to higher inflow of patients. Specifically, a 1 percent increase in efficiency on an average hospital would lead to a 0.3 percent increase in patient inflows.²¹²As mentioned, these results are supporting the hypothesis that patients are selecting those hospitals that present a higher performance as more qualified. Higher efficiency performance seems to be working as a pull factor that attracts patients from neighboring regions. This effect can also be arising from patient referrals from other (low-performer) hospitals, which do not account with the necessary resources to treat complex pathologies. The information available in our dataset does not allow us to disentangle the size of these effects. We leave this question to be explored in future research.

Interestingly, hospital efficiency is also displaying a significative and negative network effect. This means that 1 percent increase in the efficiency of a given hospital is increasing the patient movements going to neighboring hospitals –different from their initially preferred hospital of destination– in 0.15 percent. These finding goes in line with Piedra-Peña (2020), suggesting a competitive effect where higher efficiency in neighboring hospitals increase patient inflows.

Before drawing any conclusions, we carried out a series of robustness checks to test both for the validity of the estimations in the first stage as well as the second stage of our analysis. One important dimension to check the robustness is by considering the spectrum of treated diseases. There is the possibility that the pulling effect could be mainly driven by the presence of specialized hospitals versus other basic hospitals that provide another scope of treatments. Thus, we split the sample in two different subgroups by distinguishing between basic and specialized hospitals (this latter include chronic and acute hospitals).²¹³

212 Note that values bigger than 1 are inefficient.

213 In our database, acute hospitals embed infectious hospitals, obstetric-gynecological hospitals, pediatric hospitals, general hospitals that treat acute diseases and other hospitals of specialization. Whilst chronic hospitals embed oncology and pneumology hospitals

Table 2: Scalar summary effects by hospital type

Table 2 presents the scalar summary effects for efficiency and the parameters ρ_d, ρ_o and ρ_w for each hospital type. It is not surprising to note that the destination effect for basic hospitals disappears, suggesting that the pulling effect of hospital efficiency performance is mainly being captured by specialized hospitals, because the magnitude of the estimation is larger. As basic hospitals spread across the country, what seems to be driving people to travel to high-income regions is the performance of specialized medical institutions, which are more concentrated in those cantons. However, high performance of an average basic hospital is not enough to attract interregional patients as they are prone to receive medical attention in their local hospital to treat a common disease. Instead, in the case of specific or severe illnesses, patients will select a particular hospital on the basis of the quality of the treatment they perceive they will attain over there, which is being captured by our efficiency variable. Nevertheless, spillover effects are still statistically robust and comparable in both the cases, which means that both arrangements are valid to guarantee patient mobility across the territory. One explanation endorsing these results (particularly for basic hospitals) is that even though the increase in efficiency of a given hospital is not enough to attract intraregional patients, those hospitals are taking advantage of patient inflows, initially attracted by other hospitals (most likely neighbor specialized hospitals).²¹⁴

6. CONCLUSIONS

This study aims to analyze whether the higher efficiency performance of Ecuadorian public hospitals is resulting in a higher inflow of interregional patients to a destination hospital, and whether this is also leading to a higher inflow of patients to neighboring hospitals within the same region. To determine the effect of efficiency on the patient migration network, we follow an innovative two-stage strategy where the first step is to estimate robust conditional order-*m* efficiency values, based on the economic concept of Pareto efficient allocation and the second step makes use of a spatial Durbin interaction model to estimate the effect of hospital efficiency in patient migration flows, and separates the spillover effects in the form of larger inflows of patients for neighboring hospitals. We contribute to the empirical applied literature by estimating a model that considers different origins and destinations in the OD dyad, that—to the best of our knowledge—has not yet been applied.

We are referring to a structure in which regional disparities are modeled by means of healthcare asymmetries over time, producing a healthcare performance gap across regions and motivating a patient mobilization pattern since the majority of the influx of patients was concentrated in developed regions. Our results support the hypothesis that hospital efficiency performance is a strong pulling factor for this inflow, and the direction of this effect is robust according to different specifications and estimation methods. However, when we split the sample separating basic and specialized hospitals, this effect disappears for the former, but gets even stronger for the latter. In addition, we identify spillover effects in the mobilization flows, not just in the form of patients arriving at neighboring destination hospitals from an origin canton, but from patients arriving at a given hospital from cantons close to that origin, and arriving at adjacent hospitals as well. This evidence has two implications. First, the efficiency effect suggests that patients are perceiving—to some extent—hospital performance as a proxy for hospital quality that is encouraging cross-border migration to receive a better medical treatment than what they can get in their local area. However, this decision is based on the availability of specialized hospitals in the destination region, which are mostly concentrated in highly developed areas. The possibility also exists that other hospitals are referring patients for complex diseases, as they do not possess the resources to treat them. Second, spillover effects present in the data are suggesting that other hospitals neighboring the specialized ones are also capturing some of those inflows of patients. According to Brekke et al (2014), if there were competition among hospitals (which we find with the statistical significance of the network effects), this could entail a beneficial effect on the welfare of the population, as more competition encourages higher quality of care. However, hospitals from less-developed regions might not be benefiting from that welfare increase, as there is no incentive to provide better medical attention and hence just those that travel beyond regional borders may enjoy it.

Our results deliver useful suggestions for policy makers. On the one hand, new reforms need to be well-planned not just in terms of territorial discrepancies but also in terms of hospital specialization. For example, decreasing the limitations to specialized care could incur an increase of healthcare demand, that, if not controlled, could lead to negative consequences like congestion effects. Negative shocks to specialized hospitals induce a negative impact on their performance as well as the demand for the hospitals that surround them and as consequence, affects the efficiency of the

²¹⁴ For example, patients traveling to get specialized medical attention could incur in additional costs that are not covered by their insurance, but similar treatments could be offered in alternative public hospitals. Other scenario could imply that patients would seek medical attention in adjacent hospitals if the waiting time for specialized ones is long enough.

hospitals of the whole region and the welfare of the population. Public authorities could identify those key players in the healthcare network to target strengthening reforms that could encourage better performance within the public healthcare system of the region due to spillover effects.

Public healthcare policy can devote a larger share of their resources to targeting investment in those less-developed regions. The significant origin-based spatial dependence suggests the existence of clusters of less-developed cantons that are recording an outflow of patients. If there were not enough demand for local hospitals to compete, there would be no incentive to increase the quality of care over there. Therefore, public investment could be focused on the creation of specialized hospitals –or specialized wards in existing hospitals– in these regions to attract more demand. Once the inflow of patients is established, new spillover effects could arise, benefiting adjacent hospitals and bringing improvements both for the regional healthcare performance and welfare so as to benefit the low-income patients of that place, who cannot afford to receive treatment in other cantons.

**STRUCTURAL TRANSFORMATION, LAND USE AND AGGLOMERATION:
SECTORAL IMPACT GM SOY INTRODUCTION IN BRAZIL**[Jaime Carrion Fialkow](#)

VU Amsterdam, Netherlands

ABSTRACT

Our papers studies the relation between agricultural productivity and manufacturing employment, focusing on impact heterogeneity and its determinants. We build a three-sector model of an open economy with factor-biased shocks on agriculture and agglomeration economies to manufacturing and analyse how these interact, focusing on a labor-augmenting shock in agricultural production; moreover, we look at the role of land supply flexibility in shaping the impact of such a shock. In our model, a shock on agricultural labor productivity might decrease agricultural employment if land and labor are strong enough complements, which may increase manufacturing employment; agglomeration economies lead to or a smaller positive effect of the shock on manufacturing employment, as its direct effect on lowering agricultural employment dampen the impact of the shock on the sector. Furthermore, when we allow for flexible land supply, the labor-saving effect of the shock on agriculture may be counteracted by undeveloped land being put to use and attracting labor as it becomes profitable after the shock increases agricultural rents.

We empirically test the model using the introduction of genetically modified (GM) soy in Brazil after 2003 as a labor productivity shock; FAO-GAEZ data shows the potential benefit of changing soy production from low to high-inputs by municipality, which determines how the speed in which a municipality introduces the genetically modified seeds - faster where the potential change is larger. Using 1996 and 2006 Agricultural Census and 1991, 2000 and 2010 Demographic Census data, we look at the impact of the shock on sectoral employment. To test the agglomeration impact we interact agglomeration variables with the shock. Consistent with our model, the shock leads to lower agricultural employment and larger manufacturing employment - and regions with an initially larger manufacturing base present a smaller effect, while a more general measure of agglomeration, population, positively correlates with the shock effect: larger cities benefit more from the shock in terms of manufacturing employment growth, but more industrialized cities don't. To look at the role of land supply, we split the sample by Brazilian macrorregions, focusing on the two main soy-producing regions, South (where soy substitutes labor-intensive agriculture and land availability is roughly fixed) and Center-West (where soy expands on previously undeveloped or underdeveloped land), finding that reaction of agricultural employment to the shock differs markedly. In the South the behavior is consistent with the baseline model: GM soy introduction leads to a fall in agricultural employment and growth in manufacturing employment; in the Center-West, however, there is no fall in agricultural labor, pointing to the importance of land use in determining the shock's impact. Moreover, in the more economically developed South the shock boosts manufacturing employment as a whole, while in the less developed Center-West only soy-related manufacturing employment is significantly boosted.

Special Session: SS36 - Glocalization and Regional Development

GLOCALIZATION OF NATURAL FARMING AND REGIONAL DEVELOPMENT

[Shinya Ishizaka](#)

¹ Faculty of Law & Letters, Ehime University, 3 Bunkyo-cho, Matsuyama, 790-8577, Japan, ishizaka.shinya.xj@ehime-u.ac.jp

ABSTRACT

The purpose of this paper is to examine the relationship between glocalization and regional development by focusing on how natural farming has been transformed and spreading in India. Natural farming is a farming method that follows the principles of no tillage, no fertilizer, no pesticides, and no weeding, and this method was advocated by the late Japanese farmer and philosopher, Masanobu Fukuoka, who lived in Ehime, in southwestern Japan, in the 1950s. It is also known as “do-nothing farming.” This method is a form of alternative agriculture that does not use any machines, chemicals or biotechnology.

The first half of this paper analyses the mechanism of glocalization of natural farming that started in Ehime, Japan and spread to various parts of India, focusing on the following three dimensions. The first approach focuses on the power of promotion in the “disembedding” phase of the glocalization process. The second approach focuses on the background of the “re-embedding” phase of the glocalization process. The third approach highlights the “complex” dynamism of the glocalization process, where various unintended distortions occur and mutual feedback is activated.

The latter half of this paper examines how natural farming have been contributing to regional development in India. I describe the situations of a farmer who has fully practised Fukuoka’s natural farming and another farmer who has partially practised Fukuoka’s natural farming based on field surveys.

Glocalization, natural farming, regional development

1. INTRODUCTION

The purpose of this paper is to examine the relationship between glocalization and regional development by focusing on how natural farming has been transformed and spreading in India. Natural farming is a farming method that follows the principles of no tillage, no fertilizer, no pesticides, and no weeding, and this method was advocated by the late Japanese farmer and philosopher, Masanobu Fukuoka, who lived in Ehime, in southwestern Japan, in the 1950s. It is also known as “do-nothing farming.” This method is a form of alternative agriculture that does not use any machines, chemicals or biotechnology. Natural farming has been accepted by many in various parts of the world as a means of radical dissent against conventional agriculture and modern civilization in general.

The first half of this paper analyses the mechanism of glocalization of natural farming that started in Ehime, Japan and spread to various parts of India, focusing on the following three dimensions. The first approach focuses on the power of promotion in the “disembedding” phase of the glocalization process. The second approach focuses on the background of the “re-embedding” phase of the glocalization process. The third approach highlights the “complex” dynamism of the glocalization process, where various unintended distortions occur and mutual feedback is activated.

The latter half of this paper examines how natural farming have been contributing to regional development in India. I describe the situations of a farmer who has fully practised Fukuoka’s natural farming and another farmer who has partially practised Fukuoka’s natural farming based on field surveys.

2. GLOCALIZATION OF NATURAL FARMING

In past studies on glocalization, it has been elucidated that globalization does not necessarily result in uniformity or homogenization of the world, but globalization always involves localization (or indigenization). The perspective of glocalization seeks to reveal the ways in which particular localities are directly connected to other localities in the world. Thus, the glocalization of natural farming can be described as follows. Natural farming, which had been embedded in a locality, is disembedded from that locality and then re-embedded in other localities in different parts of the world.

This section analyses the mechanism of glocalization of natural farming that started in Ehime, Japan and spread to various parts of India, focusing on the following three dimensions. The first approach focuses on the power of promotion in the “disembedding” phase of the glocalization process. The second approach focuses on the background of the “re-embedding” phase of the glocalization process. The third approach highlights the “complex” dynamism of the glocalization process, where various unintended distortions occur and mutual feedback is activated.

2.1 The promotion of natural farming

Masanobu Fukuoka was born in 1913 in a village in Ehime on Shikoku, the fourth largest island in southwestern Japan. Fukuoka was a scientist who worked in the plant inspection section of Yokohama custom house, and in 1937, he suddenly fell ill and was hospitalized. After a while, his condition improved but was not entirely relieved and he was roaming around in Yokohama city. One day in the early morning, when he was still half-sleeping at a park, he told us, that he had a sudden encounter with God, and he understood that everything in this world was nothing (Ishizaka 2017: 23-24). After that enlightenment experience, he quit his job at Yokohama, returned to his native farm in Ehime, and began his experiment with alternative methods of farming. In approximately 1950, he concluded that natural farming would be the best method for sustainable agriculture.

Masanobu Fukuoka's name became globally known after 1978, when the English translation of his book, *One-Straw Revolution*, was published in the United States. Since then, Fukuoka's books have been translated into more than 30 languages (Ishizaka 2018: 19). If Fukuoka had not written his books and if his books had not been translated, natural farming would not be as widely known in the world today.

It is also important to note that Masanobu Fukuoka visited more than 17 countries around the world, and he was actively engaged in promoting his methods and philosophy (Ishizaka 2018: 19; Ishizaka 2021).

2.2 The diffusion of natural farming in India

In India, the most important supporters of natural farming have been Gandhian activists and their networks. Gandhian activists are people who aim to realize M.K. Gandhi's dream and are engaged in various activities such as social work, educational work, and social movements. Other supporters have included a Japanese Buddhist sect, Nipponzan Myohoji, and a Quaker community in the Hoshangabad district of Madhya Pradesh. Fukuoka visited India four times, delivering lectures and giving instructions to farmers in various parts of India. These visits were made possible mainly because of the supporters' efforts. For Fukuoka's travels in India, these supporters provided invitations and interpretation and cared for his well-being including the provision of food, accommodation, and sometimes his travel fees.

I would like to highlight two reasons for the emergence of natural farming practices in various parts of India. In the 1980s and 1990s, criticism of the Green Revolution focusing on negative aspects such as environmental degradation and widening disparities and opposition to the development of large dams gained momentum. In the 2000s, the movement against the introduction of genetically modified crops also began. Furthermore, water shortage problems such as falling groundwater levels and the depletion of water sources and farmer suicide due to difficulties repaying loans became major concerns. Natural farming has attracted attention partly as a solution to these problems.

The second reason is the weak organisational capacity of agricultural cooperatives in India. In Japan, for example, not using pesticides or chemical fertilizers is against the wishes of many agricultural cooperatives. It is difficult to practise natural farming without clashing with farmers' cooperatives and surrounding farmers. In India, by contrast, individual farmers seem to be able to more freely and independently choose what kind of farming methods they want to adopt. However, the nature of farming and rural life in India varies greatly from region to region and needs to be more carefully analysed.

In India, top-level politicians and bureaucrats, such as Prime Minister Rajiv Gandhi and Prime Minister Narasimha Rao, met with Fukuoka during his visits to India. Recently, the promotion of "natural farming" has been advocated in several states, with each chief minister taking the lead. It is a significant feature of India that not only the grassroots level but also the government has been paying attention to natural farming.

2.3 The complex dynamism of the glocalization of natural farming

Although Fukuoka was invited to visit various parts of the world, there were often gaps in understanding between Fukuoka and his hosts. After observing the arid zone in the United States from the air during his first visit to the country in 1979, Fukuoka's lifelong mission became the prevention of desertification. For that purpose, he enthusiastically visited Africa, India, and China. However, according to a person who accompanied him on his travels, many people who wanted to meet Fukuoka in those areas were interested in his philosophy and methods of farming and not necessarily his methods for preventing desertification.

It is also interesting that the *One-Straw Revolution* was not necessarily regarded as a book on agriculture, the environment, or philosophy. In a bookstore in Thailand, the book is displayed on a shelf in the social sciences section along with books by Max Weber and Benedict Anderson (confirmed by the author during a visit to Bangkok in July, 2017). In China, it is in the Japanese literature section along with novels by Haruki Murakami (confirmed by the author during a visit to Shanghai in September, 2017).

However, natural farming is not something that has one definitive or "real" method. Natural farming, even according to its founder, is always in a constant state of change and will continue to change forever. We tend to think that the "original" or "real thing" exists as determined by the originator and that it is gradually "distorted" as it spreads around the world. However, it may be useful to avoid such a view and analyse the issue of natural farming by not assuming the existence of the "original thing".

Fukuoka's methods and philosophy were transforming throughout his entire life until he passed away in 2008, more than 30 years after the publication of his classic, *One-Straw Revolution*. Thus, there should not be only one, original, authentic, or final method of natural farming.

3. NATURAL FARMING AND REGIONAL DEVELOPMENT IN INDIA

3.1 The Titus farm at Rasulia

Raju Titus (1946-2018) was fortunate that, in 1988, Fukuoka visited the Titus Farm at Rasulia, Hoshangabad district in the Madhya Pradesh in India and gave him some practical advice. Titus had started natural farming two years before Fukuoka's visit. He had almost given up farming because of the bad yield when he encountered Masanobu Fukuoka's *One Straw Revolution*. Soon after reading the book, he sold his cattle and started natural farming in 1985. It was very fortunate for him that the condition of his farm improved, and in 1988, Fukuoka visited it. The meeting with Fukuoka was a decisive moment for Titus, and after that, he continued experiments with natural farming.

When I visited the Titus farm in August 2017, the main activities were (1) wheat cultivation, (2) goat rearing, and (3) use of the *subabul* trees. The goats were raised for milk and meat processing. *Subabul* trees were not only used to supply nitrogen to crops such as wheat, but also as fodder for goats and fuelwood. Pulses and vegetables were also produced.

Titus continued to experiment with the use of 'clay dumplings', which Fukuoka was keen to develop. He also faithfully followed the 'no-till' principle of Fukuoka's natural farming. As a result, large numbers of earthworms were found in the soil of the Titus farm. Another important point in the cultivation was the crimping of the *gajar ghans*, which initially looks like a weed.

There is a Quaker community, the Friends Rural Centre, which is situated approximately 1.5 km from the Titus Farm. This has been a major Quaker stronghold since the British period, and there are many Quakers living in and around Rasulia. Raju Titus was also Quaker and the name 'Titus' comes from the Bible. At the Friends Rural Centre, Marjorie Sykes (1905-1995), a British woman who was a 'disciple' of M.K. Gandhi, led a movement to reconsider the agricultural situation in the late 1970s and 1980s. The problem was that the Green Revolution, which was spreading in India at the time, was causing soil degradation and poverty in rural areas. At the end of 1983, one of the members of the community, Partap Aggarwal, discovered the English translation of Masanobu Fukuoka's *One Straw Revolution* and immediately ordered a copy of the book from the United States and held a reading session among the community members. This led to the publication of the Indian edition of *One-Straw Revolution*.

ACKNOWLEDGEMENTS

GERMAN PRISONERS OF WAR IN JAPAN AND THE REGIONAL DEVELOPMENT DURING THE FIRST WORLD WAR

[Katsuhiko Kajiwara](#)

kajiwara.katsuhiko.mg@ehime-u.ac.jp

ABSTRACT

The purpose of this paper is to investigate the effect that the approximately 4500 German POWs detained in Japan during WWI had on local Japanese cities. By looking at these POWs as producers as well as consumers in local cities, that is, as “military immigrants”, this paper tries to confirm the development that POWs generated within local cities.

On the producer side, it is confirmed that technology transfer through POWs as highly skilled workers was expected, and that such POWs actually gave technical guidance in the workspace in local cities and worked by making the best use of their skills. However, due to the short period during which POW labor was supplied, such guidance occurred only as episodes of individual technology transfer. Regarding low-skilled and unskilled labor, to avoid international trouble caused by the overuse of POWs, except for a few cases, POW labor was limited to activities in POW camps and was not employed on a large scale in agriculture as in the case of contemporary Europe. As a result, in terms of producers, except for the episodes of technology transfer, it cannot be said that German POWs had a great influence on the development of local cities.

On the consumer side, on the other hand, the arrival of POWs had brought economic benefits to local cities. First of all, the amount of money that the POWs themselves could spend was large. The amount of goods purchased at the shuhostore in the camp (post exchange) and through the direct transactions outside the camp had quite large economic impacts, considering the revenue of the local cities. Second, the amount paid for the management of POWs was also large, which was a burden for the government and the army, but such costs brought economic benefits as a kind of public works project for local cities, especially in the industries related to POW management, and a large amount of money flowed into the local market.

German POWs accounted for 0.02% of the Japanese population at that time, which was extremely small. In terms of labor supply, that of the German POWs was insignificant, except for their technical capabilities. Nevertheless, it could be said that German POWs played a role disproportionately greater than their population size in that they provided an opportunity for consumption in local cities.

Glocal Movement of Persons, Prisoners of War, Regional Development

1. INTRODUCTION

The purpose of this paper is to investigate the effect that German POWs detained in Japan during World War I had on local Japanese cities, especially from the perspective of glocal human movement and regional development.

The war in Europe that broke out as a regional conflict between Austria and Serbia in July 1914 immediately turned into a war on a global scale, and in August of that year, Japan entered into the war against Germany, obtaining its colonies in the Pacific and in China. After the fall of the German territories in the Pacific Ocean in October and of Qingdao in November, approximately 4500 German soldiers were captured and sent to POW camps built in regional Japanese cities. The path these German prisoners had taken to Qingdao followed several routes. Professional soldiers and civil servants had resided in Qingdao since before the war, while those who were engaged in economic activities in Vladivostok were forced to go there due to the war between Russia and Germany. There were others who resided in other Chinese and Japanese cities and were sent to Qingdao for conscription or as volunteers just before the war between Germany and Japan began. These Germans had migrated to East Asia and Far Eastern Russia through Germany’s worldwide colonial expansion, had gathered in Qingdao due to the outbreak of WWI, and were sent to local Japanese cities.

Such global movements of humanity are accompanied by the movement of knowledge and goods. In fact, the German POWs brought various techniques to regional Japanese cities, such as methods for manufacturing sausage and rubber. Moreover, the advent of German POWs produced the so-called ‘horyo-keiki (boom due to POWs).’ However, while the economic and social effects of these POWs have been pointed out, the relationship between these phenomena and regional development has not been examined. What effect did the German POWs have on regional societies, especially in terms of those societies’ development? This paper examines the local development generated by the appearance of German POWs in local cities. By looking at these POWs as producers as well as consumers in the local cities, that is, as “military immigrants” (cf. Stibbe (2008), Rass(2016)), this paper tries to confirm the development that POWs brought to these cities.

2. A GENERAL DESCRIPTION OF POW CAMPS IN JAPAN

Japan declared war against Germany and Austria and fighting began in the German South Pacific Islands and German colonial city of Qingdao (located on the Shandong Peninsula, southeast of Beijing) in October and November 1914. Qingdao fell, and approximately 4500 German soldiers were taken captive.

At the beginning of the war, POW camps were established in 13 places in Japan, mainly in the western part: Kurume, Kumamoto, Fukuoka, Oita, Matsuyama, Marugame, Tokushima, Himeji, Osaka, Nagoya, Shizuoka, Tokyo, and Narashino. The reasons these cities were selected include easy transfer from Qingdao, the existence of a military base, and their warm and mild climates. The Japanese government converted facilities such as temples, city halls, and even schools into camps. Camps were established mainly in the center of the cities, as they were managed by the Japanese army. Because of their nearness to civilian residential areas, the policing and public safety problem occurred, such as deserting and inappropriate intercourse with the local people, including sexual intercourse. There were also hygiene and space problems. The POWs had to endure mosquitos (temples usually had gardens with ponds), poorly ventilated and poorly lit rooms, and unhygienic toilets, as some of the facilities were not originally built to host a large number of people. As the war continued, to solve these problems, the 13 camps were gradually dissolved and unified into 6 relatively large camps: Kuruma, Ninoshima, Aonogahara, Bando, and Narashino. By this measure, the number of internees increased from 400 in one facility such as a temple at the beginning of war to more than 1000 in barracks after 1917. In 1920, all the POWs were released and most of them returned to Germany, Austria or one of the newly created independent countries. The POWs who found jobs were allowed to stay in Japan, and approximately 140 ex-POWs settled in Japan after WWI.

3. GERMAN POWS AS A SOURCE OF LABOR

In WWI, the European powers used POWs as a source of labor due to the lack of a male labor force given the total mobilization system. Since men were mobilized as soldiers, women had to replace or supplement their labor, but there was still a labor shortage in labor-intensive industries such as agriculture and dangerous work. Foreign labor was used to make up for this lack, and POWs were used.

The use of POWs as a source of labor was already permitted under the Hague Convention of 1907 (except for forced, harsh, or military-related work). There were also Russian POWs engaged in easy work in accordance with the Hague Convention of 1899. Based on the contemporary situation in Europe and historical experience, the use of POWs was being considered in Japan during WWI.

In "The Final Report of the POW Information Bureau" published after WWI ended (Final Report (1920)), the reason for using POWs as a source of labor was explained as follows: 1. to relieve boredom, 2. to cut the costs of POW management, 3. to promote industry. There was high interest in knowledge and technology, and the prior occupations of the POWs were accounted for to make use of their special skills. In other words, the use of German soldiers as a source of labor was considered, but the POWs in Europe were used more as low-skilled labor or manual labor unrelated to their occupations from before they were enrolled in military service. For example, Germany employed 1.62 million POWs (approximately 65% of their total number of POWs) in August 1916, half of whom were engaged in agriculture (Otsuru(2013:65)). On the other hand, in Japan, the focus was on employing high-tech workers.

3.1. German POWs as highly skilled immigrants

The occupations of the POWs before the war were as follows (Final Report (1920)): professional officers (70%), government officials (0.4%), free-lance professionals (0.1%), and commerce and industry workers (2.4%). Among those working in commerce and industry, 95 % had worked in commerce. More than half of them had participated in trade. Others were in the business of selling general merchandise, machines and leather goods. Those who came from industry had worked in the manufacture of electric goods and machines and in construction. This meant that most of POWs were not members of the labor force with special skills and knowledge; they were instead rather commerce and business workers.

This occupational survey was conducted after containment, apart from this, the Japanese army conducted a "POW special skills survey" (Final Report (1920)). This shows that the army was positive about hiring POWs with specific skills. Initially, the army inquired of the public and private sectors the employment of POWs with special skills, but the movement toward it was very slow for the following reasons: the conditions for use were unclear; it took time to make legal preparations (drawing up POW labor rules); the army and these inquired sectors could not come to a mutually acceptable compromise in terms of labor conditions such as the strictness employment conditions (the need to monitor) and the distance between the camp and their place of work. However, at the end of the war, especially from the cease-fire to the conclusion of the peace treaty, the employment of highly skilled POWs progressed, and employment and technical guidance were provided.

Some of these cases have been pointed out as having an impact on later corporate activities such as those of the Shikishima Bread Company (cf. Menjo (2008), Mori (2005)), and some cultural foods (sausages, baumkuchen, etc.). As already mentioned, there were few highly skilled German POWs who remained in Japan after WWI, and it is difficult to measure the impact of such highly skilled individuals on local industries.

3.2. German POWs as a low-skilled labor force

In contrast to the European case, the employment of a low-skilled or manual labor was rarely practiced. Behind this is the Japanese attitude of that time, which was characterized by fear of becoming an international problem due to the overuse of POWs. There was also concern that the use of POWs would “threaten” the Japanese labor market. This was due to the temporary depression in Japan beginning in 1914, which was caused by the turmoil in the international economy after the outbreak of WWI. On the other hand, as the war prolonged, “employment” within the camp was considered and implemented to make the prisoners themselves compensate the army for the costs associated with their management.

Regarding the use of low-skilled labor outside the camp, there was the ground-leveling work for an athletic field, and in the Fukuoka camp, 80 people were used for the construction of a historic monument (the Mongol invasion monument). For those inside the camp, there were activities such as cleaning and meal duty.

3.3. German POWs as producers

Looking at the labor situation of the German POWs as a whole, their employment was rather sluggish. In the five years from detention to release, the total number of people engaged in labor was approximately 460,000, which means that only 230 people worked per day (approximately 5% of all POWs). The total wages paid were 73,000 yen, which appears to be a large amount when converted to the current face value, but considering the size of the budgets of the local cities, it cannot be said that this was a large amount. For example, in Nagoya, a core city, as well as Kurume, a local city, the ratio was small (e.g., Aichi Prefecture Statistical Report (1917), Fukuoka Prefecture Statistical Report (1917)). In addition to the small number of German POWs themselves, the number of German soldiers employed was also small, and although the wages of German soldiers with special skills were high, their impact on the overall economy cannot be confirmed.

Note, too, that Japan experienced a so-called war economy when Europe became a battlefield during WWI, and the economy began to improve circa 1915. As a result, special demand was generated in the military and shipbuilding industries. Additionally, light industries centered on the textile industry and heavy industries such as the chemical industry expanded toward the end of WWI. Therefore, as a result of the process of the country’s industrialization as a whole, the advanced skills of German POWs were more likely to have been wanted, rather than causing that industrialization. The impact of German POW labor on the local communities was very limited, except for what can be seen in the episode regarding technology transmission.

4. THE GERMAN POWS AS CONSUMERS

In Europe, since the number of POWs that would be produced by the war was uncertain at its beginning, established facilities, including military barracks, fortresses and warehouses, were converted into camps. As they were located near civilian residential areas, some citizens were opposed to the reception of POWs, fearing the deterioration of public safety and the spread of disease. By contrast, some Japanese provincial cities competed for the right to host POW camps after the war against Germany broke out. The Japanese still remembered the “POW boom” produced by POWs in the Russo-Japanese war. During the Russo-Japanese war, Japan accommodated approximately 70,000 POWs at 29 sites in nationwide. The administration of POWs and the money used by them enriched the provincial economies. As a result, during WWI, some cities tried to obtain economic benefits by accommodating POWs (Kainan-Shinbun (1914)).

4.1. POWs and cash

The cash that POWs could use included relief remittances from inside and outside Japan, in addition to their own savings and the allowance stipulated by international conventions (equivalent to the amount paid to an officer of the same rank in the Japanese army). The total amount of remittances was 1,410,000 yen and was equivalent to more than 2,800,000,000 yen (26,000,000 dollars) in today’s values. There was high interest in POWs’ cash at the beginning of the war. The local newspapers reported that Siemens Co. had sent 6,000 yen to the Matsuyama POW camp (Kainan-Shinbun (1914)). The Matsuyama POWs decided to limit the amount of cash the POWs could keep and to put the rest in the bank since there were differences in the amount of money each POW had and there were troubles with some POWs losing money or having it stolen. According to a newspaper report in December 1915, the total savings of all POWs amounted to approximately 10,000 yen (Kainan-Shinbun (1915)). Taking into account that the annual expenditure of Matsuyama city was 130,000 yen, the money that the POWs had was quite a large amount in total.

4.2 Post exchange and direct transactions in the city

POWs could buy daily goods, tobacco, and foods (fruits, sweets, beverages, canned goods) at the shuho-store in the camp (post exchange), which was outsourced to the private sector. The amount of money paid in the post exchange was substantial, providing economic benefits to the provincial cities. For example, in the Matsuyama POW Camp, it was reported that the sales figures for the post exchange for the 3 months from December 1914 to February 1915 was 15,000 yen (Kainan-Sinbun (1915)). One yen in those days was equivalent to 1000 to 3000 yen today. Supposing 1 yen to be 2000 yen in today’s values, this amounted to approximately 300,000,000 yen (approximately \$233,000; \$1=110 yen). It was also worth as much as half a quarter of the annual budget of Matsuyama city. According to “The Final Report,” the amount of money the German POWs spent across POW camps in Japan throughout their period of detainment amounted to 3,257,000 yen. It is necessary to bear in mind the fact that inflation soared due to the war boom from 1914-1920 and

the Siberia expedition in 1918. However, even if this amount is converted from 1914 currency values, it still amounts to 6,514,000,000 yen (\$60,000,000) and actually is believed to have been worth more.

POWs also purchased goods in the city and ordered goods from other parts of Japan. It is well known that while Governor Meyer-Waldeck was accommodated in the Fukuoka Camp, he indiscriminately bought champagne in Fukuoka to celebrate the birthday of the Kaiser and ordered goods from the areas where many foreigners resided such as Kobe, Yokohama, Tokyo, Osaka. Compared to the situation during the Russo-Japanese War, the POWs could not walk in the city freely; therefore, the amount of money spent in the city was less. It was also said that German POWs were “thrifty” compared to Russian POWs and that the economic benefits might have been smaller than expected. However, the amount of money spent by the POWs, particularly by officers, was significant given the difference in the value of the two countries’ currencies. German lieutenants received a salary 10 times more than that of their Japanese counterparts.

4.3. The cost of managing POWs and its effect on local cities

During WWI, people suffered from shortages of food and goods in Europe, and the condition of POWs was severe. In Japan, the war lasted only a short time, and the situation was quite different. The Japanese government was also very keen to follow international rules and retain its reputation as a civilized nation by trying to treat POWs well. As a result, the cost of managing the POWs soared because they spent more money on food supplies than the international convention stipulated. The international convention on POW treatment stipulated providing POWs with food equivalent to that provided to native soldiers. According to “The Final Report,” the Japanese government spent 5,970,000 yen from the time the POW camps were set up to their closure, which is equivalent to more than 12 billion yen in today’s values. This amounted to 1% of annual expenditure in those days, as Japan’s average expenditure from 1914 to 1917 was 0.6 billion yen. This cost was a heavy burden on the Japanese government and military and cancelled out the economic benefits the POWs provided through post exchanges and in the cities.

However, for the local cities, the management of POWs could be described as a public work and, by engaging in this management, money flowed into the city. Local newspapers depicted temples that provided facilities, merchants dealing with the army, shopkeepers of fresh foods, butchers, and bakeries all benefiting from the camps. The custom of eating bread and beef has gradually spread since Japan’s modernization (Meiji Restoration in 1868), and the appearance of German POWs stimulated the demand for those foods, particularly in local cities. The amount of beef sold in Ehime Prefecture, whose capital is Matsuyama, was 1460 kg in 1914, 4800 kg in 1915, 7760kg in 1916, and 5000 kg in 1917 (Ehime Prefecture Statistical Report (1917)). We can observe a positive correlation between the increase in the demand for beef and the time of the opening of a camp to its closure. The demand for pork had also begun to rise in 1914. Japanese meat-eating habits expanded during WWI alongside with the war boom. However, at least from the end of 1914 to 1917, local provinces like Nagano Prefecture, which flourished with the rapidly advancing textile industry caused by the war boom but which did not accommodate POWs, did not observe an increase in the demand for meat (Nagano Prefecture Statistical Report (1917; 1918)). This explains why the accommodation of POWs affected the expansion of the meat industry in local cities. Due to the lack of statistical data and the rise in prices due to inflation, it is difficult to discern how far the demand for other commodities was stimulated by the appearance of the POWs; however, it is estimated that the economic benefits the POWs had generated in local cities were significant considering the central government’s and military’s large expenditure on the POWs.

5. CONCLUSION

During WWI, German soldiers were detained as POWs in local cities in Japan. Through this case related to POWs, this paper tried to confirm the effects of these military immigrants.

First, on the producer side, it was confirmed that technology transfer through POWs as highly skilled workers was expected and that such POWs actually gave technical guidance in the workspace in local cities and worked by making the best use of their skills. However, due to the short period of during which POW labor was supplied, such guidance occurred only as episode of individual technology transfer. Regarding low-skilled and unskilled labor, to avoid international trouble caused by the overuse of POWs, except for a few cases, POW labor was limited to activities in POW camps and was not employed on a large scale in agriculture as in the case of contemporary Europe. As a result, in terms of producers, except for the episodes of technology transfer, it cannot be said that German POWs had a great influence on the development of local cities.

On the consumer side, on the other hand, the arrival of POWs brought economic benefits to local cities. First, the amount of money that the POWs themselves could spend was large. The amount of goods purchased at the post exchange in the camp and through direct transactions outside the camp had quite large economic impacts, considering the revenue of the local cities. Second, the amount paid for the management of POWs was also large, which was a burden for the government and the army, but such costs brought economic benefits as a kind of public works project for local cities, especially in the industries related to POW management. Compared to the cost of managing POWs during the Russo-Japanese War, which reached 20% of national expenditure, the cost during WWI was 1%, which gives the impression that standards were lower. However, given that the number of POWs during the Russo-Japanese War was approximately 20 times that during WWI, a large amount of money can be considered to have flowed into the market.

German POWs accounted for 0.02% of the Japanese population at that time, which was extremely small. In terms of labor supply, that of the German POWs was also insignificant, except for their technical capabilities. Nevertheless, it could be

said that German POWs played a role disproportionately greater than their population size in that they provided an opportunity for consumption in local cities.

RELATIONSHIP BETWEEN ECONOMIC GLOCALIZATION AND THE DEPOSIT-LOAN RATIO OF REGIONAL BANKS IN JAPAN

Masashi Chikahiro

Ehime University, 3 Bunkyo Matsuyama-City Ehime-Pref., JAPAN, chikahiro.masashi.mf@ehime-u.ac.jp

ABSTRACT

The deposit-loan ratio of banks in Japan, especially regional banks, has been declining. From the perspective of endogenous money supply theory, the deposit-loan ratio is basically unchanged because banks' lending assets and deposit liabilities increase or decrease by the same amount. But that is actually happening. I argued that the reason for the decline the ratio is banking sector have huge JGBs to finance government' deficits. Economic glocalization force the comparison of profit rates of industries on a global scale. As workers are not easy to move, local economies that have lost the global battle for profit rates need government expenditure. The deposit-loan ratio of banks in Scandinavian countries has been maintained or increased. Economic glocalization requires the movement of workers from low to high area of profit rates, and the productivity gains that make this possible. In Japan, there are few workers going abroad and that productivity does not improve. BoJ and private banks hold most balance of JGBs. In the case of Japan, economic glocalization requires a "big government" and "nationalization" of central bank.

KEYWORDS

Deposit-loan ratio, government expenditure, nationalization of central bank

1. INTRODUCTION

1.1 Deposit-loan ratio of banks in Japan

In Japan, the deposit-loan ratio of banks has been declining for 30 years and has recently approached 60%. The ratio is said to be one of the indicators of bank's function. Previous studies on this issue have said that the reason for this is that the demand for borrowing for investment is not strong in the Japanese economy.

1.2 Why does the deposit-loan ratio decline?

From the perspective of endogenous money supply theory, the deposit-loan ratio is basically unchanged because banks' lending assets and deposit liabilities increase or decrease by the same amount. I pointed out the following two factors for the decline in the deposit-loan ratio in Japan. These are the off-balancing of bad loans and the holding of JGBs by BoJ and private banks. Thus, the decline in deposit-loan ratio is neither due to a decline in the functioning of the banks nor to difficulties in finding lenders.

2. THE EVER-INCREASING BALANCE OF JGBs

2.1 Japan's money stock growth is largely due to fiscal factors

The reason for the increase in JGBs is the need to increase government spending in order to maintain GDP. In Japan, due to the non-constrained nominal interest rates, monetary policy is not effective and fiscal policy must be relied on. Over the last two decades, fiscal factors have increased Japan's money stock by 200 trillion (JPY), resulting in a marked decline in banks' deposit-loan ratio. As workers are not easy to move, local economies that have lost the global battle for profit rates need government expenditure.

2.2 Glocalization of the economy and government expenditure

The reason to Japan's GDP is sustained by government expenditure is that Japan has not been able to respond to the glocalization of own economy. Equilibrium is achieved by the mobility of firms and workers when the profit rate of an industry is subject to international competition. However, Japanese workers have a bias to stay within the country and are not willing to move to regions with higher profit rates. As the economy becomes more glocalized, the profit rate falls relatively and the reliance on government expenditures is reinforced.

GLOCALIZATION OF LOCAL GOVERNMENT REFORM AND REGIONAL DEVELOPMENT

[Kyoko Ohta](#)

Ehime University, 3 Bunkyo-cho, Matsuyama, Ehime, Japan, ota.kyoko.du@ehime-u.ac.jp

ABSTRACT

This paper examines the case where the policy idea of governmental reform is applied in the context of Japanese local government reform. By following the process in which an imported policy idea spreads and is embedded in local governments under the pressure of stagnant economies and demographic changes, this paper tries to capture the phenomenon of glocalization from the perspective of public administration.

Since the 1980s, many developed countries have been working on a series of administrative reforms widely known as “new public management”. Local governments, in particular, face the challenge of austerity and retrenchment while managing and steering a variety of public services for their citizens. Under such circumstances, various policy ideas for local government reform are introduced and shared by the global community of academia and administrative practice. Public-private partnerships have long been a major scheme for local government reform, and one of the latest ideas is the social impact bond (SIB). The idea of SIB was born in the United Kingdom in the 2000s, and is understood as a performance-based financial support mechanism utilizing private funds. SIB is now widely adopted by governments outside Anglo-Saxon countries.

In Japan, several municipalities have introduced SIBs in collaboration with major foundations and banks. On the other hand, Higashiomi City, Shiga Prefecture, has introduced the SIB scheme to make the subsidy system of the local government more transparent, involving local people, and achieving results that lead to regional development. This unique version of the SIB is largely due to the history of citizen’s activities in the fields of environment and social welfare in Higashiomi since the 1970s. The purpose of the new SIB, launched in 2017, is to offer the startup grant for community businesses which tackle local issues such as job training for the young adult who withdraw from society. Based on the qualitative case study on the community-based SIB in Higashiomi, this paper examines the process by which the new idea of governmental reform was embedded in the individual backgrounds and issues of a certain municipality and discusses the relationship between glocalization of local government reform and regional development.

Citizen activities, diffusion, local government, policy idea, social impact bond

1. INTRODUCTION

This paper examines the case where the policy idea of governmental reform is applied in the context of Japanese local government reform. By following the process in which an imported policy idea spreads and is embedded in local governments under the pressure of stagnant economies and demographic changes, this paper tries to capture the phenomenon of glocalization from the perspective of public administration.

Since the 1980s, many developed countries have been working on a series of administrative reforms widely known as “new public management”. Local governments, in particular, face the challenge of austerity and retrenchment while managing and steering a variety of public services for their citizens. Under such circumstances, various policy ideas for local government reform are introduced and shared by the global community of academia and administrative practice. Public-private partnerships have long been a major scheme for local government reform, and one of the latest ideas is the social impact bond (SIB).

SIB has been adopted by local governments in Japan as a new policy instrument for administrative reform. Decentralization and cuts to central government grants have impaired Japanese local governments with shrinking financial resources who then must attempt to mobilize other community resources (Ohta 2020). Some officers themselves become coordinators to connect various resources outside government. Through collaborative projects such as developing community funds, various local resources (individuals, ideas, knowledge, and money) are linked to be actively circulated in the community. By investigating a case of developing community fund and social impact bond (SIB) project in a suburban area, Higashiomi, this paper analyzes the factors that underlie effective collaboration between Japanese local governments with limited administrative resources and citizen activities with various service deliveries, and the process that affects the development of governance capacity in the community.

In the latter part of this paper, a case study of how the local government in Higashiomi and citizen activities produced policy innovation through a close collaborative relationship is described in depth. It shows that local governance capacity is improved through cooperation between the local government which has limited resources under the decentralization and the decline of grants from central government, and citizen activities, with their numerous ideas and means of service

supply. The output of the collaboration, an innovative method of a local government subsidy programme (community-based SIB) for community business, was investigated.

2. DIFFUSION OF POLICY IDEA IN SUBURBAN REGION

2.1 Policy idea: social impact bond (SIB) in Japan

The idea of SIB was born in the United Kingdom in the 2000s, and is understood as a performance-based financial support mechanism utilizing private funds (Figure 1). SIB is now widely adopted by governments outside Anglo-Saxon countries.

Source: SITAWI Finance for Good website (<https://www.sitawi.net/social-impact-bonds-2/>)

Figure 1: Typical SIB structure

Japan's SIB initiatives began in Kobe City and the Setagaya Ward of Tokyo in collaboration with the Tokyo Foundation, a Japanese major private foundation. These were started as institutional investor-type SIBs involving major banks such as Mizuho Bank and Sumitomo Mitsui Banking Corporation. Furthermore, through the leadership of the Ministry of Economy, Trade and Industry and the Ministry of Land, Infrastructure, Transport and Tourism, as of 2019, around 50 municipalities countrywide are reportedly working on administrative SIBs (Home Office Pay for Success website). In particular, there are still a limited number of bottom-up and community-invested SIBs based on local initiatives, including the community fund in Higashiomi (Figure 2).

Types of Social Impact Bond

- Overseas SIBs (mainly in Anglo-Saxon countries, but also in other countries)
 - Social impact investment and social ventures + Performance-based administrative reform
 - Types of Investor: sovereign funds in the UK; large private foundations and individual investors in the US
 - Also applied in the context of development assistance
- Japan's SIBs (mainly by national government and major financial institutions)
 - Part of administrative reform for cost reduction
 - Pilot project in local government, mostly led by the Ministry of Economy, Trade and Industry, the Ministry of Land, Infrastructure, Transport and Tourism, Mega Banks, or Nippon Foundation
- Community-based SIBs (Higashiomi city and Saijo city in Japan)
 - Part of performance-based subsidy reform
 - Characterized by local initiative and citizen participation
 - Investors are mostly from local community
 - Emphasis on involving residents as stakeholders and supporters, rather than reducing administrative costs

Figure 2: Types of SIB

2.2 Research methods

The empirical research described in this paper is based on a qualitative single case study of Higashiomi, Shiga prefecture, Japan. The author has been following the process of collaboration there for over five years. Higashiomi is a typical Japanese suburban community with a medium-sized city population, typical land-use composition in Japan (65% is forest, 14% farmland, and the rest is composed of industrial, commercial, and residential areas), and a mostly conservative political climate. On the other hand, as mentioned in the next section, historically, Higashiomi has been successful in environmental citizen activities and has a relatively rich social capital. In addition, since 2000, the local government has promoted various collaborative actions in response to local citizen activities, resulting in changes in local governance capacity. Therefore, from this case, we can understand the development of the government-citizen relationship in a suburban area which has typical issues of industrial structure and demographics found in Japan (such as ageing, the decline of local industries, and a local government financial crisis) in recent years.

The case study described here is based on a combination of the following methods. First, the author conducted fieldwork research to clarify the trajectories of local practices. Higashiomi has historically been involved in citizen activities, details of which are recorded in public relations documents and materials of various groups. These materials have not been published and were obtained directly from the relevant organizations in the field. In addition, the information on historical background is supplemented by interviews with relevant parties where appropriate. Second, as a documentary survey, the author used administrative documents, official commission's papers and websites for the background of administrative activities, and newspaper articles for changes in the local political environment.

Third, the author conducted in-depth interviews in Higashiomi. The main purpose of the interviews was to explore the background, experience, and intentions of individuals and key persons; the details of human relationships and their impacts on individuals; how institutions and policies were perceived and influenced by people; and the propagation and acceptance of ideas. All interviews were conducted on 18 and 19 July 2013; 10 February, 2014; and 2 September, 2018, with more than ten key persons including local government officials, senior and frontline staff representatives of NPOs, and community entrepreneurs.

3. COMMUNITY-BASED SOCIAL IMPACT BOND IN HIGASHIOMI

This section examines the case of developing a community-based SIB and related projects in a suburban area in Japan (Higashiomi). Higashiomi has experienced problems that are typical in Japan's local communities such as ageing, the decline of local industries, and a local government financial crisis. Based on the environmental movement since the 1970s in the area, experimental initiatives have been developed since the 2000s in various fields such as renewable energy, social services, and employment training. Furthermore, to secure resources for these efforts, a new governance mechanism was developed to change the relationships between these initiatives and the local government.

3.1 Background

The municipality of Higashiomi has a population of 120,000 people and is located roughly in the centre of Japan. With Japan's largest lake nearby, an abundant water reservoir and forest, and its proximity to the industrial areas of Nagoya and Kyoto-Osaka-Kobe, many residents work for local factories and offices on weekdays and practise small-scale farming over the weekends. The local economic and social structure has changed since the middle of the 1990s after the collapse of the bubble economy. Some local factories went bankrupt and others moved overseas, and national government revenue deficits brought healthcare budget cuts to local governments and elderly care.

Development of citizen activities

An environmental movement emerged in the Higashiomi region in the 1970s when activists protested the pollution of Lake Biwako, the largest lake in Japan. In the 1980s, citizens organized a closed loop for collecting used cooking oil as an ingredient to be used in soap, fuels, and fertilizer, and since the 1990s, have been growing rapeseed to meet the growing local demand for fuels and fertilizer (The Canola Project Network website). Local activists have been actively lobbying the Ministry of Agriculture, Forestry and Fishery and Environmental Agency regarding sustainability issues. Their policy recommendations to central government sometimes led to acquiring subsidies for their activities. Issues pertaining to the environment, climate change, and the need for local revitalization amidst a budget deficit have become common language fuelling various community-based initiatives in Higashiomi. The agenda of the movement expanded from the environment to include welfare, low-carbon energy and food, and this human network has also expanded exponentially (Ohta, 2019).

Policy environment since the 2000s

Institutional changes that occurred in the 1990s and 2000s at the national level also affected local citizen activities. After the decentralization in 2000 and municipal merger policy of the national government, seven municipalities merged in 2006 to form the current city of Higashiomi. Although the new city increased in both population and fiscal size, like many other municipalities throughout Japan, it was left in a serious financial condition with the added problem of an ageing population.

In 2008, the national government's science foundation selected Higashiomi Municipality to develop a municipal Low-Carbon Vision for 2030. Higashiomi City and the Shiga Prefecture Environmental Research Institute worked together to formulate a vision and roadmap to halve CO₂ emissions by 2030 through innovation in the local economy. Along with

socioeconomic analysis and simulation, they organized a series of discussion meetings named the Environmental Roundtable for Low-Carbon Vision. To organize the roundtable, Michiko Yamaguchi, a Higashiomi municipality official, and her team included not only key persons in the environmental policy area but also those in other fields including agriculture, forestry, commerce, industry, welfare, medical care, and urban planning. From 2010 to 2011, the Roundtable for Low-Carbon Vision met 20 times and provided opportunities for local frontrunners to engage with new viewpoints about a low-carbon municipality and sustainability (Mizuguchi et al., 2016, p. 82).

Although the Great East Japan Earthquake and Fukushima Daiichi Nuclear Power Plant accident in 2011 had strong impact on the society, no major energy policy change was evident at the national level under the LDP administration, and the citizen activities of Higashiomi entered a new phase under more severe financial conditions than before.

3.2 Development of collaboration for community-based SIB

Key actors and their relationships/interactions

During the decades of citizen activities and the administrative efforts of Higashiomi and Shiga prefecture area, many actors played an active role, establishing a network between them. Though difficult to describe the entire network, this section introduces two key persons, especially those involved directly in the Round Table for Low-Carbon Vision, namely the department and its staff in charge at Higashiomi city government, and the 'outsiders' who provided new ideas for the Vision.

The most important figure in the process was likely Michiko Yamaguchi, a middle-rank municipality official with a background in forest engineering and work experience in the prefecture government after majoring in forestry at university. She played a role in connecting a series of citizen initiatives with the administration. Originally an official of Shiga prefecture, when dispatched to Higashiomi city, she was attracted by the abundant citizen activities and innovative efforts rooted in the area and relocated to the Higashiomi city government. Yamaguchi examined issues on the administrative side, and supported citizen activities linking the revitalization of forestry and job support for younger persons.

Yamaguchi's role entailed belonging to many NPOs and organizations outside the government office and incorporating the personal connections she developed into the administrative business. She has experience working at different levels of government in both prefecture and city; has a degree in forest engineering and has worked for local environmental NPOs; she is a hybrid player who crosses different sectors and fields herself. Taking advantage of these attributes and network, she explored more effective policy innovation to grant and support cross-sectoral citizen activities.

The efforts in Higashiomi were also greatly affected by those from outside the region who were involved. One such outsider was Professor Masataka Fukao at Ryukoku University. Fukao was involved in many community development activities as a consultant and social entrepreneur and served as a committee member for formulating the city's Community Development Plan. He also chaired the committee (examining financial resources) five times in 2015 to revise the city's Environment Basic Plan and review the new community fund. While on the committee, he introduced the idea of SIB which Yamaguchi, as a government officer searching for a new way of subsidizing cross-sectoral citizen activities, approved. These committees in the Higashiomi government functioned as arenas where key actors with different affiliations met and shared ideas and goals. His own company, Plus Social Investment Co., Ltd. was entrusted with the SIB project, which forms one pillar of the new community fund (Higashiomi Sampō-yoshi Fund) described later. He serves as deputy director of the fund.

Hukao was initially involved in Higashiomi city government as an outsider consultant. It is not uncommon for a municipality to outsource such expertise for local planning, but it is Fukao's multi-faceted commitment that has made him a boundary spanner (Van Meerkerk and Edelenbos 2018) in collaboration. Perhaps it was also because the people in Higashiomi were earnestly seeking new ideas, especially someone who brought ideas to the table for the purpose of restoring the regional economic cycle. In particular, it would be significant for Yamaguchi to act as a bridge between him and the local community.

Focus on the regional economy

As mentioned, since the initiative in Higashiomi was developed around efforts to address environmental issues, administrative and policy development have become centred on the environmental field. The main arena of the development in the city government was the Forest and Water Policy Division, established in 2015, where Yamaguchi worked as a member. That same year, the revision process of the Environment Basic Plan (nine-year plan) began with the Forest and Water Policy Division in charge.

The revision process focused on the economic cycle in the region. Since around 2010, the city government has, from a financial perspective, studied the necessity of establishing a community fund to support citizen activities. The regional economic cycle was analyzed as preparation for the establishment of the fund. In the committee reviewing the new community fund, which convened five times in 2015, the relationship between this economic flow and the natural capital of the area supporting the flow was discussed. In the revised Environmental Basic Plan, the establishment of a community fund was announced, and the role of the fund clarified as enhancing the sustainability of the region by focusing on the environment, the economy, and local social issues as a whole, not individually.

Development of community fund and community-based SIB

As a result of examining issues in the regional economic cycle and as a means of creating a new flow of money, the community fund (Higashiomi Sampō-yoshi Fund) was established in 2017. Members of the preparatory body included people from various sectors such as the Higashiomi city government, local economic sector, civic sectors, consultants, and administrative scriveners. The secretariat was jointly carried out by the staff (Yamaguchi and others) of the Forest and Water Policy Division of the Higashiomi government and a local community-building NPO. In addition, they obtained donations for its establishment, collecting three million yen (which became the basic property of the fund), from 772 people over a period of six months. In June 2017, the fund was established as a general incorporated foundation (and approved as a public interest incorporated foundation in 2018).

The purpose of the community fund is to utilize the region’s potential resources such as donations, dormant deposits, and bequests through the fund in the form of investment, subsidies, and loans to solve local problems and revitalize and support community businesses (Sanpo-Yoshi Fund website). One current core project of the fund is the community-based SIB (Figure 3). This can be considered a policy innovation realized at the meeting of Yamaguchi, who was searching for a subsidy reform of the city, and Fukao, who was involved in Higashiomi as a social entrepreneur and conceptualized the idea of an SIB. This social investment project is jointly carried out by the fund, Higashiomi city government, and the private company, Plus Social Investment. By raising the funds necessary for citizen’s activities from the private sector, it is expected that the people and companies that invested will support the activities, ensuring the success of the project.

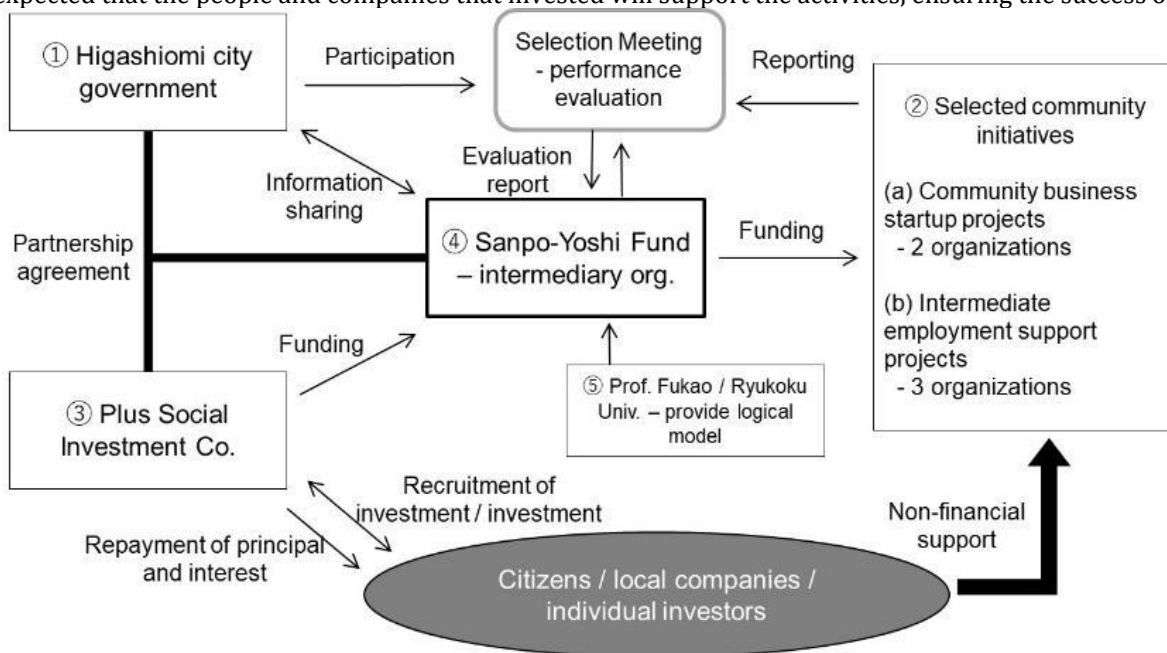

Figure 3: Logical map of Higashiomi SIB

Plus Social Investment collects funds (20,000 yen per year for 2017, with a target redemption rate of 2% per year) from investors, mostly from the local community, who support the applicant’s project. When the performance targets set for each applicant are achieved at the end of the project, the funds are given to the applicant, and the investors are redeemed by adding interest to the funds invested. The goals that applicants are expected to achieve within the fiscal year are determined in agreement with the fund, city government, and experts. To evaluate the project results, experts, the city government, and directors of the fund cooperate.

In 2016, as a trial stage, the agriculture-based community development association received support. In 2017, the formal launch year, five projects were selected from two fields, namely Community Business Startup Support and Intermediate Employment Support, and 500,000 yen per project was invested. In 2018, two cases were selected in the same two fields.

SIB as a government subsidy reform

The SIB programme of the community fund is also positioned as an attempt to introduce performance-linked subsidies from the Higashiomi city government. In 2014, the city government launched a community business startup support project as a regular subsidy programme. The new SIB programme is the evolved version of this subsidy programme. By introducing the SIB, the roles of related actors in the ordinary subsidy programme have transformed as follows.

First, in the past system, the Higashiomi city government used to investigate how funds were spent because the government itself paid subsidies to recipient organizations. Under the new SIB programme, subsidies are granted to applicants on the condition that the expected outcome is reached. Therefore, rather than just checking how the fund is used, the government supports the recipient so that they can produce results while collaborating with intermediary organizations such as the community fund.

Second, the citizens of Higashiomi were once mostly involved as service recipients from businesses. Under the SIB programme, they themselves can invest in the business they want to support while there is no principal guarantee and

the principal is broken if the outcome is not achieved. Thus, the citizens as investors are made aware of themselves as stakeholders and become active supporters of the business.

Third, intermediary organizations such as the community fund and Plus Social Investment used to be in a position to support government subsidy programmes within the scope entrusted by the government. Under the SIB, these organizations provide the necessary support to raise funds in collaboration with both government and recipients to produce expected results.

The key characteristic of the Higashiomi SIB is the mechanism used to ensure citizens' wide involvement. In ordinary subsidized projects, most citizens are merely beneficiaries of the services of the subsidized businesses. However, in the SIB, citizens are not only beneficiaries but also investors, so the relationship with subsidized providers is double-tracked. In addition, citizens can address local issues through investment action and support projects from an investor's standpoint. By setting indicators to measure the outcomes of the business and visualizing it, the provider has clear goals and citizens can share the outcome.

4. CONCLUSION

In Japan, several municipalities have introduced SIBs in collaboration with major foundations and banks. On the other hand, Higashiomi has introduced the SIB scheme to make the subsidy system of the local government more transparent, involving local people, and achieving results that lead to regional development. This unique version of the SIB is largely due to the history of citizen's activities in the fields of environment and social welfare in Higashiomi since the 1970s. The purpose of the new SIB is to offer the startup grant for community businesses which tackle local issues. Based on the qualitative case study on the community-based SIB in Higashiomi, this paper examines the process by which the new idea of governmental reform was spread and embedded in the individual backgrounds and issues of a certain municipality.

The potential downsides and challenges seen in this case are as follows.

In Higashiomi's SIB programme, Plus Social Investment is one of the core actors in the network, so it is necessary to coordinate commercialism and the public interest that the programme should have. Specifically, the issue is how to respond when the company decides to withdraw from a management perspective. In addition, as an issue related to wider public interest, there are inadequate mechanisms for local democratic representatives to properly monitor the programme.

On the other hand, in terms of relations with local politics, how to keep distance from the political activities of the mayor (the head of the administrative department of the local government), is also an important point. The SIB programme is currently strongly supported by the mayor, but the continuation of the project may be affected if the mayor is replaced in an election. This has the potential for recipient citizen initiatives to be subordinated to government not only in terms of money but also in a more complex political structure.

In addition, the fact that the influence of a particular person in the administration is exceptionally large can make governance capacity vulnerable. There is no issue with an individual's influence being great in the launch and development of the programme, however, if it is too reliant on particular persons for its continuation, organizational ability may not be developed and become unsustainable. If the individual is exhausted, the whole may not function. Charisma may be necessary in the early days and development stages, but in the stability stage, it is necessary to change to a sustainable organization management that does not rely excessively on individuals.

Currently, Higashiomi's SIB programme only replaces a small portion of municipal subsidies and has no effect on the majority. Above all, it is important that this innovative programme expands steadily on the grounds of Higashiomi's long-standing citizen's activities.

POST-STUDY MIGRATION BEHAVIOUR – DIFFERENCES BETWEEN NATIVE, FOREIGN AND INTERNATIONAL UNIVERSITY GRADUATES IN GERMANY

[Annekatriin Niebuhr](#)^{1,2}, [Anne Otto](#)¹, [Anja Rossen](#)¹, [Christian Teichert](#)¹

¹Institute for Employment Research, Germany. ²Christian-Albrechts-Universität zu Kiel, Germany

ABSTRACT

We investigate differences in mobility behaviour between graduates who completed secondary school in Germany (German, foreign) or abroad (international) and analyse factors that might give rise to disparities in mobility after graduation. Our analysis focuses on the importance of job-relevant networks and work experience for mobility decisions that are linked to labour market entry because these factors are likely correlated with spatial job-search and the migration decision. The results of an event history analysis show that the long-term share of 'stayers' in the study region is relatively low among international graduates. Regression results indicate that differences in the probability to leave the region of study are associated with individual, study-related and regional factors. In particular, pre-study mobility and work experience turn out to be important predictors. The probability to stay in the university region does not significantly differ between German and international graduates, once we account for these factors. In contrast, foreign graduates who attended school in Germany show a higher propensity to leave the region of study for labour market entry than other graduate groups conditional on covariates.

DO RETURN INITIATIVES PROMOTE INTERREGIONAL RETURN MIGRATION? - EVIDENCE FROM GERMANY

Moritz Meister¹, Jan Cornelius Peters², Anja Rossen¹

¹Institute for Employment Research (IAB), Germany. ²Thünen Institute of Rural Studies, Germany

ABSTRACT

This paper investigates whether the establishment of so called 'return initiatives' within the last 20 years increased the likelihood of interregional return migration of workers within Germany. Demographic change leads to a significant decline in (regional) labor supply in Germany like in many other western countries. In particular rather rural regions are hit by this development, partly caused by a net migration loss among young people. Furthermore, these regions typically do not benefit from immigration from abroad like agglomerated regions because destinations of international immigration are often densely populated areas.

Since the beginning of the new millennium in more and more regions of Germany return initiatives have been established. They aim at promoting interregional return migration, i.e. the return of workers who previously left the local labor market in which the respective return initiative is situated. The early initiatives focused on the return of workers from East Germany, who moved to other eastern regions or the western part of Germany after re-unification. However, since 2010 return initiatives also exist in peripheral parts of West Germany and their number is increasing. Among others, they provide information on local vacancies and firms in order to increase the probability that the job search in the 'home region' of a worker, who would like to return given she finds a suitable job, is successful and she indeed returns.

To analyze the effects of return initiatives on return migration, we merge our unique panel data on return initiatives with information provided by the Integrated Employment Biographies (IEB) of the Institute for Employment Research (IAB). The IEB contains, inter alia, administrative data on all workers subject to social security in Germany such as daily information on individual employment relationships (e.g. wages, workplaces) as well as annual information on places of residence. Specifically, we use a 25% percent random sample of all (medium skilled) workers, who completed vocational training in Germany in the period 2000-2013 and who moved to another local labor market until 2014 (14% of all former apprentices). Applying event history estimation, we observe that about 40 percent of these workers return in subsequent years to the labor market of residence during vocational training.

To investigate whether there is a significant and robust relationship between the establishment of a return initiative and return migration rates, we combine discrete time survival data analysis and diff-in-diff estimation. More precisely, we study whether the likelihood to return to a certain region is significantly higher after a return initiative has been established than before conditional on time varying characteristics of the individual, regional labor market conditions as well as region and time fixed effects. Our results indicate that return migration rates are, conditional on covariates, about 10 percent higher after a return initiative has been established than before. However, further analyses suggest that region specific time trends might play an important role in this context, meaning that (some) return initiatives might have been established in regions, for which return migration rates were increasing anyway.

BEING A LONG DISTANCE OUT-COMMUTER OR HOME EMPLOYEE IN A RATHER PERIPHERAL REGION?

[Stephan Brunow](#)¹, [Ramona Jost](#)²

¹University of Applied Labour Studies, Germany. ²Institute for Employment Research IAB, Germany

ABSTRACT

After reunification a net outmigration from East German regions occurred until the late 1990th. Many relatively younger people were looking for jobs in the west. About 30 years later outmigration flows exist but net migration is almost zero. However, still about 76.000 individuals out-commute for work-related purposes from the Federal State Mecklenburg-Vorpommern (MV). To the same time, employers in MV claim labour shortages. In this paper, we distinguish out-commuters and employees in MV to get a deeper insight into this interesting phenomenon. We especially address the question whether out-commuters are a selective group of individuals working in occupations that are not requested in MV. Additionally, we focus on the wage differential to work out potential strategies to get out-commuters back to work within MV. Lastly, we consider the number of workers that might be willing to work in MV and stop out-commuting. First evidence suggests that this would not appear. Labour demand in MV and respective wage levels are too low and the economic structure is too weak to sufficiently gain back out-commuters from a MV-perspective. Especially females suffer from the job-market weakness in MV.

ANALYSIS OF ECONOMIC AND ENVIRONMENTAL IMPACTS OF SHUTTING DOWN THE MOROCCAN REFINERY SAMIR: AN INTERREGIONAL INPUT-OUTPUT APPROACH

Eduardo Haddad¹, Inácio Araújo², Rachida El Mansoum³, Chaimaa Chawki³, Marouane Masnaoui³

¹University of São Paulo, Brazil. ²Department of Economics, University of São Paulo, Brazil. ³FGSES, Mohammed VI Polytechnic University, Morocco

ABSTRACT

The closing of Samir's Mohammedia refinery in August 2015 due to financial constraints has dramatically affected fuel oil market in Morocco. In this paper we assess the economic and environmental impacts of the disruption of activities of Morocco's only refinery. We are able to isolate the oil refinery sector associated with Samir in a fully specified interregional input-output database, considering 20 sectors in 12 Moroccan regions. We base our empirical strategy on the "hypothetical extraction" method, which serves as the methodological anchor to isolate the systemic measures of value added and CO2 emissions related to the refinery activities in a typical year of operation. The overall impact of the shutdown is close to 5% of the country's output, with stronger regional impacts faced by Grand Casablanca-Settat, followed by its neighboring regions.

FROM GLOBAL TO LOCAL: EXPLORING INTERREGIONAL LINKAGES OF MOROCCAN EXPORTS IN DOMESTIC VALUE CHAINS

[Elhoussaine Wahyana](#)^{1,2}, [Mahmoudou Alioum](#)¹, [Daniel Sitota](#)¹, [Inácio Fernandes Araújo](#)³,
[Eduardo Amaral Haddad](#)³

¹FGSES- Mohammed 6 Polytechnic University, Morocco. ²Mohammed 5 University, Morocco. ³University of Sao Paulo, Brazil

ABSTRACT

There is substantial value-added of services incorporated in goods exports, from intermediate services and services bundled with goods. In the quest for increasing and sustaining its competitiveness in Global Value Chains (GVC), Morocco still requires policies, capabilities, and infrastructure to promote intermediate services. On one hand, locational aspects of specific services, such as transportation services, are associated with relatively less concentrated spatial patterns, as production and consumption are more strongly locationally interdependent. On the other hand, knowledge-intensive business services (KIBS) tend to be highly concentrated in Casablanca. However, this does not exclude some movements towards dispersion observed in some business services, as long as working skills limitations are surpassed, which may give room for coordinated regional and trade policies to enhance participation in value addition in Local Value Chains (LVC) of peripheral, natural resource-rich, exporting regions. In this paper, we estimate the contents of services value-added incorporated in goods exports in Morocco, exploring the local dimension of the results. We use inter-regional input-output analysis to trace and map domestic value-added embedded in Moroccan exports. We also look at other dimensions of local value chains of exports in the country.

MULTIDIMENSIONAL POVERTY IN MOROCCO: AN EXPLORATORY SPATIAL APPROACH

Eduardo Amaral Haddad¹, Inácio Fernandes¹, [Zineb Sijelmassi Idrissi](#)², Chanelle Ihezagire²,
Youness El Bouazzaoui²

¹University of São Paulo, Brazil. ²FGSES, Mohammed VI Polytechnic University of Benguerir, Morocco

ABSTRACT

In spite of the overall decrease in poverty in Morocco in the recent past, the pace of change did not affect regions equally. Poorer provinces faced slower reductions, increasing the relative gap in poverty indicators. In this paper, we explore the results of a multidimensional poverty indicator produced by the High Commission for Planning (HCP), the Moroccan official statistical agency, for the period 2004-2014. The Multidimensional Poverty Index (IPM) allows investigating the spatial aspects of different dimensions of poverty in the country. We find a clear spatial process underlying the distribution of the IPM. Moreover, the analysis undertaken at the province level suggests a persistent poverty hot spot in the northeast part of the country associated with poor infrastructure. Other poverty areas are more heavily associated with low quality of public services, particularly education and health. We provide a typology of geographically targeted sectoral policies, showing that there is no single recipe for all regions, since structural features matter.

LINKAGES AND INTERDEPENDENCE OF THE AGRICULTURE SECTOR IN MOROCCO: A REGIONAL PERSPECTIVE.

Fatima Ezzahra Mengoub¹, Imane Oumellouche², Wissal Morchid², Nassima Nairi², Eduardo Amaral Haddad³

¹Policy Center for the News South, Morocco. ²Mohammed VI Polytechnic University, Morocco. ³University of São Paulo, Brazil

ABSTRACT

In Morocco, the agriculture sector plays a major role in economic and social development. Agriculture contributes 12% of GDP and employs about 34% of the labor force of which 40% are women. In addition to its importance in terms of value added creation, the sector plays a key role in poverty reduction, giving that the marginalized and poorest areas tend to be rural areas where the main economic activity is agriculture. It also contributes to food security by diversifying and stabilizing agricultural production, which has a direct impact on prices, especially those of basic staple food. Given the significant weight of the agricultural sector and the importance of the rural world in the Moroccan economy, this paper develops an in-depth analysis of the sector by region in order to show its systemic relevance in each region and to identify its potential to contribute to the green, inclusive recovery of the Moroccan Economy in the post-pandemic crisis. To do so, we base our analysis on structural properties of the interregional input-output table for Morocco, combining with detailed labor market and environmental databases.

TOWARDS COHESION AT THE INTERFACE BETWEEN THE EU STATES? CROSS-BORDER ECONOMIC ASYMMETRY AND CONVERGENCE IN THE EUROPEAN UNION

Andrzej Jakubowski¹, Piotr Wójcik²

¹UMCS, Poland. ²University of Warsaw, Poland

ABSTRACT

State borders are barriers that disrupt the course of socio-economic processes and interactions. They adversely affect the development of border areas, traditionally perceived as peripheral, lagging behind and economic outliers. Hopes for overcoming this situation are associated with the process of European integration. Within its framework, barriers resulting from the existence of traditional state borders are being gradually removed. The internal borders of the EU are becoming more and more "invisible".

Previous research does not provide a satisfactory answer to the question about the impact of border opening and economic integration on reducing the level of disparities in cross-border areas. On the one hand, the research results lead to the conclusion that EU enlargement should foster the cohesion of cross-border areas. Other analyzes indicate an increase in disparities in the level of economic development of cross-border areas in the EU. Therefore, this issue requires clarification, especially as it is of great importance in the context of the effects of the EU cohesion policy. There are numerous studies on regional convergence and socio-economic cohesion of European regions, but they do not take into account the criterion of cross-border location.

This paper aims to fill this gap. Its main purpose is to examine the impact of reducing barriers resulting from the existence of traditional state borders on the relative level of development of border areas, i.e. on cross-border convergence (or divergence). Contrary to the existing literature on the subject, the article does not focus on border areas, but cross-border areas, pairs of regions including bordering areas located on both sides of the inter-state border. The article is the first empirical analysis conducted in such a spatial and temporal scope, which allows to deepen the knowledge on the impact of European integration and border opening on the economic cohesion of border areas.

The study takes into account the cross-border areas (NUTS3) adjacent to internal borders between EU countries in the period 1980-2015. The scope of the surveyed units is extended in accordance with the subsequent stages of the EU integration process. The basis for the convergence analysis is the indicator of relative asymmetry of economic development comparing the level of regional GDP per capita (in PPS) in two neighboring border regions from different countries. It reflects the disproportion in the level of economic development of the border region of one country in relation to the neighboring region from another country.

The obtained results confirm that the process of European integration leads to a gradual equalization of the level of economic development of cross-border areas on a European scale (cross-border σ -convergence). It was also observed that increased border permeability allows less developed border areas to benefit from additional development factors. As a result, they achieve faster growth than the more developed border regions on the other side of the border. The level of asymmetry in economic development in cross-border areas is reduced (absolute cross-border β -convergence). The results of the analysis also suggest that cross-border convergence is generally slower than convergence at the inter-state level.

CONTEMPORARY SOCIO-ECONOMIC DIFFERENCES IN POLAND: (1) SPATIAL POLARIZATION OF DEVELOPMENT

Pawel Churski, Tomasz Herodowicz, Barbara Konecka-Szydłowska, Robert Perdał

Department of Regional and Local Studies. Faculty of Human Geography and Planning. Adam Mickiewicz University, Poznan, Poland

ABSTRACT

The results of political elections in Europe and the world in the second decade of the 21st century show a clear trend of strengthening populist movements. One of the fundamental root causes is the persistent and even growing differentiation of the socio-economic development level, which results in permanent peripheralisation and marginalisation of some areas. This results in polarization and radicalization of electoral behavior as a consequence to the unsatisfactory effectiveness of earlier implemented development activities and the economic exclusion of a part of the society living below the social minimum. The results of our study indicate the persistence of development disparities in Poland, despite the relatively positive trends in economic growth at the national level. We draw attention mainly to the strong significance of historical conditions (relict borders). Against this background, we identify the scope and direction of geographical changes in Poles' electoral behaviour. We aim to determine the relationship between the level of socio-economic development and the support of political parties in spatial terms. The final conclusions emphasize the persistence of "territorial underpinnings" and socio-economic conditions of electoral populism in Poland, which to a large extent results from historical factors. Not only has the distribution of populism not been changed as a result of transformation and integration changes in Poland, but it has in fact been reinforced.

The research procedure consists of three stages presented on separated posters: (1) spatial polarization of development, (2) political scene and electoral behaviour, (3) relations between development level and political preferences.

First stage analysis of this cycle in this aims at determination of the scale and causes of subregional development differences in Poland. The analysis deals 2,478 Polish communes (LAU 2) and describes the period of 2004-2016 allowing for interactions determined for Poland during over last two centuries.

The research procedure involved the following steps: standardization of variables (23 indicators corresponding to five development factors), cluster analysis using the k-means method for 13 observations, verification of the typology using modified classification trees, creation of the typology for each observation in the pattern of communes with different level of development (five class), and finally the creation of a synthetic typology of the communes in the adopted pattern of development classes. The study used published data of the Central Statistical Office in Warsaw. The obtained results confirmed the occurrence of clear and persistent developmental differences in the space of Poland. They are largely determined by the polycentricity of the settlement network, the distribution of economically strong raw materials and industrial areas, as well as they show a large relationship with historical determinants permanently rooted in Polish space.

This study is carried out as part of the FORSED research project (www.forsed.amu.edu.pl) funded by the National Science Centre (No. 2015/19/B/HS5/00012): New challenges of regional policy in shaping socio-economic development factors of less developed regions.

CONTEMPORARY SOCIO-ECONOMIC DIFFERENCES IN POLAND: (2) POLITICAL SCENE AND ELECTORAL BEHAVIOUR

Tomasz Herodowicz, Paweł Churski, Barbara Konecka-Szydłowska, Robert Perdał

Adam Mickiewicz University in Poznań, Poland

ABSTRACT

The results of political elections in Europe and the world in the second decade of the 21st century show a clear trend of strengthening populist movements. One of the fundamental root causes is the persistent and even growing differentiation of the socio-economic development level, which results in permanent peripheralisation and marginalisation of some areas. This results in polarization and radicalization of electoral behavior as a consequence to the unsatisfactory effectiveness of earlier implemented development activities and the economic exclusion of a part of the society living below the social minimum. The results of our study indicate the persistence of development disparities in Poland, despite the relatively positive trends in economic growth at the national level. We draw attention mainly to the strong significance of historical conditions (relict borders). Against this background, we identify the scope and direction of geographical changes in Poles' electoral behaviour. We aim to determine the relationship between the level of socio-economic development and the support of political parties in spatial terms. The final conclusions emphasize the persistence of "territorial underpinnings" and socio-economic conditions of electoral populism in Poland, which to a large extent results from historical factors. Not only has the distribution of populism not been changed as a result of transformation and integration changes in Poland, but it has in fact been reinforced. The research procedure consists of three stages presented on separated presentations: (1) spatial polarization of development, (2) political scene and electoral behaviour, (3) relations between development level and political preferences.

This presentation is about stage 2, the purpose of which was to characterize the Polish political scene and the electoral behavior of Poles. The temporal scope of the analysis covers mainly the years 2005 and 2015. The analysis is conducted at the level of LAU-2 units (gmina), enabling detailed identification of intra-regional disparities. During analysis there were used desk research and indicators of electoral support level noticed in the parliamentary elections in 2005, 2007, 2011, and 2015. The formation of the Polish political scene during the transformation period was dynamic and characterized by the emergence of new antagonisms. In a generalized perspective the Polish political scene can be divided along two axes: conservatism vs. liberalism and individualism vs. communitarianism. Political parties can be further aggregated into two main political camps: "Solidary Poland" – more conservative and 'Liberal Poland' – more progressive. The results of the parliamentary elections justify the statement that the Polish political scene is subject to polarization, which in fact brings the party system closer to the bipolar system. The highest concentration of support for the "Solidary Poland" camp was observed in the south-eastern part of the country. On the other hand, the relatively highest support for the "Liberal Poland" camp was in north-western Poland.

This study is carried out as part of the FORSED research project (www.forsed.amu.edu.pl) funded by the National Science Centre (No. 2015/19/B/HS5/00012): New challenges of regional policy in shaping socio-economic development factors of less developed regions.

CONTEMPORARY SOCIO-ECONOMIC DIFFERENCES IN POLAND: (3) RELATIONS BETWEEN DEVELOPMENT LEVEL AND POLITICAL PREFERENCES

Robert Perdał, Paweł Churski, Tomasz Herodowicz, Barbara Konecka-Szydłowska

Adam Mickiewicz University in Poznan, Faculty of Human Geography and Planning, Poland

ABSTRACT

The results of political elections in Europe and the world in the second decade of the 21st century show a clear trend of strengthening populist movements. One of the fundamental root causes is the persistent and even growing differentiation of the socio-economic development level, which results in permanent peripheralisation and marginalisation of some areas. This results in polarization and radicalization of electoral behavior as a consequence to the unsatisfactory effectiveness of earlier implemented development activities and the economic exclusion of a part of the society living below the social minimum. The results of our study indicate the persistence of development disparities in Poland, despite the relatively positive trends in economic growth at the national level. We draw attention mainly to the strong significance of historical conditions (relict borders). Against this background, we identify the scope and direction of geographical changes in Poles' electoral behaviour. We aim to determine the relationship between the level of socio-economic development and the support of political parties in spatial terms. The final conclusions emphasize the persistence of "territorial underpinnings" and socio-economic conditions of electoral populism in Poland, which to a large extent results from historical factors. Not only has the distribution of populism not been changed as a result of transformation and integration changes in Poland, but it has in fact been reinforced. The research procedure consists of three stages presented on separated posters: (1) spatial polarization of development, (2) political scene and electoral behaviour, (3) relations between development level and political preferences. Geographically Weighted Regression (Fotheringham, Brunsdon, Charlton, 2002) was used to study the relationship between the level of socio-economic development and political preferences in Poland in 2005-2015. The value of the synthetic indicator was used as the explained variable describing the level of socio-economic development (see Part 1). In turn, the explanatory variable was the percentage of votes for political parties representing "Solidarity Poland" (mainly currently ruling Law and Justice) (see Part 2). Regression modelling has showed that the relatively largest support for the "Solidarity Poland" bloc is found in communes with low and very low levels of socio-economic development. It should be stressed that the examined relations are not limited to such a simple relationship and require more detailed interpretation, inter alia, as regards the level of socio-economic development, socio-cultural characteristics of the inhabitants and the urban-rural layout. In general, it can be assumed that the greatest support for "Solidarna Polska" occurs mainly in small municipalities, with dominant agriculture, located in the lands of the former Russian and Austrian Partition with a dominant population professing traditional Catholic values and with low mobility.

This study is carried out as part of the FORSED research project (www.forsed.amu.edu.pl) funded by the National Science Centre (No. 2015/19/B/HS5/00012): New challenges of regional policy in shaping socio-economic development factors of less developed regions.

DIGITAL TRANSFORMATION OF UNIVERSITIES AND INDUSTRY 4.0: A COMMON STRATEGY FOR REGIONAL DEVELOPMENT

[Maria Begoña Peña-Lang](#)

University of the Basque Country UPV/EHU, Spain

ABSTRACT

Never before have we experienced so many changes at such speed. We have been saying for years that the education sector cannot produce structural changes as fast as the labor market may need, but in recent months we have seen profound changes in all economic sectors.

In documents such as "The Future of Jobs Employment, Skills and Workforce Strategy for the Fourth Industrial Revolution", 20 Educational Keys for 2020 and Future Work Skills 2020, different interpretations of what would be the most demanded competencies by the labor market were already observed, taking into account all the technological, social and socio-economic changes.

On the other hand, there is extensive literature on competencies and their incorporation into the curriculum at the university level as a teaching innovation practice. Among them are generic or transversal competencies that are being developed internationally by different universities, competencies that are supposed to be in demand in the future, citing among them as the most promising: social intelligence, strategic design, new media literacy, interculturality and focusing on the future of education or the professional profiles that will be in demand in the coming years, given their importance as a contribution to success in the knowledge society.

But the question arises as to whether there is a clear strategy in the digitalization of universities at the European level that minimizes the gaps for the agents involved; the skills demanded by the labor market and those that the university develops in the classroom.

Therefore, it is necessary to stop and think about what strategies are being carried out in the universities so that students are aware and informed of what their future position will demand and if these strategies are effective, to find out if students understand the concept of competencies, if they conceive that they develop some of these competencies in the classroom and not others, to know how to integrate them in the development of their CV and to know how to locate those activities or courses that complement the competencies that have not been developed during their academic life.

If we are talking about the professional community, we should know if they have enough information about the competencies implicit in a candidate's CV and if they have sufficient criteria to verbalize the competencies that are needed today in their sector.

About the University, we should question whether it has a curriculum in line with these competencies and whether it has interlocutors with the labor market that makes it offer updated studies.

These questions make us think of a situation in which the digital era we are living in may require greater clarity in the common strategy between the educational sector and the labor market for regional development. To this end, we propose a descriptive study of the shortcomings associated with each of the agents by analyzing the information of certain recently published job offers, the websites of several universities, and their assessment by a sample of students from the University of the Basque Country (Spain).

ABSTRACT

For historical reasons due to its colonization process, but also institutional ones, including economic policy strategy, Brazil concentrated its industrial production base in the Southeast, followed by the South. A consequence of this process was a concentration of the higher education system and of the country's research, science and technology institutions in the Southeast and South regions of the country, with repercussions, also, in the geographic distribution of innovations and patents in the country, being possible to state that there are marked differences between the State and Regional Innovation Systems in the context of the National Innovation System. Thus, from the calculation of dispersion measures and spatial concentration indicators, this article presents elements that attempt to create a temporal systematization in the evolution of regional inequalities in the indicators of Higher Education, Science, Technology and Innovation in the country, which characterize the differences between the State / Regional Innovation Systems in the country. Considering these indicators, it can be said that the country has four very different moments. The first moment goes back to the beginning of the formation process of Higher Education, C, T & I institutions in the country, lasting until the beginning of the 1990s, where the concentration of these indicators in the Southeast and South regions is clear. It begins, still, in the beginning of the decade of 1990 and goes until the year 2000, with a sharp drop in the spatial inequality of these indicators between the Brazilian regions. A third moment, located between the first half of the 2000s and the years 2013 and 2014. With the maintenance of deconcentration, now more slowly. And the last phase, starting in 2014, which seems to point to a new reconcentration, still, how small.

KEYWORDS

Higher Education; Innovation Systems; Science, Technology and Innovation (S, T & I)

1. INTRODUCTION

Since its origin, the conformation of the Brazilian National Innovation System (NIS) presents unequal characteristics in its quantitative and qualitative elements when analyzed from a regional (RIS) and local (LIS) perspective, each one at a different level of aggregation of spatiality and relationship with the whole. Thus, the physical infrastructure of RIS/LIS, their linkages and performance indicators are not homogeneous in Brazil; although in recent decades there has been a movement towards geographic spreading-out that has been more favorable to the poorer regions of the country: North, Northeast and Center-West.

The Innovation System in Brazil, as in Latin America, has been formed by several factors that places it to other regions or countries in the world in an incomplete or weak position. This can be attributed to several factors: old institutions that have prevailed since the 1980s, periods of great macroeconomic instabilities, high levels of poverty and great income inequalities, as pointed out by Albuquerque et al. (2015). However, it is necessary to take into account how these factors are distributed and intensified at the regional level.

In this context, to follow the asymmetric evolution of Regional, Local and Sectorial Innovation Systems involves understanding the different trajectories that each one has followed. These trajectories have emerged and reproduced under heterogeneous economic structures between Brazilian regions. Each region imposes different demands and needs for the creation of a scientific and technological base, having as inputs: the training and qualification of labor, the production of knowledge, the development of products and services aimed at research and innovation.

Nevertheless, the degree of unequal development among LIS is linked to the dynamics of change in the productive sector and to the fact that public policies in science, technology and innovation (S, T & I) in Brazil and the research funding channels are at the federal and state level.

Archaic structures, little technologically evolved, with low complementarity and sectorial interdependence, are simultaneously product and producer of Innovation Systems that contribute little to the alteration of this process. These

systems function at the margin of modernization and advances at the technological frontier, and of the production of knowledge and innovation; from a fragile degree of articulation in terms of S, T & I.

Freeman (1995) showed in a historical perspective the existence of a systemic relationship between the degree of development of the "professional scientific-technological" apparatus and the productive sector. Additionally, the author indicates that the influence of institutions that support this relationship are a decisive factor in the success of radical innovations, especially those associated with the rate of diffusion and productivity gains.

The level of each productive structure is associated with: 1- the human capital (experiences, skills, competencies, formal and informal learning processes), 2- the organizational systems (accumulated knowledge from routines, procedures, techniques), 3- the technical-physical system (the material base of machinery, equipment, IT systems) and, 4- products and services. All this moves the infrastructure and the productive process, configuring the technological base of a given sector or industry and of the entire economy, at different levels of spatial configuration (Cook, 2001; Figueiredo, 2006; Schwartz and Trippi, 2011).

According to Suzigan and Albuquerque (2011a, 2011b), and Lemos and Cário (2013), Brazil has gone through at least four "waves of institutions" created in the areas of Science and Technology from the time of the Empire to the present day. This division does not portray how these institutions have spread throughout the Brazilian territory in terms of regional concentration over time.

The objective of this article is to map the evolution of the process of concentration of S, T & I institutions in Brazil over the last 30 years. Thus, this article is divided into 4 more sections besides this introduction and references. The second section addresses the evolution of S, T & I institutions from a regionalized perspective. The third centralizes the discussion on the evolution of S, T & I indicators. The fourth presents the methodology of the regional concentration indexes used. The fifth section turns to the interpretation of these indexes and the last section presents the conclusions.

2. THE REGIONAL EVOLUTION OF INSTITUTIONS AND S, T & I INDICATORS

The first wave of S, T & I institutions in Brazil dates back to the migration of the Royal Family to Brazil in 1808 and the developments of the installation of the Portuguese Crown in Brazil (Suzigan & Albuquerque, 2011a, 2011b). Thus, the first professional training courses were created to meet the growing demand for more qualified jobs and services, such as in the health and legal areas. During this period, the following were created: the Anatomical, Surgical and Medical School at the Military Hospital of Rio de Janeiro; the Royal Library and the Royal Military Academy; the Botanical Garden; the Fine Arts Academy; the Royal Museum, the Brazilian Historical and Geographical Institute (Fávero, 2006; Figueirôa, 2011).

Between the beginning of the Republic and the 1930s, other research entities are created, the most centralized in the Rio de Janeiro - São Paulo axis: the Natural History Museum of São Paulo (1893), the Institute of Experimental Pathology of Manguinhos (1908), the Butatã Institute (1901). Also, the Biological Institute (1927), the Ezequiel Dias Institute (1936), the Evandro Chagas Institute (1940) and the Technological Research Institute (1934).

Still in the imperial period, institutions were created to train teachers in Brazil (Marchelli, 2017): School of First Languages at the Portuguese Court (1823), Normal School of Niterói (1835), Normal School of São Paulo (1846) and nine more Normal Schools in the state of Minas Gerais (1872, 1879, 1881 and 1884). The core of these institutions centered in four states: Rio de Janeiro, Minas Gerais, Bahia and São Paulo.

The first colleges of Medicine, Law and Polytechnics date from 1830. The first university was the "University of Rio de Janeiro" created in 1920 by Presidential Decree No. 14,343. The first university regulation "Statute of Brazilian Universities" was approved in 1931 in the Vargas Government under the Ministry of Education and Health. In 1934, the state of São Paulo created the first public state university, the University of São Paulo, bringing together independent faculties, with the Faculty of Philosophy, Sciences and Letters as its central axis.

Between 1945 and 1964, 22 Federal Universities were created, one for each state of the federation. In the 1950s, the National Research Council (CNPQ) and the Coordination for the Improvement of Higher Education Personnel (CAPES) were created. They are responsible for policies on the training of higher education teachers, the implementation and evaluation of graduate courses. In addition, they stimulate the dissemination of research through incentives such as the distribution of research and graduate scholarships (*Stricto Sensu*), allocation of funds for capital, funding and realization of academic events, among others.

CNPq invested in structuring research by creating specialized organizations such as the Institute for Pure and Applied Mathematics (IMPA) and the Amazon Research Institute (INPA), which incorporated the Emílio Goeldi Museum of Para. In addition, between 1950 and 1970, the Aeronautical Technological Institute (1950), the Military Institute of Engineering (1959), the National Institute for Space Research (1960), the Nuclear Engineering Institute (1962) and the Brazilian Agricultural Research Corporation (1973) were created.

Until the 1960s, the institutional and organizational structure of the areas of Science, Technology and Innovation in the country, with a few exceptions, was strongly dependent on federal agencies. This begins to change from the 1960s when some states in the Southeast and South regions of the country created from their state secretariats of education, specific secretariats to operate scientific and technological development that soon incorporate research and innovation agendas. The time line of the creation of S, T & I institutions among the regions of the country presents very marked differences between the Southeast and South regions and, to the North region. The Research Support Foundations (FAP) of the states of São Paulo (1962), Rio de Janeiro (1980); Minas Gerais (1985); Rio Grande do Sul (1964); Paraná (1998) and Santa Catarina (1995), were created before the turn of the century and with marked temporal differences between the pioneering ones and the others.

By the end of the 1990s, most FAPs in the Northeast and Midwest regions had also been created. Meanwhile, the FAPs of the North region were created from the year 2000, being that those of Rondônia and Tocantins were created in 2011 and Acre in 2012 (Tables 1 and 2).

As for the innovation environment, the first experiences were the incubators of technological companies, some of them linked to private initiative. The first two emerged in 1986, in Santa Catarina and Paraíba. In the 1990s and 2000s there was a centralized distribution in the states of the Southeast, South and Northeast (Tables 1 and 2).

Between the 1980s and 1990s the first Technology Parks were created, with a centrality in the Southeast and South regions: Technological Park São Carlos (1984), Gênese Institute (1997) and Innovation Agency of the Federal Fluminense University (1999). Also, the Technology Management Agency (1990), Tecnópolis (1994) and Center for Enterprises in Informatics of the Institute of Informatics of the Federal University of Rio Grande do Sul (1996) are included. On the other hand, the Northeast region was responsible for two others: Technological Park of Paraíba (1984) and Technological Development Park of the Federal University of Ceará (1991). In the first decade of the 2000s there was a diversification of Technological Parks and Innovation Agencies throughout the country with a centrality in the Southeast and South regions. In fact, the first Technology Parks in the North region were only created in 2010.

The National Institutes of Science and Technology (INCT) emerged from the improvement of the Millennium Institutes (2005), as an initiative of the Ministry of Science and Technology, to promote the formation of research networks. The National Institutes of Science and Technology Program of the Ministry of Science and Technology (MCT) was officially instituted in 2008, and re-edited in 2014. And today it brings together 30 institutions regionally distributed with 15 concentrated in the Southeast Region, 6 in the South, 5 in the Northeast, 3 in the Midwest and only 1 in the North.

In the first two decades of the 2000s, the states of the Southeast and South regions, created their own Innovation System, organized and networked, such as the Innovation System of Rio Grande do Sul, which brings together 27 technology centers, 12 accredited technology parks and 14 parks associated with the gaúcha network of parks and incubators - REGINP. REGINP currently has 25 associated incubators, two startup accelerators (WOW and Ventur) and more than 190 startups. Similar examples appear in the state of São Paulo, which created the São Paulo Network of Technological Innovation Centers, with 8 already in operation and 13 accredited Technological Parks and 8 more under negotiation. Rio de Janeiro, which created the Network of Innovative Enterprise Promoting Agents that gathers around 200 technology-based incubators and 33 design and Creative Economy incubators.

3. REGIONAL CONTEXT AND EMPIRICAL METHODOLOGY

There is an uneven distribution of innumerable S, T & I indicators in Brazil, considering the major Brazilian regions, both in relation to indicators that can be said of performance for example: number of students with qualifications in stricto sensu postgraduate courses; number of graduate students in undergraduate courses; patent filings; production of scientific articles, among others, as well as process indicators such as: number of higher education institutions; number of stricto sensu graduate programs and vacancies; number of research groups; number of research group relationships with companies; number of postgraduate scholarships, number of doctors, masters and productivity researchers, among others.

Whichever indicator is selected, there is a very asymmetrical relationship in its distribution, with the Southeast and South regions, concentrating a relative participation that reached more than 80%, at least until the 1990s (Table 3).

Table 3. Relative Participation in Selected C, T & I Indicators according to Brazilian Regions

Elaboration by authors.

The Table 3 shows some of these indicators in relative terms between Brazilian regions: master and doctoral scholarships from the CAPES system; number of places offered at universities and number of research groups, where this disproportionate relationship between regions is quite evident, although with a decreasing trajectory since the 1990s. To verify the evolution of the degree of concentration of the institutions related to the Local and Regional Innovation Systems, classic measures of concentration will be used. To calculate the indices, the participation of the most representative institutions of the Local/Regional Innovation Systems was considered, in terms of: number of higher education institutions (HEI), number of undergraduate courses, number of graduate stricto sensu programs, and number of research groups. Follows the description of the concentration indices used in this study:

The Concentration Ratio (CR) is used to determine the relative share of the largest units in the whole (Table 4). It was observed that five states for each institution considered concentrated more than 50% of the absolute values, so it was preferred the choice of the measured CR5 among the years of each series. In this way, during the period, were few changes among the five most representative states: São Paulo, Minas Gerais, Rio de Janeiro, Paraná and Rio Grande do Sul; all of them located in the Southeastern and Southern regions.

Nevertheless, in order to have an idea of the degree of asymmetry between the extremes of the distribution in each series, we calculated the CR5 (-). That is the sum of the participations of the less representative states, which also varied little in the period. These states are: Roraima, Acre, Amapá, Rondônia, Tocantins (or Sergipe) and, they are located in the North and/or Northeast region. The result of the CR (-) was divided by the CR (+) to get an idea of how well the less representative states were positioned relative to the less representative states.

The Herfindahl- Hirschman's index refers to the sum of squares of the share of the observation units considered (Table 4). Where, S_i^2 represents the square of the share of the j-th spatial unit relative to the total (of space - among k possible locations) of the variable of interest, and thus takes on the character of a measure of spatial concentration. Implicitly in the calculation of the HHI, the participating of states are considered to have equal weight.

As Braga and Mascolo (1982) note, by replacing p_i with participation s_i one can interpret the entropy index as an inverse measure of concentration. The lower the index, the higher the degree of concentration. For its minimum value: if the states' shares are identical ($s_i = 1/n$), then the concentration is minimum for a given n, and $E = \ln(n)$, its maximum value. In the present study, the Gini index was used as a way to express the degree of density of the technological higher education courses offered in Brazilian's HEI (Table 4). Using the number of enrollments as the control variable, the Gini coefficient was calculated as defined by Krugman (1991).

Table 4. Concentration Indexes

Concentration Indexes	Formula	Limits	Obs
Concentration Ratio (CR)	$CR = \sum_{i=1}^k p_i$ For k = 5	$0 \leq CR \leq 1$	p_i = the share of the state, order i in the total units considered.
Concentration Ratio in Extremes	$\frac{CR(+)}{CR(-)} = \frac{\sum_{i=1}^k p_i}{\sum_{i=1}^k p_i}$		
Herfindahl- Hirschman's index	$HHI = \sum_{i=1}^n S_i^2$	$\frac{1}{n} \leq HHI \leq 1$	
Entropy measure (E)	$E = -\frac{1}{\ln(n)} \sum_{i=1}^n s_i \ln(s_i)$	$0 < E < \ln(n)$	$\ln(n)$, its maximum value
Gini Index (G)	$G_i = \frac{1}{\sum x_j^2} x \sum (s_j - x_j)^2$ For $i=1, \dots, N$; $j=1, \dots, M$.	$0 \leq G \leq 1$	

Elaboration by authors.

4. CALCULATION AND INTERPRETATION OF EMPIRICAL RESULTS

In order to remove the effect of the very different population size between the Brazilian regions, especially, considering the greater demographic participation of the Southeast and South regions, in relation to the other regions of the country, all concentration indexes were calculated per capita.

Table 5 shows the concentration indexes for institutions and on-site courses of higher education between the years 1995 and 2019. Comparing the behavior of the two series, three movements are observed. Between the years 1995 to 2000/2002 there is a slight concentration increase process with some oscillations. The contribution of the states with the highest participation - CR5 (+) continues to grow in the case of higher education institutions until the year 2000, while for face-to-face courses this process extends to the year 2002. A second movement that can be highlighted, it is a more pronounced drop in concentration indicators from 2002 to 2008. A Third movement is identified between the period 2009 to 2019, where a relatively continuous drop of less intense intensity of concentration was observed, although, for higher education institutions there is some fluctuation between 2008 and 2011.

Table 5. Concentration Indexes for Institutions and On-Campus Higher Education Courses

As there is a great heterogeneity between higher education institutions, as well as undergraduate courses inserted in them as to their capacity and performance of Education, Science and Technology indicators, Table 6 calculates the Gini coefficient, considering the density of technological courses offered by HEIs from the enrollment of undergraduate students in technological courses. It is observed that due to the lack of coverage in the Higher Education Census, organized by Inep, some coefficients of states in the Northern Region, mainly, could not be estimated in the years 1995 and 2000. In general, it appears that this increase it is greater in the South and Southeast regions, although with a higher growth rate of this density in the North and Midwest regions.

Table 6. Evolution of the density of technological courses in HEIs by States

As for the behavior of graduate courses and research groups (Table 7), a more continuous process of decrease is observed throughout the analyzed period. There is some level of maintenance of the concentration until the second half of the 1990s, with the increase of the participation of the states of greater participation CR5 (+), but the process of decline is more regular at the end of this decade, maintaining itself from then on. The degree of intensity of the fall is greatest between 2005 and 2010/2011 and from this period onwards the decrease occurs at a slower level.

The joint analysis of the results presented in Tables 6 and 7 allows us to point out that there are three moments about the evolution of the asymmetries of the institutions that most directly produce the disparate indicators of C, T & I: higher education institutions; undergraduate courses; graduate courses and research groups. A first moment until the end of the 90's and beginning of the 2000's, where it is possible to identify some still positive oscillations of the concentration process. In the beginning of the first decade of the year 2000 until approximately the beginning of the following decade, the process of deconcentration is more accentuated, although there is some fluctuation. Finally, from the year 2012 onwards, a last period is identified where the fall is more continuous, but at a slower pace.

It seems to us that this process is also related to the dissemination of other institutions of the Local Innovation Systems, in particular, the Foundation for the Support of Research and Business Incubators that gained great momentum in the first decade of the 2000s between the North and Northeast regions.

The Table 8 shows the average growth rate of the evolution of the increase in institutions: HEIs; On-Campus Courses Higher Education; Stricto Sensu Postgraduate Courses and Research Groups among the three periods highlighted above. It is clear that between the years 2000 and 2011 with greater intensity and between the years 2012 and 2019 with less intensity the institutions located in the North-Northeast regions present growth rates higher than those located in the Southeast and South regions, reflecting if the behavior of the concentration indicators as observed before.

Table 8: Average Growth Rates over Selected Periods

Growth Rate Higher Education Institutions					
Region	North	Northeast	Southeast	South	Midwest
Until the end of nineties	7.89	11.26	3.11	5.38	10.05
2000-2011	11.77	10.68	5.77	8.17	6.18
2012-2019	3.12	4.22	-0.56	0.14	2.63
Growth Rate Higher Education Institutions					
Region	North	Northeast	Southeast	South	Midwest
Until the end of nineties	7.51	11.83	8.20	9.51	9.90
2000-2011	11.30	11.40	10.78	8.94	9.85
2012-2019	2.41	4.63	1.09	1.70	3.95
Stricto Sensu Postgraduate Courses					
Region	North	Northeast	Southeast	South	Midwest
Until the end of nineties	8.33	8.38	7.24	11.52	9.09
2000-2011	17.16	11.47	5.58	9.48	11.75
2012-2019	6.82	5.20	3.55	5.37	5.15
Research Groups					
Region	North	Northeast	Southeast	South	Midwest
Until the end of nineties	18.73	22.80	17.06	20.93	17.52
2000-2010	15.01	11.36	6.70	10.35	11.94
2010-2016	8.84	6.26	3.16	4.84	5.71

5. FINAL REMARKS

The results presented from the behavior of the concentration indicators considered show at least three distinct phases when considering the regional differences that these indicators describe in the analyzed period, for the variables considered: higher education institutions, classroom courses, graduate programs and research groups. The first period, which extends to the end of the 1990s, is marked by a high regional concentration in the Southeast and South regions. A second period, between the first decade of the 2000s and the beginning of the following decade, where there is a more intense deconcentration process. And, finally, the last period starting in the year 2012, where the fall is more regular, but at a slower pace. For the first phase, we can call it stabilization of the concentration, for the second, intensive deconcentration and for the last, extensive deconcentration.

HOW COOPERATION WITH UNIVERSITIES CAN AFFECT THE CORPORATE COMPETITIVENESS?

[Adrienn Reisinger](#)

Széchenyi István University, Hungary

ABSTRACT

Higher education institutions (HEIs) are one of the key actors of the social and economic development. There are two classical roles of the universities, such as the education and the research; in the past two decades the third mission role has appeared, too. Nowadays these three roles mean the triple role of HEIs. The third mission role has different kind of approach, but in general it means all missions of the HEIs which are not related directly to the education and research. On the one part the third mission is related to the Triple Helix model, on the other part it can be all of the activities of the HEIs which are not related directly to the scientific activities. All in all, the third mission means those activities of the HEIs which are for the society and for the economy.

In the past two decades more and more HEIs identify their activities related to this third role. They realize that being part of the social and economic life could be an investment into the future and help them to be embedded in the settlement, region, country, etc. where they operate. The third mission means different kind of activities from supporting the local communities to taking part in the development of the companies. The presentation focuses on the latter, and would like to give answers to the question: How the HEIs-companies relations and cooperation can contribute to the corporate competitiveness? I believe that these relations can have an effect on the competitiveness, because they help companies to find good business solutions, to find new methods for development or to open new ways of management.

There are wide range of potential activities which can be part of the third mission activities, such as organizing workshops, trainings; taking part in common projects, supporting students practice, etc. These relations could be important for HEIs, because they will be closer to what the market desires and will know better the current issues in the for-profit era. These relations are good for the companies because they can use the knowledge of the researchers, they can cooperate with students and they can use these activities to be a better one in the market, so to be more competitive. The aim of the presentation is to show the third mission activities which are related to the HEIs-companies relations and to show how they could contribute to the competitiveness. The presentation demonstrates guidance for also practitioners and researchers and it also adds to the literature some possible good examples about managing HEIs-companies relations in the framework of the third mission.

MIGRATION AND INNOVATION: MEASURING THE EFFECT OF SKILL-SPECIFIC FLOWS ON PATENTS, TRADEMARKS AND DESIGNS ACROSS ITALIAN PROVINCES

[Adriana C. Pinate](#)¹, [Alessandra Faggian](#)¹, [Claudio Di Bernardino](#)², [Carolina Castaldi](#)³

ABSTRACT

This paper investigates the effect of both international and interregional migration data, differentiated by educational attainment, on the generation of new knowledge on the receiving Italian provinces (NUTS-3). The research extends previous analysis focalized on patents statistics by using other intellectual property rights (IPRs), i.e. trademarks and design, to capture different shades of the innovative process. Using a dynamic panel models of simultaneous knowledge production function equations (KPF) between 2003-2012, we employ three separate IPRs as innovative output. As for the inputs, we include, as our variable of interest, the share of international and interprovincial migrants, divided by educational level (e.g. Hunt and Gauthier-Loiselle 2010; Miguélez and Moreno 2013; Gagliardi 2015; Bratti and Conti 2018). The model includes also "traditional" knowledge inputs such as investment in research and development (R&D), human capital endowment, population density, labour market characteristics (employment in manufacturing and services) and the degree of openness of the provinces to foreign markets.

Our results indicate that, when migration flows are broken down by educational attainment, the multi-faceted role of different skills on innovation emerges very clearly. First, as far as international migration is concerned, no positive or negative significant consequences were found on the patent productivity of the destination provinces, a finding that confirms the previous results by Bratti and Conti (2018). Nevertheless, for trademarks and design a positive relationship with highly-educated migrants - and a negative one for medium/low-educated migrants - was found. These differences suggest that the use of other intellectual property rights, in addition to patents, allows to grasp more widely a latent and heterogeneous performance of innovation in the provinces and thus have a better understanding of the consequences of knowledge flows. As for interregional migration, highly-educated migrants had a positive effect on patents and trademarks, but not design. Medium/low-educated migrants had, instead, a negative effect on all three IPRs, suggesting that large inflows of med-low-educated migrants may induce a higher employment of unskilled labour in traditional non-innovative sectors hampering the provincial capacity to innovate.

By providing a more detailed picture of the relation between migration and innovation, this article may help policy makers in their endeavour to find the appropriate migration policies to foster local economic growth and innovation. This is particularly important in countries, such as Italy, characterised by a North-South dualism. Our contribution points also to the fact that using only patents to account for innovation might not be enough anymore. To appropriately account for the quality of the new ideas, policymakers must consider the use of different indicators of innovation as well as differentiating by group and skills of migrant. Furthermore, the empirical methodology can become a useful tool for regional migration policy strategies since the use of the three IPRs are already implemented by the European Commission in their Regional Innovation Scoreboard (RIS) to measure the innovation performance of regions.

National Session: SS49 - Sharing Economy and Urban Sustainability in Thailand

EMERGING PATTERNS OF URBAN PUBLIC SPACES IN THE SHARING ECONOMY

Shusak Janpathompong¹, Akinobu Murakami², Jirapatr Jitwattanasilp³, Nutnaree Jaruniphakul⁴, Yanin Chivakidakarn Huyakorn¹

¹Chulalongkorn University, Thailand. ²University of Tsukuba, Japan. ³Urban Studies Lab, Thailand. ⁴Regional, Urban, & Built Environmental Analytics, Thailand

ABSTRACT

The advance in digital and telecommunication technology has given rise to the sharing economy to utilize idling capacities of assets and resources. For urban areas where resources are agglomerated and shared, the concept of sharing economy is highly relevant, especially in urban public spaces. This is particularly significant in many cities of the developing world, where the provision of quality public spaces is a goal for improving quality of life and urban sustainability for all.

Using Bangkok as a case study representing a city in the emerging economy, this study aims to characterize urban public spaces in two key dimensions, accessibility and ownership, in order to better understand the current usages of these shared urban public spaces. The study also reviews several case studies of sharing public space platform from cities around the world and explore the patterns of activities and spaces in Bangkok with potentials for a pilot area of sharing public space platform. By using extensive questionnaire surveys and in-depth interviews with community leaders, urban dwellers' needs for public spaces and their online platform engagement for outdoor activities are identified. Together with the interviews with major land/space owners, event-organizers, and urban advocates, the results of the study show the greater needs of urban dwellers for accessibilities to public spaces and identify the urban spaces with high development potentials. Opportunities and challenges in deploying sharing economy system to provide additional urban public spaces for the city are highlighted as a policy recommendation toward more efficient usages of public spaces and an inclusive society that could lead to urban sustainability.

BANGKOKIAN'S COMMUTING MODE CHOICE BEHAVIOR: READY FOR A SHIFT TOWARDS SHARED MOBILITY?

[Eva Ayaragarnchanakul](#)^{1,2}, [Felix Creutzig](#)^{3,1}, [Nattapong Puttanapong](#)⁴

¹Sustainability Economics of Human Settlements, Technische Universität Berlin, Germany. ²Faculty of Economics, Prince of Songkla University, Thailand. ³Mercator Research Institute on Global Commons and Climate Change, Berlin, Germany. ⁴Faculty of Economics, Thammasat University, Thailand

ABSTRACT

The economy has transitioned from owning to sharing underutilized goods and services to improve efficiency. Vehicles cause negative externalities – too many of them are on the streets. Shared mobility encourages private idling vehicles to be used to its full capacity, decrease the overcrowded modes of public transportation, and improve accessibility and connectivity to public transportation.

We aim to understand the mode choice behavior of commuters in Bangkok when shared mobility is present and the metro system is extended through the revealed preference (RP) questionnaire and stated preference (SP) experiment. The aim of this paper is not to gain the most efficient design of the SP experiment, though we did not overlook the importance of the experimental design and intend to achieve robust results with least complexity in addition to the reliability supported by the RP data. Random designs are empirically evidenced to be no less robust than other designs such as the abundant use of orthogonal designs and the emerging use of efficient designs. Hence, we carefully design our experiment by eliminating dominant alternatives and ensuring utility-balance and attribute level-balance. Also, using real data from the Bangkok Household Travel Survey (2017) to set the attribute levels.

Commuter's choice is dependent on their captivity and nested into single-mode and multi-modes transport from origin to destination for their current travel behavior. For the choice experiments, the modes considered are private vehicle (car, motorcycle), public transport (bus, metro), shared mobility (ride-hailing, shared-taxi), and multi-modes (a transit from the motorcycle taxi or shared taxi to the metro system). The travel time is used as a factor linkage. Other mode-specific attributes cover ride fare, fuel cost, toll fee, parking fee, and the crowdedness of public transport and shared taxi. Descriptive statistics are presented to find the socioeconomic and travel characteristics of commuters that are likely to use shared mobility modes. The logistic regression analysis will be performed in the next stage to confirm the results with this stage and estimate the value of time saved, including the mode alternative travel attributes that are important for mode-shifting decisions.

Bangkokians commonly live in a 2-person household and typically value the travel time, convenience, and safeness rather than privacy or comfortability. Travel cost is more important to public transit (mainly bus) users than to private vehicle users. This supports using shared mobility since owning a private car is inefficient for small families and commuters care less about riding alone. However, affordable ecocars and the relatively costly public transports other than the low-quality bus encourages Bangkokians to drive alone in their own car, even when they are commuting within inner Bangkok, where various modes exist. In order to encourage shifts toward more sustainable modes, we suggest increasing private vehicle ownership and usage cost such as congestion and parking pricing.

FROM SHARING ECONOMY TO PEER-TO-PEER ACCOMMODATIONS: A CASE STUDY OF THAILAND

Sutee Anantsuksomsri^{1,2}, Areen Phuntarakit², Jean-Claude Thill³, Nij Tontisirin⁴

¹Department of Urban and Regional Planning, Faculty of Architecture, Chulalongkorn University, Bangkok, Thailand.

²Center of Excellence in Regional, Urban, & Built Environmental Analytics, Faculty of Architecture, Chulalongkorn University, Bangkok, Thailand. ³Department of Geography & Earth Sciences, College of Liberal Arts & Sciences, University of North Carolina at Charlotte, USA. ⁴Faculty of Architecture and Planning, Thammasat University, Pathumthani, Thailand

ABSTRACT

Sharing economy has recently shaped a new direction of economic activities. Sharing economy is broadly defined as the value created from underutilized assets in a form of peer-to-peer (P2P) exchanges. Since sharing economy enable these assets to be accessible to others, it leads to reduced needs for ownership of these assets. Particularly, accommodation industries have been transformed in the sharing economy, from hotels/hostels to P2P accommodations, which can offer unique experiences or socializing opportunities, yet affordable, for consumers. For P2P accommodations, exchanges for stay can vary diversely; Exchanges medium can be monetary or non-monetary. In addition, an emergence of digital technologies enables sharing economy to expand beyond its localized territories. Globally known P2P accommodations platforms includes Airbnb, Couchsurfing, and Onefinestay, while there are also regional P2P platforms such as Agoda Home or Favstay in the Southeast Asian region.

With over 38 million foreign visitors in 2019, Thailand has been one of the world's tourist destinations for its rich history and culture, culinary, tropic climate, and affordability. Accommodations in Thailand ranges from luxury hotels to affordable hostels. Since 2012, Airbnb has entered P2P accommodations in Thailand. In 2019, there were over 99,000 accommodations listed on Airbnb in Thailand. Yet, little has known about the impacts of global sharing economy platforms for accommodations on local economy and communities as well as on the localized legal challenges.

The objective of this study is to explore the P2P accommodation industry in Thailand to better understand its localized characteristics and implications on the housing industry. The analysis uses both listing and host information on Airbnb website because it holds the largest market share in Thailand. The data are drawn from many tourist's destination cities in Thailand, including Bangkok, Pattaya, Chiang Mai, Phuket, Cha Am, and Hat Yai. The results show that there are great variations in P2P accommodation characteristics and pricing in these cities. The results also suggest that P2P accommodation has become a new model for hospitality businesses in Thailand, rather than a pure sharing economy as the P2P accommodations first emerged.

WALKING DISTANCE IN TROPICAL-CLIMATE CENTRAL BUSINESS DISTRICT DURING LUNCH TIME: A CASE STUDY OF BANGKOK

Shusak Janpathompong^{1,2,3}, Sutee Anantsuksomsri^{1,4}, Akinobu Murakami³

¹Regional, Urban, & Built Environmental Analytics, Faculty of Architecture, Chulalongkorn University, Thailand.

²Department of Landscape Architecture, Faculty of Architecture, Chulalongkorn University, Thailand. ³Graduate School of System and Information Engineering, University of Tsukuba, Japan. ⁴Department of Urban and Regional Planning, Faculty of Architecture, Chulalongkorn University, Thailand

ABSTRACT

During a working day, going out for a meal at “lunch break” is a routine of most workers and, in fact, it represents the longest break within a working day and allows freedom to them for their desire activities. This research focuses on office workers’ walking distance during their “lunch break”, in CBDs of the tropical climate of Bangkok. The study areas are three major business areas in the inner area of Bangkok: Silom-Sathorn, Ploenchit, and Asoke. The result shows that the average walking distance is approximately 300 meters. However, workers significantly perceived their walking distance to be much error than the actual distance with the average of approximately 175 m. Using cluster analysis, the result shows the patterns of how office workers perceived their walking distance in relation to physical environment of their walking routes: thermal comfort, pavement condition, sidewalk obstruction, traffic safety, grade change, and walking distance itself.

The constant hot climate of Bangkok is expected to be the most concerned when people go out for their lunch time. Instead of thermal comfort that people in Bangkok always complain, a sidewalk obstruction is the most important factor that alters how workers perceived their walking distance in the CBD of Bangkok. Walking distance, pavement condition, and grade change also play important roles in their walking perception. However, traffic safety is less of the concern due to the crowded Bangkok’s CBDs during lunch hours. The results can be used to assess the walkability index and as guidelines for improving urban conditions of the CBD making the more pleasant CBD for better lunchtime spending.

CO-EVOLUTION OF FOOD DELIVERY SERVICES AND RESTAURANTS IN THE SHARING ECONOMY: A CASE STUDY OF BANGKOK, THAILAND

Yuri Mansury¹, Sunattha Reangsirikan², Supapitch Intarasut², Sutee Anantsuksomsri^{2,3}

¹Lewis College of Science and Letters, Illinois Institute of Technology, USA. ²Regional, Urban, and Built Environmental Analytics Research Unit, Faculty of Architecture, Chulalongkorn University, Thailand. ³Department of Urban and Regional Planning, Faculty of Architecture, Chulalongkorn University, Thailand

ABSTRACT

Technological advances have made it easier to build settlements and cities, protect ourselves from disasters and diseases, farm and harvest, produce and work, and put foods on our tables for thousands of years. However, for the past 25 years, technology has changed immensely, especially in information and communication technology. The internet and smartphones have facilitated us to access information and services easier and faster. In previous years, the food delivery service has been one of the most popular businesses before and during the COVID-19 pandemic. In Thailand, the market value of the service has increased from around 24 billion Bahts in 2014 to around 70 billion Bahts in 2020. The service has not only changed customer behaviors and operations of restaurants, but also urban sustainability. This study focuses on the development and roles of food delivery service in the context of the urban economy in Thailand as well as the impacts of the service on customers, restaurants, and food deliverers in Bangkok. In addition, the study aims to provide guidelines in physical and socioeconomic contexts of sustainable urban development.

The results from the studies of customers, food deliverers, and restaurants show that people are likely to order food deliveries rather than have dining services at restaurants due to the increasing number of available delivery services of restaurants on delivery platforms and their public health issues during the COVID-19 pandemic. The food deliveries reveal that the average number of delivery trips has been much higher since 2020, and the ranges of food delivery service have been wider due to the higher demands of foods from popular restaurants. In addition, the number of food deliveries has been dramatically increasing during the pandemic. On the other hand, the number of restaurants has been decreasing due to the impact of the pandemic. The restaurants have had to adapt themselves to delivery services. For example, some restaurants no longer have storefronts and seats to operate their services. Cooking and delivery services in “ghost kitchens” can be operated anywhere in urban areas. The changes in food delivery service and restaurant supply chains will have impacts on the urban economy in terms of consumption behaviors, employment, and public safety of the city.

ASSESSMENT AND MAPPING OF THE VULNERABILITY TO EROSION AND GULLYING IN THE RURAL COMMUNE OF EL FAID

Ali Azedou, Abdellatif Khattabi, Said Lahssini, Mohamed Sabir

Ecole Nationale Forestière d'Ingénieurs, Morocco

ABSTRACT

Erosion is the main threat to sustainable water and soil management in Morocco. It has a negative impact from an environmental, social and economic point of view. Located in the Souss-Massa hydrographic basin, the rural commune of El Faid remains an area where gully erosion is strong, causing devastating floods for agricultural land and infrastructure. This study aims to map the areas with high susceptibility to erosion in order to propose gully correction interventions to reduce the risk of flooding. First, we analyzed the vulnerability to erosion at the scale of the commune's territory and then we diagnosed the gully process based on a gully inventory already established and validated in the field. The RUSLE model was used to map erosion vulnerability. Second the dynamics of the evolution of the beds of the main wadis crossing the territory of the commune were analyzed to illustrate the extent of the erosion/flooding phenomenon. We determined the main predisposing factors for soil erosion and gulling, and then, for each factor we drew the corresponding map by determining the interaction of each factor with its corresponding phenomenon.

CONTRIBUTION OF A NEW-DESIGN MULTIFUNCTIONAL ARTIFICIAL REEFS TO THE SUSTAINABLE MANAGEMENT OF COASTAL AREAS

[Isabel de Almeida](#)

CIAUD, ISCTE-IUL, Portugal. Lusiada University, Portugal

ABSTRACT

Coastal territories are the focus of constant antagonism and conflict. The lack of integrated management of maritime and terrestrial resources causes serious tension among various sectors of activity (fisheries, agriculture and services). Consequently, the sustainable development of the coastal areas is put on hold. So, how to find a sustainable solution that balances the need to preserve the shoreline and economic development (local or regional)? Scientific knowledge about climatic changes, theoretical background in shorelines infrastructures construction, coastal engineers' awareness, controlling, monitoring and managing of coastal related operations could not avoid a relevant impact on coastal sustainability. Coastal resources are under increasing pressure and specific management programs strive to protect coastal resources for future generations while balancing today's competing economic, cultural and environmental interests. This management programs are determined to balance all the dimensions of the coastline importance (Tourism, Resource Extraction, Wildlife Habitat, Settlements and Industry). These interventions are socially important: they are concerned with the fair allocation/use of coastal resources while sustainably managing these areas so that they can be used by future generations. Sustainable coastal management should involve all parties in the decision-making process so that resources are used fairly without permanent damage. Without sustainable coastal management, there could be a loss in a country's economy and, even, no economic growth. The problem of coastal erosion has been sharpening in Europe. Several publications discuss pressure situations and erosion processes across the entire coastline, pointing to critical situations together with the densification of coastal urban areas partly due to successive waves of human migration towards coastal areas and estuaries. Portugal owns 2830 km of coast, islands included, and is one of the European countries where the growth of coastal urban areas was faster, the growth of population along the shoreline was higher, the most agricultural area along the coast was lost to other uses, and evident loss of dunes is due to construction/exploitation. So, how to find a sustainable solution that balances the need to preserve the shoreline and economic development, either local or regional? Rock walls, breakwaters or groynes usually serve the purpose of protecting land from erosion and/or enabling safe navigation into harbours and marinas, but other commercial value and multi-purpose recreational and amenity enhancement objectives can also be incorporated into coastal protection and coastal development projects. Submerged breakwaters (also called multifunctional artificial reefs (MFARs)), made partially from sludge muds resulting from dimensional stone cutting process, could be an interesting and efficient strategy, not only to protect a coastal system but because recycling and incorporating such wastes into building materials is a practical solution for pollution problems from stone industry. Moreover, MFARs will improve the bathing conditions of some coastal zones and cope to enlarge sea biodiversity. This research main objective is to find a sustainable solution that balances the need to preserve the shoreline in a sustainable way by enhancing the use of stone cutting sludge waste in the production of MFARs, reducing both the environmental impact and the production costs.

SCALING OF URBAN HEAT ISLAND AND NO₂ WITH URBAN POPULATION: A META-ANALYSIS

[Yufei Wei](#)¹, [Geoffrey Caruso](#)¹, [Rémi Lemoy](#)²

¹University of Luxembourg, Luxembourg. ²University of Rouen, France

ABSTRACT

Due to urban population growth worldwide, thermal anomalies and toxic air pollution are increasing concern for citizens. Despite this increasing challenge and indications, there is still no consolidated understanding of the effect of city size on urban heat island (UHI) and nitrogen dioxide (NO₂) pollution. Meanwhile, nowadays cities are viewed as organisms where their magnitude of socio-economic outcomes changes along with their population size, and these changes can be generalized by scaling laws. However, we find most studies dedicated to UHI or NO₂ consider only a single city or a few cities within the top ranks of specific world regions or globally.

We fill this gap by conducting a qualitative synthesis of the literature and performing a statistical meta-analysis from published work with the aim to uncover scaling laws of UHI and NO₂ with the population size of cities. Under the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guideline, we collect and filter about 500 research outcomes on UHI and NO₂ from Scopus and Google Scholar. We select 22 articles at the stage of qualitative synthesis and summarize them based on their measurement types and geographical locations. The qualitative synthesis of UHI studies includes 384 nonduplicated cities from Asia, Europe, North America, and Oceania. 52 cities are measured by car traverse, 12 cities are measured by monitoring stations, and 328 cities are measured by remote sensing. The qualitative synthesis of NO₂ studies includes 1653 nonduplicated cities from Asia, Europe, Africa, North America, and South America. 4 cities are measured by handy sampler, 61 cities are measured by monitoring stations, and 1588 cities are measured by remote sensing.

Then, for meta-analysis, we group those 22 articles and conduct ANalysis Of VAriance (ANOVA) to identify significant model specifications (linear, semi or double log relations). Through ANOVA we identify significant relations of maximum UHI intensity and logarithmic maximum UHI intensity with logarithmic population size among 52 nonduplicated cities in Asia, Europe, North America, and Oceania. These 52 cities are all measured by car traverse. We also find significant relation of logarithmic annual mean NO₂ surface concentration with logarithmic population size among 24 nonduplicated Asian and European cities. 2 cities are measured by handy samplers, and 23 cities are measured by monitoring stations.

The results of meta-analysis show moving from a city with a population of 100-thousand to a city with a population of 1 million, the max UHI intensity increases by 2.66 °C, the annual mean NO₂ surface concentration increases by 14.95 g/m³. Moving from a city having a population of 1 million to a city with a population of 10-million, the max UHI intensity increases by 3.87 °C, the annual mean NO₂ surface concentration increases by 21.72 g/m³. Thus, larger cities have higher levels of UHI effects and NO₂ pollution. We also give the progress of verifying the NO₂ scaling using census data and in-situ and RS-measured NO₂ data at the level of Urban Atlas 2012.

INEVITABLE TRADE-OFF BETWEEN ECONOMIC DEVELOPMENT AND ENVIRONMENTAL PROTECTION FROM ISLAND UTILIZATION: EXPERIENCES FROM CHINA

Dou Shiquan

China University of Geosciences, China

ABSTRACT

An island is an important part of the global ecosystem. Islands are faced with an inevitable tradeoff between economic development and environmental protection. This article is concerned with the sustainability of island utilization. The paper chose eight island counties from China as a case study to analyze the relationship between economic development and environmental conservation in long-term series. The habitat quality and nighttime light data are used to value the ecosystem quality and human activities scale, respectively. To further explore the impact of human activities on the island ecosystem, we select a typical tourist island for microscopic analysis. This paper reveals the temporal and spatial changes of the island ecosystem under human pressure on a micro-scale. The ecological footprint, habitat quality, and social network location data are used to support the research. We identify, quantify, and spatially exhibiting the damage generated by human activities and revealing the relationship between this ecosystem change and human activities. The result reveals that 1) Humans bring more pressure on the island's ecosystem; 2) Island has the potential risk of over-exploitation. 3) The island ecosystems face a higher utilization intensity than that of land. We analyze the challenges and opportunities faced by islands. The paper reflects the trade-off between economy and development is essentially a choice between the short-term and long-term interests of humans. We build a sustainability action system to support island development.

RIOTS IN MUMBAI: COMPLEX INTERACTION OF VULNERABLE COMMUNITIES

Abdul Shaban

Tata Institute of Social Sciences, Mumbai, India

ABSTRACT

Varshney (2002) argues that about 95% of Hindu-Muslim riots in India till 1995 have been in Urban Centres, especially major urban centres of the country. Mumbai has been one of the Western Indian megacities which has faced highest numbers of Hindu-Muslim communal violence with devastating consequences. These violence in the city have been analysed through various lens including Hindus and Muslims as two opposing blocks pervaded by political interests. However, the complex relations between Hindu lower castes and Muslims have not been examined in detail as has been done elsewhere specifically in the case of Gujarat riot in 2002 (Shah 2002). The present study, therefore, attempts to examine the complex relations which have unfolded between the lower caste Hindus and Muslims in the city and how does that translate in turning the lower caste Hindus into 'foot soldiers' to attack Muslims. This is important in the backdrop of the fact that Hindu lower castes and Muslims have largely have similar lower level of development be it education, employment, housing, or household asset base. Many scholars and political parties have attempted to draw possibility of class-based alliances between them and occasionally these alliances have worked as in Gujarat during 1970s and 1980s, in Uttar Pradesh during 1980s and 1990s or in Bihar for a long time from 1970s to till date.

The question then is what prompts them to cannibalise their own class? Whether religion-based identity become a stronger marker during riots than class identities? How are the caste barriers overcome during these riots and ideologies of a sections of upper castes is accepted by the lower caste Hindus, who otherwise are in conflict with them to secure their own social space within the caste hierarchy? How and why everyday normal social transaction between lower marginalised caste Hindus and Muslims breaks down during the riots? How are the spaces occupied by the Hindus and Muslims get designated during the violence and bodies inhabiting these spaces get marked and identified?

The present paper is structured along these important questions. The data for the paper are drawn from relevant studies on Hindu-Muslim riots in the city since 1901 till date. However, special focus has been on the Hindu-Muslim riots during 1992-93 in the city, which was one of the most violent riots city experienced after the independence. The study has used the ethnography and indepth interviews with Hindus and Muslims in different localities of the city (specially in Dharavi and Byculla, the two localities which witnessed massive violence but are inhabited by the marginalised sections of the population from both the Hindu and Muslims) to understand the spatial interactions/conflicts and boundary formations during the communal riots.

The study employs various theoretical postulates to explain the causes of the riots and that range from electoral return theory of Wilkinson (2002), civic association theory of Varshney (2002), essentialism, constructivism, instrumentalism, and institutionalism (Upadhyay and Robinson 2012) to 'aspiration for a broader identity and a larger political role' theory by Engineer (1994).

**SPATIAL JUSTICE, RESILIENCE AND SUSTAINABILITY. REVELATIONS
OF THE EVOLUTION OF THE POPULATION HIERARCHY OF THE
REGIONS OF PORTUGAL**

Tomaz Dentinho

University of the Azores, Portugal

ABSTRACT

The article studies the evolution of the population hierarchy of the regions of Portugal to understand the role of geography, history and related political and economic developments affect the hierarchy of city regions. The work suggests the estimation of resilience and sustainability indicators based, respectively on the standard deviation of the population weight of each city region from the long-term weight of the city region. With the support of the instrumental Zipf's Curve - that relates city region hierarchy with the respective population weight - the analysis shows that there is a growing urban concentration since the sixties of the XX Century, faster during left driven government and the European integration. The approach method also shows that big and small city regions are more vulnerable than medium city regions, that geography measured by remoteness and latitude have a negative influence in vulnerability and the same happens with the fast growth of sprawling suburbs and changeable port city regions. Non-Sustainability, measured by the distance to the long-term weight of the city-region and its actual weight reasserts the profile of winners and losers of changes in the political economic regime.

**OPTIMAL OPENNESS FOR SUSTAINABLE DEVELOPMENT OF PEOPLE
AND PLACES**

Tomaz Dentinho

University of Azores, Portugal

ABSTRACT

The paper chapter addresses the question of how open should and city-region be? The approach is rooted in the literature on Spatial Interaction Models subject to environmental, institutional, economic and technological constraints. The argument begins with the formulation of an open spatial interaction model with two channels: Cardo for the internal interactions constrained to environmental and technological restrictions and Decumanus for the external interactions limited by institutional and economic limitations. Results indicate that there two interdependent components for the optimal openness. First, the structural spatial interaction of the region, or the length of Cardo and Decumanus, or on the relative structural centrality of the city-region. Second, the multiplier effects of external flows that depend on the technological, institutional and economic constraints.

National Session SS48A - Arctic regions: economic, climate and epidemiologic challenges

<https://us02web.zoom.us/j/88511789571>

Chair Alexander Pelyasov

RUSSIAN ARCTIC REGIONS AND COVID-19 CHALLENGES

Alexander Pilyasov

Lomonosov Moscow State University, Russian Federation

ABSTRACT

The regions of the Russian Arctic, due to a younger population and a less densely populated space, as a whole, showed a lower (COVID-dependent) excess mortality rate in 2020 than the rest of Russia. However, against the background of generally better COVID-situation within the Arctic zone of the Russian Federation itself, inside the Arctic the picture was highly contrasting. First, the regions where resource “growth poles” and the rotational work organization were the first to face a pandemic back in the spring of 2020. Several shift camps of Arctic resource corporations “blazed” to such an extent that a local quarantine regime was introduced in order to avoid contamination of the rest of the Arctic region. Then, general recommendations were adopted on restrictions for shift camps during a pandemic of the state agency for control of the epidemiological situation (Rospotrebnadzor). Against this background, many Arctic regions introduced stricter restrictions on shift camps, up to a two-week quarantine for everyone who came here from outside. However, the regional peak of excess mortality was observed in the Arctic territories not in the first wave, which captured the most contact-intensive and permeable regions of the center, large urban agglomerations of the country, but already in the summer and autumn of 2020, during the second wave, which came here with some lag behind more densely populated areas. In general, larger urban regions of the Arctic have suffered from the pandemic more than sparsely populated and small urban regions, for example, the Chukotka Autonomous Okrug, rural Yakutia, etc. In the Republic of Sakha-Yakutia, for example, in the main regional law on covid restrictions, the Law on High Preparedness, it was expressly stated that all quarantine measures do not affect “areas with limited terms for the delivery of goods”, that is, roadless, remote, inaccessible.

RUSSIAN CENTRAL REGIONS AND THE ARCTIC PERIPHERY UNDER THE COVID-19 2020 PANDEMIC

[Nadezhda Zamyatina](#), [Boris Nikitin](#)

Lomonosov Moscow State University, Russian Federation

ABSTRACT

The usual approach to assessing the spread of a pandemic in space is through the cells of administrative-territorial entities, regions and municipalities. Our approach is completely different. We were interested in the place of the city, the region in the system of settlement of the country. The most important result of the 2020 pandemic, manifested in the Russian space, was that it further exacerbated the gap between the centers and the periphery of Russia. The consequences of the pandemic, its perception, discipline in the implementation of official restrictions differed radically between the centers and the periphery of the country. The centers reacted according to the formats of neighboring European states: the thoroughness of the implementation of restrictions, the re-profiling of hospitals, bans on mass events, etc. On the other hand, the peripheral territories, while formally duplicating the restrictions of the federal authorities, in fact observed them much weaker, with a certain serenity towards mortal risk.

With this approach, the Russian pandemic space reveals the negative effects of large urban agglomerations, the phenomena of mass migrations from large cities to summer cottages during a pandemic, etc.

TYOLOGY OF THE RUSSIAN AND ARCTIC REGIONS UNDER THE CONDITIONS OF COVID-19 PANDEMIC

Yegor Kotov, Ruslan Goncharov, Yuriy Kulchitskii, Varvara Molodtsova

Higher School of Economics University, Moscow, Russian Federation

ABSTRACT

Intensive socio-economic interactions are a prerequisite for the innovative development of the economy, but at the same time, they are a cause of increased epidemiological risks. The same spatial processes, features of the labor market and sectoral structure, as well as government policy measures that contribute to an increase in the density and intensity of socio-economic contacts in an urbanized area, can both increase economic returns and increase risks in the event of a crisis. The pandemic forces us to reconsider many of the views on socio-economic development, innovation processes, the viability of territories, and the role of territorial structures of the economy and society in these processes.

A set of local conditions affects the intensity of socio-economic interactions and the stability of the region. The intensity of interactions influences the severity of the impact of a pandemic. Excess mortality is the most revealing and accessible indicator reflecting the severity of the pandemic in the region. Thus, the regions can be divided into types by the nature of socio-economic interactions that explain the level of excess mortality.

When developing the typology, statistical methods of data analysis were used - factorial and regression, cluster analysis, as well as spatial analysis of open data. The typology was based on indicators characterizing: migration flows, the socio-demographic composition of the population, income level and data on the structure of employment of the population, the level of economic development of the region and digitalization, the level of transport, climate, commercial activity, the provision of medical care, the number of search queries for the selected keywords. In total, about 170 indicators were considered, for each of which an individual relationship with the target variable was analyzed, after which a shortlist of 95 key factors was formed.

The excess mortality was modeled on the Manski model, which allows one to take into account the local and global effects of the neighborhood of regions. The final model, explaining the level of excess mortality by region, determined the role of climatic and socio-economic factors.

Based on the factors selected by the model and the target variable, the regions were divided into types. The results obtained can serve as the basis for several new fundamental and applied research, in particular, they are planned to be used to develop territorially differentiated measures to regulate socio-economic interactions, labor markets, and the sectoral structure of the local economy, aimed at achieving a balance between economic development and minimizing epidemiological risks.

REGIONAL INEQUALITIES IN CROATIA VS. CEE COUNTRIES – WHAT TO EXPECT AFTER THE CORONA CRISIS

Dubravka Jurlina Alibegovic¹, Katarina Marošević²

¹ The Institute of Economics Zagreb, J. F. Kennedy Sq. 7, Zagreb, Croatia, djurlina@eizg.hr; ² Faculty of Law Osijek, S. Radića 13, Osijek, Croatia, katarina.marosevic@pravos.hr

ABSTRACT

Most Central and Eastern European countries (CEE) record significant differences to European Union average, according to various indicators. Croatia is not an exception. Namely, Croatia also records significant sub-national inequalities i. e. regional inequalities, with respect to different level of socio-economic development. In this paper inequalities are presented among CEE countries and NUTS 2 level of CEE countries. This paper presents results of research on measuring inequalities according to composite index of (regional) development of CEE countries and gives a perspective of inequality expectations in the post-corona period. It gives an overview of most used indicator of GDP per inhabitant in order to gain insight into the changes that happened during three year period time (2017-2019). The growth of GDP per inhabitant can be observed, but it is lagging behind most CEE countries compared to EU 27 average (of 2020), and even their lagging behind of most of them compared to average of CEE countries. Based on mentioned, an adequate suggestions are drawn out and elaborated on. It is important to emphasize that calculation of composite development index is not used for the same period since the development index is created according to the latest available data nor it is used for the regional perspective, but for the development index of certain cities. Therefore, it is a novel that can be used and serve to the economic policy decision makers. Furthermore, certain expectations are drawn for institutional, economic and social level.

KEYWORDS

CEE countries, NUTS 2, inequalities, composite development indicator

1. INTRODUCTION

Achieving an even level of development is a joint goal of various national economies and their parts. Therefore, academic and professional literature is plentiful in research regarding the subject of disparities. However, when looking from the perspective of European Union, it is apparent that there is an obvious east-west division. After the transition period countries of Central and Eastern Europe (CEE) have tried to manage and achieve contemporary modern economic transformation. Some of them had complex unsolved questions – war, economic system transformation, external debt, centralization and many others. Taking into account their lower development level compared to their western neighbours, in order to become a part of European Union they accepted the rules they needed to accomplish and even nowadays remained in subordinate position. On their path to better life standard, some of them have adapted much better and closer to that aim, considering the measure of GDP per inhabitant. In order to compare CEE countries, the aim of this paper is to present today's differences among CEE according to GDP per inhabitant and to make a ranking of CEE countries according to calculated development index of CEE countries and cluster CEE countries NUTS 2 level according to achieved GDP per inhabitant. According to mentioned aim adequate measures can be created, directed to the institutional, economical and social level.

The structure of the paper is as following – after introduction, the second part of the paper gives theoretical perspective of regional inequalities among and in CEE countries and their importance. The third part of the paper is focused on empirical analysis, where after presenting differences on GDP per inhabitant level among CEE countries and differences among GDP per inhabitant of NUTS 2 of CEE countries, the chapter presents methodology and data regarding composite index of regional development calculation for CEE countries and the results are presented. The fourth chapter is based on the main and major contributions in the field of regional development differences.

2. REGIONAL INEQUALITIES AMONG AND IN CEE COUNTRIES: THEORY AND LITERATURE REVIEW

Regional inequalities can be defined differently. They most often refer to regional income inequalities within countries. Convergence (or divergence) of interregional income inequalities is mostly analysed by variation between regional incomes per capita, or related inequality measures (Rietveld, 1989). There are theories that have different approaches in addressing regional inequalities. The World Bank favours the theory of new economic geography school that underlines the influence and efficiency of large metropolitan areas and the need to support them for aggregate wellbeing. This theory suggests how historical events can form economic geography, and how ongoing differences in creating parameters can generate change in spatial formation (Krugman, 1989). In the other hand, the OECD has different approach and favours location-based regional policy that relates to place specificities and territorial resources, designed in a transparent and comprehensive way by local actors with the support from multi-level governance. Location-based regional policy is also

accepted in a certain way in the European Union (EU). The goal of the EU Cohesion Policy is overall harmonious development and reduced disparities between levels of development of the various regions and the backwardness of the least favoured regions. In conducted studies Bachtler (2010: 54) indicated a shift in the model of regional policy in Europe, including trends in regional policy design and delivery at national and European Union level, and explained how the principles of regional location-based policy operate in practice. McCann and Varga (2017) showed important elements of the reformed EU Cohesion Policy to provide a consistent overall context. Although its goal is to encourage growth and development in all member countries, including CEE countries, some of the key elements in the reforms, contribute to achieving that goal by introducing smart specialization approach to policy prioritization and resource allocation, the underlying location-based reason for the policy, and general results orientation and evaluation of the policy. The policy objective is equality of regional per capita income. More precisely, the goal is to achieve close to uniformity of income at NUTS2 level. Disparities among NUTS2 regions are measured using different indicators (per capita income, unemployment, educational accomplishment, R&D investment and other). Studies has shown that goals of the implemented EU regional policy have not been achieved and that there are inequalities in regional development among European regions.

Boldrin and Canova (2001) conducted research on results of EU regional policies by measuring income and labour employment dispersion across NUTS 2 regions of the EU. They concluded that result of EU regional policy is neither convergence nor divergence within Europe. Recent research on regional inequalities introduces new approaches in analysis of existing regional economic divergence in Europe. Iammarino, Rodriguez-Pose and Storper (2018) elaborated on the presence of several different modes of regional economic performance in European regions that cannot be explained by current theories. They suggested a different approach to analyse regional inequalities and recommend measures for strengthening the most developed European regions in the one hand and promoting less-developed regions in the other hand. The authors introduced a new approach and labelled it as "location-sensitive distributed development policy".

In literature we can find many articles that explain and report disparities between Eastern and Western Europe and increased regional differentiation within the CEE countries. Focus on societal, economic and political situation in CEE countries is significant on academic (Meyer, 2000; Grieveson et al., 2019), but also on professional and organizational level (f. i. European Parliament, 2015). It was like that with the question of inequalities from the very beginning of the CEE countries transition process - and it is becoming more and more important (Heyns, 2004; Fuest, Niehues and Peichl, 2013; Perugini and Pompei, 2015). Besides, since potential new crises and threats are constantly occurring, Schweiger and Visvizi (2018) warn on having diverse effects on different countries, especially on some CEE countries. Therefore, Schweiger (2018) emphasises that in years to come CEE countries should position themselves as this will substantially influence the direction of the European Union. Their peripheral position in economic, social, and increasingly in political terms, should not be allowed (Schweiger, 2018). It is important to bear in mind that European Union has a huge impact on CEE countries institutions and an impact on the entire range of public policies in CEE countries, setting more than 80 percent of economic regulations. "European Union conditionality might be encompassing, but it may not be effective in particular issue areas or countries and policy or institutional changes in particular issue areas may not be causally related to it" (Schimmelfennig and Sedelmeier, 2005: 2). When speaking of determinants and the evolution of income disparities across regions within CEE countries, they are investigated by Chapman and Meliciani (2018). One of the topics relates to analysis on levels of income inequality and poverty in CEE countries (Förster, Jesuit and Smeeding, 2003), territorial and non-territorial forms of social inequalities (Heidenreich, 2003), the relations between the level of economic growth in CEE countries and economic inequalities (Suszynska and Wojciech, 2017), territorially unbalanced growth in CEE countries because of the structural problems of old industrial regions, enormous rural areas and regions located on the EU's borders, huge differences in social, cultural and geographical characteristics, declining or stagnating regions or economic peripherality faced with negative effects of rural depopulation, "brain drain", disinvestment and unemployment and below-average levels of socio-economic well-being (Smetkowski, 2013).

Conducted research of regional development in CEE showed that the countries observed an increase in the level of regional disparities, mostly because of the rapid development of their capital city regions (Capello, 2007; Smetkowski, 2013). The level of regional disparities in gross domestic product (GDP) per capita differed from country to country. Ezcurra, Pascual and Rapu (2006) elaborated on the progress of territorial imbalances in per capita income in the CEE countries by distribution dynamics of factors such as national component, spatial location, productive structure, agglomeration economies and the percentage of GDP dedicated to investment. To reduce regional disparities, countries provide various regional policy measures. These measures mainly relate to support for new employment and investment in research and development that indirectly influences economic growth at the regional level. The EU also pursues regional and structural policies that stimulate economic growth in member states. Boldrin and Canova (2001) submit research evidence that EU regional and structural policies are intended to redistribute and have minor relationship with fostering economic growth.

Last several months we find in the literature more and more research focused on the impact of COVID-19 on health and everyday life of urban residents, measures taken by states, regions, cities, and municipalities to provide adequate living and working conditions for residents in the pandemic circumstances. It predicts more research on the environmental, socio-economic, cultural, demographic, fiscal, and financial impacts of COVID-19 on the overall development of countries, and especially the impact on regional disparities in development in CEE countries. In this research we try to provide an overview of COVID-19 impacts related to regions and regional inequalities in CEE countries by reviewing recently published literature. In addition, we intend to present some quantitative evidence on differences in regional development

in CEE countries and the impact of COVID-19 on selected indicators of social and economic development. In territorial sense, according to Römisch (2020: 3) there are big intra-country differences caused by COVID-19 related to the degree of the regions' participation in global value chains, their pattern of specialisation, their degree of urbanisation, the quality of governance and whether or not they are pandemic hotspots. Therefore, Römer (2020:4) emphasizes that Böhme and Besana construct an index measuring the regions' exposure and sensitivity to the COVID-19 crisis, creating 9 categories of the index where results in the context of regions of CEE countries were the following: the coastal Croatian as well as the Western Slovenian region are particularly vulnerable to the COVID-19 crisis. Potentially strong effects could also occur in the industrially strong regions in Czech Republic and Slovakia. By contrast, Polish and especially Hungarian regions are estimated to be relatively resilient to the pandemic. Besides, there are eleven regional characteristics particularly useful in assessing a territory's sensitivity to lockdown measures (European Committee of the Regions, 2020: 33): the share of employment in risk sectors, reliance on tourism, reliance on international trade, the share of people at risk of poverty and social exclusion, the share of youth unemployment, the share of employment in micro-enterprises, the share of self-employment, cross-border employment, regional GDP per capita, national debt, quality of government. Analysing available literature, the core of research on the impact of COVID-19 on regional level relates to several thematic areas, namely: (1) socio-economic impacts, (2) job losses and increase in unemployment, (3) restrictions in intercity travel, touristic sector, and restaurant industry, (4) culture and entertainment industry. As this implies a different research review, the first area covers topics related to different socio-economic factors which affect the current level of diversity in CEE countries and in particular the differences in development between different regions. The social consequences of the COVID-19 pandemic have been discussed in context of many countries, including CEE countries. Attention is given to negative impacts, but there are also surveys discussing positive social activities driven by the pandemic crisis. Several studies have analysed different issues caused by long-term structural inequalities.

Differences in regional development are described by numerous indicators, from differences in regional GDP per capita, economic strength index, unemployment rates, regional distribution of health care institutions and their equipment and human potential for providing necessary health care in pandemic times, differences in providing public services in culture, different level of education, environmental protection, transport connections to different fiscal capacities and the level of fiscal decentralization in individual countries. The results of all these studies can be used for post-COVID regional development planning and decrease of regional inequalities in CEE countries. Besides, not only that identifying differences is preferable, but is almost a must in detection of right path in achieving development. Having in mind that differences in identification are possible in various ways the upcoming parts of the chapter deal with analysis of differences between CEE countries – on NUTS 1 and NUTS 2 level according to development index calculation, and also of differences on NUTS 2 level of CEE countries, clustering them below EU 27 average (of 2020) according to the GDP per capita.

Generally, present experience indicates that the COVID-19 crisis can serve as an excellent opportunity for public decision makers in all CEE countries to make new strategic decisions and launch a series of measures to achieve strong, and sustainable development at regional and national level – with special emphasis on institutional, economical and social level.

3. ANALYSIS OF REGIONAL DIFFERENCES AMONG CEE COUNTRIES AND IN NUTS 2 CEE COUNTRIES LEVEL

3.1. Analysis of differences between CEEs

There is a whole constellation of differences that can be identified at various levels, after which this chapter is going to focus more on the economic ones and economic perspectives. When speaking of GDP per capita differences among CEE countries in the period 2017-2019 according to Eurostat all CEE countries GDP per inhabitant are far below EU 27 average (31.200) based on 2020 (Figure 1). According to 2019 data, there are also significant differences among CEE countries. GDP below 10.000 EUR per inhabitant is also noted, although in one among CEE countries Bulgaria (8.800); GDP from 10.000 - 20.000 is noted in most CEE countries, Romania (11.500), Croatia (13.300), Poland (13.900), Hungary (14.900), Slovakia (17.900) and above 20.000 in Czechia (21.000) and Slovenia (23.200).

Figure 1: GDP per inhabitant in chosen CEECs, 2017-2019

Source: Eurostat, Gross domestic product (GDP) at current market prices by NUTS 2 regions (online data code: NAMA_10R_2GDP), https://ec.europa.eu/eurostat/databrowser/view/NAMA_10R_2GDP_custom_874936/default/table?lang=en

Keeping in mind above mentioned data and ranks, it is obvious that most CEE countries (five out of eight) are also below CEE GDP per capita average, which for 2019 was 15.475 euro per inhabitant. On the NUTS 2 level of CEE countries according to GDP per capita for 2019 there are significant differences. If we cluster NUTS 2 into four groups, less than 10.000, from 10.000-20.000, from 20.000-30.000, above 30.000; noting that the EU 27 average (for 2020) was 31.200, there were only three NUTS 2 of CEE countries close or above this average – Praha (46.400), Budapest (30.900) and Bratislavsky kraj (39.700), while most NUTS 2 of CEE countries are in the rank of 10.000-20.000 EUR per inhabitant. There is a few NUTS 2 in the rank of 20.000-30.000, but unfortunately for some countries (f. i. Bulgaria) many of NUTS 2 are in the lowest rank, below 10.000 or, as in case of Romania, there is a similar number of NUTS 2 regions in the lowest group below 10.000 as in the rank of 10.000-20.000.

Since GDP per capita is mostly the measure used, there are obvious differences that do exist according to this indicator. However, taking into account that GDP per capita does not take into account components other than economic ones, upcoming chapter presents methodology and results of the index of regional development in the selected CEE countries.

3.2. Methodology and data

In this part of the study, we started from the assumption that among CEE countries there are differences in development at the regional level that are influenced by numerous factors. To determine the extent to which individual factors contribute to the level of development of NUTS 2 regions in the eight analysed countries, we proceeded to create our own regional development index. In the selected CEE countries – Hungary, Poland, Slovakia, Czech Republic, Croatia, Slovenia, Romania, and Bulgaria – we have measured the level of regional development in NUTS 2 regions using customized formed composite index of regional development by authors Jurlina Alibegović, Slijepčević and Šipić (2013). Index of regional development consists of two parts. The first part consists of seven regional development indicators: demographic, social, economic, educational, environmental, transport and ICT indicators. The second part of the index consists of democracy indicators: share of regional self-government budget revenues and expenditures in gross domestic product (GDP) (see Table 1).

Table 1: Structure of composite index of regional development at NUTS 2 level

Indicator	Name of variable	Source
Regional development		
Demographic indicator (ponder 10%)	Fertility rates by age and NUTS 2 region, total	EC, Eurostat, Regional statistics by NUTS classification, https://ec.europa.eu/eurostat/
Social indicators (ponder 10%)	Health personnel by NUTS 2 regions, medical doctors, per 100,000 inhabitants	
	Hospital beds by NUTS 2 regions, per 100,000 inhabitants	
Economic indicators (ponder 20%)	Long-term unemployment (12 months and more) by sex, age, educational attainment level and NUTS 2 regions, % of active population	
	Employment in technology and knowledge-intensive sectors by NUTS 2 regions and sex (from 2008 onwards, NACE Rev. 2), % of total employment	
	Gross domestic product (GDP) at current market prices by NUTS 2 regions, euro per inhabitant	
Educational indicators (ponder 10%)	Population by educational attainment level, NUTS 2 regions (%), tertiary education level, level 5-8, ISCED 2011, from 25 to 64 years	
Environmental protection indicators (ponder 10%)	Municipal waste by NUTS 2 regions - pilot project dana, waste generated, 1,000 tonnes	
Transport indicators (ponder 10%)	Stock of vehicles by category and NUTS 2 regions, all vehicles	
ICT indicators in communication between citizens and public administration (ponder 10%)	Individuals who used the internet for interaction with public authorities, % of individuals	
Democracy		
Fiscal capacity indicators (ponder 20%)	Share of local budgets revenues in GDP	IMF, Government Finance Statistics (GFS), https://data.imf.org
	Share of local budget expenditures in GDP	

Source: Authors' systematisation.

The composite index of regional development was calculated based on sub-national (regional) statistics collected by European Commission, Eurostat, Regional statistics by NUTS classification that was developed within Eurostat regions statistics²¹⁵. These databases consist of a wide variety of data for the regions and cities across Europe. To calculate the fiscal capacity of sub-national government units we used data from the Government Finance Statistics (GFS)²¹⁶ composed by the International Monetary Fund (IMF). Share of local budgets revenues and expenditures in GDP was used as a measure of fiscal capacity for sub-national government in analysed country.

In calculation of the composite index of regional development at NUTS 2 level for eight CEE countries we used the weighted procedure, where weights represent an equal portion (10 percent) of all regional development indicators, with exceptions being economic indicators (unemployment rate, tertiary educational accomplishment, and GDP per capita by NUTS 2) and democracy index. For these two groups of indicators weights were 20 percent because they have a stronger impact on the economic situation and development at regional level in a particular country. Higher unemployment at regional level has a great negative influence on existing and potential regional development. On the other hand, higher share of inhabitants with university diploma has a positive influence on development in the region. Higher share of regional self-government budget revenues and expenditures in general government revenues and expenditures as well as greater share of regional self-government budget revenues and expenditures in GDP shows a higher degree of decentralization in the country which means a potential larger influence on possible regional development.

We used the share of regional budget revenues and expenditures in GDP as indicators of democracy because these data are available for all NUTS 2 regions in eight explored countries. Based on the IMF GFS database, there are differences between countries regarding the current level of fiscal decentralization. Jurlina Alibegović, Slijepčević and Šipić (2013) clarified that a larger value of that indicator in the composite regional development index means a better difference between centralized and decentralized countries, since in more decentralized countries regional authorities exercise greater influence on decisions affecting (positively or negatively) regional development.

3.3. Results

Results of the development level of CEE countries is given in the Table 2 measured by composite index of regional development. The analysed countries are divided into three groups measured by the composite index of regional development. The first group of countries has composite index of regional development under 20 and presents countries with the lower level of regional development. Four countries are represented in this group – Bulgaria, Croatia, Slovakia,

215 <https://ec.europa.eu/eurostat/web/regions/data/database>.

216 <https://data.imf.org>.

and Slovenia. The second group of countries consists of three countries – Romania, Hungary, and Czech Republic. This is a group of countries with index of regional development between 20 and 40 and represents medium level of regional development. Poland has the highest value of regional development index (above 40) and present a country that is the most developed at the regional level.

Table 2: CEE composite regional development index

Countries grouped by the level of composite index of (regional) development	Composite index of (regional) development
Under 20	
Croatia	16.09
Bulgaria	16.39
Slovakia	18.89
Slovenia	19.15
Between 20 – 40	
Romania	21.60
Hungary	21.93
Czechia	24.39
Above 40	
Poland	41.00

Source: Authors' calculation based on Eurostat, and IMF data.

Two types of data were used to calculate the regional development index, one referring to relative amounts (percentages or shares), while the other indicates actual data in units of measure. Therefore, the regional development index at the national level for each analysed country does not indicate the sum of the indexes calculated for NUTS 2 regions in the country. Both indexes (the one at the national level and the one at NUTS 2 level) were calculated using the same weights. Data presented in the Table 3 shows ranking of NUTS 2 regions according to the regional development index. Presented data indicated that NUTS 2 regions from almost all analysed countries belong in the group of regions with low level of development measured by used data. The highest ranked regions according to the index used are three regions that comprising the capital area in Czech Republic (Praha), Hungary (Budapest) and in Slovakia (Bratislavský kraj). Praha is ranked as the first NUTS 2 region in the regional development index.

Table 3: Ranking of NUTS 2 regions according to the regional development index

CZ01 Praha	25.30

Note: The latest available data in databases were used, and did not contain changes in the number of NUTS 2 regions in Croatia. Besides, the table 3 presents ranks according to achieved score of the country, not individual NUTS 2 of a specific country, but the scores are listed. Source: Authors' calculation based on Eurostat, and IMF data.

4. CONCLUSION

Allmost all CEE countries or their NUTS 2 regions are lagging behind compared to western neighbours and their NUTS 2 regions. Keeping in mind that every crisis brings along some new circumstances economies need to deal with, CORONA-19 as a one of this centuries hardest social, health, economic and other aspects crisis, is the one that needs adequate attention. Although differences among CEE countries are evident on various levels – as well on the NUTS 2 level of CEE countries – and they have been evident even before the crisis, it is expected they are going to rise more and more in all segments. Therefore, after this crisis, it can be expected that differences on various levels will keep growing, having in mind following perspectives especially influencing territory's sensitivity to lockdown measures of COVID-19 crisis that need to be managed (according to the theoretical part mentioned in the paper): a) to take care of employment and sectors that were hit by the COVID-19 crisis and regarding special sensitive groups by appropriate active measures, b) to attempt to encourage domestic unemployed people to participate in retraining in order to encourage new products and industries, c) to engage people already hit by the poverty or that are in the group of poverty to engage in available projects, if they are able, d) to take care of the quality of public services to ensure equal access to the necessary public services and goods to all.

The most used indicator in economic sense for registering present differences is GDP, and therefore this measure was used to see the changes in the period 2017-2019. Although there is growth of GDP per inhabitant registered in mentioned time period, the differences that occur for mentioned period are evident. Having in mind that life standard and human life does not only consist of economic perspective, development index was calculated for all CEE countries. The results are not much different from the perspective given only from the GDP per inhabitant. Therefore, although economic side of life satisfaction is not the only one, it is very important in order to have opportunity to change all other aspects. Speaking of differences, development index results speak of a great differences in NUTS 2. Therefore, development index could definitely be used on NUTS 1 level and NUTS 2 level in order to consider economic and social side of certain achieved level and stage and is usually a key factor for economic policy decision makers.

ASSESSING TRANSPORT ACCESSIBILITY OF ISLANDS FOR ECONOMIC RESILIENCE: EMPIRICAL FINDINGS FROM CROATIAN ISLANDS

Vinko Muštra, Josip Grgić, Blanka Šimundić

Faculty of Economics, Business and Tourism, University of Split, Croatia

ABSTRACT

Great volatility and uncertainty during last decades has been characterized by highly heterogeneous territorial impacts and promoting the resilience concept for understanding the factors behind these fluctuations.

Most of the studies have been driven by dominant narrative of urban economics and focusing and promoting large and dynamic metropolitan areas. However, recent studies underlined lack of urban dominance over rural regions; especially during periods of crisis (Giannakis. & Bruggeman, 2019).

While transport infrastructure and accessibility can contribute to production of heterogeneous socio-economic effects among territories (Van Wee, 2016; Guzman et al, 2017), past studies have given almost no attention to the role of transportation accessibility on building resilient regional economy (Chacon-Hurtado et al, 2020). This has been especially the case for spatial units heavily defined by transport accessibility - islands. (Karampela et al, 2014). Under the discontinuous space context, constraints of scale economies, micro-climate, and spatial reach of networks, accessibility has unique role for the island communities (Karampela et al, 2014; Birgilito et al, 2018).

In this paper, we fill this gap by exploring the relationship between regional resilience and the degree of transportation accessibility for the islands. By focusing on the resistance and recovery phase of resilience among islands in Croatia in period 2007-2017, we provide profound foundation for development and policy discussion.

Our empirical findings indicate higher level of resilience for less isolated islands, especially as a result of faster recovery after economic downturns. However, degree of transportation accessibility doesn't play important role for resistance among our spatial units.

Finally, study provide clear insights for policy makers in delivering more effective development policy measures during turbulent periods for unique spatial units – islands.

DUTCH DISEASE AND RESILIENCE – THE CASE OF CROATIA

[Josip Viskovic](#)

Faculty of Economics, Business and Tourism, Croatia

ABSTRACT

The concept of the Dutch disease was for the first time used by "The Economist" in 1977 to describe the sharp rise in wealth in the Netherlands during the 1960s caused by the discovery of large gas reserves. After the discovery, there were negative effects on the Dutch production, mainly through the subsequent appreciation of the real exchange rate. Namely, as the revenue from exports rose, Dutch guilder appreciates having detrimental effect on other industries. Similarly, the rapid growth of the tourism sector can have possible negative effects as well. The availability of natural resources (such as national parks, nature parks, beaches, sunshine hours etc.) becomes a comparative advantage of the tourist product with subsequent specialization in tourism, neglecting other sectors with all the negative aspects such as real appreciation of domestic currency (decline in competitiveness), low growth rates of the industrial production, artificially high real wages, reallocation of production factors from tradable to non-tradable sector, the drop in the relative productivity of the tradable sector and similar. Such a scenario is possible to be seen in coastal part of Croatia and therefore the aim of this paper is to research possible indications of Dutch disease in Adriatic region of Croatia on the county level. Moreover, the aim is to scrutinize resilience power of those counties, especially in the context of current COVID-19 pandemic situation. Results of the paper should provide valuable information to policy makers whether there is a need to take a necessary policy decisions with the aim of managing negative consequences timely and preventing slower economic growth in the future.

THE ROLE OF POLICY SUPPORT IN THE DEVELOPMENT OF REGIONAL HEALTH TOURISM – THE STATE OF THE ART IN CROATIAN REGIONS

Blanka Šimundić, Kordić Lana

University of Split, Faculty of Economics, Business and Tourism, Croatia

ABSTRACT

The changes in lifestyles of modern travellers (globalization, less free time, more stress, etc.) have induced the rise in the health tourism demand globally (Hall, 2011). A new concept in the tourism sector regarding health tourism development is present in the last decade (Connell 2011). This concept relates to active promotion of health tourism on national level and to high national support through the development of health tourism infrastructures and policies (Mainil et al., 2017). The rationale behind this support is in perception of health tourism as a generator of regional economic growth (European Union, 2016). According to Mainil et al. (2017) health tourism supports development of quality value-added products and services in a destination by mobilizing specific local resources and by contributing to smart regional specialization. Hence, health tourism helps diversification of tourism products, reduces seasonality and vulnerability of a destination in general and in times of crisis when reduction in general tourism demand occurs.

The purpose of this research is to analyze whether the improvement in national policies induces the rise in the efficiency of health tourism services providers in Croatia. More precisely, the panel DEA was used to analyze the relative technical efficiency of the providers of health tourism services, special hospitals and natural spas, in Croatia. The analysis is performed for 8-year period. The results indicate that in the analyzed period, due to the innovation in services, the shift in efficiency level and in efficiency frontier is achieved. Furthermore, by analyzing all of the Malmquist index components, results reveal that special hospitals and natural spas in Continental Croatia have achieved better results in term of technical efficiency, in relation to those in Adriatic Croatia. Knowing that the rise of efficiency of health care facilities can be brought by supportive actions of public and private sector, the study indicates that the national health-tourism policies are more favourable for special hospitals and natural spas in Continental Croatia. Moreover, it can be concluded that present economic policy is actively meeting and responding to multiple challenges the health care infrastructure is facing, which influences the reduction on regional disparities and vulnerabilities in Croatia.

REORIENTATION AS A TOOL FOR RECOVERY: ANALYSIS OF REGIONAL ECONOMIC RESILIENCE IN CROATIAN NUTS 3 REGIONS

Zvonimir Kuliš¹, Bernarda Kuliš^{2,3}

¹University of Split, Faculty of Economics, Business and Tourism, Croatia. ²Aspira University College – Split, Croatia.

³Regional Development Agency of Split-Dalmatia County, Croatia

ABSTRACT

Recently, since the 2010s, regional economic resilience has been a specific interest of the researchers' focus. Among many, one of the pioneer, yet most comprehensive definitions was offered by Martin in his research from 2012 when he explained that regional economic resilience could be viewed through the capacity of a regional economy to reconfigure, that is adapt, its structure (firms, industries, technologies, and institutions) to maintain an acceptable growth path in output, employment, and wealth over time. In the same research, Martin identified four dimensions of the regional economic resilience: i) resistance (the vulnerability or sensitivity of a regional economy to external shocks, for example, recession), ii) recovery (speed and degree of recovery from such shocks), iii) reorientation (the degree to which the regional economy goes through structural changes and adjusts after the shock), iv) renewal (continuation of the growth path of the regional economy before the shock).

Following Martin's division of the resilience's dimensions, this paper focuses on reorientation and recovery. Precisely, it aims to investigate if reorientation affects the recovery in Croatian NUTS 3 regions. As noticed by Đokić, Fröhlich, and Rašić Bakarić in their research from 2016, the latest global financial crisis harmed Croatian national and regional development and led to significant regional disparities. This paper analyzes recovery and reorientation in Croatian NUTS 3 regions and sets up the model to investigate the impact of reorientation on the recovery process in Croatian NUTS 3 regions. In the context of resilience, recovery has been proxied by many authors (for example Romão in 2020, Muštra, Šimundić and Kuliš in 2020, Giannakis and Bruggeman in 2017 and 2020). The possible indicator could be the ratio of the values of the employment change in the year (or years) of the economic recovery period and the starting year of the crisis period. On the other side, the indicator for reorientation can be calculated following the example of the research performed by Ženka, Pavlík and Slach in 2017 as Finger-Kreinin index of structural shifts in employment (or possibly in GVA).

Data will be collected from Croatian Bureau of Statistics (CBS) for a period of ten years (2009-2018). The analysis is based on a panel data approach. The dynamic panel data model is formed to estimate the effects of regional reorientation on the recovery in 21 Croatian NUTS 3 regions. The model is tested using standard diagnostic tests for dynamic panel data analysis. Results are expected to show the positive impact of reorientation on recovery in Croatian NUTS 3 regions. Furthermore, the descriptive analysis made in the paper identifies the best performing regions and best performing sectors. Empirical conclusion alongside descriptive analysis offers valuable insight for policymakers: the reorientation, including key structural changes, as a tool for regional recovery. Those findings are of big importance considering the latest global crisis due to the coronavirus pandemic. Finally, this paper is one of the rare attempts which investigates regional economic resilience in Croatian regions.

National Session: SS65 - Urban Neighborhoods: Accessibility, Segregation, and Neighborhood Change

**ARE HISTORIC DISTRICTS A BACKDOOR FOR SEGREGATION? YES AND
NO**

Jamie Bologna Pavlik¹, Yang Zhou²

¹Texas Tech University, USA. ²University of North Texas, USA

ABSTRACT

Historic districts preserve the heritage of designated areas and attract tourism income. However, these districts also come with restrictions and increased housing prices that could cause segregation. We study how two historic district programs impact residential segregation in Denver. We find that homebuyers are more likely to be White within historic districts, but that the official historic designation has no effect on this probability. Similarly, we find that most transactions flow from White sellers to White buyers, regardless of official designation. Thus, while historic districts tend to be more segregated, official designation does not seem to amplify this existing problem.

PREDICTING NEIGHBORHOOD CHANGE: CHALLENGES, OPPORTUNITIES, AND POSSIBLE NEW DIRECTIONS

[Isabelle Nilsson](#), [Elizabeth Delmelle](#)

University of North Carolina at Charlotte, USA

ABSTRACT

Gentrification and back to the city movements has gained traction in cities across the United States over the past several decades. However, recent disruptive events such as the COVID-19 pandemic may have changed residential location preferences and subsequently altered the neighborhood change process. These shifting geographies can have important consequences for people's lives and is continuing to challenge long-term plans and investments of planners and local policy makers. Hence, understanding and predicting shifting residential sorting patterns and subsequent neighborhood outcomes has become increasingly important. In this paper, we review the current state of knowledge on predicting neighborhood change and stability. This is followed by a discussion of methodological and data challenges and opportunities in predicting neighborhood change. Finally, we present a new approach based on text and attribute data from property advertisements and publicly available, frequently updated mortgage application data. The usefulness of this method is demonstrated in a case study on Charlotte, North Carolina, a rapidly growing city in the southeastern United States. We begin by classifying neighborhoods into five classes of neighborhoods based on who is applying for mortgages in the neighborhood. We then use machine-learning techniques and information from property advertisements to predict the racial and socioeconomic composition of mortgage applicants at the neighborhood scale. We examine common words used to market different types of neighborhoods and the relative importance of various terms in discriminating neighborhood types. Despite the small sample, we are able to achieve relatively high predictive power. We are also able to show that the inclusion of neighborhood and street names increased the predictive strength, especially in the case of white and higher-income neighborhoods where highly regarded neighborhoods are marketed more heavily. We end the paper by discussing the potential and limitations of these data sources and methods in predicting neighborhood change. As a proof of concept, the blending of these two datasets proves effective in identifying currently gentrifying neighborhoods and show promise for revealing urban dynamics in more real time than relying on retrospective census surveys.

DOES RIDESOURCING PROVIDE EQUITABLE ACCESSIBILITY?

[Sicheng Wang](#)

Rutgers, the State University of New Jersey, USA

ABSTRACT

In this study, we conduct a comprehensive evaluation of the accessibility offered by ridesourcing services. We measure ridesourcing accessibility by applying gravity-based metrics that include the attractiveness and travel impedance factors. We use transportation network providers' data for Chicago to calculate the average travel times between origins and destinations for ridesourcing trips. Travel impedance factors are computed based on the real travel times. Both the employment volume by sector and points of interest locations are used to measure the opportunity attractiveness. We estimate accessibility for three types of non-work destinations: healthcare facilities, restaurants, and grocery stores, and compare the accessibility between ridesourcing and transit. Given the presence of spatial autocorrelation in our data, we estimate both ordinary least squares regression models and spatial autoregressive models to examine the associations between ridesourcing accessibility and census tract-level demographic and socioeconomic indicators. We find that ridesourcing has a less equitable distribution compared to transit, based on the median household income of census tracts and minority populations. Ridesourcing accessibility is also negatively associated with the percentages of three age groups (0 - 5, 6 - 17, and 65 plus) but positively associated with the percentage of zero-vehicle households. These results provide guidance for policy makers on the inequities associated with new mobility options and how best to offer improved accessibility for disadvantaged populations.

THE IMPORTANCE OF DESIGN AS A CREATIVE PROCESS IN BUSINESS SCHOOLS: HOW TO FILL THE DESIGN/BUSINESS KNOWLEDGE AND COMMUNICATION GAP?

[Isabel de Almeida](#)

CIAUD, ISCTE-IUL, Portugal. Lusiada University, Portugal

ABSTRACT

In most Business Schools (BS), Design in business education plays a minimal role. It is neither part of the core basic learning courses nor part of the electives. No courses in design, corporate identity, graphic design, communication design, environmental design, or product design were found in this study. When business students are enrolled in design principles, they learn it loosely, as part of new product development or entrepreneurship classes. Business teachers simply assume that when corporate design decision-making is needed, the managers will simply ask a designer. However, designers are not educated in business and business managers are not educated in design. Without design in the curriculum, BS is far away from the real business world. Therefore, why BS does not change the curriculum to meet the real business-world needs? The current study addresses the (i) perceptions of business education and training experts; (ii) accreditation and curriculum requirements; and (iii) scientific journal articles, books on current standards and processes in business education. The curriculum specifications for business programs are generally established by the International Association for Management Education (AACSB). Our results reveal that the AACSB demanding: the business curriculum should include "accounting, economics, mathematics, statistics and behavioural science" alongside "basic written and oral communication skills and quantitative analysis". No mention of design or quality analysis is done. Moreover, the specific content of the course does not matter for the accreditation process. Instead, the business programs evaluation is performed following their goals. Design and design management were not mentioned when comparing goals and curricula from several Portuguese business schools. In our research, when business teachers were questioned about the hypothesis of curriculum changing, one of the most cited answers was that 'Someone should have a vision. If there is no leader, nothing will happen' However, to develop non-traditional curricula, it requires efforts from all, and several faculty members, particularly the teachers, are overstretched. Likewise, it is much easier to teach the same subject multiple times. We conclude that the teacher's passion for design must be sufficiently robust to drive change. But, in another hand, the business students must demonstrate curiosity and willingness to engage. When a new course is introduced in a traditional curriculum it will be appreciated, and the first criterion is the extent of demand for it. An average of 30 students must enrol. The second is concerning the professor and the new course must be well taught. If both conditions are met, they can continue. But the new and real-world-touching courses are always introduced as electives, and students put a lower priority on electives than on core needs - the compulsory courses. As a result, what needs to be done to overcome the curriculum stalemate, the priority of the students, and the burnout of the faculty members? What could cause business schools to change? What would make possible the inclusion of design in Business curricula, despite the above- mentioned obstacles? The present work is a search for adequate answers.

CITIZENS CO-PRODUCTION IN URBAN INNOVATION: CRITICAL PERFORMANCE FACTORS

[Marina Geenhuizen](#)

Delft University of Technology, Fac. Technology, Policy and Management, Netherlands

ABSTRACT

Urban places that facilitate experimentation and innovation in urban sustainability solutions, are quickly increasing in number in Europe today. Such places are strongly needed given rigidity of the socio-technical systems involved and complexity in multi-stakeholder situations. Which factors are critical in their performance, however, are hardly known. First, we address transitions in socio-technical systems and potentials of experimentation in so-called protected places or 'niches'. Secondly, to improve understanding of these places, the core concept of 'citizens co- production' in innovation is discussed, as it has developed on the basis of various societal trends, for example, emphasizing that users are important sources of innovation (user-centered innovation) and emphasizing the larger societal role of universities and democratization of science. Next, derived from literature and case study analysis, a set of critical performance factors of these initiatives, is designed and discussed. We divide them into factors concerning stakeholders involved and factors concerning the solution. This is followed by an illustration with three types of urban projects, namely, citizen science, living labs and technology incubation. The sectors involved in our analysis are sustainable energy and sustainable (inclusive) healthcare. All in all, experimentation is needed to identify whether the solution works (solves problems) on a larger scale and real-life setting/time, matches with different urban context, matches with specific user needs and viable business models, can deal with restrictions from regulation, standards etc., and contributes to a wider transition in cities.

E-COMMERCE IN SOUTH AFRICA: BUSINESS PRACTICES IN CUSTOMER ACQUISITION AND RETENTION

[Thebe Magapa](#)¹, [Adee Athiyaman](#)²

¹Vaal University of Technology, South Africa. thebem@vut.ac.za; ²Western Illinois University, USA, athiyaman@wiu.edu

ABSTRACT

Internet reaches 57% of SA's population, a sizeable number for the continent. This has influenced businesses to use the Internet for customer acquisition and retention, but research suggests that issues such as privacy and trust are preventing the rapid spread of e-commerce in the nation. To overcome customer's privacy concerns, businesses provide policy statements indicating how customer's personal information will be used for business purposes. However, comprehending the legal language of the privacy policy makes it a difficult task for the customer. The consequence, 71% of the customers do not complete web forms and provide the needed information for e-commerce transactions.

It is the argument of this paper that behavioural economics principles would help in designing web-form that would facilitate customer engagement with businesses, overcome trust issues; the premises of the argument, BE principles and contextual influences relevant for web-form completion are highlighted.

KEYWORDS

Marketing, Nudges, Permission

1. INTRODUCTION

The battle for customer acquisition and retention has resulted in a plethora of marketing messages, a lot of clutter has ensued. To differentiate themselves, companies are finding innovative ways to communicate, acquire, and retain customers. Online permission-based marketing (OPBM) is one of these avenues; it enables firms to target customers with tailored marketing communications (Godin 1999). Personal information collected using a web-form is often used to tailor content of the message to the customer; personalized marketing communications have a greater likelihood of being processed (Terres, Klumpe, Jung & Koch 2019:4;).

In general, time constraints could prevent the customer from filling out the web-form or opt-in to the marketer's communication. It is the argument of this paper that registration costs, including time spent by the customer in filling out the web-form, could be minimised using behavioural economics tactics such as heuristics, message framing and anchoring as well as default options. While qualitative discussions on how nudges can assist in overcoming customer's privacy concerns exist (see for example, Acquisti et al (2017:20), little or no research has been directed to design and test these nudges in an empirical setting. This research is an initial attempt in filling this gap in knowledge.

2. LITERATURE REVIEW

Today's interconnected networks of computers provide companies great opportunities to interact with customers. The interaction requires that a customer accepts a firm's invitation to receive messages at a specified time, frequency and communication channel (Kiran & Kishore 2013:115; Chaffey & Ellis-Chadwick 2016:313). Privacy concerns and beliefs such as that the communication will be intrusive are found to prevent customers from engaging with the business online (Krafft, Arden & Verhoef 2017:50).

To overcome customers' privacy concerns, businesses often provide a privacy policy link for customers to read about the intended use of their shared personal information. However, comprehending the legal language of the policy makes it a difficult task for the customer (Zimmer, Arsal, Al-Marzoug, Moore & Grove 2010:397; Martin, Borah & Palmatier 2017:21). This is where behavioural economics (BE) could help.

Economics is a science which studies relationship between ends and scarce means (Williams, Liu, Muir & Waxman 2018:178). Classical economic theory is premised on the notion that individuals are rational agents following their own interests in making decisions between these ends and scarce means. However, BE argue that individual behaviour deviates from normative principles of economic behaviour; people in general don't process lots of information before they make decisions as such they rely on mental shortcuts or heuristics for decision making (Thaler 2017:767).

BE recognizes individuals' cognitive biases in making decisions; for example, that individuals tend to discount the value of far-off loss at the expense of immediate rewards (Guthrie 2017:701). In business, 'nudges' are used to guide these decisions toward immediate rewards. A nudge is defined as "any aspect of choice architecture that alters the customer's behaviour in a predictable way without forbidding any options or significantly changing their economic incentives" (Thaler 2017:17). For example, customers can be nudged to opt-in to business's OPBM by discounting the fear of privacy invasion (a long-term problem) for the immediate benefit of receiving new product information, for example (Berg 2014:223).

Xu, Dinev, Smith & Hart (2011:812) experimented with heuristics (third-party approval) and observed positive customer responses. Xu et al 2011:812 demonstrated that when third party seal of approval (logo) is displayed, respondents shared their personal information with an intention to receive marketing communications. Other studies have successfully used BE principles to influence individuals to engage in fitness-related activities and reduce hospital claims (Lambert, da Silva, Patel, Fatti, Kolbe-Alexander, Noach, Nossel, Derman & Gaziano 2009: 6), reduce water usage, reduce electricity consumption, and change driver behaviour to reduce accident claims (Guszcza & Portillo 2015:66). BE principles have also been influential in steering one's behaviour toward a certain goal. For example, Hou (2017:210) demonstrated how technology-interface cues influenced customer's food ordering amounts from an online food ordering website. A combination of default and anchoring nudges on credit card repayment was found to have increased the minimum repayment amount among customers (Key & Wang 2014:17). Also framing prices as gains, for example, three items for the price of two, were found to have increased product purchases among customers (Berg 2014:226; Welch 2010:1). An investigation nudging household water conservation used households' social norms and financial savings as frames and the results reduced water consumption levels among households by 1.5 percent (Brent, Lott, Taylor, Cook, Rollins & Stoddard 2016:29).

In summary, the principles of BE that inform web-form design suggest:

- (i) displaying third party privacy seal of approval simplify customer decision making when faced with the question of personal information disclosure and permission granting – principle of heuristics.
- (ii) Purchase options can be framed either as a gain or loss for the customer. In general, customers can be influenced about their product choice by framing marketing communications in a positive way (David & List 2015:388) – principle for framing messages.
- (iii) Individuals place higher value for their tangible possessions, for more than what they are worth at the marketplace (endowment effect). This is one reason for customer unwillingness to share personal information. The endowment effect could be overcome by anchoring a positive statement which the customer can use a reference point to adjust behaviour by sharing personal information and opt-in (Strack & Mussweiler 1997:440)-principle of anchoring.
- (iv) As mentioned earlier, privacy policies are ineffective because they are hard to read (full of technical jargon) and lengthy (Madden et al 2013:30). These problems have resulted in development of privacy nudges (Wang et al 2013:15). De-coupling privacy policy into short statements and setting them as default, opt-in agreements are tactics related to the principle of nudges.

Given the above principles of BE and the efficiency of nudges in the previous studies, we posit that web-form interface designed with principles of BE could influence customer to share personal information and opt-in to OPBM (Krebs 2013:2; Szaszi, Palinkas, Palfi, Szollosi & Aczel. 2018:355). A web-form, when deployed ethically, should elicit positive customer responses, for example, positive attitude towards the marketer. However, research suggests that most web-forms in use today on the African continent deter positive customer responses (da Veiga, 2018: 350). To elicit positive responses, web-forms need to be developed, incorporating BE principles of nudges (Krebs 2013:2). Since Africans are no different from other nationalities in terms of privacy concerns (Pelteret & Ophoff 2016: 280; Tshiani & Tanner 2018: 65), the following hypotheses are presented.

3. THEOREMS

Attitude toward online advertisements is negative in SA (Worku, Shitamin, Mebrate & Andaregie 2020:9); privacy issues of control are perceived important for South Africans (Beneke 2015:12). The online behaviours of most South African can be segmented into two groups: privacy pragmatists and privacy fundamentalists. Privacy pragmatists believe in privacy as a right, whereas privacy fundamentalists believe in privacy as a right and personal responsibility (Ponciano, Barbosa, Brasileiro, Brito & Andrade 2017:5). The members of these groups are typically aged between 18-34 years, an age group that is economically active and an important for online business (Ponciano et al 2017: 6).

To address the privacy concerns of the groups, established BE principles such as nudges and endowment effect can be used. Thus,

Theorem: For Privacy groups, to share personal information and grant permission to engage with the marketer online, salience of heuristics, framing of positive popup message, anchoring of a gain statement, and decoupling and default of privacy policy and opt-in options are pre-requisites. It is necessary to define these constructs before we hypothesize. Table 1 below provide definition of each construct with an example.

Table 1: Nudges

Nudges	Definitions	Examples
Heuristics	A stimulus such as a trust symbol used to provide positive reinforcement for customer behaviour.	
Defaults	Pre-selecting options by setting default choices on the assumption that the customer will accept the defaults.	<input checked="" type="checkbox"/> I consent to receiving communication for marketing activities. <input checked="" type="checkbox"/> I consent to profiling activities. <input checked="" type="checkbox"/> I consent to receiving communication from third parties for marketing activities.
Framing	An act of designing a decision frame in a way that influences an individual's behaviour to respond in a positive.	"Saves 200 lives" sounds better than "400 people will die".
Anchoring	A deliberate presentation of certain information to serve as a reference point to ease the burden of decision making.	"Most customers benefited from our services by sharing biographical information".
De-coupling	Simplification of information considered to be time consuming and difficult to read and comprehend in a short period of time.	I consent to receiving communication for marketing activities. I consent to profiling activities. I consent to receiving communication from third parties for marketing activities.

Source: Adapted from Weinmann, Schneider & Vom Broke (2016: 433-436); Acquisti, Adjerid, Balebako, Brandimarte, Cranor, Komanduri, Leon, Sadeh, Sleeper, Wang & Wilson (2017:41); Eigenbrod & Janson (2018:6).

4. HYPOTHESES

4.1 Heuristics

On-screen opt-in decisions require a customer to make judgments, decisions and choices about uncertain future events. Heuristics assist in ensuring a customer make appropriate choice decisions (Acquisti, Adjerid, Balebako, Brandimarte, Cranor, Komanduri, Leon, Sadeh, Sleeper, Eigenbrod & Janson 2017:5). For example, the impact of store atmospherics, specifically ambient scent, colour and imagery, were found to act as primes to nudge shoppers to healthier food purchasing within a supermarket context (Phillips 2017:173). Online usage of contextual clues-heuristics is demonstrated by Wang et al. (2014:2368); in their study, nudges on Facebook were used to remind users about the audiences for their post (showing five profile pictures-nudge). The study found the nudges to be beneficial for Facebook users, especially for the users who post personal thoughts (Wang et al 2014:2374). Generalizing these findings to the present study suggests that:

H1. *The display of a third-party seal of approval on a web-form will facilitate opt-in to online permission-based marketing.*

4.2 Framing

Businesses frame communication messages to nudge customers to make positive choices. Huber, Jung, Schaule & Weinhardt (2019:5) posit framing as a "conscious formulation and description of the decision situation" with the goal of encouraging customers to act in a certain way. For example, a social framing 'nudge' to steer website visitors to accept a cookie may be framed by stating "majority of users like the visitor had accepted the cookie" (Coventry, Jeske, Blythe, Turland & Briggs 2016:6). Framing of consent options has shown a significant impact on customer privacy choices (Hermstruwer 2017:19). Bertrand, Karlan, Mullainathan, Shafir & Zinman (2010:302) studied the usage of framing advertising content. Bertrand et al (2010:286) framed a direct mail flyer for a short-term loan advertisement by stating "A special rate for you", "A low rate for you", and the advertisement had a two week deadline for clients to respond. The study found advertising content had a statistically significant effect on short-term loan take-up among South Africans. Framing a request as a gain seem to result in positive response than a negative frame. This makes framing effects most effective when combined with a default, pre-checked box after the frame statement. For example, a customer can be presented with a positive choice frame like "I would like to benefit from tailored communication messages ". A statement framed as a 'gain' will influence the customer to try to not lose that gain (Hermstruwer 2017:20). This study posits that framing will increase customer opt-in.

H2. *Framing a statement as a gain for the customer will increase customer opt-ins to OPBM.*

4.3 Anchoring

Contextual cues influence individuals' behaviours in making decisions. Customers are found to use the first available information as a reference point to decide on the next presented choices (Acquisti et al 2017:7). This reliance on

presented information is labelled ‘anchoring’. Acquisti et al. (2017:18) study found that online customers disclosed sensitive information such as home address when it was stated that other customers have provided such information. Hou (2017:202) conducted a field study to test the impact of anchoring-heuristic cues on a food-ordering website. An anchoring-heuristic was implemented by showing participants the “average number of cookie other users ordered”; participants ordered less food when a low starting anchoring cue was set up (Hou 2017:209). The importance of anchors in eliciting positive customer responses is further illustrated by Keys and Wang’s (2014:18) study that used two anchoring statements for credit card customers. Customers were sent two different anchoring statements of “Late payment warning” stating that the customer will incur a penalty of \$35 for late payment”, and another statement with the caption “minimum payment warning” which stated that the customer will pay less in interest and pay off balance sooner. As expected by the researchers, credit card customers paid more than the minimum before the due date. Hence:

H3. *Utilising anchoring tactics in the web-form will increase customers to opt-in to OPBM.*

4.4 De-coupling of privacy statement

Typically, an online customer has little or no time to click and read privacy statements and thoroughly analyse every bit of information. Often, a business’s privacy policy is clouded by semantics legal jargon and lengthy statements, hidden behind a website link; thus, rendering the intended objective of privacy statements ineffective (Barth 2008:75). De-coupling the privacy statement into subsets for customers can assist the customer in processing the information quickly (Hermstruwer 2017:21). Hence:

H4. *Displaying of de-coupled privacy statements will influence customers to opt-in to OPBM.*

4.5 Defaults

The use of de-coupled privacy statements is important but not enough for a time-pressed customer to act on an opt-in request such a web-form. Displaying de-coupled privacy statements with an activated default has proved successful in eliciting positive response (Ghesla, Grieder & Schmitz 2019:10). Activated defaults reduce cognitive efforts of having to manually choose to opt-in to different options (Wroblewski 2008:239). In one study, more than double the number of people approved pro-social giving compared to the no default option (Ghesla et al. 2019:10). Since defaults simplify customers’ cognitive effort, the following hypothesis is stated:

H5. *Activated opt-in defaults on decoupled privacy statements of a web-form will increase the number of customers opting-in to the OPBM.*

The above hypotheses are proposed as a guideline to design a web-form employing behavioural economics principles of nudges. It is not the intention of this paper to test the hypotheses, but to put BE principles of nudges in a practical way. Below we explain the web-form example design on where and how the nudges have been incorporated.

5. PROPOSED WEB-FORM DESIGN

The web-form given below, designed using BE principles, will be field tested for effectiveness in influencing potential customers to share their personal information and opt-in to OPBM. Top left is display of third-party seal of approval is the heuristics nudge; followed by a frame nudge in the form of a popup message when the individual is about to make a selection of his/her preferred medium of communication to steer him/her to provide an e-mail address above all other choices. An anchor nudge is highlighted in red colour to nudge potential customers to share a WhatsApp number or cell number to avoid missed messages. Business’ privacy policy has been decoupled into three short statements and default is the opt-in to OPBM.

6. SUMMARY AND CONCLUSION

The internet enables businesses to collect customer information for personalization purposes, but customers believe that data collection instrument, most often a web-form, is insecure in its current design. Seventy one percent of the customers do not complete web forms and provide the needed information for e-commerce transactions. Privacy concerns, registration efforts, and the customer's belief that the communication will be intrusive are often used to explain customer's negative behaviours to engaging with the business online. This research proposes application of behavioural economics principles on a web-form.

It is essential for e-commerce businesses to engage in ways in which they are perceived to be preserving potential customers privacy rights and freedom while encouraging them to opt-in to OPBM. Unless online businesses employ nudges on web-forms, there will be little to no return on investment.

ANALYSIS OF NON-TECHNICAL INNOVATION, KNOWLEDGE PRODUCTION AND PROXIMITY THEORY IN THE SUCCESS OF TURKISH SERIES

Eser Çapik, Murat Ali Dulupçu

Süleyman Demirel University, Faculty of Economics and Administrative Sciences, Turkey, esercapik@hotmail.com,
muratdulupcu@sdu.edu.tr

ABSTRACT

For TV series exports, Turkey was in second place after the United States in 2018. Turkey's exports were 350 million \$ while it was only 10 million \$ in 2008 (AA, 2018).

In addition to factors such as content structure, type, star cast, high budget, creative and innovative perspective, the feedback provided by the audience through various network tools such as social media was also determinant in this success (García, 2016). Cultural, geographical, cognitive, and technological proximity types have been effective in the creation of information in this process where information dissemination is effective (Boschma, 2005). Especially in geographical proximity, it plays an important role in information sharing, transfer, and technological development (Huber, 2012) and the main point here is tacit knowledge (Gertler, 2003).

The TV series sector in Turkey brings the question of the effect of non-technical innovation to this success to the mind. In this study, different from previous studies, the role of non-technical innovation (marketing and organizational innovations) (OECD et al., 2006) in the success of Turkish TV series will be estimated within the framework of a probit model (Long & Freese, 2001) within the scope of knowledge production and proximity theories.

The dependent variable is a dummy indicating if the series is exported or not. The explanatory variables are IMDB score, type of series, a dummy for the director representing tacit knowledge, a dummy indicating the type of scenario, the distance between Turkey and the top importer representing the geographical proximity, and the number of influencer comments as an indicator of non-technical innovation.

The empirical results indicate that non-technical innovation, tacit knowledge, and product innovation increase the probability of export of a series while the distance has a negative impact.

SMART SUSTAINABLE SATELLITE CITIES: THE DAISY FLOWER CONCEPT

Faisal Awadallah

American University of Sharjah, UAE. Birzeit University, Palestine

ABSTRACT

This paper provides an overview of the alarming urban traffic congestions, which is an international phenomenon. It studies the effects of urban congestion on travel delay, air pollution, energy consumption, and general cost for government agencies and the individual traveler. In addition, to the effect of urban congestion on city development and general quality of life. The paper addresses various urban planning and transportation options to reduce motorized traffic congestion, particularly, reduction of the number and duration of vehicular trips in order to achieve a sustainable urban transport system. The paper analyzes the various environmental concerns that result from the various modes of transportation, especially during traffic congestion. It stresses the positive significance of walking, bicycling, and increasing the reliance on public transport, and making it more affordable and attractive for commuters. Smart cities are not particularly renowned for technological advancement. Viable technological advancement moves rapidly to all cities; however, a smart city is a sustainable, environmentally friendly and provides an overall good quality of life. Smart cities are mainly achieved through appropriate land use mixtures and appropriate transportation facilities that encourage walking and bicycling and limit usage of the private auto. An urban planning concept of a new satellite city is introduced using the "Daisy concept". In this concept, an urban satellite city is inspired from a daisy flower, where a flower's petals represent the mix land uses that provide for most daily activities of a household. The center of a daisy flower represents the satellite's city central business district, which is connected to the major urban center and major airport via commuter rail. The Daisy concept outlines conceptual plans for mixed land use clusters (petals) connected to the satellite city center. The residences within the clusters are within walking distance to employment offices, schools, light shopping, and recreation. The daisy concept emphasizes walking bicycling facilities particular sufficient width sidewalks, which include designed areas for walking and for bicycles. While the center of each residential 'petal' has employment offices and light commercial areas with wide sidewalks that also include street furniture, such as café' seating areas. In addition, at the daisy city center, it is pedestrian only streets with provisions for off-street parking along the circumferential road surrounding the core of the satellite city. Environmentally friendly trams that do not have overhead cable (having ground protected power lines) to avoid visual pollution are envisioned. Public transit policy and pricing would highly encourage usage, especially when coupled with providing sufficient parking spaces and drop-off and pick-up locations for employees coming from outside satellite city; in addition to parking regulations for residents that encourage auto sharing and renting and limit usage of private auto within the daisy city. Planning is a key issue in introducing smart cities, but policy, citizen awareness campaigns, regulations and enforcement are all essential in making smart cities functional and sustainable.

SPATIAL EQUITY IN CONTEXT: PERCEPTIONS AND PREFERENCES IN THE PLANNING OF PRIMARY SCHOOLS

[Ian Wolf](#), [João Lourenço Marques](#), [Fillipe Feitosa](#)

Research Unit on Governance, Competitiveness and Public Policies (GOVCOPP) of the University of Aveiro, Portugal

ABSTRACT

Equity has long been considered and overarching policy goal in spatial planning, where it expresses the idea of justice in the management of property rights, the distribution of public resources or the location of spatial amenities and disamenities. While there is a broad consensus regarding the importance of equity in planning decisions, there are multiple challenges in defining its meaning in practice. These challenges are, partly, conceptual and regard the principles that best express a broad idea of justice, their formulation, or how to prioritize them when they conflict, leading to an extensive debate in the literature (where authors such as Rawls or Amartya Sen stand out). But even if assuming a given set of principles, this does not automatically provide a clear way for assessing the justice of planning decisions, which tend to be the outcome of broad compromises between policy goals and interests, and reflect practical considerations, which are very dependent on the specific policy and context. There are, therefore, no simple answers to questions such as: What criteria best express equity in a given planning decision? How to consider, and weight, different groups' advantages or disadvantages? What are the relevant thresholds for considering a state-of-affair equitable or inequitable? This stresses the relevance of discussing spatial equity in real planning contexts and the importance of taking into account the conceptions and preferences of local stakeholders and decision-makers. This work contributes to this discussion by analyzing principles of spatial equity in the accessibility to primary schools at the local scale. For this, first, a conceptual discussion of principles of justice and the way they can be applied to inequalities in the accessibility to spatial services was made. Second, a questionnaire was applied to territorial agents involved in a school planning exercise in a municipality in Portugal. This allowed to assess: what these agents consider to be the most relevant policy goals for the spatial planning of primary schools; what is the relative importance of spatial equity compared to other policy goals; what specific principles best express equity in the spatial distribution of primary schools. Third, an exploratory digital tool was applied to evaluate the agents' preferences regarding the balance between accessibility and costs – how are cost-minimizing and accessibility-maximizing solutions ranked in a pair-wise comparison.

DO REGIONAL ENTREPRENEURIAL ECOSYSTEMS ALWAYS CONTRIBUTE TO REGIONAL ECONOMIC PERFORMANCE?

Sebastien Bourdin

EM Normandie Business School, France

ABSTRACT

In a recent body of the entrepreneurship literature, an attention is paid to the role of entrepreneurial ecosystems (EEs) and their contribution to relevant economic outcomes (Stenholm et al., 2013; Lafuente et al., 2018 ; Szerb et al., 2019 ; Lafuente et al., 2020). Rather than using standard entrepreneurship metrics, these studies point to the need to analyze the entrepreneurial context. The premises of these works can be found in the paper of Gnyawali and Fogel, who defined the dimensions of the entrepreneurial context as early as 1994. It includes socio-economic factors, the entrepreneurial and commercial skills of the project promoters, the level of financial assistance, and institutional and governmental policies and procedures (Bonnet et al., 2005).

However, research at national level appears insufficient at present, and the benefits of entrepreneurship can be better captured at sub-national level (Acs and Armington, 2004). Several researchers, such as Audretsch and Keilbach (2005) analysing the German regions or Sterlacchini (2006) for European regions, showed that differences in growth trajectories can be explained by different levels of business creation. We go further than previous research, however, as instead of directly using "new business creation" as an explanatory variable to explain spatially differentiated regional levels of economic performance, we use EEs. Thus, our research questions seek to understand the links between EEs and regional economic performance. We also examine whether there is spatial heterogeneity in these links since recent work suggests that the optimal level of entrepreneurship is heterogeneous across territories and that entrepreneurship rates are not always linked to economic performance (Prieger et al., 2016; Lafuente et al., 2018 and 2020).

We measure EE quality using the REDI developed by Ács et al. (2017), which, from this standpoint, is a crucial indicator of regional economies in the sense that opportunity entrepreneurship stimulates regional economic performance (Shane, 2012, Szerb et al., 2019).

We therefore consider the REDI from an econometric approach that links regional economic outcome with EEs. We propose a local variation of the 'classic' spatial econometric models by adopting a 'local' one, in other words, a geographically weighted regression (GWR) in order to examine the issue of non-stationarity of regional development. This is particularly relevant as EEs are defined as unique (Acs et al., 2017; Szerb et al., 2019) and are thus likely to have different effects on regional economic performance.

The originality of our contribution is threefold. It consists of (i) analyzing to what extent there is heterogeneity in the influence of entrepreneurship on economic performance at a regional level, (ii) assessing the spatial dimension of this non-linearity of effects, and (iii) taking EEs – rather than the traditional new start-up rate – into consideration as an explanatory factor for regional economic performance. It is also original in that it is conducted across all regions of the EU and examines whether the choices made by the European Commission via The Entrepreneurship 2020 Action Plan are likely to generate the effects expected by the Cohesion Policy guidelines for 2014-2020 and after.

INTERNAL REGIONAL COMPETITIVENESS: LOMBARDY, A MULTI-SPEED REGION?

[Federico Fantechi](#), [Ugo Fratesi](#)

Department ABC - Architecture, Built environment and Construction engineering - Politecnico di Milano, Italy

ABSTRACT

The paper analyses regional competitiveness at sub-regional level through a novel methodology which adopts a matching design. By using firms-level data for Lombardy, a large and competitive European region, the analysis shows that the different territories of the region are differently competitive in different industries, and that static and dynamic analysis provide different results. A cumulative effect is shown to exist, by which firms located in the metropolitan area of Milan are more competitive and increasingly as such in time. Additionally, important differences also arise between the other provinces and, in most cases, cumulative effects are present also among them, with more positive dynamics arising in places where specialisation and static competitiveness are high. The differences between territories, and the centripetal effects, are also evident when the analysis is performed by adopting a territorial classification based the National Strategy for Inner Areas and on the degree of urbanization. These results are especially relevant to the design of Smart Specialisation Strategies, because they show, on one hand, that Nuts2 regions may be strongly dis-homogeneous inside and, on the other, that cumulative processes may leave territories behind inside the regions.

THE RESILIENCE OF THE CULTURAL AND CREATIVE INDUSTRIES IN ITALY IN THE FACE OF THE GREAT RECESSION: A GEOGRAPHICAL EXPLORATION

Maria Giovanna Brandano, Giulia Urso

Gran Sasso Science Institute, Italy

ABSTRACT

The cultural and creative industries (CCIs) have been subject to increasing policy and academic attention in the past years. The sector has been seen variously as a stimulus for urban regeneration and, more broadly, for local and regional development. Very interestingly, in U.K. and other EU countries, the cultural economy has been one of the few sectors that has weathered the storm of the 2008 Great Recession.

Starting from the curiosity that these premises arise and from the paucity of studies to date on the Italian CCIs, we analyze the resilience of the sector in the face of the economic-financial shock in order to ascertain whether this was the case also in Italy and whether the reaction to the disturbance shows spatial patterns. To this end, we use data from Aida-Bureau van Dijk database on more than 181,000 enterprises observed for the time span 2010-2018. The number of employees as well as the number of CCIs enterprises are gathered for 18 Nace Rev.2 sectors, in order to better disentangle the contribution of each sub-sector to the growth of the industry. Information is available at firm level, but to the purpose of this paper it is used at provincial (NUTS-3) level. Using a System Generalized Method of Moments (GMM-SYS) approach, and after controlling for socioeconomic characteristics, the determinants of the CCIs growth are analyzed.

We ultimately contribute to the still under-researched debate on the role of CCIs in regional economic resilience proposing some reflections also on their ability to reactivate more rural regions, hence usefully informing policies.

EU MACRO-REGIONAL STRATEGIES AND THE SMART SPECIALISATION STRATEGY: SYNERGIES

Donato Iacobucci, Roberta Ruggeri

UNIVPM, Italy

ABSTRACT

The aim of this paper is to provide a first assessment of the potential synergies and actual integration between the EU macro-regional strategies and the Smart Specialization Strategy (S3). S3 was a major novelty for the allocation of cohesion funds in the 2014-2020 programming period; It required countries and regions to identify key areas where public and private investment in R&D and innovation should be focussed. Macro-regional strategies emerged during the last decade as a way of addressing common challenges faced by defined geographical areas, including EU members and third countries to strengthening cooperation and contributing to achieving economic, social and territorial cohesion. This paper analyses the overlapping and synergies between S3 and EU Strategy for the Adriatic and Ionian Region (EUSAIR) in the 2014-2020 programming period and discusses the problems that emerged for effective integration between the two strategies.

Short introduction

S3 has started before the establishment of the Macro-regional strategies and before the adoption of Agenda 2030. The EUSAIR, as well as the other 3 existing strategies (Baltic Sea Region, Danube Region, Alpine Region), emerged as a way of addressing common challenges faced by defined geographical areas, including EU members and third countries to strengthening cooperation and contributing to achieve economic, social and territorial cohesion. At the crossroads of innovation policy and regional development, S3 has become a guiding concept to make Europe more cohesive and, at the same time, to foster regions' competitiveness. It has been adopted by some 180 national and regional institutions within the EU as well as candidate countries and regions. It will remain at the basis of national and regional innovation policy in the new programming period.

In the post-covid-19 crisis and the challenges brought about by the digital and green revolution, it would be important to capitalise on the synergies between the two main pillars of the EU regional development strategy. Exploiting the potential synergies between these two strategies may foster inter-regional cooperation while contributing to sustainable regional growth and economic and social cohesion.

This paper will review the past achievement as well as the challenges and opportunities that are arising in the new programming period (2021-2027).

BUILDING A SPATIAL LAKEHOUSE SYSTEM OPTIMIZED FOR MOBILITY DATA

[Soukaina Ait Errami](#)¹, [Hicham Hajji](#)¹, [Kenza Ait El Kadi](#)¹, [Hassan Badir](#)²

¹School of geomatic sciences and surveying engineering. IAV Institute, Morocco. ²National School of applied sciences, Tangier, Morocco

ABSTRACT

With the exponential growth of location-related data, building systems that support these types of data presented a real potential to gain richer insights. Data Warehouses presented earlier the pillar of the decision support system. Thus, their spatial extension helped integrating the spatial dimension in the decision building process. However, with the emergence of Big Data, spatial data start also being produced at huge rates especially with the expansion of IoT and GPS tracking devices. The Spatial Data Warehouses showed several limitations such as the inability to support streams of IoT data and lack of scalability. Data Lakes emerged as a new technology trying to address the scalability issues and lack of flexibility related to Data Warehouses. They are defined as a repository containing data of any type and any structure. The flexibility and cost-effectiveness of data lakes were the principal reasons behind its propagation in the decision support landscape. Data Lakes presented a suitable environment for the complex queries and heavy storage of the Spatial Big data such as the storage and analytics of mobility data. Data Lakes give access to practically unlimited storage and support applying distributed analytics and advanced analytics and machine learning. However, they also showed some consistency issues. The next step, in the data architecture maturing, was the Data Lakehouse systems. The Data Lakehouse systems have the benefits of both systems; Data Warehouses and Data Lakes. The Data Lakehouse's goal is to unify all the enterprise's data workloads in the same platform. They are based on a table format storage layer implementing governance and ACID properties on top of a Data Lake. The Data Lakehouse is a combination of governed and reliable Data Warehouses and flexible, scalable, and cost-effective Data Lakes. As the location-related data is frequently an object of regulation rules, the Data Lakehouse is more compliant than the previously mentioned systems. The existing works didn't address the Spatial Big Data requirements within the Data Lakehouse. In our paper, we are going to address this aspect by presenting the different components and best practices for building a Data Lakehouse architecture optimized for the storage and computing of Spatial Big Data. The paper goes through the successive components of the Data Lakehouse and details the methods of adapting this component with the Spatial Big Data requirements going from ingestion to advanced analytics and visualization using the most suitable open-source systems for each step on the pipeline.

EXPLORING NEW DEEP LEARNING ARCHITECTURES FOR BUILDING FOOTPRINT EXTRACTION

[Hicham Mharzi Alaoui](#)¹, [Hassan Radoine](#)¹, [Hicham Hajji](#)²

¹School of Architecture, Planning & Design, UM6P, Morocco. ²School of Geomatic Sciences and Surveying Engineering, IAV Hassan II, Morocco

ABSTRACT

Mapping the building footprints can play a crucial role in urban dynamics monitoring, disaster management and transportation planning. Available free building footprints, like OpenStreetMap, provide manually annotated building footprint information for some urban areas, however, most frequently it doesn't cover entirely urban areas in many parts of the world and is not always available. Therefore, high-resolution Remote Sensing imagery, with a huge potential for meaningful ground information extraction, can be considered as an alternative and a reliable source of data for building footprint generation.

Therefore, the aim of the study is to explore the use of satellite imagery data and some of the state-of-the-art deep learning tools to fully automate building footprint extraction. To better understand the usability and generalization ability of those approaches, this study proposes a comparative analysis of the performances and characteristics of one of most recent deep learning models such as Attention-Unet for building footprint generation.

DELINEATING FINE-SCALE URBAN FUNCTIONAL USE FROM POINTS OF INTEREST DATA WITH NEURAL NETWORK MODEL

Haifeng Niu, Elisabete Silva

University of Cambridge, United Kingdom

ABSTRACT

Urban function has been studied in both urban planning and geographic information science for decades. Understanding urban functional use not only provides a geospatial feature for urban modelling but also helps to detect urban problems, evaluate planning strategies and support policy-making especially in highly urbanised and densely populated metropolitan areas (Batty, 2012; Arsanjani et al., 2013). Different from the traditional studies focusing on physical environment with remote sensing data such as land use classification and land use boundary detection, studies now focus on socio-economic characteristics of land/building functional use with detailed and fine-scaled crowdsourced data, i.e. social media data, points of interests and other open-source and volunteered datasets (Crooks et al., 2015; Frias-Martinez and Frias-Martinez, 2014; Zhi et al., 2016). Among these sources, points of interest (POIs) are popularly applied in understanding urban functional use (Niu and Silva, 2019). POIs refer to point-based locations such as commercial property, public spaces, transportation facilities, etc. associated with detail including location, name, postcode, address, and so on. The distribution of POIs and combination between POIs varies in different urban areas. This variation reflects the preference of urban activities and indicates the pattern of urban functional use at a larger scale. Moreover, POIs are highly disaggregated data with precise location and can be applied at a variety of scales. However, previous work neither frequency-based approach nor neural word embedding such as Word2Vec considered the spatial relationship between POIs in the context of the first law of geography. In this paper, we recognised the capabilities of neural word embedding in delineating urban functional use from POIs and introduce neural network model (Doc2Vec) with sentence/paragraph feature input in the context of geographic space. This paper chooses the metropolitan area of London as the study area. This paper employs POIs from Ordnance Survey, which is the national mapping services in for Great Britain. This taxonomy is three levels, including nine groups and 52 categories and 582 classes. For each item in this POI dataset, it contains information such as Identified code, name, coordinates, address, postcode, telephone number, brand, and so on. Specifically, the dataset used in this case study is updated in March 2019 with 420,559 POIs throughout the London metropolitan area. Since this paper recognised the advantage of Doc2Vec model in term of presenting the relationship between POI categories with considering the spatial heterogeneity, we apply the model to POIs data by conducting nearest neighbour query of POIs based on London road network (40,000 random points), POIs sequences construction with local tags, vectorisation for POI categories by cosine distance, evaluation of Doc2Vec and clustering urban functional areas with K-means. The contribution of this paper is to introduce a new data source and a new tool for understanding the dynamics of urban functional use from bottom-up and provide a tool to predict and monitor the impact of urban dynamics.

PERCEPTION OF THE EU BY TURKISH CITIZENS: INDIVIDUAL CHARACTERISTICS AND LOCAL ECONOMIC PROSPECTS

[Burhan Can Karahasan](#)¹, [Enrique Lopez-Bazo](#)²

¹Piri Reis University, Turkey. ²University of Barcelona & AQR, Spain

ABSTRACT

This study investigates the individual and local determinants of the EU support in a candidate country. The main objective is to focus on the uneven economic development trajectories of Turkish regions and to question whether local economic conditions have influence on the individual level of support to the EU. Controlling for a host of individual characteristics, our results show that regional differences in per capita income, unemployment and employment rate matters. Those regions with lower income and worse labor market outcomes have higher EU support. These results are robust in static and dynamic sense, suggesting that the current economic conditions and the evolution of long-run regional declines both shape the regional discontent in Turkey. Our prior knowledge from the developed EU countries validate that left behind places create the so-called discontent by opposing to integration and globalization. However, our results from a developing country show that disadvantageous left behind places demand for a change of the status-quo. In the Turkish case, observed discontent acts as a major motive to support the EU integration at the regional level.

PROTESTS ACROSS LATIN AMERICA: ARE URBAN AND RURAL AREAS DIFFERENT?

Nicola Pontarollo¹, Joselin Segovia²

¹University of Brescia, Italy nicola.pontarollo@unibs.it. ²University of Cuenca, Ecuador. joselin.segovias@ucuenca.edu.ec

ABSTRACT

The emerging literature on social discontent argues that left behind areas are more likely to vote for anti-system parties, with unemployment, education, wealth, and age playing a significant role. Latin America, however, is a special case. In the region, the rise of the middle class followed the growth of commodities' prices and international liquidity. The new middle class, largely located in urban areas, is generally fragile since part of it is unable to meet class transitions towards higher education levels or better job conditions, largely benefitting from public social programmes. With the end of the commodity boom and the contraction of the public spending, the mobilizations occurred essentially across this class. The aim of our paper is to i) examine if the share of people protesting varies across rural and urban areas and ii) which are the drivers of these protests. To reach this aim, we employ survey data for 2019 Latin American Public Opinion Project. Our preliminary results show that there are some shared factors affecting the probability to protest in urban and rural areas. Among these, we find that rising income, interest in politics, crime and internet use increase the probability of participating into protests. On the other hand, we also find evidence of drivers that differ between urban and rural areas. In the former, education, trust in public institutions, the intention to emigrate and the perception that government should implement strong policies to reduce income inequality motivate protests, while decreasing income is a driver only in the rural areas. These results may be useful to set appropriate policies to mitigate the rising discontent in the region.

KEYWORDS

Urban, rural, protests, Latin America

1. INTRODUCTION

The year 2019 has been called by some *the year of social discontent* due to the spread protests across the world. While for some it can be difficult to point out to a generalized explanation (Rachman, 2019), the UNDP (2019), has argued that there is a connecting thread: inequality. Inequality beyond traditional measures, and inequality beyond the economic realm.

The emerging literature on social discontent argues that discontent encompasses behaviour against the status quo caused by high territorial disparities between those regions left behind and those that prosper. One way this has been studied is through voting behaviour (Rodríguez-Pose, 2018) and its drivers (Dijkstra et al. 2020), as well as by exploring how different inequality measures at different geographical units of analysis might explain social discontent (McCann, 2020). According to these authors, left behind regions are more likely to vote for anti-system parties, with unemployment, education, wealth, and age playing a significant role.

Despite high levels of inequality is a common cause of discontent in Europe and in Latin America, it is worth noting that, in the former it appears as comparatively recent phenomenon. Indeed, the term *declining* places highlights that they were once economically dynamic and prosperous territories, now left behind (Rodríguez-Pose, 2018). On the other hand, high inequality is a long-dated feature of Latin America (Williamson, 2015), and data shows that despite it has been significantly reduced, its levels are still unacceptable.

In Latin America, between 2003 and 2013, the rapidly rising price of commodities (Gruss, 2014) and international liquidity contributed to the rise of the middle class in the region, which nearly doubled in size between 2002 and 2014, representing one third of the population by the end 2014. This new middle class is, however, fragile since part of it was unable to meet class transitions towards higher education levels or better job conditions (Ferreira et al., 2013). Moreover, the greatest part of people who moved out of poverty, jumped into the economically vulnerable group with considerable risk of going back into it (Ferreira et al., 2013). As noted by Biekart (2015), since this group has been largely benefited from public social programmes, it becomes the most demanding and pressing for governments. As a result, since the end of the commodity boom, the mobilizations across the region have been essentially led by the middle class.

This growth of middle class occurs in urban areas (Stampini et al., 2016), where, 81 percent of Latin America's population is living (UN-DESA, 2019). According to Ferreyra and Roberts (2018), on average, 7.16 percent of household heads age 25–35 years have migrated within their countries in the period 2009–2014. Of them, the most skilled are likely to migrate to large urban areas than to medium or small urban areas (except in Ecuador, El Salvador, and Paraguay), where there are higher education returns. This might be the reason why, according to Vakis et al. (2016), urbanized areas are also characterized by a lower share of poverty. Indeed, poverty incidence has historically been higher in rural areas; however, in the past decade it has increased relatively more in urban areas, marking important inequalities not only between urban

and rural areas, but also within urban territories (CEPAL, 2019). Cities in Latin America, indeed, are known to be divided, unequal, and spatially and socially segregated (CEPAL, 2014; UN-HABITAT, 2012). In this context, the analysis of political discontent cannot prescind from the geographical component.

Thus, in this paper, we want, first, to understand if there is a systematic difference between the share of people participating to protests across urban and rural areas and, second, to explore what are the main factors affecting the probability of taking part to protests. To achieve this aim we will use data from Latin American Public Opinion Project (LAPOP) for year 2019.

The paper is organized as followed: in the next section methodology and variables are presented, in the third the main results are discussed and the last section concludes.

2. MODEL AND VARIABLES

Since our dataset includes observations at the individual level nested at the country level, we employ a multilevel model to account for country-level variance. The model is as follows:

$$Protest_{i,j} = \mathbf{X}\beta_{i,j} + \gamma_j + \varepsilon_{i,j}, \quad (1)$$

where i denotes the individual observation and j the country. $Protest_{i,j}$ is a dummy variable taking value 1 if the respondent took part to a street protest, 0 otherwise; \mathbf{X} is a vector of individual characteristics; γ_j is the random intercept representing level 2 (nation-specific) residuals. $\varepsilon_{i,j}$ are level 1 (individual-specific) residuals. These are assumed to be mutually independent and normally distributed with zero mean and variance equal to σ^2 . Level 2 residuals are assumed to be uncorrelated with $\varepsilon_{i,j}$, mutually independent, and normally distributed with zero mean and variance equal to τ^2 . $\varepsilon_{i,j}$ residuals represent the unexplained variability of the individual discontent after considering measurable individual characteristics clustering, whereas γ_j residuals represent unexplained heterogeneity at the national level.

In particular, in vector \mathbf{X} we have the following variables:

- Sex, age, number of children, education, and ethnicity that identify personal characteristics of the respondents. We do not have a priori expectations for the first three variables, while we could guess that a better education could lead to take part to protests as it may express higher discontent, as shown by Rodríguez-Pose et al. (2019), among others. Regarding ethnicity, where mestizos is taken as a reference category, we expect that in particular being an indigenous would trigger a higher probability to participate to protests.
- A set of variables related to trust in institutions are the following: trust president, trust media, trust supreme court justice, trust in elections, trust parliament, trust peaceful demonstrations. We expect that all of them with expect for the latter have a negative effect on the participation to protests.
- Three variables regard ideology/perspectives: interest in politics, which is expected to play a positive role together with the intention to emigrate, and the fact of thinking that the government is implementing policies against inequality, which we expect a negative effect on the likelihood of participating to protests.
- Another set of factors regards economic and social characteristics: income, the expected trend of the household income in the next 2 years (improving, worsening or remaining stable, taken as a reference), as the fact of having experienced a violent crime in the last year, expected to increase the probability of protesting, and the fact of having internet in the house, which can be seen as a tool for getting information otherwise not available from standard media.

Finally, the same regression models are run for the whole sample of 19,962 observations, and separately for the 14,915 respondents belonging to urban areas, and for the 5,047 living in rural areas.

3. RESULTS

Figure 1 shows a first overview of the phenomena, with the share of people taking part to protests being systematically higher in urban areas in all countries, except for few exceptions. This empirical regularity is confirmed by the Pearson's Chi-squared test with Yates' continuity correction, whose p-values < 0.01 ($X^2 = 27.064$) reports that there is a statistically significant difference in the probability of taking part to protests between urban and rural areas, when the full sample is examined.

Figure 1: Share of people taking part to protests in 2019 by area

In Table 1, the Chow test for parameters instability confirms that they are systematically different between urban and rural area. However, some variables have common sign and significance. In particular, rising income, being of indigenous ethnicity, having an interest in politics, being victim of a crime and having access to the internet at home increases the probability of participating in protests to an equal extent in urban and rural areas. On the contrary, trust in media and in the president decrease the likelihood of protesting.

Other factors affecting the probability to protest have different effects in urban and rural areas. What motivates protests in urban but not in rural areas is education, trust in public institutions, the intention to emigrate and the perception that the government should implement strong policies to reduce income inequality. Decreasing income, on the other hand, is a driver only in the rural areas, but not in urban areas.

4. CONCLUSIONS

Results show that significant differences in the share of people taking part to protests exists between urban and rural areas in Latin America. In particular, the share of people participating to protests is higher in urban than in rural areas. Some variables contribute to explain the likelihood of participating to protests in both areas, while other are peculiar of urban or rural places.

In light of the results, policies aimed at strengthening middle class in urban areas are needed, improving the match between education levels and improved job conditions, improving institutional quality fighting inequality. Furthermore, place-based policies with the aim to avoid migration from urban areas should be implemented. In doing this, particular attention has to be put on the role of expectations, rather than actual levels of income, given that bad economic outlooks are strongly associated to the likelihood of taking part to protests.

Finally, what is needed, especially in light of the recent Covid-19 pandemic and of its social consequences is a strong institutional foresight capacity aiming at improving trust and expected living conditions.

THE URBAN-RURAL POLARISATION OF POLITICAL DISENCHANTMENT: AN INVESTIGATION INTO SOCIAL AND POLITICAL ATTITUDES IN 30 EUROPEAN COUNTRIES

ABSTRACT

Despite the prevalent focus upon increasing political divisions between urban and rural Europe, relatively little research has explored whether there is a systemic urban-rural divide in the political and socioeconomic attitudes of citizens across the entire continent. This paper aims to fill this gap. Drawing on individual-level data from the European Social Survey, it explores potential linkages between place of residence and individual attitudes. Our results show that there are strong, and statistically significant, differences between the populations in these different settings. On average, rural dwellers show stronger levels of dissatisfaction with democracy and lower trust in the political system. Yet, while we uncover stark differences in attitudes towards migration and globalisation, we do not find significant variation on some social and economic issues traditionally at the core of left-right cleavages. And our analysis suggests that this spatial divide does not operate in a binary fashion. It is more of a continuum, running on a gradient from inner cities to metropolitan suburbs, towns, and the countryside. The differences are explained by both composition and contextual effects, and underscore the importance of moving beyond 'standard' trade-offs between so-called 'people-based' versus 'place-based' policy approaches to territorial inequality.

Keywords

Urban-rural divide; regional inequality; geography of discontent; Europe.

1. INTRODUCTION

While, for much of the Twentieth Century, political scientists tended to assume that political cleavages in western democracies revolved around differences in class position and attitudes towards distributional questions and the role of the state, in recent decades there has been a growing emphasis on those associated with various kinds of group identity, and, latterly, with the importance of place (Glaeser and Ward 2006; Kenny 2014; Kriesi 2010). In the US, a large body of work has documented how political differences are increasingly driven by a distinctive – and deepening – geographical cleavage, with almost all large cities being Democratic strongholds and rural counties being a cornerstone for the Republicans (Gimpel and Hui 2015; McKee 2008; Monnat and Brown 2017; Morrill, Knopp, and Brown 2007; Scala and Johnson 2017; Tam Cho, Gimpel, and Hui 2013).

Across Europe too, notable recent political events, such as the UK 2016 Brexit vote, and the 2018 *Gilet Jaunes* protests in France have shed light on marked political divergences between urban and rural places. Yet, despite growing evidence from individual countries such as the UK (Becker, Fetzer, and Novy 2017; Carreras, Irepoglu Carreras, and Bowler 2019; Garretsen et al. 2018; Goodwin and Heath 2016; Jennings and Stoker 2016; Lee, Morris, and Kemeny 2018; MacLeod and Jones 2018), France (Eribon 2013; Guilluy 2016; Ivaldi and Gombin 2015) and Italy (Agnew and Shin 2017, 2020; Rossi 2018), relatively little research has explored in a systematic way whether the growing political divide between urban and rural areas mapped in some countries is apparent across the whole continent. Indeed, given the prevalent focus upon Anglo-American comparisons within the Anglophone literature, there is a pressing need to consider whether the same phenomena are discernible across Europe.

The current paper aims to fill this gap. Drawing on individual-level data from the European Social Survey (ESS), it provides systematic comparative evidence across 30 European countries over the period 2002-2018. We explore links between place of residence and attitudes on a range of different socioeconomic and political issues. To anticipate our conclusion, we find that there is a strong and significant divide between the political outlooks of urban and rural Europe. But this divergence is not best seen in binary terms, and is better understood as a gradient running from inner cities to metropolitan suburbs, towns, and the countryside (as anticipated by Scala and Johnson, 2017). We show how, compared to dwellers in inner urban cores, respondents living in suburbs, towns and rural areas are more likely to be conservative in their orientation, dissatisfied with the functioning of democracy in their country, and less likely to trust the political system, even though they are – strikingly -- more likely to participate in it, especially by voting. However, while our analysis highlights some stark geographical variances in attitudes towards migration and globalisation, we do not find significant variation on issues which have traditionally been at the core of left-right cleavages, such as support for welfare state redistribution. And, finally, we show that these differences are explained by compositional *and* contextual effects.

This article contributes to the growing literatures in the neighbouring disciplinary fields of geography and political science devoted to the spatial dimensions of political disenchantment in three distinctive ways. First, in line with a growing emphasis in much social scientific research on a widening ‘cosmopolitan-nationalist’ polarization, we show how differences associated with the urban/rural continuum are significant across a range of attitudinal dimensions. Most recent studies of the ‘geography of discontent’ (McCann 2019; Rodríguez-Pose 2018) consider the evidence supplied by voting patterns in elections and referendums. Yet, such events may well be linked to candidate-related factors and contingent political developments, and may relate only indirectly to underlying shifts in popular attitudes (Abrams and Fiorina 2012; Ford and Jennings 2019). In fact, many political scientists suggest that electoral campaigns do not change public opinion that much but, rather, ‘activate’ some considerations over others (Mutz 2018), increasing the extent to which particular issues matter for voters when they choose a candidate. It is, therefore, important to understand in more depth the factors explaining the underlying dynamics of public opinion. We seek to address this challenge using attitudinal data, and our findings suggest that the linkage between place of residence and political attitudes is not confined to attitudes towards iconic and contentious questions such as the EU (Dijkstra, Poelman, and Rodríguez-Pose 2019) or migration (Maxwell 2019). Instead, we conclude, it encompasses a wider range of political and socioeconomic issues including perceptions of political behaviour and trust in political institutions. There are intimations in these results, we suggest, of distinct worldviews that are manifested by spatially segmented parts of the population of many developed democracies.

Second, in line with the work of Scala & Johnson (2017) on the US, we show that the geographical divide in European political attitudes should not be thought of as a dichotomy between urban and rural places – as suggested for instance by Cramer (2016) in relation to the US – but conceived instead as a gradient. This finding is in line with some recent analyses which underline the importance of inequalities within urban places (Baum-Snow, Freedman, and Pavan 2018) and suggest that, as a result, residential segregation between inner urban areas and suburbs is on the rise across many European cities (Musterd et al. 2017). We point to the merits of applying a more finely grained geographical lens to the contemporary urban-rural divide in Europe, arguing in particular for more nuanced, place-sensitive typologies.

Third, we provide a preliminary analysis of the factors that may be most significant in explaining the differences along the urban/rural continuum. In his analysis of attitudes to immigration, Maxwell (2019) argues that differences between urban and rural areas are more strongly driven by sociodemographic characteristics – that is, by compositional effects and the geographical sorting of people with different attributes and outlooks – than by the influence of place of residence over individual outlooks. In contrast, we underline how attitudes vary across sociodemographic *and* geographical dimensions. We show that while people’s attitudes are heavily stratified by key individual observable characteristics, such as age, education, and occupational status, there is a non-negligible correlation between places and their inhabitants’ attitudes towards various political and social issues (Agnew 1987). This conclusion has important implications for the ongoing debate about what kinds of policy solutions are best equipped to address growing territorial inequalities, and whether these should be place-sensitive or not (cf. Barca, McCann, & Rodríguez-Pose, 2012; Crescenzi & Giua, 2019; Iammarino, Rodríguez-Pose, & Storper, 2019).

Further research, we suggest, is needed to disentangle potential compositional effects based on unobservable – rather than observable – characteristics such as intrinsic ‘cognitive underpinnings’ (cf., for example, Lee et al., 2018; Zmigrod, Rentfrow, & Robbins, 2018). And analysts should also explore in more depth the mechanisms through which the kinds of setting in which people live can influence the development of individual traits, especially during early-age socialisation (Bosquet and Overman 2019; Hackman and Farah 2009; Rentfrow, Gosling, and Potter 2008). Yet, irrespective of whether divides in attitudes are driven by compositional effects or by the contextual influence of places on people, marked demographic sorting and the overlapping of territorial and attitudinal cleavages signal a deepening geographical fracture in European societies which, in the long term, may have significant implications for the challenges of generating social cohesion (Wilkinson 2018) and addressing the implications of rising disenchantment with democracy (Foa et al. 2020). The paper is structured as follows. Section two reviews the existing literature on the urban-rural polarisation, and develops our main, empirical hypotheses. Section three describes the data and the analytical strategy that we have employed. We then present the key results in section four, and discuss the implications of our findings in section five. In the final section, we offer some discussion of their implications in relation to ongoing policy debates, and suggest areas where further research would be profitable.

2. POLITICAL POLARISATION ALONG THE URBAN-RURAL DIVIDE

The polarization of electorates across the urban-rural divide is by no means a new, or recent, phenomenon. At the peak of the industrial revolution, between the end of the Nineteenth Century and the beginning of the Twentieth, many European and North American countries were divided politically between the interests of rural and small-town dwellers, engaged in agricultural production, and those of urban residents, experiencing rapid technological and socioeconomic change and a new spatial economic order dominated by manufacturing in large urban agglomerations (cf. Lipset and Rokkan 1967; Vidal de la Blache 1913).

In the second half of the Twentieth Century this stark divide faded partially, as sharper political cleavages, which reflected economic issues, class divisions and the role of the state in society, emerged (Lipset and Rokkan 1967). Yet, across many advanced economies, the processes of economic globalisation over the last three decades have generated new socio-economic divides (Ford and Jennings 2019) and contributed to the emergence of a new dimension of political conflict, cutting across these older divisions. Although the extent and nature of this divide remains contested among social scientists (Norris and Inglehart 2019), a growing number of studies show that the classic class-based Left-Right cleavage

in party competition is today overlaid by a new division based on education and cultural attitudes. Scholars support this claim with reference to survey data (Tabellini and Gennaioli 2018), the positioning of political parties (Inglehart and Norris 2016), and the composition of party supporters (Piketty 2018).

Three accounts figure prominently in this debate, each proposing a distinct explanatory framework to explain this new cleavage: “materialism” as opposed to “post-materialism” (Inglehart 1977, 1990, 1997); the divide between “winners” and “losers” of globalisation (Kriesi 1998, 2010); and a “transnational” conflict of values between “liberals” and “conservatives, authoritarians, and/or nationalists” (Hooghe and Marks 2018; De Vries 2018). While each approach emphasizes a specific trigger, the literature overall points to the increasing salience of geography in relation to this new attitudinal cleavage, and to growing political disagreements between cosmopolitan, highly educated, and socially progressive urbanites, and nationalist and socially conservative residents of ‘hinterland’ areas. The determinants of the recent rise in populism and anti-establishment sentiments across many established democracies are numerous and interlinked.²¹⁷ Support for right-wing populist parties relates to a number of variables including age, ethnicity, education and employment. Yet, these fault lines are characterised by many commentators as linked to a distinctive geographical divide, with political differences among inhabitants in urban and rural places becoming increasingly marked.

In the US, a significant amount of work has documented how electoral politics falls increasingly into distinctive spatial patterns, with almost all large cities being Democratic strongholds and rural counties being the cornerstone for the Republicans (Gimpel and Hui 2015; Monnat and Brown 2017; Morrill, Knopp, and Brown 2007; Rodden 2019; Scala and Johnson 2017). While a broad division between ‘blue’ and ‘red’ America has been observed for some decades (Abramowitz and Saunders 2008),²¹⁸ the emergence of a salient divide between urban and rural areas has become more palpable over time, and was particularly clear during the 2016 presidential campaign (McKee 2008; Wilkinson 2018). Analysing recent opinion polls and the latest US presidential elections, Scala and Johnson (2017) for example identify a consistent gradient of conservative sentiment from the most urban to the most rural counties on a wide range of socioeconomic issues. Their results show that differences in outlook remain statistically significant even after controlling for factors such as education, income, age, ethnicity, and religion.

Across Europe too, there are signs that many different political systems are adapting to this new cleavage, and an increasingly spatially divided electoral geography is emerging (Agnew and Shin 2020; Hooghe and Marks 2018). France is a much-cited exemplar of this trend. There is a growing political divide between the large urban centres – ‘globalised’, ‘gentrified’, and increasingly inhabited by cosmopolitans and ‘bobos’ (bourgeois bohemians) – and the *banlieues* populated by immigrants of recent arrival, and the remaining medium and small-sized cities and rural areas, where long-time immigrants and the ‘white’ working classes experience economic decline and are increasingly disaffected with the political system (Bacqué et al. 2016; Cusin, Lefebvre, and Sigaud 2016; Eribon 2013; Foa et al. 2020; Guilluy 2016; Ivaldi and Gombin 2015).

Similarly, England has witnessed a gradual ‘bifurcation’ (Jennings and Stoker 2016) in political terms between people with higher education and good employment opportunities who live in metropolitan areas and those living in ‘backwater’ areas associated with economic decline, hostility to immigration and the EU, and a stronger sense of English identity (Garretsen et al. 2019; Kenny 2014, 2015). While there is a strong regional dimension to the geography of discontent in Britain (Garretsen et al. 2018; McCann 2016, 2019; Tyler et al. 2017), in the UK and elsewhere, the urban-rural fault-line has become increasingly prominent.

Some research into the causes of these spatialized political patterns suggests that the urban-rural political divide has become more intense in recent decades. Exploring a rich dataset on referendum results at the municipal level, Mantegazzi (2018)’s work on Switzerland for example provides a compelling picture of the growing geographical polarisation which, since the 1970s, characterises Swiss politics. This increasingly leads to a distinctive pattern, with voters in large cities positioning themselves in a ‘Left-liberal’ space as opposed to ‘Right-conservative’ municipalities that are increasingly clustered in rural areas.

But whilst many commentators observe this pattern in a few, paradigmatic countries, little research has explored whether there is a systemically rooted urban-rural divide in political and socioeconomic attitudes across the whole European continent. And there is still considerable disagreement about the causal dynamics and processes underpinning this division. Two broad explanatory accounts of his deepening divide, respectively focused on composition and contextual effects, are most notable within current academic literature.

The first of these relates to the spatially heterogenous distribution of individuals with different characteristics (composition effects). Research on political disenchantment and populism primarily identifies the archetype of the anti-system supporter based on age, education, and income (Becker, Fetzer, and Novy 2017; Dijkstra, Poelman, and Rodríguez-Pose 2019; Essletzbichler, Disslbacher, and Moser 2018; Ford and Goodwin 2014; Goodwin and Heath 2016). As an example, ‘typical’ ‘left-behind’ Brexit supporters have been described as “older, working-class, white voters [...] who live on low incomes and lack the skills that are required to adapt and prosper amid the modern, post-industrial economy” (Goodwin and Heath, 2016, p. 325).

217 In the last years the literature on populism has thrived. See, inter alia: Akkerman, Mudde, & Zaslove, 2013; Ford & Goodwin, 2014; Guiso, Herrera, Morelli, & Sonno, 2019; Inglehart & Norris, 2016; Jens Rydgren, 2010; Kriesi, 2014; Rodrik, 2018; Rooduijn, van der Brug, & de Lange, 2016; Van Gent, Jansen, & Smits, 2014; Zaslove, 2008.

218 Some scholars have challenged the view of America as a country divided into two clearly distinct and politically homogeneous areas (cf. Fiorina & Abrams, 2008; Fiorina, Abrams, & Pope, 2010; Glaeser & Ward, 2006).

Composition effects may be amplified because of increasing demographic ‘sorting’ among voters along spatial lines (Bishop 2009) – which occurs primarily through the dynamic self-selection of younger, more educated and socially liberal individuals in large, urban cores. While the extent of demographic sorting dynamics and their influence on political outcomes is debated (cf. Abrams & Fiorina, 2012), recent research has established that voters relocating across different US counties are influenced by the partisan composition of their destinations (McDonald 2011; Tam Cho, Gimpel, and Hui 2013). Some researchers contend that this pattern reflects a hardwired preference for homophily – the tendency to favour the presence of others with similar tastes and preferences (Gimpel and Hui 2015; Motyl et al. 2014; Schelling 1971). Others highlight the dramatic transformations that have occurred in the last decades in the technical structure of the economy, and the increased returns which these have brought to those with higher levels of human capital as key factors (Keuschnigg 2019; Moretti 2012). In this changing social landscape, large urban areas incubate more economic opportunities and attract those with greater skills, while, conversely, smaller towns, rural areas and cities with an outdated industrial mix become increasingly ‘left behind’, losing their younger, more skilled populations and facing economic stagnation or decline (Lee and Luca 2019; Wilkinson 2018). The increased wage bonuses and productivity associated with high skills and education (Baum-Snow, Freedman, and Pavan 2018) may have amplified the geographical self-selection of the highly educated and more liberal-minded into larger urban cores. Driven by these deeply rooted economic dynamics, spatial sorting effects can lead to a growing urban-rural divergence in values and attitudes.

The second explanation focuses on the socio-economic trajectory of places and their contextual role in shaping individual attitudes. Across Europe, there is increasing economic divergence between core cities and areas that are lagging behind in economic terms (Iammarino, Rodriguez-Pose, and Storper 2019). Commentators hence point to an emerging ‘geography of discontent’, reflecting the unhappiness of people living in places which are stagnating or facing comparative economic decline (Garretsen et al. 2018; Los et al. 2017; McCann 2019). Rodríguez-Pose (2018, p. 201) for example shows how “[i]t has been thus the places that don’t matter, not the ‘people that don’t matter’, that have reacted”. Rising opportunities and growth in thriving urban cores not only attracts younger, more educated and more liberal individuals, but also contributes to shifting urban dwellers towards more progressive social values (Friedman 2005) and cosmopolitan preferences (Vertovec and Cohen 2002). Conversely, declining or stagnant material prospects in peripheral towns and rural places tend to generate a growing sense of disaffection, anxiety and resentment, driving citizens to adopt a more protective, “zero-sum, ‘us or them’ frame of mind” (Wilkinson, 2018, p. 5). Lee et al. (2018), for instance, show that in the Brexit referendum, support for Leave was notably higher for those living in the same county in which they were born than those who had left their county of birth. Importantly, the correlation between residential immobility and Leave voting was only strong in peripheral places where wages had stagnated after the 2008 crisis (Crescenzi, Luca, and Milio 2016), or in areas which had experienced steep recent increases in the number of immigrants moving to them. In times of growing economic inequality, residents of rural areas and small towns seem to have moved towards increasingly socially conservative and anti-liberal positions.

Place-dependent grievances are not confined to economic issues. The differences between urban and rural life, and feelings among rural and town dwellers that their places have been neglected by economic and political elites, have led to growing resentment based on cultural-identity issues which shape a growing sense of mutual alienation (Lichter and Ziliak 2017). As Cramer (2016) argues, what may look like disagreements over specific policy preferences can often be traced back to this more fundamental difference of worldview, which is rooted in questions about identity and contending “ideas about who gets what, who has power, what people are like, and who is to blame” (Cramer, 2016, p 5). In her (ibid.) account, ‘rural consciousness’ develops out as an attachment to place, and is linked to a sense that politicians and decision-makers systematically ignore peripheral places, failing to provide them with their fair share of resources, and to acknowledge their distinct lifestyles and values. Identities rooted in peripheral places seem to have, at least partly, come to shape the political preferences of a much larger group of people.

In summary, there is considerable evidence within a wide-ranging body of literature to support the contention that there is a clear political fracture between metropolitan and rural (and semi-urban) communities. But, as yet, it remains unclear whether this pattern works similarly across the European continent. One study – Maxwell (2019) – has provided a body of comparative evidence about popular attitudes towards immigration in European countries. Our analysis builds on his work, seeing to explore a broader range of socioeconomic and political issues, and testing whether differences on these are also reflective of spatial differences. Drawing on the existing literature, our first research hypothesis is the following: H.1 = There are discernible differences in the collective outlooks of people who live in urban and rural places.

But, as Scala & Johnson (2017) suggest in relation to the US case, it may be misleading to think of the urban/rural divide in dichotomous terms. ‘Rural America’ is an elusive and deceptive term, incorporating a great diversity of types of place (ibid.). Similarly, even within metropolitan areas, there are significant differences between urban cores and suburbs (Baum-Snow, Freedman, and Pavan 2018; Musterd et al. 2017). Drawing on such insights, our second research hypothesis is the following:

H.2 = the urban/rural divide is best understood as a continuum rather than a dichotomy.

In addition, we aim to provide a preliminary exploration on the determinants of attitudinal differences across places, distinguishing between composition and place effects, based on our attitudinal data. We test whether differences in attitudes across the urban/rural continuum might not be exclusively explained by compositional effects – that is, by the sorting of younger, more educated and economically better off individuals in large urban centres. Our last two hypotheses are the following:

H.3 = differences in attitudes across the urban/rural continuum are explained by compositional effects.

H.4 = differences in attitudes across the urban/rural continuum are not exclusively explained by composition effects and, hence, are linked to some of the intrinsic characteristics of places.

3. RESEARCH DESIGN

3.1 Data

We analyse pooled, cross-sectional individual-level data from the European Social Survey. Since its inception in 2002, the Survey has conducted, every other year, face-to-face interviews across most participating countries. We exploit data on the EU27 Member States plus the UK, Norway and Switzerland from all the nine available waves, covering the period 2002-2018. The Survey is representative of all persons aged 15 and over, regardless of their nationality or language (we exclude respondents below 18). Individuals are selected through a multi-stage random probability sampling procedure. The ESS uses sampling designs where some groups or regions have higher probabilities of selection. To reduce sampling errors and potential non-response bias, we apply country-specific ESS post-stratification weights constructed using information on age, gender, education, and region.²¹⁹ Furthermore, we also apply country population size weights to account for the fact that countries participating in the ESS have relatively similar net sample sizes (roughly between 900 and 2700 individuals per country) even if the size of their general population varies considerably (e.g. from 1.1 million residents in Estonia to 71 million in Germany during ESS wave 8). These weights ensure that each country is represented in proportion to its actual population size.

3.2 Model and Estimation strategy

To test our research hypotheses, we estimate the following equation:

$$Y_{i,t}^j = \beta_1 U_{i,t} + \beta_2 X_{i,t}^L + \alpha_c + d_t + \varepsilon_{i,c,t} \quad (1)$$

Where Y is a vector of ordinal variables measuring individual attitudes on each issue j of person i in the ESS wave t . U is our main regressor of interest, and represents a categorical variable indicating whether each respondent resides in a big city (the baseline category), in the suburbs/outskirts of a big city, in a town/small city, in a country village, or in a farm/home in the countryside. Alas, due to the nature of the data we cannot control for more fine-grained geographical determinants. While this is a potential limitation of the analysis, in our approach we follow earlier work on the urban/rural divide (Maxwell 2019) and aim to maximise the cross-country coverage offered by the ESS.

X is a vector of sociodemographic controls L which may affect individual attitudes. European countries are highly unequal in many geographical (e.g. land size) and socioeconomic aspects. We hence add state fixed-effects (FE) α_c , which are included to absorb any country-specific idiosyncrasies. We also add ESS wave fixed-effects d_t , to account for cross-sectional common shocks throughout the years. $\varepsilon_{i,c,t}$ is the error term. We adopt robust standard errors in all regressions. Each of the dependent variables j included in the vector Y is either a dummy or ordinal categorical. In these cases, adopting a linear regression model (cf., for instance, Maxwell, 2019) would be inappropriate because the assumptions of OLS are violated. We hence estimate model (1) by means of a logit estimator when the outcome is binary, or by means of a proportional odds estimator (ordinal logit) when the outcome is ordinal categorical. In the second case, we assume that, for each outcome j , there is only one model and one set of coefficients, and the only dependent variable parameter to change across the values of the explanatory ordinal variable are the specific intercepts α (the cut-off points) – what is called the proportional odds assumption. Brant tests, available on request, confirm the assumption is not violated (significant at the 1% confidence level).

It is important to bear in mind that this analysis does not claim to provide a causal interpretation of the link between place of residence and political attitudes. Instead, it seeks to present a broad and systematic analysis of a set of quantitative, stylised facts, which might well be explored in more depth, with the use of more advanced causal-inference tools, in future research.

3.3 Variables and definitions

Y is a vector of either binary or ordinal categorical variables measuring individual attitudes on each issue j of person i in the ESS wave t . We consider ten issues, grouped along two main dimensions:

Attitudes towards the political system and political engagement. We are, first, interested in the link between place of residence and individual attitudes towards the political system, as well as the ways in which people engage with politics. We focus on attitudinal responses and views of modes of political behaviour as these are also revealing expressions of deeper-lying attitudes towards the political system. We explore, specifically, the extent to which people engage via conventional political channels, such as voting, and the extent to which respondents evince trust in political parties, since recent research has identified a close correlation between discontent with the parties and a deeper mistrust of the political system (Bromley-Davenport, MacLeavy, and Manley 2019; Cramer 2016). Relatedly, we explore the extent to which people feel satisfied with the way in which democracy functions in their country. To provide a comparison, we also present evidence on how people feel satisfied about their life more generally, in order to help us understand better the nature and extent of individual satisfaction and dissatisfaction with politics.

Attitudes towards specific issues. We are also interested in exploring how people in different places along the urban/rural continuum respond to specific socioeconomic questions. We first consider people's self-placement along the left-right political spectrum, and then explore their attitudes in three areas: welfare state support, which is conventionally treated

²¹⁹ Cf. <https://www.europeansocialsurvey.org/methodology>, accessed on 5 July 2019.

as integral to the left/right divide; law and order, and trust in the police, drawing on the extensive literature on the rise of ‘authoritarian values’ (Foa and Mounk 2016); and attitudes towards globalisation, which we consider via perceptions of immigrants and attitudes towards the EU, where we draw from an emerging literature on a new ‘transnational cleavage’ in politics (Ford and Jennings 2019; Hooghe and Marks 2018). Political disenchantment has been widely interpreted as an essentially populist reaction against elite politicians who are perceived as being increasingly globalist in their orientation by those more inclined to identify with national identities and social traditions (Goodhart 2017; Inglehart and Norris 2016, 2017), and our findings shed light on the geographically rooted nature of these beliefs.

As anticipated, U represents a categorical variable indicating whether each respondent resides in the inner part of a large city (the baseline category), the suburbs/outskirts of a big city, a town/small city, a country village, or a farm/home in the countryside. Out of the total pooled sample, 19.46% of respondents report that they live in a big inner city, 12.04% in suburbs, 30.59% in towns or small cities, 31.41% in a country village, and 6.5% in a farm or isolated home in the countryside.

X is a vector of individual sociodemographic controls L which may affect attitudes, and for which micro-level information is available. In particular, X includes the following covariates:

Age. Following a pattern clearly established in the literature, we may expect attitudes to be highly stratified by age groups, with younger generations being more likely to embrace cosmopolitan and progressive views (inter alia: Goodwin & Heath, 2016; Harris & Charlton, 2016) and, at the same time, being less engaged in electoral politics, given their familiarity with social media and less conventional forms of political engagement (Foa et al. 2020). The variable is expressed in Ln.

Gender. As customary, we control for the gender of the respondent.

Educational attainment. Some contributions to the growing literature on political discontent have established a positive association between lower degrees of education and higher levels of anti-establishment feeling, as well as more nationalistic/inward-looking sentiments (inter alia: Becker et al., 2017; Dijkstra et al., 2019). We hence control for respondents’ highest level of education attainment by including dummy variables for each of the ISCED (International Standard Classification of Education) levels.

Native. We add a dummy for people born in the country of residence, as we may expect this variable to affect our outcomes.

Employment status. We similarly include dummy variables for each of the following statuses: employed in paid work, education, unemployed - looking for job, unemployed - not looking for job, permanently sick or disabled, retired, in community or military service, housework or looking after children, and other.

Occupation. The literature on political discontent has linked growing resentment with economic insecurity in sectors and occupations under higher threat from automation and trade competition (Autor et al. 2016; Ballard-Rosa et al. 2017; Colantone and Stanig 2018). We hence additionally include dummies for each different type of occupation. We follow the International Labour Office’s (ILO) two-digit ISCO-08 (International Standard Classification of Occupations) codes, distinguishing between each of the 50 different categories (out of the 96 codes) represented in the ESS sample.

Unemployment spells. While employment status captures current unemployment, we include a dummy for respondents who, in previous years, have been unemployed for more than three months.²²⁰

Partner’s unemployment. We also include a dummy if a respondent’s partner is unemployed.

Benefits. We control for whether the main source of household income claims state benefits. We include this variable, as well as the following ones, to account for potential divides between “winners” and “losers” in the contemporary economy.

Household income feelings. We create a dummy capturing whether respondents feel that life with their present household income is difficult or very difficult.

General economic satisfaction. The variable captures the overall level of individual satisfaction towards the national economy.

Research on the “geography of discontent” has pointed to a link between political disenchantment and relative regional economic status and decline (McCann 2019; Rodríguez-Pose 2018). In the final part of the analysis we will hence also include three regional-level economic indicators which may affect individual attitudes. (While for most countries the ESS matches respondents to their NUTS2 level region, in some cases persons are matched with either NUTS1 or NUTS3 regional identifiers. See Appendix A.1 for more details.) The variables we consider are:

Average regional per-capita GDP. This is included to account for the overall economic development of the region where respondents live.

Regional per-capita GDP growth. We control for changes in GDP levels over the previous four years.²²¹

% ratio regional per-capita GDP / national average. We add a measure of relative regional economic wealth.

Appendix A.2 reports key weighted summary statistics, while Appendix A.3 provides a detailed description for each variable.

4. RESULTS

This section presents the baseline results of our analysis. In Table 1, we explore the overall differences in attitudes that we find along the urban/rural continuum, when not controlling for composition effects. For each issue j , the table presents the proportional odds ratios (i.e. the exponentiation of the ‘raw’ logit/ordinal logit coefficients) of respondents

²²⁰ Data on long-term unemployment is unfortunately missing for the majority of respondents.

²²¹ We calculate variations over an even-numbered interval of years so that the measure coincides with ESS waves.

living in each of the geographical categories compared to respondents residing in large urban cores, the baseline category. In all models, we include country and year fixed-effects.

The first four columns of Table 1 report outputs for attitudes towards modes of political engagement and the political system, and illuminate the extent to which people engage via ‘traditional’ political channels such as voting (column one), whether they trust political parties (column two), or whether they are satisfied with democracy in their country (column three). And, as a point of comparison, we also report respondents’ satisfaction with life (column four). Column five provides insights into people’s self-placement on the left-right spectrum, while the last five models focus on specific socioeconomic issues. Models six and seven, respectively, focus on attitudes towards welfare state support and trust in the police. Finally, the last three models report results relating to the ‘transnational cleavage’, namely perceptions towards immigrants (columns eight and nine) and attitudes towards the EU (trust in the European Parliament, column ten). The results broadly confirm our prior assumptions, and provide strong evidence in support of hypothesis H.1. Across most issues covered, there are stark and statistically significant differences between urban and rural places. Besides, in line with hypothesis H.2, Table 1 shows that the divide in attitudes is a gradient linked to urban density, running on a continuum from inner cities to suburbs, towns, villages, and isolated rural houses.

Controlling for country and year idiosyncrasies, respondents living outside large inner cities are, on average, significantly more likely to vote. At the same time, however, they tend to show less trust towards the political system. For instance, the odds of somebody voting, or reporting a one-unit higher level of trust in parties (which is measured on a scale 0-10), if they live on a farm or in an isolated rural area (the last category), are, respectively, 33.5% higher and 16.2% lower than those of an average resident of a large urban core. These results suggest that, while levels of trust in the political system are lower in rural areas, in these places traditional modes of political engagement are more prevalent.²²² Our results, more generally, confirm that the residents of these places are far less likely to engage in non-conventional political behaviours, like signing petitions and boycotting products.²²³ But they are also, paradoxically, more sceptical than their urban counterparts about the political system and the choices it presents them with.

In line with characterisations of a cosmopolitan/conservative divide between large urban centres and elsewhere (Guilluy 2016), the results of column five show that people living in urban fringes, towns and the countryside are significantly more likely to identify as conservatives, tending to place themselves on the right of the political spectrum. As an example, the odds of a person living in a country house feeling one-unit closer to the political right on the left-right spectrum (which is measured on a scale 0-10, where zero is left and 10 is right) is 57.2% higher.²²⁴

Interestingly, however, we do not find any substantial difference in support for the welfare state (model six), an issue which has traditionally played an important role in left-right political cleavages in western democracies, or, indeed, in the trust they place in the police. It may well be that in the era of populism, worries about welfare and law and order are no longer a source of significant divergence between those who live in different parts of a country.

By contrast, results from the last three models provide clear evidence of a stark urban/rural divide on issues associated with the new ‘transnational cleavage’ (Hooghe and Marks 2018; Kriesi 2010). The results of columns eight and nine show significant differences in attitudes towards international immigration. As an example, compared to an inner-city dweller, the odds for a rural home resident reporting a one-unit higher level of belief in the positive role of migration in enriching

222 Levels of trust in parties are virtually identical to levels of trust in politicians. By contrast, levels of trust in the national parliament are slightly lower, consistent with the hypothesis that disenchanted rural dwellers may be more trustful of individuals or specific political parties than the political system overall. These additional results are available on request.

223 These additional results are available on request.

224 Results not presented but available on request equally show statistically significant differences on matters such as family issues and women rights.

the national culture (measured on a scale 0-10) are more than 55% lower. A very similar picture emerges with respect to attitudes towards the EU (column ten).

In Appendix B.1 we plot the predicted probabilities for models three and eight from Table 1. The graphs provide visual evidence of the differences in attitudes across the urban/rural continuum.

In table 2 we test hypotheses H.3 and H.4, and present the results, controlling for individual observable characteristics. We are unable to control for unobservable factors such as cognitive traits and personality types. Nevertheless, we work from the assumption that any residual correlation between place of residence and attitudes that is not explained by personal socioeconomic characteristics might well be related to places, and their contextual effects. With the exception of life satisfaction and, partially, also for trust in the police, for all other outcomes the differences across places after conditioning on individual covariates reduce in magnitude and significance, lending support to hypothesis H.3.

In Appendices A.4 and A.5 we break down the results of Table 2, respectively controlling for only sociodemographic or only economic observables, to explore the extent to which composition effects are linked to demographic factors such as education, age, and indigeneity, as opposed to labour market and economic factors. The results suggest that both groups of regressors are important in explaining attitudinal differences along the urban/rural continuum (in fact, including either group leads to relatively similar reductions in the size of the urban/rural coefficients). Among the economic regressors, additional tests we ran suggest that only employment status and sector of occupation play a role in mediating the link between place of residence and individual attitudes, while proxies for individual deprivation such as being dependent on public benefits, anxiety about household income and overall satisfaction with the economy, have a very minor mediating effects.²²⁵

In Appendices A.6 and A.7 we stratify the sample of Table 2 respectively distinguishing between Western European countries (EU14 Member States plus UK, Norway, and Switzerland) and the 13 countries which joined the EU in the 2004/07 enlargements, most of which were formerly part of the Eastern Bloc. The outputs suggest how attitudinal heterogeneity along the urban/rural continuum is particularly pronounced across all the countries of Western Europe. By contrast, EU13 Members show significantly less marked differences.

In Appendices B.2, B.3, and B.4 we then plot the predicted probabilities for models three and eight of Table 2. In each of the appendices we plot probabilities distinguishing between age groups, educational attainments, and occupation, and holding other variables constant at their means. As the results suggest, the role of age, education and occupation in explaining variation in attitudes is significantly larger than the residual variation attributable to idiosyncratic place effects. Hence, the findings from Table 2 suggest that attitudes are significantly stratified by sociodemographic measures, as suggested, for instance, by Maxwell (2019).

Nevertheless, we underscore how, even after controlling for individual observable characteristics, places still have a non-negligible correlation with people’s political attitudes, especially on issues such as voting behaviours (column 1 of Table 2), left-right placement (column 5), and migration and globalization (i.e. the dimensions relating to the ‘new transnational cleavage, columns 8 to 10). For instance, compared to an inner-city dweller, even after controlling for individual observables, the odds for a rural home resident reporting a one-unit higher level of satisfaction with democracy in their country (measured on a scale 0-10) are more than 10% lower, while the odds of them reporting a one-unit higher level of belief in the positive role of migration in enriching the national culture (measured on a scale 0-10) are more than 26% lower. In other words, we do not fully reject hypothesis H.4, but instead conclude that, while

225 These additional results are available on request.

compositional effects are very important in shaping attitudes, they are not sufficient to explain the urban/rural divide in political views in these European countries.

To understand what may explain the link between place and individual attitudes, we finally estimate equation (1) controlling for sociodemographic observables and economic status while also adding regional economic characteristics. Before wave 4 the ESS did not report respondents' region of residence. Besides, not all individuals are matched with a regional identifier, while we do not have regional economic data for the latest ESS wave 9. We are hence able to merge regional-level characteristics to only waves 4-8 and a sub-set of respondents. (For comparison, Appendix A.8 re-estimates the regressions of Table 2 on the restricted sample. With the exception of 'Satisfaction with democracy', which loses significance, results are overall similar to those from the full sample.) Results, reported in Appendix A.9, suggest that controlling for regional economic dynamics has only a minor effect on the link between place of residence and individual socio-political attitudes. Additional tests we ran equally suggest that the regional economic variables do not act as moderators, as their interactions with place of residence are statistically insignificant.²²⁶ While some recent analyses of the "revenge of places that don't matter" (Dijkstra, Poelman, and Rodríguez-Pose 2019; Rodríguez-Pose 2018) have underlined a link between contemporary political grievances and territorial economic stagnation and decline, we conclude that differences in attitudes along the urban-rural continuum are primarily linked to cultural-identity issues, as highlighted for example by Cramer (2016).

5. DISCUSSION AND IMPLICATIONS FOR POLICY

These findings carry significance for debates prevalent in both academic and policy circles in relation to two broad, related phenomena. One is the growth of political disenchantment in many non-metropolitan locations across Europe, and the fertile soil this provides for nationalist and populist parties and causes. The other is the growing debate across Europe and other mature democracies about what kinds of policy agenda and political response are required in order to re-engage the inhabitants of what are commonly termed 'left-behind' places.

In relation to current debates about the underpinnings and scope of political disenchantment, our findings suggest the importance of a place-sensitive conception of this phenomenon, and simultaneously serve to undermine overly generalised characterisations of 'rural consciousness' or 'left-behind' disillusion – concepts that have become staples of media commentary and figure in academic analysis (Cramer 2016; Harris and Charlton 2016). The clear gradient that we identify in terms of political attitudes and social values, and their correlation with different spatial scales and kinds of community – ranging from metropolitan centres at one end of the spectrum through to more remote, rural areas at the other – suggest the need for a more detailed and contextual understanding of the geography of disillusion (see also Rossi 2018). These findings also underscore the importance of a deep appreciation of the underpinning economic and cultural dynamics which are generating such disparate and rivalrous social outlooks in different parts of these countries. While our study is not designed to resolve the question of causality, its main findings lend support to the contention that composition effects are necessary, but not sufficient, to explain differences in attitudes across the urban/rural continuum. Even though attitudes are highly stratified by individual characteristics such as age, educational attainments, and occupation, place still appears to have a non-negligible correlation with the values and outlook of a large number of citizens. More work is needed to understand better the mechanism through which this relationship works. Recent research has shown how place of birth and the context where individuals spend their "impressionable years" – i.e. the period of late adolescence and early adulthood during which people form durable political attitudes (Jeannet and Drazanova 2019) – have a significant influence in moulding both observable characteristics such as education (Bosquet and Overman 2019) and unobservable cognitive characteristics and capacities (Rentfrow, Gosling, and Potter 2008). Even in some of the most dynamic and developed economies in the world, it appears that where you are born and grow up is one of the most important facts about the life of any citizen, and this should give policy-makers food for thought. There are large numbers of people resident in areas where trust in politics and the political system is low, and where socially liberal values have only a thin presence. Yet, successful majoritarian politics require that parties of the political mainstream find ways to win the support of many of these voters, while also pursuing policies – in areas like climate change or migration – which may well be anathema to many of them.

This challenge connects with the second main implication of these results. This concerns the growing political focus upon the 'left behind' – a category that is both ubiquitous and contested. Our analysis suggests that there are degrees of 'left behindness' in terms of political worldviews, and that a firmer appreciation of the geographical specificities of different rural areas, towns and cities is integral to a more contextually informed and tailored policy responses to the challenges posed by inter- and intra-regional inequality (Iammarino, Rodríguez-Pose, and Storper 2019; Rossi 2018). For instance, research has shown how the European Cohesion Policy has contributed to generating economic growth in rural areas close to urban agglomerations, but not in those farther away from cities (Gagliardi and Percoco 2016). Hence, 'place-sensitive' development policies require a deeper and more contextual appreciation of the different patterns of economic development apparent in different places (Dijkstra, Garcilazo, and McCann 2013; Iammarino, Rodríguez-Pose, and Storper 2019). And, following recent debates about how best to tackle inter-territorial inequalities, our findings underscore the importance of moving beyond 'standard' trade-offs between so-called 'people-based' and 'place-based' policy approaches (Barca, McCann, and Rodríguez-Pose 2012; Kline and Moretti 2014) and support the idea of integrated policy frameworks that bring together individual (micro) and territorial (meso) logics (Iammarino, Rodríguez-Pose, and Storper 2019).

²²⁶ They are available on request.

Finally, this paper offers a challenge to the ingrained tendency in the worlds of Anglophone scholarship and media punditry to foreground the UK and the US as the leading exemplars of the political disruption associated with rapid techno-economic change in the contemporary period. Our results lead instead to the conclusion that there are important trends and dynamics at work across nearly all developed European economies that are exercising a powerful impact upon the public attitudes and social orientations of people resident in these different contexts. Of course, there are still key differences of political economy, history and institutional structure at work in these different countries and regions, and these need to be given due analytical consideration. But the common patterning of these results, and the close linkages they suggest between the size and kinds of community in which many people live, and how they feel about their country and its politics, lead us to conclude that the Anglo-American bias inherent in much discourse on the 'left behind' needs to be challenged. Understood as a wider phenomenon, we are much more likely to grasp the underlying economic and cultural dynamics that are driving and perpetuating these spatially embedded patterns of political disillusion.

6. CONCLUSION

Drawing on individual-level data from the European Social Survey (ESS), this paper explores linkages between place of residence and attitudes on a range of different socioeconomic and political issues, providing systematic comparative evidence across 30 European countries over the period 2002-2018. We find both that there is a strong and significant divide between urban and rural Europe, and that this is not best seen in binary terms but as a gradient running from inner cities to metropolitan suburbs, towns, and the countryside. We also show that these differences are best explained by a mixture of composition and contextual effects, rather than through an emphasis on either of these kinds of factor alone.

Our analysis shows how the link between place of residence and political attitudes is not confined to attitudes towards iconic and contentious questions such as the EU (Dijkstra, Poelman, and Rodríguez-Pose 2019) or migration (Maxwell 2019). Instead, we conclude, it encompasses a wider range of political and socioeconomic issues. In particular, we show how, compared to dwellers in inner urban cores, respondents living in suburbs, towns and rural areas are systematically more likely to identify as right-wing, dissatisfied with the functioning of democracy in their country, and less likely to trust the political system. But they still tend to be more likely to vote, a finding which has an important bearing on current debates about the future of democratic politics (Runciman 2018). And, while we uncover stark differences in attitudes towards migration and globalisation along geographical lines, we do not find significant variation on issues which have traditionally been at the core of left-right cleavages, such as support for welfare state redistribution. This too is an important finding which may add weight to the claims of those analysts who maintain that the emergence of new cleavages – around age, identity and place – in democratic politics has resulted in the depoliticisation of some of the questions which were pivotal to the political alignments and identities of earlier periods (Ford and Jennings 2019; Kriesi 2010; De Vries 2018).

Second, in line with the work of Scala & Johnson (2017) on the US, we show that the geographical divide in European political attitudes should not be thought of as a dichotomy between urban vs. rural places but, instead, as a gradient. Our analysis suggests that there are degrees of 'left behindness' in terms of political worldviews, and that a firmer appreciation of the geographical specificities of different rural areas, towns and cities is integral to a more contextually informed and tailored policy responses to the challenges posed by inter- and intra-regional inequality (Iammarino, Rodríguez-Pose, and Storper 2019; Rossi 2018).

Finally, we provide a preliminary analysis of the factors that may be most significant in explaining differences along the urban/rural continuum. We contribute to an on-going debate about whether these are driven by sociodemographic characteristics – that is, by compositional effects and the geographical sorting of people with different attributes and outlooks – or by place effects (Abreu and Öner 2020; Maxwell 2019). On the basis of our finding, we underline how attitudes vary across both sociodemographic and geographical dimensions. And, we show that while people's attitudes are heavily stratified by key individual observable characteristics, such as age, education, and occupational status, places still have a non-negligible correlation with people's attitudes on a variety of political and social issues. This conclusion, we suggest, carries implications for ongoing debates about what kinds of policy programmes are best equipped to address growing territorial inequalities. Moreover, place-sensitive development policies will have to be developed in a way that integrates an understanding of the different levels of economic development of places, but also their degree of urbanisation and proximity to urban agglomerations. Gagliardi and Percoco (2016), for instance, show how the EU Cohesion Policy has benefitted rural areas close to large cities but not more remote areas, which hence need to be the target of specific policy measures. Additionally, we observe the importance of moving beyond 'standard' trade-offs between so-called 'people-based' versus 'place-based' policy approaches (Barca, McCann, and Rodríguez-Pose 2012; Kline and Moretti 2014) and, by contrast, point to the need to develop integrated frameworks combining both individual (micro) and territorial (meso) logics (Iammarino, Rodríguez-Pose, and Storper 2019).

The paper does not claim to provide a causal interpretation of the link between place of residence and political attitudes, but, instead, seeks to present a broad and systematic analysis of a set of quantitative, stylised facts. Each of these could be explored in more depth, and with the use of more advanced causal-inference tools. Future research could in particular explore how and why the kinds of setting where people live can influence the development of individual traits, especially during early-age socialisation (Bosquet and Overman 2019; Hackman and Farah 2009; Rentfrow, Gosling, and Potter 2008). Besides, further work is needed to disentangle potential compositional effects based on unobservable – rather than observable – characteristics such as intrinsic 'cognitive underpinnings' (cf., for example, Lee et al., 2018; Zmigrod, Rentfrow, & Robbins, 2018).

Overall, we find that, irrespective of whether divides in attitudes are driven by compositional effects or the contextual influence of places on people, marked demographic sorting and the overlapping of territorial and attitudinal cleavages signal a deepening geographical fracture in European societies which, in the long term, may have significant implications for the challenges of generating social cohesion and renewing the legitimacy of democratic politics (Wilkinson 2018).

Table A3. Detailed description of variables.

Variable	Type, range	ESS question / data source
Domicile	Discrete, categorical	"Which phrase on this card best describes the area where you live? A big city; suburbs or outskirts of a big city; town or small city; country village; farm or home in the countryside."
Age	Categorical	Age group of respondents: 18-39; 40-59; over-60.
Education attainment	Discrete, categorical	"What is the highest level of education you have successfully completed? [Coded according to ISCED levels.]"
Employment status	Discrete, categorical	"Using this card, which of these descriptions applies to what you have been doing for the last 7 days? Paid work; education; unemployed looking for job; unemployed not looking for job; permanently sick or disabled; retired; community or military service; housework or looking after children; other."
Gender	Discrete, categorical	Gender of respondent.
Native	Discrete, categorical	"Were you born in [country]?"
Occupation	Discrete, categorical	"What is/was the name or title of your main job? In your main job, what kind of work do/did you do most of the time? What training or qualifications are/were needed for the job? [Coded according to two-digit ISCO08 codes.]"
Unemployment spells	Discrete, 0/1	"Have you ever been unemployed and seeking work for a period of more than three months?"
Partner's unemployment	Discrete, 0/1	"Which of the descriptions on this card applies to what he/she has been doing for the last 7 days? Unemployed and actively looking for a job".
Benefits	Discrete, 0/1	"Please consider the income of all household members and any income which may be received by the household as a whole. What is the main source of income in your household?" [Unemployment, redundancy benefits, any other social benefits or grants].
Household income satisfaction	Discrete, 0/1	"Which of the descriptions on this card comes closest to how you feel about your household's income nowadays?" [Difficult / very difficult on present income].
General economic outlook	Discrete, 0/10	"On the whole how satisfied are you with the present state of the economy in [your country]?"
Regional per-capita GDP	Continuous	Ln average regional per-capita GDP. Data from Cambridge Econometrics.
Change in regional per-capita GDP	Continuous	Overall percent variation over the previous 4 years of the regional per-capita GDP, divided by three terciles (below 1.33%, between 1.34 and 7.17%, above 7.18%). Own calculation on data from Cambridge Econometrics.
Regional/national per-capita GDP % ratio	Continuous	% ratio of average regional-per capita GDP over national average. Own calculation on data from Cambridge Econometrics.
Voted in elections	Discrete, 0/1	"Some people don't vote nowadays for one reason or another. Did you vote in the last [country] national election in [month/year]?"
Satisfaction with democracy	Discrete, 0/10	"On the whole, how satisfied are you with the way democracy works in [your country]."
Satisfaction with life	Discrete, 0/10	"All things considered, how satisfied are you with your life as a whole nowadays?"
Trust in political parties	Discrete, 0/10	Using this card, please tell me on a score of 0-10 how much you personally trust each of the institutions I read out. 0 means you do not trust an institution at all, and 10 means you have complete trust.... Political parties?"
L-R placement	Discrete, 0/10	"In politics people sometimes talk of "left" and "right". Using this card, where would you place yourself on this scale, where 0 means the left and 10 means the right?"
Trust in the police	Discrete, 0/10	"Using this card, please tell me on a score of 0-10 how much you personally trust each of the institutions I read out. 0 means you do not trust an institution at all, and 10 means you have complete trust... The police?"
Welfare state support	Discrete, 0/5	"Using this card, please say to what extent you agree or disagree with each of the following statements. The government should take measures to reduce differences in income levels".
Migration good for economy	Discrete, 0/10	"Would you say it is generally bad or good for [country]'s economy that people come to live here from other countries?"
Migration good for culture	Discrete, 0/10	"And, using this card, would you say that [country]'s cultural life is generally undermined or enriched by people coming to live here from other countries?"
Trust in European Parliament	Discrete, 0/10	"Using this card, please tell me on a score of 0-10 how much you personally trust each of the institutions I read out. 0 means you do not trust an institution at all, and 10 means you have complete trust... The European Parliament?"

The plots show predictions distinguishing between manual and non-manual occupations, while holding other covariates at their means

ALTRUISM IN THE TIME OF COVID-19: WE ARE ALL IN THIS TOGETHER, BUT WHO IS WE?

¹Kiel Institute for the World Economy, Germany. ²University of South Carolina, USA. ³Gran Sasso Science Institute, Italy. ⁴Ohio State University, USA

ABSTRACT

The unfolding COVID-19 pandemic poses the most serious existential threat to contemporary societies since WWII. This is likely to have wide-ranging consequences for patterns of cooperation and social cohesion within and between countries. Crises such as these heighten the tension between individual and collective interests, distilling the essence of a social dilemma.

The goal is to gauge the extent to which people act altruistically rather than selfishly as a function of their exposure to the COVID-19 pandemic, and, more specifically, toward which group such altruism is directed. Our study consisted of two online experiments conducted in the U.S. and Italy to evaluate the extent of altruism in the form of charitable giving, and whether such altruism has a more parochial or cosmopolitan character. In the context of an online survey, participants were given an unexpected monetary bonus and then asked whether they wished to donate some or all of the bonus and, if so, choose to which one of three charitable organizations -one international, one national, and state (U.S.) or regional (Italy) level- providing aid to those affected by the COVID-19 pandemic. Any amount donated was matched by the researchers so that the contribution to the selected charity was doubled. In order to assess the causal influence of construal of the ingroup on prosocial decision-making, our study included an experimental manipulation intended to "prompt" the participant to think about the pandemic crisis in terms of one of the three levels of inclusiveness.

Several patterns in our study are observed in both countries, lending robustness to our results. In particular, the willingness to benefit most the group at the lowest levels of inclusiveness -state/region-, the tendency for people more exposed to COVID-19 to donate more, and the moderating effect exerted by social identity. Nonetheless, contributions to more inclusive groups – national and international – were also substantial and larger in Italy than the U.S., suggesting that inclusiveness may be affected by contextual factors such as the uneven regional distribution of the threat in question, the time of the outbreak, and the nature of governmental response to the pandemic.

Our research provides a deeper understanding of the influence of pandemic-induced trauma on attitudes and behaviour, and seems to infer that even if global effort is constructed to address the current and other ongoing global crises. The preference for helping at the local level (state in the U.S. and region in Italy) should also be considered when designing relief packages and appeals for aid. Many global leaders have lamented the current failure of multi-lateral governance in addressing the spread of COVID-19, let alone facing up to other global challenges affecting our planet. Our findings suggest that whatever global effort is constructed to address the current and other ongoing global crises, it will have to consider the markedly parochial character of cooperation observed in our study.

**IDENTITY AND PLACE: HOW DO TERRITORIAL CHARACTERISTICS
AFFECT PRO-GROUP BEHAVIOURS?**

Giovanni Perucca

Politecnico di Milano, Italy

ABSTRACT

A broad literature focused on the effects of group identity on individual behaviour. Among other things, these studies pointed out that when identity is made salient, group members tend to cooperate more among them. Moreover, they systematically tend to favour in-group members over out-group individuals. Few recent works suggested that territory matters in understanding the mechanisms through which identity leads to cooperation. This study focuses on this issue, presenting the results of a natural experiment.

IS COVID-19 THE GREAT EQUALIZER? HETEROGENOUS IMPACT OF MOBILITY RESTRICTIONS IN A METROPOLITAN AREA

[David Castells-Quintana](#)¹, [Paula Herrera-Idárraga](#)², [Luis Quintero](#)³, [Sinisterra Guillermo](#)⁴

¹Universidad Autónoma de Barcelona, Spain. ²Universidad Javeriana, Colombia. ³Johns Hopkins University, USA. ⁴Universidad Javeriana, Colombia

ABSTRACT

The capacity of areas within a city to comply with mobility restrictions aimed at curbing the COVID-19 pandemic is crucial to the local dynamics of the disease. In this paper, we study the efficacy of policies implemented to restrict mobility and their impact on the COVID-19 expansion, and how this impact depends on socioeconomic differences across within-city locations. To do so, we rely on unique and novel data showing changes in movements at highly disaggregated spatial levels. We use data from Bogotá to explore the relationship between mobility restrictions, as one of the main Non-Pharmaceutical Interventions implemented, people's mobility, and the expansion of the COVID 19 pandemic. Bogotá implemented a general lockdown, followed by district-specific restrictions and subsidies. We find that the general lockdown imposed in the city significantly reduced mobility (by about 47%). By contrast, the marginal impact of district-specific restrictions and subsidies is found to be small. When looking at heterogeneous impact across locations, we find that poorer locations, with a higher share of informal workers, as well as those where households who have deficient infrastructure, reacted significantly less to mobility restrictions.

GAINS FROM AGGLOMERATION: EVIDENCE FROM MANUFACTURING PLANTS IN THE RUSSIAN EMPIRE

[Vera Ivanova](#)

HSE University, Russian Federation

ABSTRACT

I study the location patterns and the effect of agglomeration on plant-level productivity of manufacturing industries in the Russian Empire. The analysis is based on a novel micro-geographical dataset on the population of Russian manufacturing plants in 1908, augmented with geo-coded data on Imperial railroads and province-level indicators. Using continuous distance measures of geographic concentration, I show that most industries in the Russian Empire were localized at distances about 100--200 km. Also, I reveal coagglomerated industry pairs forming input--output linkages. I estimate impacts of location characteristics of each plant on plant-level productivity. I find that a firm-level TFP is bell-shaped with respect to the number of plants of the same industry in the same geographic area. I reveal a strong positive impact of closeness to railroads on firm-level productivity. These findings reflect non-trivial interplay between agglomeration and dispersion forces to which my estimation results impart empirical content.

WHO'S RIGHT, WEBER OR GLAESER?**Andrea Caragliu¹, Martijn Smit², Frank van Oort³**

ABSTRACT

Recent evidence about the relative strength of localization and urbanization economies is rather contradictory. Most empirical work on agglomeration economies has been devoted to the analysis of pure density mechanisms, which actually subsume two possible amenity effects. On the one hand, vast empirical evidence suggests the importance of productivity-enhancing features of spatially concentrated settlement structures, which attract profit-maximizing firms despite the costs associated to large population concentrations. On the other hand, cities also function as major market areas, concentrated in space and thereby offering within a limited area a large number of consumption possibilities.

These two strands of literature have seldom spoken and to date the relative importance of these sources of agglomeration benefits is not yet clear. In this paper we address this gap. We exploit two large data bases comprising (i.) 70 per cent of all house transactions in the Netherlands in the period 2005-2011, and (ii.) ORBIS data covering balance sheets of Dutch firms in the period 2005-2011. We also merge these two main data sources with Statistics Netherlands neighborhood data from the Wijk- en Buurtkaart, data on monuments from the Cultural Heritage Agency, and, lastly, LISA data of all registered firms in the Netherlands.

The paper provides two main contributions: (i.) We measure the intensity of the productivity effect of consumption and production-related advantages for the Dutch case, and (ii.) We observe whether the relative intensity of the two effects change over the observed time span, following recent theoretical predictions, that suggest the growing importance of consumption amenities as sources of agglomeration benefits (Glaeser et al., 2001; Koster et al., 2019). This empirical framework is for the first time to date explored by looking at the three main indicators of relative locational advantages, i.e. house prices, firm productivity, and worker wages, thus providing evidence on all three main sources of income (rent, profits, and wages, respectively).

Our findings suggest that both consumption and production-related externalities are reflected in house prices, firm productivity, and wages. In particular, urban land rent increases with the intensity of competition, as well as with the presence of local consumption amenities (major monuments, theatres, and restaurants). Firms also tend to be more productive when located closer to sources of consumption amenities, although the evidence is less compelling.

Results are robust to a number of robustness checks, as well as to the use of Instrumental Variables, with soil composition and historical population density as the two main instruments. Instead, we find little evidence of a relative decline of the importance of production externalities with respect to consumption amenities.
